

# PANORAMA of EU INDUSTRY 95/96

**European  
Commission**

*An extensive  
review  
of the situation  
and  
outlook  
of the  
manufacturing and  
service industries  
in the  
European  
Union*

# Principal European Union Institutions

Erratum: Tables on page 160, 162, 170 are to be replaced as follows

Table 1: Ranking of the 50 most dynamic CMAs according to Birch

Rank	Birch	Name	CMA	Country	Employment (beginning)	Employment (end)
1	12 766	CO-OPERATIVE WHOLESALE SOCIETY LTD	1	UK	20 000	28 850
2	8 798	KERRY CO-OPERATIVE CREAMERIES LTD	1	IR	2 615	6 279

Reproduction is authorized, except for commercial purposes, provided the source is acknowledged.

*Printed in Belgium*

The opinions expressed in this publication are those of the authors alone. Under no circumstances should they be taken as an authoritative statement of the views of the Commission of the European Communities. Comments under the heading "Impact of the Single Market" are the result of interviews with the European trade associations.

Panorama is commissioned by the Unit "Competitiveness and general questions of industrial and technological policy" of the Directorate-General Industry of the Commission of the European Communities (DG III), with the cooperation of the trade and professional associations of the European Union.

All professional associations/organisations known to the Commission which represent industry at the European level were asked to contribute material on their sector. At the end of each monograph, addresses and telephone and fax numbers of the respective professional association concerned are indicated.

The many consultants and associations that contributed to this edition of Panorama are listed in the introduction section of the publication.

Questions about the content of the Panorama of EU Industry should be directed to the association concerned or to the Commission service responsible for this publication:

**"Competitiveness and general questions of industrial and technological policy" Unit, Directorate-General Industry.**

Tel: (32 2) 295 7928 / 296 2072  
Fax: (32 2) 296 3028

**Statistical Office of the European Communities (Eurostat) - Directorate Business Statistics.**

Tel: (352) 4301 32745  
Fax: (352) 4301 34771

For specific sectors for which they are responsible, questions should be directed to the following services of the Commission:

**Industry: Directorate-General III**

Tel: (32 2) 295 8684  
Fax: (32 2) 295 0126

**Employment, Industrial Relations and Social Affairs: Directorate-General V**

Tel: (32 2) 295 9471

# Introduction

# TABLE OF CONTENTS

## INTRODUCTION

Table of contents	I
Message from Jacques Santer President of the European Commission	V
Preface by Martin Bangemann Member of the European Commission	VII
Preface by Yves-Thibault de Silguy Member of the European Commission	IX
Introduction by Stefano Micossi Director-General Industry, European Commission	XI
Introductory note to Panorama 1995 Time frames and statistics	XIII
Abbreviations	XV
Contributors	XVII
Questionnaire	

## SPECIAL FEATURES

Highlights on industrial Competitiveness of the EU manufacturing industry .....	1
A European approach to strategic alliances.....	31
Typical forms of transnational investments by EU firms outside the EU.....	41
The world's largest industrial groups.....	55
Industrial transition of employment - Converging trends in the EU .....	81
The new Member States: Austria, Finland, Sweden.....	87
Media services.....	99
Impact of the globalisation of markets on financial instruments available to the European capital goods industry .....	107
Traffic Management and the use of Information Technology .....	113
World information output in engineering sciences and technology.....	125

Building business: evidence from Europe and North America on growth, competitiveness and jobs.....	149
Classification of 500 cooperatives, mutual benefit societies and associations.....	159
SMEs and employment .....	173

## REVIEWS AND FORECASTS: INDUSTRIAL SECTORS

### Chapter 1: Energy

Overview .....	1-1
Solid fuels .....	1-7
Exploration and production of crude oil and natural gas .....	1-14
Nuclear fuels.....	1-19
Refining and distribution of oil products.....	1-24
Electricity generation and distribution .....	1-34
Transmission and distribution of natural gas.....	1-43
Renewable energy .....	1-50
Water supply and distribution .....	1-58

### Chapter 2: Non-energy mining and quarrying

Overview .....	2-1
Iron ore.....	2-8
Non-ferrous metal ores.....	2-13
Stone .....	2-19
Construction raw materials .....	2-24
Chemical industrial minerals .....	2-31
Crystallised salt .....	2-37
Physical industrial minerals.....	2-42

### Chapter 3: Ferrous metals

Overview .....	3-1
Iron and steel.....	3-8
Steel tubes .....	3-15
First processing of steel .....	3-22

### Chapter 4: Non-ferrous metals

Overview .....	4-1
Aluminium.....	4-5
Copper.....	4-9
Zinc .....	4-13
Lead.....	4-18
Nickel.....	4-22

Precious metals .....	4-27
Cobalt .....	4-33
Ferro-alloys.....	4-38

---

### Chapter 5: Non-metallic mineral products

---

Overview .....	5-1
Clay products .....	5-7
Cement.....	5-13
Precast concrete .....	5-17
Ready-mixed concrete.....	5-23
Glass .....	5-26
Ceramic goods.....	5-33

---

### Chapter 6: Chemicals

---

Overview .....	6-1
Basic industrial chemicals .....	6-9
Petrochemicals.....	6-15
Paints, varnishes, and printing inks .....	6-21
Other specialty chemicals.....	6-26
Agrochemicals .....	6-31
Fertilizers .....	6-35
Soaps and detergents, perfumes and toiletries .....	6-39
Pharmaceuticals.....	6-46
Maintenance products.....	6-56
Man-made fibres .....	6-60
Biotechnology.....	6-66

---

### Chapter 7: Metal products

---

Overview .....	7-1
Foundries.....	7-9
Forging .....	7-17
Secondary transformation of metals.....	7-21
Constructional steelwork.....	7-27
Boilers and metal containers.....	7-32
Hand tools.....	7-39
Light metal packaging.....	7-44
Steel drums .....	7-50

---

### Chapter 8: Mechanical engineering

---

Overview .....	8-1
Agricultural machinery.....	8-10
Machine tools .....	8-17
Textile machinery.....	8-25
Chemical machinery .....	8-31
Packaging machinery.....	8-35
Plastics and rubber machinery .....	8-40
Machinery for lifting and handling.....	8-44
Transmission equipment.....	8-49
Woodworking machinery .....	8-55

Liquid pumps.....	8-58
-------------------	------

---

### Chapter 9: Electrical and electronic engineering

---

Overview .....	9-1
Insulated wires and cables .....	9-8
Electrical machinery .....	9-12
Electrical equipment for industrial use.....	9-17
Batteries and accumulators .....	9-23
Domestic electrical appliances .....	9-28
Electric lighting .....	9-34

---

### Chapter 10: Electronic engineering

---

Overview .....	10-1
Electronic components.....	10-8
Computer and office equipment.....	10-16
Telecommunications equipment.....	10-24
Consumer electronics.....	10-31

---

### Chapter 11: Transport equipment

---

Overview .....	11-1
Motor vehicles .....	11-8
Motor vehicle parts and accessories.....	11-18
Mopeds and motorcycles.....	11-25
Bicycles.....	11-33
Shipbuilding .....	11-36
Railway rolling stock.....	11-44
Aerospace equipment.....	11-53

---

### Chapter 12: Instrument engineering

---

Overview .....	12-1
Measuring, precision and control instruments .....	12-9
Medical and surgical equipment and orthopaedic appliances .....	12-15
Optical instruments and photographic equipment .....	12-21
Clocks and watches.....	12-27

---

### Chapter 13: Food, drink and tobacco

---

Overview .....	13-1
Oils and fats.....	13-9
Meat .....	13-18
Dairy products .....	13-27
Fruit and vegetable processing and preserving.....	13-37
Processing of fishery products .....	13-45
Deep-frozen products.....	13-52
Grain milling.....	13-58
Industrial baking.....	13-65
Sugar .....	13-73
Cocoa and sugar confectionery, ice cream.....	13-79
Compound feed.....	13-87
Miscellaneous food products .....	13-94

Alcohol and spirits .....	13-104
Wine.....	13-111
Brewing and malting.....	13-118
Soft drinks, mineral waters.....	13-127
Tobacco .....	13-135

---

#### **Chapter 14: Textiles, clothing, footwear, leather**

---

Overview .....	14-1
Textiles .....	14-8
Clothing.....	14-15
Footwear.....	14-22

## Message from Jacques **SANTER**

**President of the European  
Commission**

This new edition of the Panorama of EU Industry coincides with a moment in history when the Union is embarking on a decisive phase of its development. This gives me great satisfaction for two reasons. Firstly, I remain convinced that one of the main tasks of the European

Commission is to promote the dissemination of regular and high quality information aimed at people in all professional or private circles. Secondly, I am pleased because this Commission publication is an important reference work for all those who, in their various ways, are concerned with our industry's evolution and performance, since industry has a crucial role to play in attaining the objectives we have set ourselves.

Our objectives are both ambitious and hard to achieve. They will have to enable us to respond to the demands of subsidiarity, openness and efficient decision-making in the Community, to underscore the democratic nature of the institutions and to work with our fellow citizens in a climate of confidence. Next, they will have to prepare the way for us to tackle the major challenges awaiting us at the dawn of the 21st century, notably laying the foundations for future expansions, strengthening solidarity at all levels, implementing the use of a single currency and, above all, significantly reducing unemployment and social exclusion.

The swift implementation of an industrial competitiveness policy, such as that adopted by the Council following the recent Communications from the Commission, constitutes a major springboard in this context for attaining most of the defined objectives, especially for creating jobs. Whether the expectations of success in this respect will be fulfilled will depend not only on the spirit of enterprise evinced by operators in the field but also on the determination of the public authorities to reshape the policies which influence industry. Now that the economic prospects are more favourable, we have the means to speed up the efforts required to adopt the necessary measures to strengthen our industry's potential. This is an opportunity which we must seize to enable us to create more favourable conditions for development and, as a result, to stimulate growth which corresponds more closely to the needs of our societies.

The Commission, for its part, is determined to take the initiatives required in the industrial sphere while stepping up its dialogue with the parties concerned.

It seems to me, therefore, that the regular publication of this work, which is the outcome of close cooperation between the Commission and industry, is an extremely positive element in line with the desired aims of cooperation.

I trust that all those for whom a better knowledge of the industrial world constitutes an indispensable element for their activities and reflections will be able to find in this work the information and inspiration needed to spur on their actions.

## **Preface by Martin Bangemann**

**Member of the Commission**

Economic operators are nowadays confronted with intensified competition resulting from the simultaneous globalization of trade and operators, the progressive opening up of markets and the acceleration of technological developments.

In such a context, the emergence of an information society raises a number of challenges to which both the economy and industry are required to respond more or less urgently, according to the areas and sectors of activity. Whether we call it the "super highway", the "I-way", or the "Infobahn", the information society is progressively putting tools which are increasingly more advanced at the disposal of small, medium-sized or large enterprises producing goods or services, thus enabling them to deal with ever increasing flows of information while they simultaneously expand and grapple with the various challenges confronting them.

The transition from an industrial society to an information society is speeding up due to the progressive convergence of telecommunications, computer, consumer electronics and multimedia technologies. Several technologies have now reached a stage where their applications are having a profound effect on our lifestyle. The various ways in which we now create, process, access and transfer information are fundamentally changing relations in our society. As a result, a new society will come into being. It will be a society in which new services and new applications will have a great impact on human activities and on the economy and organizational structures.

These changes, with their far reaching effects on the economic and operational environment, require companies to have a continuous capacity to adapt to rapid and constant developments affecting the means and methods of production, while simultaneously taking on board advances in science and technology. They also go hand-in-hand with the need for operators to give due weight to the importance of intangible investments (such as research and training) so as to quickly develop competitive advantages resulting from the implementation of strategies to differentiate products and processes, which are key factors for competitiveness and for the survival of firms in the long run.

It is in this environment that the approach to an industrial competitiveness policy adopted by the European Union comes into its own. It is focused more than ever on promoting the importance of intangible investments in the development and growth of industry in order to permit an increase in the value added of goods and services. The modernization of the European industrial fabric must also result from increasing cooperation among all the actors concerned.

With this in mind, the Commission recently set up a number of research and industry task forces whose purpose is to contribute to developing the technologies needed for the "clean car", "multimedia educational software", the "next-generation aeroplane", "viral diseases and vaccines", "trains of the future" and "intermodal transport systems". The particular brief of the task forces is to align research activities more closely to the socioeconomic and society related concerns of our fellow citizens. To take one example, research carried out in the field of multimedia educational software should enable individuals and firms to have easier access to the progress put at their disposal by information and communications technologies. These initiatives will also make it possible to increase the effectiveness of Community action and as a result enable the successes of European research to trickle down to its citizens, consumers and taxpayers. Great store is set by the consultation of all the parties concerned, whether they be industrialists, users, small, medium-sized or large enterprises.

Finally, the aim is to encourage industrial operators to make the most of this irreversible trend in our societies to improve trade considerably with our economic partners throughout the world, while at the same time ensuring that the fruits of these efforts are discernible in the sphere of enterprise and innovation as well as in the labour market.

## **Preface by Yves-Thibault de Silguy**

**Member of the European Commission**

Closer European union has brought many benefits to European industry, stemming from being part of a large prosperous market. However, fluctuating exchange rates within the EU still hinder the functioning of the Single Market. The exciting prospect is for a move to Economic and Monetary Union, as foreseen by the Treaty of the European Union. A single currency in a single market will be the strong foundation needed for the success of

European businesses in the twenty first century. The Commission's Green Paper, of May 1995, on the practical arrangements for the introduction of the single currency is an important step in this direction.

Even when the Economic and Monetary Union is achieved, European industry will continue to face a constant challenge from global competitors. It is necessary to stimulate competitiveness so that satisfactory economic growth and high employment levels can be attained. The question is how to establish the right framework and economic environment to promote this. It is vital for policy makers to have up-to-date and relevant information in order to be able to assess the effect of past and future actions. One of the virtues of the present publication is that it is a systematic and detailed source of analyses and statistics on a large number of industries. It achieves this by drawing on the best information sources available for each industry. European enterprise statistics are going through a period of rapid change as a result of various actions taken at European Union level to update and harmonize classifications and methods. We can look forward to greater availability of detailed official statistics of the EU in the coming years. Nevertheless, the Panorama publication shows that it is possible to find usable figures today on many industries if time is taken to gather data from professional associations and other non-official sources.

This new edition of Panorama of EU Industry is the result of extensive collaboration between specialists in many fields. As such, it constitutes an important reference work for those wanting to find out more about European industry.

## Introduction by Stefano Micossi

**Director-General for Industry of the  
European Commission**

The recent upturn in economic activity should not divert attention from the fundamental questions that will determine Europe's long-run economic performance. Though the Union's economic basis is strong, rigidities and distortions still remain that prevent Europe from fully exploiting its potential for growth and employment creation.

It is vital that European Society be open to change and innovation rather than lapsing into complacency. Policy-makers can assist by creating a favourable environment for innovation and growth, through market-based policies that encourage investment in human capital and knowledge, promote the exchange of information and remove obstacles to change.

The Commission has been diligent in responding to this challenge. Its strategy for industry is market-based and horizontal in approach, focusing on providing coordination and support while leaving to the private sector the responsibility for identifying technological and market trends.

In this context the Panorama of EU Industry, with its up-to-the-minute and detailed statistics, has become established as an indispensable tool, providing companies and organisations with an overview of the current situation and trends for the future in the various industrial sectors.

The collection and analysis of this data requires the cooperation and commitment of an extensive network of associations, who contributed statistical data and reports on specific industrial sectors, and gave their valuable comments on the final drafts. Without their hard work the Panorama of EU Industry would not exist in its present form.

As in earlier editions, the opening section of this year's Panorama comprises analyses of topical issues affecting European industry, including: strategic alliances, the typical forms of transnational investment made by EU firms outside the EU, changing patterns of employment in industry, SMEs and employment, media services, and the export finance instruments available to the EU's capital goods industry, among others. The results of these analyses, many of which are distilled from studies carried out on behalf of the European Commission, provide important insights on how the relevant public and private sector organisations might refine their operations and procedures.

This year, we have also substantially modified the introductory chapter in order to better focus on the competitiveness issues facing EU manufacturing industry. Next year's edition will be expanded to include statistical data and reports on industry in the new Member States.

I feel confident that this publication will prove to be a vital tool for analysts and policy-makers, and indeed anyone who needs accurate, up-to-date and detailed information on European industry.

# Time frames and statistics

*Panorama 1995 provides a comprehensive picture of industry and services within the European Union. It is intended for all those requiring an update on the present situation and probable future developments in manufacturing and service industries in the EU.*

*Panorama opens with a "special features" section, which takes a global approach to a number of horizontal subjects of topical interest. The main part of the book - the industry reviews - provides a macroeconomic survey of EU industry and services, tracing the major developments in production, employment, trade and structural change and includes, in most cases, detailed statistical data and forecasts.*

## Time frame

The industry reviews and forecasts were written during the third and fourth quarters of 1994. Time series run from 1984 to 1993. Gaps in the data were filled by estimates wherever information was available, and these estimates are footnoted in the tables.

For the main indicators table, 1994 estimates have also been added. Forecasts, if available, were provided up to 1997 for many of the monographs. In such cases the data for 1985-1987 has been omitted from the table.

## Industry classification system

The selection and ordering of industries and services included in Panorama is based on the NACE coding system. This system classifies economic activity in terms of the nature of goods and services produced or by the nature of the production process employed. It is arranged on the decimal system and is subdivided into divisions (1-digit codes), classes (2-digit codes), groups (3-digit codes), sub-groups (4-digit codes) and items (5-digit codes), Panorama is primarily focused on the 3-digit level.

More detailed information on the NACE codes is contained in the General Industrial Classification of Economic Activities within the European Community published by Eurostat (1985 reprint of the 1970 edition). This publication is available from the usual outlets for Commission publications.

Although most chapters are headed by the appropriate NACE code, some do not have a NACE code indicated as the sector represents too small a fraction of the total NACE group. This is particularly common in the service sectors.

Revisions to the NACE classification have been incorporated in a Council Regulation (OJ L293, 24th October 1990) and have already started to be used for data collection in some of the Member States. One of the objectives of this revision is a further breakdown of some service and industrial categories.

Even when a NACE code appears beneath the sector title this should be viewed with caution. In some cases the NACE classification does not exactly coincide with the industrial sector under discussion. Each chapter includes a preliminary section explaining the sectoral coverage of the chapter in question, and indicating the extent to which this deviated from the NACE classification. There are cases where an overlap occurs between sectors and therefore data cannot be cumulated.

## Statistical data

The three main sources of data are Eurostat, DEBA (Data for European Business Analysis, which contributed estimates for recent years) and the professional trade associations. Data sources are indicated for each statistical table.

For manufacturing industries most chapters include a summary table containing the main indicators for the industry. These cover apparent consumption (defined as production + extra-EU imports - extra-EU exports), production, extra-EU exports, net exports (the trade balance of the European Union with the rest of the world) and employment.

Data in the tables are current ECU unless otherwise stated. Indices (reference year: 1990=100) have been calculated for production and trade data providing easier reference for trend changes.

Every effort has been made to include data for all EUR-12 Member States. Figures are on a pre-unification basis, and exclude East Germany unless otherwise stated. At the time the statistics for the publication were compiled, industry data by NACE for the three new Member States was not available. Where data are not available for the EUR-12, country coverage is clearly indicated in the footnotes appearing below each table. The statistical data in Panorama should be regarded with some caution, particularly for the more recent years where data have often been estimated. Production figures for the USA derived from the Federal Administration have also been included, as have Japanese data from MITI. To compare the Panorama of EU Industry with the US Industrial Outlook, Eurostat can provide you with a table correlating NACE to the US SIC.

## Production and employment

Data for production and employment come from annual enquiries conducted by Member States relating to **all enterprises with 20 or more employees**. The exceptions to this are the United States, Spain and Portugal (until 1989) where the coverage is for firms of all sizes, and Japan where establishments employing 4 or more persons are covered by the enquiry. Figures are generally available at the 3-digit level. The production data exclude VAT, and the employment data relate to persons employed excluding home workers. The definitions are standardised, and so the figures are comparable across industries and countries.

Estimates are not supplied to Eurostat by Member States for the firms not covered by the enquiries, and the figures under-report actual employment and production. Where this is significant, either industry association sources are used or note is made in the commentary. Derived statistics which are calculated from both production and trade statistics will also be affected. Apparent consumption will be understated, and import penetration ratios and export rates will be overstated.

Gaps in Eurostat's data for production and employment sent by the Member States have where possible been filled using estimation techniques by DEBA. Germany, France, the Netherlands, the United Kingdom, Denmark and Greece provided data up to 1992. Italy, Spain and Portugal up to 1991; Belgium and Ireland up to 1990 and Luxembourg up to 1988. EU totals contain estimates for missing countries. Estimates are derived from short-term indicators such as indices of production, producer prices and employment. Data for 1994 are

based on monthly indicators for the majority of the year, but also take into account independent sectoral forecasts. DEBA's estimates are only made for the NACE 2-digit and 3-digit level. Gaps in industry association figures at the 4 or 5-digit level have normally not been filled due to the scarcity of statistics at this level.

#### **Exchange rate conversion and deflators**

All data are reported in ECU, and national currencies have been converted at the average exchange rate prevailing for the year in question. The exchange rates used for the conversions are stated in the 'Annex' section at the end of the 'Highlights' chapter. With the large fluctuations seen in currency markets from the end of 1992, the reader should consider such effects on ECU values (especially at an individual country level).

Producer price indices have been used to deflate production data. In the cases where the corresponding NACE 3-digit index has not been available, the NACE 2-digit index has been used. For Portugal, where such indicators are not available, the corresponding retail price indices have been taken.

#### **Trade data**

The trade data are reported in terms of EU trade flows with the rest of the world. In most cases, these data are based on Eurostat figures. Exports valuations are generally fob (free on board, i.e. excluding freight and insurance costs) whereas import data are c.i.f. (i.e. inclusive of carriage, insurance and freight). Import statistics may generally be regarded as slightly more accurate than export statistics due to greater ease of data collection in the former case. All trade figures are in current ECU. For comparative purposes, the ratio of exports to imports (X/M) has been calculated for each set of trade data.

# QUESTIONNAIRE

## FOR THE ATTENTION OF READERS OF PANORAMA OF EU INDUSTRY

This is the sixth edition of "Panorama of EU Industry" published by the Office for Official Publications of the European Communities. We would be grateful if you could complete this short questionnaire which will enable us to adapt future editions of Panorama to your needs.

Please mark the appropriate response(s)

**1) How do you know about Panorama?**

---

- Advertisements ( )
- Recommendations (specify) ( )
- Through work ( )
- Don't know ( )
- Other (specify) .....

**2) Where did you obtain your copy of Panorama 1995-1996?**

---

- Office for Official Publications of the European Communities ( )
- Bookshop ( )
- Local agents ( )
- Library ( )
- Other (specify) .....

**3) Do you read Panorama every year or is this the first time?**

---

- Every year ( )
- 1st time ( )
- 2nd time ( )
- 3rd time ( )

**4) What do you think of Panorama 1995-1996?**

---

- |   |    |   |   |   |    |
|---|----|---|---|---|----|
| Presentation                                  | -- | - | 0 | + | ++ |
| Content of industrial reviews                 | -- | - | 0 | + | ++ |
| Quality of information                        | -- | - | 0 | + | ++ |
| How comprehensive the information is          | -- | - | 0 | + | ++ |
| Choice of subjects for the "special features" | -- | - | 0 | + | ++ |
| Quality of the "special features"             | -- | - | 0 | + | ++ |

**5) If you have read Panorama before, how does this new edition compare with previous ones?**

---

- |   |    |   |   |   |    |
|---|----|---|---|---|----|
| Presentation                                  | -- | - | 0 | + | ++ |
| Content of industrial reviews                 | -- | - | 0 | + | ++ |
| Quality of information                        | -- | - | 0 | + | ++ |
| Comprehensiveness of the information          | -- | - | 0 | + | ++ |
| Choice of subjects for the "special features" | -- | - | 0 | + | ++ |
| Quality of the "special features"             | -- | - | 0 | + | ++ |

**6) For what reasons do you read Panorama ? (several answers possible)**

---

- Occasional reference tool ( )
- For information about specific sectors ( )
- Statistics ( )
- Overview of Community industry ( )
- Others (specify) .....

**7) Would you be interested in the following proposals:**

---

Did you know that Panorama is now also available in CD-Rom	Yes	No
Ordering a selection of certain chapters	Yes	No
An update of statistics every six months	Yes	No
Other suggestions:		

.....  
.....  
.....

**8) What additional information would you like to find in Panorama?**

---

.....  
.....  
.....

**9) Personal details:**

---

Profession: .....

Company/Organisation: .....

Please return this questionnaire to:

**EUROPEAN COMMISSION**  
Directorate-General Industry  
(DG III/A/3)  
Rond-point Schuman 6  
B-1049 Brussels

# Special Features

## Highlights on industrial competitiveness: the trade performance of the EU manufacturing industry

This article analyses the trade performance of EU manufacturing and trends in relative competitiveness by sector.

Between 1982 and 1994, the EU's trade balance for goods and services has continuously been in surplus, with the surplus shrinking between 1986 and 1989 then growing rapidly after this, reaching as much as 3.6% of GDP in 1994.

The trend in the manufactured goods balance has failed to match the positive development on the balance for goods and services, however. The surplus on the manufactured goods balance shrank more or less continuously between 1985 and 1991, only recovering partly between 1992 and 1994. To some extent, the improvement in the manufactured goods balance between 1992 and 1994 reflects the cyclical downturn in Europe, with domestic demand growing slower than in the rest of the world. The development of relative unit labour costs and exchange rates also goes some way in explaining the past trends in the EU's market share both on domestic and on export markets. Still the past trends in aggregate demand and relative costs fall short of providing a comprehensive explanation of past developments in trade.

The sectoral analysis undertaken in this article shows that the EU's export structure is less specialised than that of either the US and Japan, and that the sectors in which the EU does have a comparative specialisation (measured by that sector's share of total manufactured exports) are not necessarily good performers. Two examples are textiles and clothing, and jewellery, both of which are also high import sectors. The geographical specialisation of EU trade is also less favourable than that of its direct competitors, the US and Japan, although progress has recently been posted on this front.

The analysis also points to wide disparities in changes in cost competitiveness and market shares at the sectoral level. As to cost competitiveness, a small majority of the sectors has actually recorded an improvement in relative unit labour cost competitiveness over the period 1987-94, thanks essentially to faster productivity growth in Europe than in the US and Japan. Among those sectors which reported declining labour cost competitiveness were, however, a number of high technology, fast growth sectors, among which electronics and electrical goods, and automotive. Taking into account the past trends in intermediate input costs (excluding capital costs), it appears that the EU's total unit cost competitiveness has improved in a number of areas, among which pharmaceuticals, basic chemicals and the leather goods sector, along with ferrous metals, office & EDP and aerospace equipment.

Looking at the trends in market shares, one finds that there are a number of sectors in which EU companies increased their share of export markets over the period 1987-94. However, their coverage of the domestic market has generally deteriorated, so that the overall trade performance still looks poor over the period considered. Although a few sectors have managed to lift their market shares in spite of adverse cost developments, the EU has lost market shares in most of the electrical/electronics sectors as well as in two of its largest export sectors, namely mechanical engineering and automotive equipment. To some extent this poor record reflects the fact that improvements in cost competitiveness have only taken place in recent years and have not yet fully translated into improvements in market shares.

Two other important factors influencing a country or sector's relative performance are R&D and innovation. A comparison

**Table 1: EU macroeconomic trends**  
(% annual change)

Total manufacturing	100	100	1.00	1.00

(1) share of sector in total EU manufacturing exports divided by the same share calculated for the OECD

(2) sectoral cover ratio (i.e. exports divided by imports) adjusted for the overall cover ratio of the manufacturing industry

Source: Eurostat, DEBA, DFI

of the EU's performance on these two counts with its main world competitors indicates that the European technological system appears to suffer from an over-emphasis on fundamental research at the expense of commercial innovations, and from a lack of clear technological edge at the sectoral level. Although the EU has a relatively strong position in terms of new registered patents in the aerospace and other transport equipment sectors, as well as in pharmaceuticals and general engineering, its share of new patents has been falling steadily in all sectors except aerospace with a particularly fast decline in the electronics sector, a sector in which R&D is most intense at world level and which increasingly drives innovation throughout the whole of industry.

## INTRODUCTION

This article analyses the trade performance of EU manufacturing at a sectoral level. In recent years most of the research carried out to evaluate the competitiveness of the EU economy has focused on macroeconomic factors. It is, however, increasingly evident that production costs, exchange rates and demand conditions can not solely explain a country's trade competitiveness, and that sectoral and structural factors constitute fundamental parameters of a country's trade performance. An additional, somewhat different, justification for a sectoral approach to competitiveness is the fact that industrial sectors show large disparities in their response to changes in the macroeconomic environment. Consequently, a sectoral approach is required to avoid improperly extrapolating and applying conclusions from a macroeconomic analysis to the sectoral level.

Given its structural character, the analysis presented in this article is essentially of a long-term nature. However, a pre-

liminary study of the recent past and of the influence of the business cycle is needed to understand the structural issues. An introductory section is therefore devoted to the macroeconomic picture of competitiveness, and to bridging the gap between the structural analysis and recent short-term developments. The structural analysis is developed in four sections. The first examines the trade structure of the EU, i.e. the nature of its sectoral and geographical specialisation. The two following sections investigate long-term developments in cost competitiveness and trade performance. Again, the objective is to highlight disparities in the response of industrial sectors to changing macroeconomic conditions, rather than to comment on recent developments. The last section of the structural analysis is devoted to a comparative evaluation of EU performance in research and development. The choice to include this topic is motivated by two observations. First, research and development seems to be one of the most important factors of non-price competitiveness. Second, the EU posts a poor industrial performance in several high-tech sectors, so that it is relevant to question the performance of its R&D system.

## THE MACROECONOMIC OUTLOOK

A country or region's current account reflects its balance of overall economic relations with the rest of the world. When a country's citizens spend more in foreign countries than they earn, the current account will turn negative. This deficit is then financed by borrowing foreign capital, selling foreign assets, or selling central bank reserves. On the other hand, a country achieving a surplus on its current account accumulates foreign assets.

Figure 1 depicts the evolution of the trade balance for goods and services of the EU, the US, and Japan between 1982 and

1994. Over the entire period under consideration, the EU's balance for goods and services has been positive. The surplus has fluctuated with lows in 1982 and 1989, and highs in 1986 and 1994. Since 1989, the EU's trade surplus has risen continuously, with the rate of growth accelerating after 1992. In 1994, the surplus on the EU's trade balance equalled a remarkable 3.6% of GDP, even higher than the 2.1% figure achieved by Japan.

Japan's trade balance also posted a surplus over the entire period 1982-1994, in most years greater (relative to GDP) than that of the EU. The US, in contrast, ran a continuous deficit which peaked at 3.3% of GDP in 1986 and 1987. Between 1987 and 1991, the US deficit was substantially reduced (to 0.5% of GDP), but since then it has been widening again, reaching close to 2% of US GDP in 1994. Notice that the evolution of the US trade balance almost mirrors those of the EU and Japan: in the years that the trade balance deteriorates in the US, it improves in the EU and Japan, and vice versa.

The balance of goods and services can be broken down into three components: the balance of services, the balance of primary commodities (energy products agricultural products, and other raw materials) and the balance of manufactured goods. The EU has traditionally been running a surplus in services which tends to be relatively stable as a share of GDP though it has slightly weakened since the early 1990s, reaching 1.1% in 1994. The balance of primary commodities, which was largely negative in the early 1980s, has improved almost continuously since that period turning into a surplus in the early 1990s and reaching 2.5% of GDP in 1994. The improvement in the balance of primary commodities explains much of the

observed rebound of the European balance in goods and services after 1989. On the other hand, the balance of manufactured goods has evolved comparatively poorly since the mid-1980s. As is apparent from Figure 2, the manufacturing balance exhibits a very different behaviour than the overall balance for goods and services. Although the manufacturing balance has remained positive over the 1982-94 period, the surplus shrank continuously between 1982 and 1991, coming down to 0.1% of GDP. By 1993, the surplus had increased to 1.3% of GDP, but the recovery was both later and slower than that of the overall trade balance. The sharp improvement of the EU's overall trade balance in the last few years therefore hides the absence of a significant improvement in the manufacturing sector.

Japan's manufacturing surplus is much higher than its overall trade surplus, as the country relies heavily on exports of manufactured goods to pay for the imports of nearly all its raw materials and energy requirements and for a trade deficit in services. In the peak years, 1984 and 1985, the manufacturing surplus exceeded 9% of GDP. As in the EU, the surplus declined continuously between 1985 and 1991, followed by a weak recovery thereafter. Nevertheless, in 1994, Japan's manufacturing trade surplus still accounted for 5.6% of GDP. The US registered a deficit in the trade of manufactured goods over the entire period 1982-1994. In this case, the evolution of the manufacturing and overall trade balances were very similar.

The remainder of this section will be devoted to an analysis of some macro-economic determinants of manufacturing trade performance. In succession, the influence of demand and of cost competitiveness will be explored.

Table 2C: Sectoral breakdown of Japanese exports, 1994

(1) share of sector in total Japanese manufacturing exports divided by the same share calculated for the OECD

(2) sectoral cover ratio (i.e. exports divided by imports) adjusted for the overall cover ratio of the manufacturing industry

To some extent, changes in the trade balance can be related to lags in the business cycle. Indeed, if an economy experiences an early recovery compared to the rest of the world, faster growing domestic demand will tend to fuel imports and to depress its trade balance. To examine the causality between EU domestic demand and the trade balance, both variables are plotted in Figure 3.

The measure used for domestic demand is defined as real EU domestic demand relative to that in the industrialised countries. The measure is defined in such way that it will decrease if domestic demand in the EU, adjusted for EU inflation, grows faster than the weighted average of domestic demand in the industrialised countries, also adjusted for inflation. Similarly, the measure for domestic demand in Figure 3 will rise if real demand in the EU grows *more slowly* than real demand in the rest of the industrialised world. Such a *relative decline* of domestic demand in the EU is indeed expected to yield an improvement of the trade balance.

Figure 3 shows that slow demand in the EU in the early eighties (1982-1985) and the early nineties (1992-1994) can explain the sharply increasing trade balance surpluses in those periods. However, in the intervening period, the evolution of the trade balance appears unrelated to developments in domestic demand.

Another explanatory factor of manufacturing trade performance which deserves investigation is cost competitiveness. Figure 4 presents the various factors determining unit labour cost, i.e. the labour cost per unit of real production. While for an individual firm or sector, intermediate materials and components purchased from other firms or sectors often represent a major part of production costs, for the economy as

a whole, labour is by far the most important cost component (intermediate input costs will, in contrast, be very relevant in the sectoral analysis below). All indicators shown in Figure 4 refer to the manufacturing sector, and are presented as indexes with base year 1990 (1990=100).

Changes in unit labour cost can be separated into two components: changes in wage rates and changes in real labour productivity. For each of these three variables, a competitiveness indicator has been calculated which compares changes in the variable considered in the EU to a weighted sum of changes in the same variable in the US and in Japan. In the case of nominal variables (unit labour costs and wage rates) the weighted sum is based on current exchange rates while in the case of the real variable (labour productivity) it is based on constant 1990 exchange rates. The competitiveness indicators have been plotted in Figure 4. Note that the indicators have been calculated in such a way that an increase corresponds to an improvement in the competitiveness of the EU. It is immediately apparent that, in terms of productivity, the EU position has remained fairly constant over the period considered. The European manufacturing industry has achieved productivity gains which on average have been similar to those observed in the US and Japan between 1982 and 1993. The Union has even managed to improve its relative position in terms of productivity in 1994. It is therefore unsurprising that the fluctuations in the indicator of wage rate competitiveness (which compares changes in wages and salaries per employee) is fairly similar to fluctuations in unit labour cost competitiveness except in 1994.

Figure 4 shows that between 1984 and 1990, the unit labour cost competitiveness of the EU compared to US and Japan deteriorated by about 30%. The indicator remained static in

Figure 1: Trade balance (1) - goods and services - EU (2), US, Japan

(1) as a share of GDP  
 (2) EU does not include former Eastern Germany  
 Source: Commission Services, AMECO

the following two years, and has improved by about 15% since then.

The most important determinant of the evolution of labour cost competitiveness, i.e. the deterioration in 1984-1990 and the improvement after 1992, has been the exchange rate. Figure 4 therefore also displays the effective exchange rate of the ECU. The effective exchange rate summarises the various bilateral exchange rates into a single number reflecting the average value of a currency. It is calculated as the weighted average exchange rate of a country's currency against the currencies of its trading partners, where the values of mutual trade are used as the weights. Here, the effective exchange rate of the ECU has been obtained as the appropriately weighted average of the dollar/ECU and yen/ECU exchange rates.

Examining Figure 4, it is clear that the unit labour cost (or wage rate) indicator and the effective exchange rate have mirrored each other year after year. Between 1984 and 1990 the effective exchange rate of the ECU appreciated by about a third (mainly a result of the depreciation of the dollar). This appreciation accounted for most of the deterioration of labour cost competitiveness over the same period. The value of the ECU remained fairly stable over the next two years, and decreased by about a fifth between 1992 and 1994 (due to stabilisation of the dollar and appreciation of the yen), contributing to a restoration of EU labour cost competitiveness.

The definition of the market share indicator is straightforward. The indicator is based on the share of EU exports in Triad exports, and is expressed as an index with base year 1990. The indicator of the domestic market share is more complicated. It has been calculated as the rate of coverage of EU domestic sales of manufactured goods by EU production, divided by the same ratio for the entire Triad. A decline of this indicator means that the EU supplies relatively less of its home market than the US and Japan, and thus loses domestic market share.

Figures 5 and 6 show that both export and domestic market shares are loosely related to cost competitiveness (the cost indicator has been lagged by one period for a better visual fit). The deterioration of cost competitiveness in the second half of the eighties has been associated with a loss of both export and domestic market share.

However, the fit is loose. In particular, cost competitiveness can not explain the very different development of export and domestic market shares in the early nineties. While the modest restoration of cost competitiveness in 1993 and 1994 seems to have triggered a sizeable recapture of export markets, performance on the domestic market remained weak.

To summarise, aggregate demand and cost variables can roughly account for recent developments in manufacturing trade performance, and are clearly important determinants of competitiveness. However, they fall short of providing a comprehensive explanation, suggesting that there are many other factors at play. To identify and investigate these other factors, a disaggregated, sectoral approach is indicated. This forms the subject of the following sections of the article.

### TRADE STRUCTURE

As mentioned above, simple macroeconomic factors such as the business cycle, costs developments, or exchange rate fluctuations cannot fully explain observed trade performances. It is now increasingly apparent that a country's sectoral structure plays a key role in determining its overall competitiveness and trade performance. This section will shed some light on the structure of EU trade and the nature of its sectoral and geographical specialisation.

Based on the observation that countries do not determine their exports on a random basis but specialise in those sectors or products for which they have a comparative advantage (such as proprietary knowledge, the use of a specific natural resource, particular human skills etc.), the strengths and weaknesses of a country can be inferred from a simple analysis of its trade patterns. Note that, although much of the discussion below will be based on 1994 data, the analysis is essentially

Figure 2: Trade balance (1) - manufacturing - EU (2), US, Japan

(1) as a share of GDP  
 (2) EU does not include former Eastern Germany  
 Source: Eurostat

of a medium- to long-term nature as the structural indicators used tend to be very stable over relatively long periods of time.

When analysing the structure of EU exports, two characteristics become rapidly apparent: first, compared to the rest of the Triad, the EU is less specialised, and second, its specialisation is marked by a number of weaknesses, in particular in relation to the sectoral and geographical specialisations. Each of these two aspects will be investigated in turn.

An examination of the contributions of the various NACE 3 sectors (a more detailed level of disaggregation than in the tables presented in this article) to the total exports of manufactured goods of a given country/region, shows that the sectors which account individually for more than 3% of total exports, represent less than 30% of total EU manufacturing exports. The comparable figures are 51% for the US and 62% for Japan. Exports are therefore more uniformly spread across sectors in the case of the EU than in the case of the US or Japan. In other words, the EU is less specialised in terms of the structure of its exports than the US or Japan. The indicator is obviously sensitive to the sectoral classification used and the threshold adopted but it is fairly robust as to the country ranking it implies. Indeed, the same ranking, with Japan the most and the EU the least specialised in the Triad, can be obtained using a wide range of thresholds, and also with other indicators such as the standard deviation of export shares. However, to the extent that specialisation is linked to the size of the country considered (a small country will tend to specialise in a more limited number of sectors) these results are difficult to interpret and it is impossible to conclude whether the EU is or not sufficiently specialised.

Rather than absolute specialisation, it is thus considerably more revealing to investigate the relative sectoral and geographical specialisation of trade in order to determine the nature of the comparative advantage of the EU.

Table 2 provides a snapshot of the sectoral structure of EU trade. Mechanical engineering is the largest exporting sector accounting

for 16% of total EU exports. It is followed by automotive equipment (8.7%) and food, drink and tobacco (6.5%). Other large exporting sectors include chemicals, particularly specialty chemicals and pharmaceuticals, and electrical engineering, particularly industrial electrical equipment.

The third column of Table 2 provides a more meaningful way to assess the nature of the EU's specialisation by comparing it to the average OECD export pattern. For a given sector, the indicator of export specialisation is calculated as that sector's share of the total manufacturing exports of the EU, divided by the same share evaluated for total OECD exports. A value of one therefore indicates that the weight of the corresponding sector in total exports is the same as the OECD average, in other words that the country considered shows no specialisation compared to the OECD average. Table 3 gives a snapshot of the relative specialisation patterns of the EU, the US, and Japan. Based on the indicator described above, the table lists those sectors which post either a strong or a moderate specialisation pattern.

A number of observations can be drawn from the table.

- The specialisation of the US is much closer to the OECD average than that of the EU or Japan. Only aerospace appears in the strong specialisation group. The country also appears relatively strong in electronics-related industries
- Japan has developed a strong comparative advantage in the electronics- and transport-related sectors.
- The EU has a large number of 'specialised' sectors but these appear little related except in the case of the textile cluster and, to a lesser extent, chemicals.
- Contrary to the US and Japan, the EU has little or no specialisation in electrical- and electronics-related sectors (computers, precision instruments, consumer electronics sectors etc.). More generally, pharmaceuticals appears as the only high-tech sector in the EU which benefits from a strong or moderate specialisation ratio.

Figure 3: EU (1) trade balance in goods and services and domestic demand

(1) EU 15  
 (2) Real domestic demand relative to industrial countries (inverted scale)  
 (3) Left scale  
 Source: Commission Services, AMECO

- Several sectors (such as food, drink and tobacco, and aerospace) which are traditionally considered as EU strengths, actually have a specialisation indicator only slightly higher than the OECD average and are not even included in the moderate specialisation category.

One of the weaknesses of the EU trade performance becomes more obvious when examining the weights of the sectors with a strong specialisation. In short, in the EU most of the sectors posting a strong or moderate specialisation account for less than 3% of manufacturing exports. The largest specialised sectors are the specialty chemicals and the textile sectors, whose individual shares of total exports are less than 5%. By contrast, many 'strong' sectors in Japan represent more than 8% of the country's total manufacturing exports. The only 'strong' sector in the US, namely aerospace, accounts for close to 8% of American exports. Overall, most of the sectors which account for the largest share of total EU exports either post a 'normal' specialisation (as in the case of mechanical engineering) or a weak specialisation (as for automotive equipment) compared to the US and Japan.

Another feature of the specialisation of European trade is that it does not necessarily entail performance, if performance is measured by the trade balance. Figure 9 shows the average cover ratio (i.e. exports divided by imports) for the specialisation categories defined above. To avoid differences linked to the business cycle or to exchange rates, the cover ratios have been adjusted for the average cover ratio for all manufacturing sectors in the region considered. In the EU, the cover ratio of strong sectors averages 0.8 (which corresponds to an adjusted deficit, meaning that the trade balance performance of the sectors of strong export specialisation is worse than that of manufacturing as a whole) against 6.2 in the US (though admittedly the group only covers one sector) and 2.6 in Japan. Overall, the average trade ratio for strong and moderate sectors hardly exceeds 1.0 in the EU against 1.4 in the US and 2.5 in Japan. Note that, in the EU, the specialised sectors which register a poor trade balance are either sectors

which generate large flows of imports of primary materials (oil refining and jewellery) or textile sectors (textile, leather, clothing, footwear etc.). EU exports are specialised in textile and clothing products but the trade balance of this sector has deteriorated markedly over the 1980s under the pressure of competition by low wage countries and increasing outward processing of European production. Besides, it is worth stressing that the sectoral picture provided here has to be considered as an average which can, in some cases, hide wide intra-sectoral performances. In the case of the textile sectors, for instance, an average bleak performance can conceal a much better performance in higher value added sub-sectors.

A systematic analysis of cover ratios adjusted for the overall trade surplus or deficit points to other features of EU industry structure.

The weighted average of the adjusted cover ratios must be equal to one. Schematically, these ratios can therefore point to two types of patterns:

- a relatively uniform distribution of ratios around one indicating that most of the sectors tend to post similar trade performances
- or large fluctuations in the distribution indicating that some perform well in terms of trade and that their large (adjusted) trade surpluses are compensated by large (adjusted) trade deficits in other sectors.

The first situation is a good description of European trade whereas the second corresponds to Japanese trade. The US is located somewhere between the EU and Japan although it is certainly closer to the EU than to Japan. Table 2 presents the adjusted cover ratios for EU manufacturing sectors. Note that the highest ratio (mechanical engineering) hardly exceeds 2.0. In the meantime, Japan totals five sectors with a ratio exceeding 2.0, and the US has four such sectors. In the EU, most of the above-average cover ratios correspond to specialised sectors. The only notable exceptions are mechanical engineering, automotive equipment and ferrous metals. The

**Figure 4: Indicators of EU cost competitiveness (1) - manufacturing industry**

(1) Each indicator measures the improvement/deterioration of the corresponding cost item in the EU relative to the US and Japan. Positive growth indicates an improvement in EU competitiveness

 Source: Eurostat, DEBA, DRI

problem of mechanical engineering which posts an export specialisation ratio slightly above the OECD average (but insufficiently high to be incorporated in the moderate specialisation category defined above) highlights one of the limits of this type of approach. Given the size of the sector in total exports (16% in the case of the EU), a high export specialisation ratio is difficult to imagine unless the country considered devotes a very high share of its resources to the sector. In fact, the EU is more specialised than both the US and Japan and it is clear that a high cover ratio indicates a comparative advantage in that case. The case of automotive equipment is quite different as the combination of a high cover ratio and of a weak export specialisation indicates that the EU exhibits both lower relative exports and lower relative imports compared to the OECD average. In other words, the EU is less integrated in world trade in this sector than the OECD average, something which is certainly linked to the trade restrictions practised in various Member States over the period considered. These restrictions have somewhat sheltered domestic producers from world competition and have fostered foreign direct investment. In this case, thus, the existence of a high cover ratio does not reflect the existence of a comparative advantage in that sector.

The analysis has so far focused on the sectoral specialisation of European trade but another important dimension is its geographic specialisation. It is of little benefit to a country to specialise in fast growing and high value added sectors if it only sells to stagnating export markets where the high sectoral potential can not be exploited.

The comparison of cover ratios and exports specialisation indices has already pointed to the danger of measuring comparative advantage on the basis of a single criteria.

Table 4 presents a geographic breakdown of exports of the EU, Japan, and the US. Unsurprisingly, each region dominates nearby export markets: the EU in EFTA, the Mediterranean Basin and Eastern Europe; the US in Canada and Latin Amer-

ica; and Japan in the NICs. Both Japan and Europe also have very strong export relations with the US.

Like its sectoral specialisation, the geographic structure of the EU's exports exhibits significant weakness compared to the other Triad members. In particular, the EU is less specialised in fast growth destinations and more dominant in slow growth destinations. When measuring export market growth by the increase of OECD exports between 1987 and 1993, the four fastest growing destinations were the NICs, China, Central and Eastern Europe, and Latin America. OECD exports to each of these regions rose by more than 100% over the 1987-1993 period. In 1993 these four areas of fast growth accounted for 23% of the EU's exports, against 35% of US and 42% of Japanese exports.

The four slowest growing destinations were the rest of the world (OPEC, Africa, ...), EFTA, Other Asia, and the EU itself, with OECD exports to these regions increasing by less than 30% between 1987 and 1993. The EU sold 40% of its exports in these four areas of slow growth, compared to 22% for Japan and 27% for the US.

A positive element is that the EU is improving its geographic specialisation. Between 1987 and 1993 it increased its share of Triad exports to the NICs, the fastest growing export destination, from 14% to 24%. This was largely at the expense of Japan, which saw its share fall from 59% to 50%. Furthermore, the EU maintained a very high market share (93% of Triad exports in 1993) in Central and Eastern Europe, and marginally increased its share in China. On the other hand, it lost market share in Latin America. Between 1987 and 1994, its share of Triad exports to Latin America fell from 30% to 24%, largely to the benefit of the US. Already a very strongly growing export market, Latin America is expected to become much more important in the future as economic reform programmes are laying the foundations for a rapid economic development not far behind the performance of the Asian NICs.

### COST COMPETITIVENESS

Table 5a summarises changes in the cost competitiveness of the EU over the 1987-94 period, and Tables 5b and 5c present similar information for the US and Japan respectively. The choice of such a relatively long period is motivated by the focus on long-term sectoral trends in competitiveness and not on recent developments. Each indicator in the table compares changes in EU costs to changes in the costs of Europe's main competitors. Due to data availability at the sectoral level, these competitors have been restricted to the US and Japan.

Total production costs can be broken down into a number of individual items such as labour costs and intermediate input costs. A specific indicator has been calculated for each of these items in order to be able to determine which particular factor is responsible for an increase or decrease in a sector's competitiveness. For instance, a relevant question is whether an observed deterioration in unit labour costs in the EU compared to the US and Japan is attributable to insufficient productivity gains or to fast-growing wage rates. As can be easily seen from the table, different indicators can exhibit quite different trends over the 1987-94 period. Furthermore, a deterioration in labour cost competitiveness is not systematically associated with a deterioration in total costs.

Starting with the analysis of labour costs, a small majority of sectors have experienced an improvement in labour cost competitiveness over the period considered (note that for all indicators, an *increase* indicates an *improvement* in the competitiveness of the EU). Many of these sectors report relatively large gains, particularly basic chemicals, leather and leather goods, footwear and clothing. Sectors which report a loss in competitiveness essentially include all electronics and electrical goods sectors (except computers), all transport sectors (except aerospace), food, drink and tobacco, and wooden products. Except for some electrical goods sectors, losses remain limited but they affect most of the larger exporting sectors and are therefore not without consequences for the average competitiveness of the manufacturing industry.

Breaking down unit labour costs into a wage rate and a productivity effect, only very few sectors in the EU have seen an improvement in wage rates competitiveness compared to the US and Japan. These are metal products, aerospace equipment, leather products, and textiles and clothing. In practice the list is probably even smaller as the indicator might not be very meaningful in the case of leather and textiles, two sectors for which the US and Japan are not major competitors.

In contrast, only very few sectors have suffered from lower productivity gains than their major trade competitors. Poor performers are mainly found in a group for which the competitiveness of the EU is known to be particularly problematic, namely electronics-related sectors such as office and EDP, consumer electronics, and instrument engineering. Sectors which have registered a particularly good performance on the productivity front include the primary metals sectors (both ferrous and non-ferrous), the three chemical sectors (though specialty chemicals remain somewhat behind), the textile cluster (particularly textiles and leather goods) and the wood cluster (wood products, pulp and paper, and printing and publishing). In most cases, the stronger productivity gains in Europe thus made it possible to offset the relatively faster growth of nominal labour costs, hence resulting in an improvement in unit labour cost competitiveness.

Only very few sectors have suffered a loss in competitiveness in terms of intermediate input costs per unit of output. To some extent, this positive result might result from the impact of changes in exchange rates on intra-EU trade. Sectors which report a loss in intermediate input cost competitiveness include automotive equipment, food, drink and tobacco, and footwear and clothing. Though it is difficult to draw further conclusions without more detailed analysis of relative input cost structures and price developments by country/region, one may wonder whether the European automotive manufacturers do not lag their US and Japanese counterparts in terms of rationalising their links with their suppliers.

**Figure 6: EU cost competitiveness and market shares (domestic market) - manufacturing industry**

(1) Indicator of unit labour cost competitiveness lagged by one year  
 (2) left scale  
 (3) Indicator of the coverage of EU demand by EU production compared to a similar ratio calculated for the Triad  
 Source: Eurostat, DEBA, DRI

The total unit cost indicator presented in column five of Table 5a is defined as the weighted average of unit labour costs and purchases of intermediate inputs per unit of real output. Total cost competitiveness therefore covers all cost components except capital costs and takes into account the weight of each component for each sector considered. Table 5a indicates that the European manufacturing industry has generally managed to improve its cost competitiveness over the period 1987-1994, though these gains remain marginal. Sectors such as automotive equipment, other means of transport and, to a lesser extent, food and drink, household appliances, and non-metallic minerals have all lost ground compared to their competitors. However, these losses remain generally relatively small. More dispersion can be observed in the case of the sectors which improved their cost competitiveness compared to the US and Japan. The pharmaceuticals, basic chemicals, and leather goods sectors are revealed as the clear winners followed by ferrous metals, office and EDP, and aerospace equipment. Note that, although these winners have generally improved their position both in terms of labour costs and in terms of intermediate input costs, the latter item seems to play a particularly important role in overall cost performance. This, again, highlights the danger of over-emphasising labour cost issues in a sectoral analysis.

Before turning to the next section, which is dedicated to the analysis of the trade performance by sector, it is necessary to emphasise that the relatively good cost performance observed over the 1987-94 period owes much to a marked improvement in costs and exchange rate conditions between 1992 and 1994. Given that trade adjusts only slowly to changes in costs, the EU trade performance over 1987-94 will look somewhat pale compared to its cost performance.

**MARKET SHARES**

Table 6 provides a number of indicators of trade performance, again for the 1987-94 period. The indicator of export market share compares EU exports to average OECD exports. The indicator of domestic market share is calculated as the coverage

of European consumption by European production (in practice, production minus exports divided by domestic sales) divided by a similar ratio calculated for the Triad. The trade balance indicator is simply defined to be the trade balance as a share of production.

The indicators only rarely point in the same direction. The overall performance appears poor, however, particularly when measured by the coverage of the domestic market. The EU manufacturing industry lost overall domestic market share, and this loss was widespread. Only very few sectors have managed to improve their domestic market share compared to the other members of the Triad. On the other hand, performance is considerably less uniform in the case of export market share. More than half of the sectors have raised their share of total OECD exports over the period considered, while the others saw their share shrink.

Based on these two indicators, the food and drink and the mineral oil refining industries seem the unquestionable winners. The sectors have managed to raise their share of OECD trade and to maintain their coverage of the European market in spite of adverse cost developments. They indeed belong both to the group of sectors which in 1994 were still hampered by inferior cost competitiveness when compared to 1987. Note however, that the apparent good performance of the food sector is, to some extent, explained by problems with trade data and that the actual performance of the EU food industry might be somewhat weaker.

A number of sectors have managed to limit losses on the domestic market, while significantly improving their export position and thus raising their trade surplus. These are usually sectors commonly regarded as relatively strong in the EU, such as aerospace equipment, pulp and paper, and households appliances.

By contrast, the chemical cluster, which is usually also regarded as relatively strong in the EU, appears in an intermediary position with a performance less bright than that of the

sectors above but still slightly better than the manufacturing average. Indeed, the chemical sectors have reported limited gains in market shares on the export market but also improvements in the trade balance and limited losses on the domestic market. Sectors which report a poor trade performance compared to the manufacturing average include textile products, footwear and clothing, rubber and plastics, motor vehicles and the electronic/electrical cluster. Excluding household appliances, the performance of the electronic/electrical cluster looks particularly bleak. All sectors in this cluster have experienced an increase in their trade deficit. Office and EDP and consumer electronics report good performances on the export market, but these are more than offset by a poor record on the domestic market. Electrical and telecom equipment have both lost ground on their domestic and export markets, most likely as a result of a deterioration of their cost competitiveness. Note that if the trade performance in electrical engineering is not particularly bright, the performance of the EU in mechanical engineering is also worrying. Indeed, the mechanical engineering sector has lost shares both on the domestic and the export markets though this counter-

performance is somewhat offset by an improvement in the trade balance.

It is somewhat difficult to assess the impact of worsening cost conditions on trade, both in terms of the magnitude of this impact and because of the lag between changing costs and trade performance. The average improvement in cost competitiveness between 1987 and 1994 is largely a result of improving cost and exchange rate conditions between 1992 and 1994. It is likely that for most sectors this improvement has not yet been entirely passed through. Table 6 therefore also includes a column providing the growth in cost competitiveness lagged by one year. For most of the sectors the lagged indicator indeed shows no or a much smaller improvement of cost competitiveness. Only ferrous metals, basic chemicals, pharmaceuticals, and leather goods have enjoyed an early improvement in terms of cost. Note that all of these sectors, except ferrous metals, also achieved an unambiguously favourable trade performance.

To summarise this discussion in terms of performance, good trade performers can be classified into two groups:

**Table 4: Geographic breakdown of exports, EU, US and Japan - 1993**

	Share of region in world imports	EU	Japan	US			
EFTA	6.5	21.4	2.0	2.9	167 186	167 186	6.5

(1) Each indicator measures the improvement/deterioration of the corresponding cost item in the EU relative to the US and Japan. Positive growth indicates an improvement in EU competitiveness  
Source: Eurostat, DEBA, DRI

- those sectors which have improved their trade performance over the period considered in spite of adverse cost developments (food, drink and tobacco, mineral oil refining and household appliances)
- those sectors which have managed to improve their cost competitiveness (basic chemicals, specialty chemicals, pulp and paper, and aerospace).

Note that the second group includes sectors for which cost competitiveness is not the key explanatory factor of changes in market share observed in past years (specialty chemicals and, to a lesser extent, aerospace), and that most of the good performers do not belong to the specialised sectors defined in the section devoted to the analysis of the trade structure.

As to poor trade performers, three comments can be made:

- The EU has continued to lose ground in the electrical/electronics sector. It has also suffered from adverse cost developments in the two sectors of the cluster for which it is generally considered as more competitive, namely electrical and telecom equipment.
- The EU has also lost market shares in the textile and clothing sectors though it has registered a good performance for leather products. Remember that the EU exhibits a relative specialisation in these sectors.
- Two of Europe's largest exporting sectors post worrying signs of weakness. Both mechanical engineering and auto-

otive equipment have lost market share and seem to have suffered from poor cost developments.

## RESEARCH & DEVELOPMENT

Research and development is obviously a key factor of competitiveness and growth, but the links between technology and economic performance are complex and difficult to measure. The technological system, which covers both scientific and industrial research, is largely an open system insofar as scientific discoveries and innovations tend to be diffused across borders through the publication of scientific papers and through the technologies embedded in exported products. In this context, the relationship between technology and competitiveness may appear somewhat elusive, but there is now a broad consensus around the view that countries tend to develop a limited number of areas of technological leadership which underpin their competitiveness in related industrial sectors, and which benefit from the cross-fertilisation between first grade research organisations, high-performing companies, and dedicated training centres.

Technological specialisation of course confers a much less stable and enduring advantage than the more traditional forms of specialisation resulting from factor endowments in labour or capital. Commercial innovations can be replicated more or less rapidly by competitors and a technological cluster will only confer a lasting competitive advantage if it manages to constantly renew its leadership. Note that although much of the recent economic research has emphasised the role of

**Table 6: Indicators of trade performance, EU

innovation in non-price competitiveness, the impact of technology on price competitiveness must not be overlooked. Innovation allows both the marketing of higher quality products for which price competition will play a limited role, and the improvement of production processes thereby raising productivity and curtailing costs.

In recent years, considerable effort has been geared towards the construction of databases of technology and R&D statistics for the EU and its main competitors, both for the technological system as a whole and at a sectoral level (see for instance *The European Report on Science and Technology Indicators - European Commission 1994* on which much of the discussion thereafter is based).

There are a number of ways to evaluate R&D activity. Dedicated statistical publications generally distinguish two types of technological indicators: those based on input measures, i.e. the amount of resources allocated to the research activity, and those based on output measures, i.e. the outcome of the R&D process. In most cases, input indicators are evaluated either in terms of R&D spending or in terms of human capital stock (the number of scientists or researchers employed). Output indicators can be measured either in terms of scientific output, generally proxied by the number of scientific publications, or in terms of technological output, generally proxied by the number of patents. Each of these measures suffers from specific statistical shortcomings and none of them is perfectly correlated with the actual technological performance of an economy or sector. Besides, these measures do not cover all the actual innovation effort as many innovations, particularly in terms of labour organisation, are captured neither on the input side nor on the output side. Nonetheless, the simultaneous analysis

of all these measures gives a reasonably clear picture of the strengths and weaknesses of the European technological system.

Overall, this picture is somewhat dreary, both at the level of the technological system as a whole and in terms of sectoral specialisation. To summarise the arguments developed hereafter, the European technological system suffers from an over-emphasis on fundamental research at the expense of commercial innovations, and from a lack of clear technological edge at the sectoral level.

Starting with the analysis of the technological system as a whole, Table 7 provides data on the resources allocated to R&D in the EU, the US, and Japan. Measured as a share of GDP, the EU suffers from the lowest R&D spending in the Triad. Other indicators of technological input such as the size of the existing pools of research scientists and engineers involved in R&D (commercial and non-commercial) point to a similar lag.

Another weakness of the EU technological system is a comparatively low contribution of business enterprises to total R&D. Both in terms of R&D performed and in terms of R&D financed, EU companies appear to be less involved in R&D than their American or Japanese counterparts. This is confirmed by data on the share of business research scientists or engineers in the labour force. Note that while company contributions to R&D do not necessarily have an influence on the quality of the research carried out in a country, they can be considered as an indicator of the commercial efficiency of this research. Therefore, the EU seems to suffer from a double handicap: a lower level of research spending combined with a less commercially oriented research effort. The latter

**Table 7: Structure of R&D spending in the EU, US and Japan, 1991**

	EU	US	Japan
Total R&D spending in GDP	2.0	2.6	2.9
Share of total R&D performed by business	62.6	71.6	66.0
Share of total R&D financed by business	53.2	59.0	68.2
RSEs (1) per 1000 labourforce	4.4	7.6	9.7
Business RSEs per 1000 labourforce	2.2	6.1	5.6

(1) Research Scientists and Engineers  
 Source: European Commission DG XII

conclusion is confirmed by measures of technological output such as the number of scientific publications or the number of patents. While the EU by and large continues to hold its rank in terms of scientific publications or Nobel prizes, its position in terms of commercial innovations seems to have deteriorated. Table 8 highlights the clear decline in the EU's share of the total number of patents granted in the US or in the total number of patent applications in the EU.

Two additional factors contribute to a somewhat dismal diagnosis of Europe's technological competitiveness. First a substantial share of European research is devoted to military ends. Given the general trend towards declining defence budgets and the increasing difficulty in developing civilian applications from military research (in particular because military research aims at technical prowess which are of limited use for civilian applications) a high share of defence R&D can be considered as a competitive handicap for European companies. Arguably, the US economy suffers from a similar handicap but such is not the case of Japan, which remains little involved in the defence industry. The second handicap of the European technology system, and this time compared both to the US and to Japan, is a costly duplication of research centres and activities which owes much to the national basis on which tech-

nology has developed. European integration should, however, progressively alleviate this problem.

Turning to the sectoral aspects of technological competitiveness, the EU's major weakness is that it has only few sectors with a strong research specialisation pattern and a clear technological edge. Table 9 presents the information of Table 8 detailed by sector. Between 1984 and 1993, the EU loses patent share in all sectors except aerospace and transport equipment. Both these sectors are, however, very minor in terms of the number of patents granted or applied for. Furthermore, the performance in aerospace owes much to the heavily subsidised defence-related sector. The losses are limited in chemicals, pharmaceuticals and engineering. The most worrying observation is the rapid further deterioration of the EU's already weak position in the electronics sectors (including information technologies). It is exactly those sectors that research and development activity is most intense at world level, while their products have a large impact on the productivity in many other industries.

There are no signs of a significant improvement in the position of the weak sectors. In contrast, after more careful consideration, the position of several stronger sectors where the EU is holding ground, or even leading, looks less than prominent.

EU leadership is not exclusive but shared with other members of the Triad, and it looks threatened in the medium term.

In electrical engineering, for instance, Japan has undertaken a major technological effort since the early 1980s which now translates into a much higher R&D intensity and also a much higher R&D spending level than in the EU. Even in mechanical engineering, the EU's largest exporting sector, R&D intensity is estimated at about 1.5%, against 1.3% for the US which is presently its major competitor, but 2.6% for Japan, which is the third largest world player in the sector. In the chemical sector, the US and the EU are the two traditional leaders, both in terms of patents granted and in terms of absolute level of spending but, there too, Japan has undertaken a considerable effort since the early 1980s which now results in a much higher R&D intensity than for the two other members of the Triad. That this effort is bearing fruit is evidenced by a marked increase in the share of Japan in the number of engineering and chemicals patents in Europe and in the US, as is apparent from Table 9.

In the aerospace sector, the problem is somewhat different to the extent that the EU appears to be squeezed between the US, which remains the unquestionable leader in the sector, and Japan which has somewhat reduced its admittedly considerable lag in recent years. The US has a much higher R&D intensity than the EU and Japan and, given the size of its industry, this leadership turns into an overwhelming domina-

tion in terms of the absolute level of R&D spending. Japan still remains a second order player in the field of aerospace, with a nearly negligible share of patents granted in the US or in Europe, and an absolute level of R&D spending which looks insignificant compared to that of the US or the EU. However, Japan's potential long term role in civilian aerospace should not be neglected. Japan's R&D intensity has surged since the late 1980s and is now close to that of the EU. Moreover, the American, and to a lesser extent European, domination in absolute R&D spending owes much to government subsidies particularly in terms of defence research. When considering the research intensity restricted to business-financed R&D, Japan ranks first and the EU only third.

In conclusion to this analysis of high-tech sectors, the EU suffers from a lack of clear technological domination and its traditional areas of strength look increasingly challenged. In addition, the European position appears particularly weak in the fast growing area of information technologies and electronics. Another worrying point is that Europe's relative weakness in high-tech sectors is not offset by a marked technological advantage in traditional or low- to medium-tech sectors.

## CONCLUSION

Looking at the trade balance, the competitiveness of the EU does not seem a cause for worry. The trade balance has permanently registered a surplus in the last decade. In the last years, the surplus increased spectacularly, and in 1994 it stood at 3.6% of GDP, which is even higher than in Japan.

However, the picture looks much darker when considering only the trade in manufactured goods, thus leaving out primary commodities and services. The trade balance in manufactured goods declined almost continuously between 1982 and 1991, when it remained barely positive. Since then, the manufacturing balance has recovered, but its performance has been sluggish compared to that of the overall trade balance of goods and services. The sharp improvement of the overall trade balance after 1989 has therefore hidden the persistent problems of the manufacturing sector.

An examination of the structure of EU exports reveals several weaknesses compared with the US and Japan, both in sectoral and geographical specialisation. First, the sectors in which the EU shows some degree of specialisation have unfavourable characteristics. For instance, they only include one high-tech sector, pharmaceuticals. Besides, the trade balance of sectors in which the EU has a significant export specialisation is relatively worse than that of other manufacturing sectors. With respect to the destination profile, export performance is handicapped by the EU's weaker trade links with some of the fastest growing markets, the NICs and Latin America. The structural problems of European competitiveness are widely recognised. For instance, they are summarised in the *First Report on Enhancing European Competitiveness* of the Competitiveness Advisory Group, which was published in June 1995.

The analysis of cost competitiveness and market shares clearly illustrates the value of a disaggregated, sectoral approach. Behind the indicators of overall trade performance and cost competitiveness, a wide disparity of sectoral developments is hidden. Of the many items discussed in these sections, a few observations are especially worth remembering. Two of

the EU's largest exporting sectors, mechanical engineering and the automotive industry, register a worrying loss of competitiveness, visible in a loss of market share and unfavourable relative cost developments. For individual sectors, the evolution of the cost of intermediate inputs is as equally decisive as that of labour costs in determining overall cost performance. Many sectors achieving good results in cost competitiveness and trade do not belong to the current sectors of EU specialisation. Examples are basic chemicals, pulp and paper, and aerospace.

The last section of the article complements the cost analysis by examining another important factor in competitiveness: research and development. The main conclusion is very similar to the result of the structural trade analysis. In particular, the absence of high-tech sectors in the trade specialisation of the EU reappears in its R&D performance. The EU has only very few sectors with a strong research specialisation and a clear technological edge. The sectors in which research is concentrated are often medium-tech, while the EU is only very weakly represented in information technology and electronics. In addition, even in mechanical engineering, the largest exporting sector, a medium-tech industry where the EU is relatively strong in R&D, the EU's R&D efforts are lower than those of Japan.

# A European approach to strategic alliances

## STRATEGIC ALLIANCES: MAIN ISSUES

Much of the debate on the significance of strategic alliances has traditionally been about the supposed conflict between "competition" on the one hand, and "competitiveness" on the other.

Free market economics, and much of both classical and recent theory on the subject, stresses that wealth creation is driven primarily by competition within the context of large, free markets. This idea is at the heart of most anti-trust and market-expanding legislation in the developed market economies and the European Union itself.

However, at the firm level, there are a number of arguments and indeed a considerable body of literature which suggests that there may be significant short and even long-term benefits from allowing some forms of "concentration" to develop.

In trying to resolve this apparent dilemma, it would be helpful to have a clearer picture of the following issues.

1) What are the criteria for assessing "gains" and "losses"? How can these be measured, and even if measured, are we still not in the territory of comparing different categories of impacts?

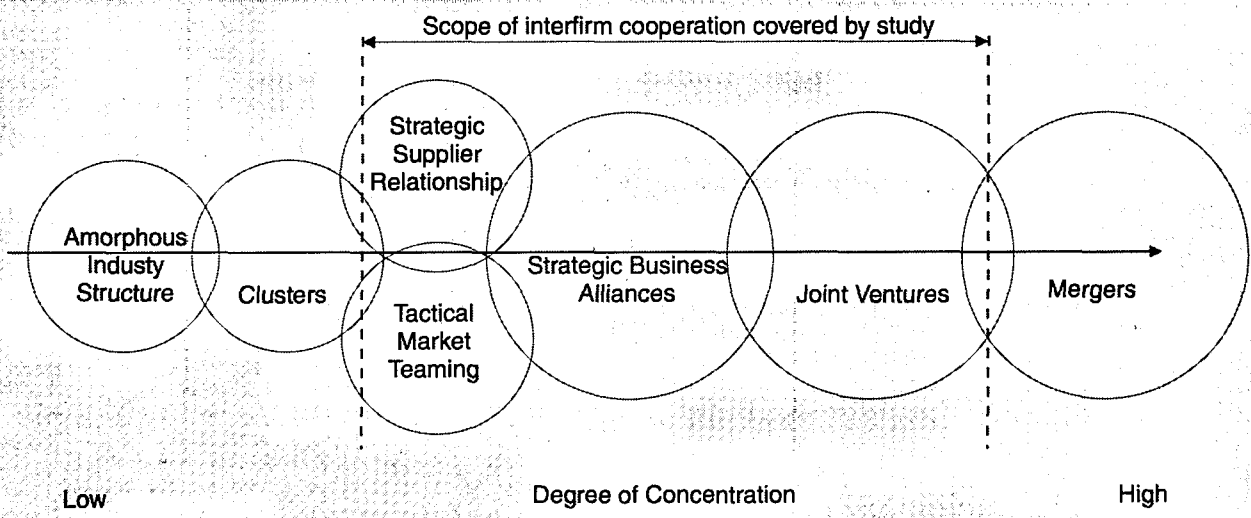

2) Case-by-case judgements do not resolve all the issues at stake. What is the overall pattern of such agreements? In general, should agreements be encouraged because they enhance competitiveness in global terms? Or should they be discouraged because they reduce competition? Or instead should we leave the forces of the market to determine general patterns and only intervene on specific cases as the need arises?

3) In many cases there may not be a "trade-off" at all. If an alliance allows two firms to survive that might have gone out of business separately, then the longer term impact of their association could well be to increase, not decrease, competition.

These issues are critical precisely because of more general questions that are already enshrined in European policy.

The European Commission White Paper on "Growth, Competitiveness and Employment"<sup>1</sup>, for example, calls for several measures which relate to alliances and competition between firms. These include the recognition that firms engaged in a number of critical sectors of the economy "come together in extremely complex groups and alliances" and that, "new balances must be sought between competition and cooperation". More specifically the White Paper calls for "the establishment

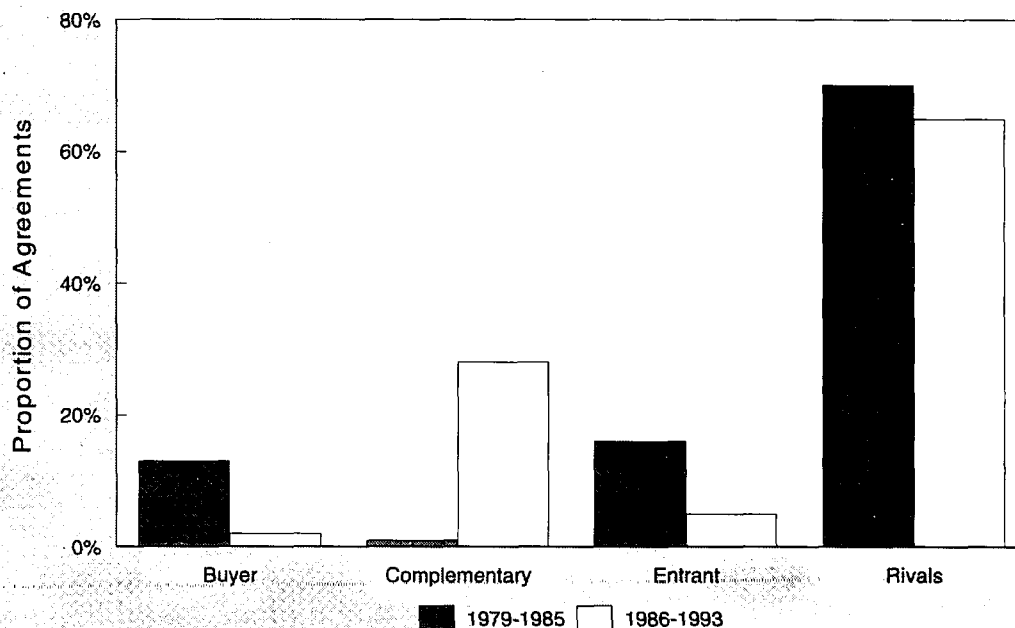

**Figure 1: Taxonomy of interfirm cooperation / concentration**

Figure 2: Strategic alliances: competitive position

Source: INSEAD database

of a coherent and concerted approach to strategic alliances" which prevents the development of "oligopolistic situations prejudicial to competition" but simultaneously does not go so far as to disadvantage Europe in terms of world competitiveness.

This study examines a number of key questions which have an important bearing on the Commission's further deliberations:

1) What is the most useful framework for thinking about alliances? Are all alliances the same or can they be usefully categorised into "types"? If so, what difference might this make in policy terms?

2) Is it possible to make empirical generalisations about alliances? This is important because supposed generalisations directly influence policy debates. For instance, the "supposition" that European businesses may be less likely to enter into alliances than, say, Asian ones, may be influencing our views about the importance of encouraging alliances. Or the "supposition" that alliances are very frequently motivated by a desire to collude or share markets may be important in assessing the stringency of anti-trust regulations. The data summarised here will help assess the weight which should be given to these, and similar perceptions, in discussing policy.

3) What can be said about alliance outcomes? Does it matter whether they are more or less prone to failure than, say, mergers and acquisitions? Is it possible, and perhaps more useful, instead, to provide managers and policy makers with some guidelines about what is more or less likely to lead to success? And in place of thinking about regulation in terms of a simple "Yes/No" proposition, can we use the research findings to suggest a more "conditional" set of approaches to the question?

### TOWARDS A USEFUL DEFINITION

Strategic alliances defy single one line definitions, just as they defy simplistic generalisations of other kinds (see below). A broad taxonomy of inter-firm cooperation (Figure 1) is a good place to start. Inter-firm cooperation is a continuum ranging from "Amorphous" at one extreme to "Mergers" at

the other. Various types of cooperative intensity occupy the space in-between.

Empirical evidence from the INSEAD database on Strategic alliances and from a number of case studies, further suggests that when an alliance is strategic it demonstrates some or all of the following main features:

- (1) Its "intent" is strategic. That is, the partners mean the alliance to further some highly important objectives for the firms concerned.
- (2) In so doing, the alliance is likely to exist for a longer rather than shorter period of time - in practice several years.
- (3) There is a specific goal or goals to do with generating competitive advantage in either products, key activities or major markets.
- (4) Partners often "give up" something important in their own competence in return for the success of the alliance. For example in Airbus the participants no longer individually possess all the technologies of commercial airliner design. So although partners may "gain" rewards, they sometimes lose the ability to operate alone in the longer term.

### TYOLOGIES AND CATEGORIES

Much of the previous thinking on the question of alliances has been concerned about categorising them into "types". This has always seemed a promising line of enquiry because the data on alliances is so large and so "messy" that it has seemed difficult to think of them in a unified way. Management writers have suggested a variety of typologies.

Lorange, Roos and Simic Bronn<sup>2</sup> develop a taxonomy of motivation for forming alliances depending on the strategic objective. The four categories identified are:

- Defence
  - Company needs to defend its strategically important core business
  - Alliances might be formed for access to new competencies, new markets, new technology or other specific resources.

Figure 3: Alliances and R&D by sector: Europe

(1) R&D intensity is based on the relationship between the amount of R&D in each sector and the weight of that sector in the economy. Hence the aerospace sector has the highest R&D intensity, although the total spent is less than in electronics, for example. Alliance intensity is calculated in a similar way. Source: OECD 'ANBERD' 1992; Braxton/Horack Adler analysis

- Catch-up
  - Company needs to catch-up in a core business
  - An alliance can help bolster the firm's competitive position and allow it to retain leadership, examples may include access to new products or markets
- Remain
  - A company with a leading position in a peripheral business may use an alliance to extract the maximum value from that business
- Restructure
  - Alliances can be used to help restructure and exit businesses by allowing rationalisation of production capacity, etc.

Game theory has also been used to demonstrate that co-operative strategies can be more successful than competitive strategies. Axelrod<sup>3</sup> invited game theorists to test different strategies in a competitive simulation. The overall winner was a strategy called "Tit for Tat" which responds positively to co-operative moves but negatively to competitive moves. The strategy was further tested in a second, much larger, round of the game and was again the overall winner.

There is no doubt that alliances are somewhat "in fashion" at the moment, seemingly with many companies rushing to form alliances. However, although there may be an element of fashion now, it is clear that the literature supports the use of alliance as a means of gaining access to strategic resources.

In addition, successful management of alliances receives considerable attention in the literature. A recurring theme is that

strong, autonomous management is important for success of the alliance. Management of alliances clearly has great potential for conflict between parents, who may have different objectives, therefore the stronger and more autonomous the alliance, then the greater the chance of success.

Killing<sup>4</sup> looks in detail at the management structures most likely to be successful. He distinguishes between independent ventures which are usually successful (by definition) and those that are more closely tied to their parents, which may have shared management or dominant parent management. Shared management often results in slow and confused decision making, whereas ventures which have one of the parents dominating the management of the venture are most likely to be successful. Only in situations where it is essential for both parents to be involved in the day to day management of the venture, i.e. where the skills of both parents are critical to success, should shared management be adopted.

Partner top management have to be fully committed to the alliance and set clear objectives for the alliance which are communicated throughout the alliance organisation.

Understanding cultural differences between partners, and the more tangible strengths and weaknesses of partners, is important to ensure that the alliance can benefit to the greatest extent from its parentage. The quality of the relationship is important to ensuring success; trust is often cited as an important factor. The greater understanding of cultural differences and partner strengths and weaknesses will be important in helping to avoid breakdown in trust. Development of alliances in phases is also recommended as a route to building trust gradually; as experience with alliances grows between

partners then the extent and depth of the alliance can be expanded.

Commitment of the best personnel to the alliance can, as with any business, increase the chance of success. Partners must resist the temptation to staff alliances with their second best personnel. The partner will also benefit through the greater learning capacity of the best personnel. Learning can also be facilitated through long term commitment of the individual to the alliance. The western career management system of continuous rotation can hamper the learning process.

Monitoring the progress of the alliance against objectives helps alert the partners to changing circumstances which may demand a change in the alliance structure, or indeed withdrawal from the alliance. Constant monitoring can ensure problems are avoided; an alliance is like a marriage, it has to be worked at all the time. Exit strategies should be planned at the time the alliance is formed. Partners need to avoid becoming "alliance dependent", such that they can still continue their business without access to the alliance.

There are two main conclusions from the management literature.

First, the most useful and meaningful framework for categorising alliances is one that depends more on looking at the purpose or intent of the alliance than at its form or structure, or indeed whether it involves firms from the same production and marketing stage (horizontal) or a different one (vertical). This is discussed in more detail below.

Second, the analysis of the INSEAD database as well as the case studies, demonstrates that the distinction between joint ventures, cooperative agreements or other forms and structures is largely irrelevant to the actual impact or outcome of an alliance. Differences in treatment by the regulatory authorities based on structure or form rather than on intent or outcome are therefore problematic or even confusing.

Through their work looking at core competencies, strategic alliances and global strategy, Hamel, Doz and Prahalad have

developed a taxonomy of alliances which is useful in understanding where different theories and ideas can be applied in practical situations.

### Alliances aimed at managing maturity and restructuring

Here alliances are designed to allow reduction of productive capacity and the orderly restructuring of mature industries. They are frequently horizontal alliances which could be interpreted as collusive.

The logic of such alliances is essentially the management of over-capacity or the orderly reduction in scale of "sunset" industries. In one such alliance, EVC, it seems clear that while the potential for collusion and anti-competitive behaviour is real, the critical issues are also related to the logic of restructuring. In this instance, the European Commission allowed the agreement in order to facilitate the restructuring of the PVC industry in Europe while maintaining its role in the investigation of alleged price-fixing. The joint venture has had, on balance, some success in achieving its objectives of restructuring the PVC industry in Europe, while avoiding a much more painful and unmanaged reduction in capacity had it not been allowed.

Broadly speaking, such cases will always involve complicated trade-offs between permitting otherwise prohibited market sharing and the difficulties of market restructuring. However, the alternative to permitting agreements may be the closure of both parties' business and with a consequent reduction, not increase, in competition. In this, as in other similar instances, the use of conditional approvals which are time-bound and performance-related seems extremely sensible.

The other real difficulty with this category of alliance is the possibility of such agreements being informal or "subterranean". Of course in such cases regulations which depend on notification are in any case meaningless. The suspicion that market power may be exercised to the detriment of competition will always be present.

Figure 4: Strategic alliances: type of agreement

Source: INSEAD database

### Alliances aimed at establishing technical standards

Where fragmentation of technical standards may prevent or delay the introduction of a new product or technology, then alliances may be formed to establish industry standards and allow orderly development of new markets. The most commonly quoted examples are the alliances designed to establish a common VCR format.

When VCRs were first introduced, a number of different technical standards were introduced by companies such as Sony of Japan and Philips of the Netherlands. However, none of these standards dominated, VCRs remained expensive and total market penetration was low. In the late 1970s Matsushita introduced the VHS format which gave the longer play time which consumers were demanding. Matsushita formed a number of alliances around the world including those with Thomson in France and Thorn in the UK which ensured that a number of manufacturers had access to the technology and key components.

The much larger manufacturing volumes ensured that low costs could be achieved for the key components, thus ensuring much more rapid penetration of VCRs than would otherwise have been possible. Thus consumers have clearly benefited by such co-operation by having access to VCRs earlier than they would have done otherwise.

An important aspect of this type of alliance is that it alters the basis of competition from the core technology itself to other "non-core" product features and indeed, price. This type of alliance can also eliminate the genuinely economically wasteful development of different standards.

Not all alliances of this type have been successful. Through the Japanese Broadcasting Corporation (NHK), the Japanese government sought to set a technical standard for high definition television (HDTV); the development effort included

NHK and a number of the major electronics manufacturers. However, rapidly changing technology and the high cost of the HDTV televisions resulted in failure to establish a standard. In contrast, in the USA, a competition was used to select the best technical standard for HDTV from a number of competing consortia.

### Alliances aimed at achieving complementary advantages

Complementary alliances are formed where partners either undertake different activities within an alliance or collaborate on one central activity. The partners may be from the same or different industries. Of course, the partners are able to undertake specific activities because they have the technology, assets and organisational ability necessary to execute those activities.

Very many alliances have partners from the same or related industries undertaking complementary activities. Examples include "technology for market access" alliances which are very common, as well as OEM supply agreements. From a policy perspective, a key issue is how close the shared activities become and therefore whether the alliance effectively reduces competition.

Alliances which genuinely share different activities would not usually be considered anti-competitive provided that there is no evidence of collusion in the end product market.

A less traditional use of alliances is for un-related industries to collaborate in the development of new product types or even completely new industries. The most commonly used example is the convergence of computers and communications, e.g. the use of software in PABX exchanges. Here, alliances have been used to combine the different technologies needed to create new products and even establish a new industry. The ability to form alliances of this nature is core to the competitiveness of emerging industries. This is an example

Figure 5: Strategic alliances

Source: INSEAD database

**Figure 6: Alliance typology: summary of key issues**

Type of alliance	Purpose/Intent	Regulatory questions	Measurement issues	Industries
Managing maturity / restructuring	Capacity reductions; orderly restructuring; changing competitive structure	Balancing potential for collusion against need for change in industrial structures	How to measure market power; how to monitor "subterranean" agreements	Mature, end of life cycle industries. Social and employment impacts likely to be important, especially in specific regions
Establishing standards	Creation of technical standards for products and processes; changing the basis of competition	Balancing potential for collusion against need to encourage new markets	Recognition of need for standards; balancing market creation against potential for abuse	Usually "sunrise" or embryonic industries
Achieving complementary advantages	Achieve fairly rapid competitive advantages of scale, specialisation	Complex cooperation / competitive industry structures, blurring edges of corporation	Inherent complexity of industrial structures makes traditional rules of thumb (e.g. degree of concentration) obsolete. New measures needed	Probable coverage nowadays of most industries at most phases of product life cycles
Learning	Often "pre-competitive" or "catch-up"; strong R&D focus aimed at developing core competences	Should public authorities intervene at all? Should such alliances be encouraged as a key part of industrial policy?	How to assess effectiveness; how to pick winners not losers?	Should focus on technologies and processes as well as industries

Source: Author

of a situation where alliances can be economically more efficient than arm's length economic transactions as the work of Balakrishnan and Koza<sup>5</sup> demonstrates.

Such alliances represent the great majority of strategic alliances. Figure 2 shows that explicitly "complementary" alliances (between firms in different industries) represented about 30 % of all alliances in the period 1986-1993. Alliances between "rivals" (firms in the same approximate industry) - the largest single category - include a majority whose "intent" was to achieve complementary advantages.

For example, in the case of the advertising agency Publicis, the company had several choices in implementing a growth strategy. It could have allowed itself to be bought, but this was not acceptable either to the owners or management.

A second alternative, that of buying another agency was discarded because the company would have had to stretch itself financially, putting the rest of the group at risk.

Unwilling to be bought and unable to buy, Publicis decided to form an alliance with FCB. It seemed clear that from a strategic point of view, the alliance seemed "a good fit." Publicis was the largest agency in France, with a successful European network; FCB was strong in the United States and Asia, but its presence in Europe was negligible. The client portfolios were complementary: besides Nestle, the two agencies shared SC Johnson and Colgate-Palmolive. In addition, there were few competing clients, an important consideration since many advertising industry joint ventures had run into difficulties because clients were unwilling to deal with an agency which also served a competing brand.

Figure 3, showing the relationship between the intensity of alliances by sector and the intensity of R&D, adds further weight to the view that most alliances are formed to solve real competitive problems (sharing R&D or production "effort") rather than to engage in explicitly collusive behaviour.

An additional consideration is the fact that many alliances, especially successful ones, evolve and change over time. In Airbus, for example, the participants began with competencies in all aspects of aircraft design and manufacture. Over time, and because of specialisation, participating firms could no longer sustain all the skills necessary to build high performance commercial aircraft. What was once a "horizontal" alliance may now be a "vertical" one.

In most cases, there is more variation in the relative degree of success or failure than in the degree of threat to the public interest through collusion, price-fixing or anti-competitive behaviour.

To take another, example Corning's skill in forming and managing alliances effectively has given the company the ability to leverage technical development rapidly and widely. Such an ability, might, in some circumstances, enable the lead partner to exert undue market power, especially where competition is restricted through natural or legal monopolies. An example with some potential for this was the situation involving agreements between Corning and the European cable manufacturers.

These agreements were designed to develop and exploit the development of fibre optics. The cable companies were essentially sole suppliers to monopoly telecom operators in each of the major European countries. Corning initially formed joint development agreements in 1973-74 with each of the European cable companies, with the purpose of developing the cabling technology necessary to use fibre optics in practical situations.

Between 1975 and 1978 Corning also formed an exclusive distribution agreement with each partner for the sale of optical fibres in their respective countries. The agreements also allowed Corning to sell directly in each country. The main reason for offering exclusive agreements was to ensure the interest of the European manufacturers.

Figure 7: Strategic alliances: proportion of agreements by sector

Source: INSEAD database

These agreements were further developed during the early to mid 1980s into manufacturing agreements with each of the partners. In 1981 Corning formed a 50/50 joint venture with BICC in the UK as an unlimited partnership called "Optical Fibres" and a 40/60 joint venture with Compagnie Financiere pour les Fibres Optiques in France, called "Fibres Optiques Industries". The joint venture with Siemens (Siecor) was also expanded to include a 50/50 manufacturing agreement in 1985. In addition, Corning were licensor to one of Pirelli's three factories. Through these agreements, Corning developed considerable strength in the European market.

The underlying reason for Corning's strong position in the European market was built upon the optical fibre technology that Corning had been the first to develop. However, the use of exclusive distribution agreements had the effect of increasing Corning's influence in each individual market, eliminating any potential competition in the manufacturing and marketing activities of the joint venture companies.

In this instance, the outcome of what were originally technical and market access agreements, might have been to significantly leverage Corning's technological advantage into significant market power. The nature of the industry with regulated monopoly telecom providers was also a significant multiplier. This is one example where the use of alliances showed some potential of developing into an anti-competitive situation, hence the European Commission decided to reduce Corning's power while still allowing an important new technology to develop. The Commission gave Corning the option of withdrawing from all but one of the joint ventures or moving to a minority voting position in all of them. Corning chose the latter option.

In such cases, competition is maintained if the "end product" markets retain competition. Although this conclusion begs the question of how this degree of competition should be measured or ascertained, it seems that the principle at least is clear. Moreover, it is certainly possible to show that competition was increased relative to the prior situation in the case of most of the alliances reviewed in depth. However, it does not necessarily follow, that other options may have existed which would have allowed competition to develop even further.

### Learning alliances

Global competitive advantage is increasingly dependent on the development and exploitation of core competencies. Core competencies are the core technologies, skills and abilities which define the corporation's competitive ability. As such, competencies are difficult to acquire in the short-term. Even if competencies are available through acquisition, it is sometimes difficult to transfer knowledge and learning from an acquired company.

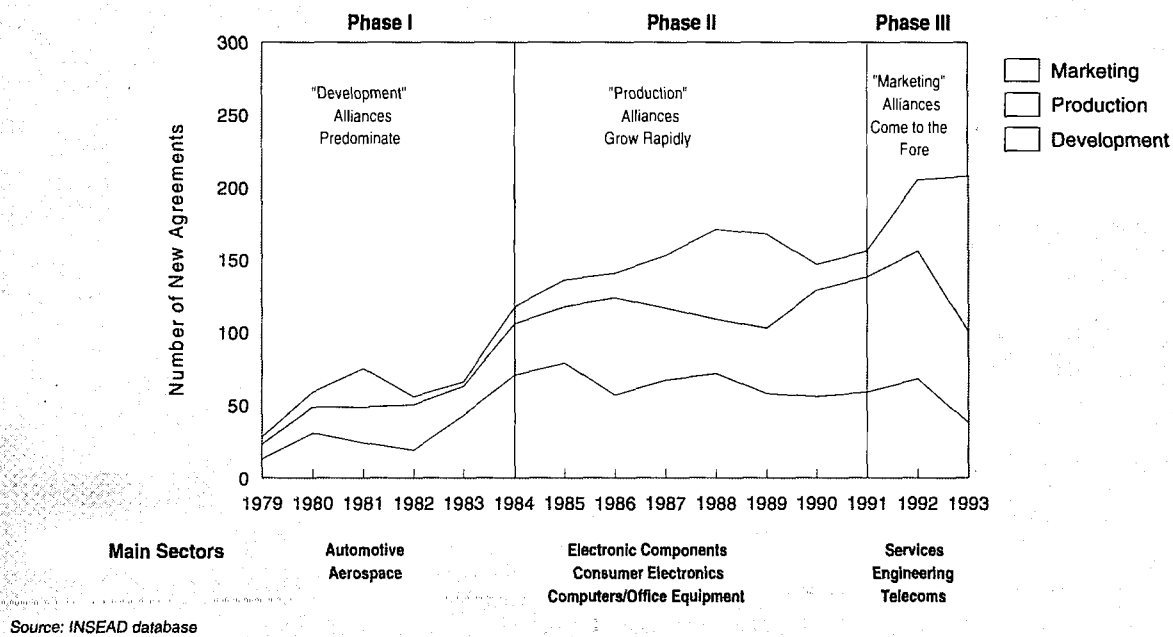

Alliances are a route through which corporations can acquire new learning. Increasingly, the objective of alliances is to acquire new skills by learning from partners. An example of a learning alliance may be the Rover-Honda alliance in which Rover was given an opportunity to improve its manufacturing skills in return for providing Honda with European production capacity and access to distribution.

Honda also had an opportunity to learn from the alliance. Honda's core technical competence is well known to be in engine and other powertrain components. Like most Japanese automotive manufacturers, Honda's abilities in chassis engineering were less well developed because the driving conditions in Japan and the USA are relatively undemanding compared to Europe. Honda needed to develop the ability to engineer cars for the European market if it was to become a truly global automotive manufacturer.

Although the complementary nature of the alliance was probably the most important reason for its formation, the ultimate success was due in no small measure to the intent of both partners to learn from each other. Indeed with complementary abilities, it is almost inevitable that one of the potential outcomes of such an alliance will be significant learning for the partners. It seems that in this case, the learning intent was recognised and deliberately developed and became a defining feature of the alliance.

In the INSEAD database, it is possible to track alliances that have strong "learning" agendas by looking at those which involve development. These are defined as alliances designed for pre-competitive and basic research, as well as product and component development. Alliances that explicitly address

Figure 8: Strategic alliances: number of agreements by type

development account for 25 % of agreements in the period 1986-1993 (see Figure 4).

Learning alliances are essentially about gaining or enhancing the core competencies of the organisation. As such they are frequently "pre-competitive" in nature and include programmes such as Europe's ESPRIT and Japan's VLSI programmes. Although the latter have strong governmental inputs, many learning alliances exist at the initiative of firms themselves.

In several case studies which involve learning, the European partner in each case probably learned as much or more than the non-European partner (although other benefits from the alliances were more equally shared). Other evidence suggests that where "learning" is an explicit goal, European firms can be as effective in this regard as any other nationality (e.g. Thomson's learning of micro-mechanical technology from JVC). However, studies of Asian firms' attitude to collaboration suggest a far greater "learning orientation" on their part. In other words, learning depends on whether managers explicitly see collaboration as a learning device.

In addition, there is little very serious evidence that alliances on balance favour non-European companies or result in general in unwanted or undesirable transfers of knowledge to non-European companies. Although this may happen in specific instances, it seems that the opposite is about equally likely to occur. The critical questions are about management's orientation to the process.

Furthermore, as Figure 5 shows, there is nothing inherent in the proportion of alliances between firms from the major economic blocs which suggests that European firms are fundamentally missing out on learning or alternatively giving too much away.

The arguments set out in this section are summarised in Figure 6.

### MAIN TRENDS IN ALLIANCES

Alliances continue to grow rapidly in the world economy as a major tool of strategic management for companies in almost all industries and most major trading blocs (see Figure 5). In the face of these trends, it is probably meaningless to ask whether alliances should or should not be encouraged or indeed

whether they are "good" or "bad". The fact is they are now an established and major feature of the business landscape.

For this reason, it may no longer make much sense to keep looking for any broad generalisations about alliances. Simplistic generalisations are almost certain to be misleading because of the multiplicity of counter examples.

First, there is little or no evidence that Europe is in some way "missing out" or "losing ground" in terms of propensity to alliance behaviour. About one-quarter of the agreements in the INSEAD database involve intra-EU agreements while about another 40 % involve Europe plus another partner. A growing number of alliances involve a European plus another non-US, non-Japanese partner from Asia or East or West Europe.

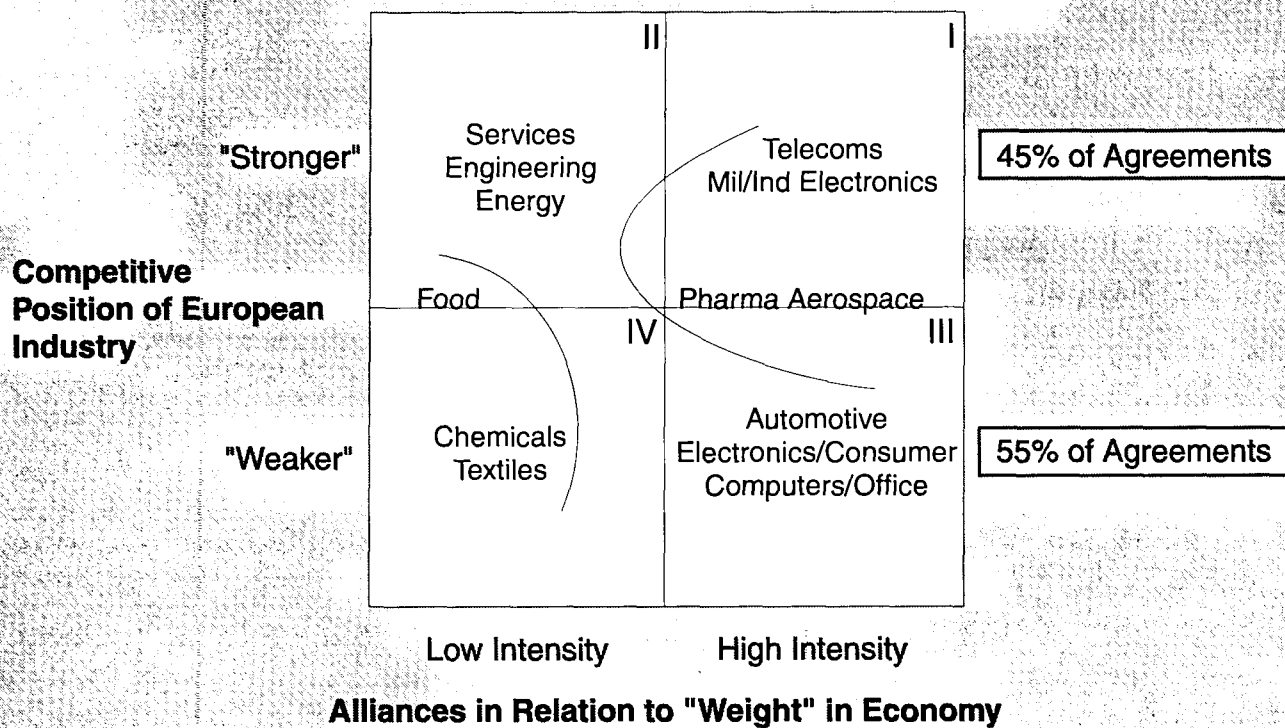

Second, the sectoral pattern as well as the "drivers" of alliances have changed considerably over time. Early adopters of alliance behaviour tended to concentrate in automobile, aerospace and other similarly capital intensive industries. More recently, we observe alliances spreading to other sectors especially services and electronic components (Figure 7).

Third, these changes are accompanied by changes in the nature of alliances (see Figure 8). Whereas in the early 1980s, (Phase I), "development" was the most frequent reason for entering into an alliance, by the mid 1980s (Phase II) production sharing agreements were more common. Most recently (Phase III) there has been a remarkable upsurge in alliances focused on marketing as more service oriented businesses have become global players and improvements in computer systems and telecommunications have facilitated worldwide coordination of activities on a day-to-day basis (e.g., airline and hotel reservations systems).

Fourth, agreements do not appear, in the vast majority of cases, designed to reduce competition or increase collusion. "Complementary" alliances which are between firms in different product/market segments and tend to emphasise new product development are now 30 % of the total in the INSEAD database for the period 1986-93. Even alliances between "rivals" are usually of a developmental nature.

Of course, this does not mean that regulatory authorities do not need to remain diligent and continue to monitor, or if

Figure 9: Relationship between alliances and competitive position of European Industry (1)

(1) Based upon work carried out by DRI, we have classified industrial sectors according to whether European companies are broadly stronger or weaker in international competitive terms (left axis) and whether there are more (high intensity) or less agreements (low intensity) than could be expected by the size of the sector. Source: DRI; Braxton; INSEAD database

necessary, bar, agreements which reduce competition. But it strongly suggests that alliances, in general, do not seek to reduce competition as a primary goal, or have that result in the majority of cases.

The evidence also suggests that alliances are about as likely to occur in economically "stronger" as in economically "weaker" segments of the economy. According to a classification by DRI of segments defined by whether they are economically "stronger" or "weaker", roughly 45 % of agreements have been in the "weaker" segments and 55 % in "stronger" ones (Figure 9).

In terms of industrial policy, there is an interesting comparison to be made between sectors which are generally weaker but also alliance intensive versus sectors which are weaker but where alliances are less common. The evidence suggest that alliances are frequently a beneficial strategy for "weaker" firms (GE SNECMA, Honda Rover). This view is strengthened by other examples such as Toyota/GM, Thomson/JVC, etc. Provided that alliances are well managed, they can provide life-saving advantages for the weaker, as well as benefits for the stronger, participants.

**MANAGEMENT ISSUES**

Alliances pose particular difficulties in terms of management. Their complexity, relative to the comparatively straightforward merger or acquisition of one company by another - which results in a single, wholly owned, corporate structure - requires that extremely careful consideration be given to the way in which the alliance is structured and managed. If the management approach is unsound, the alliance is likely to founder and, indeed, management complexity is often cited as a reason for the relatively high failure rate perceived in alliances<sup>6</sup>.

As described earlier, the structure of alliances can take many forms, ranging in fact from informal agreements, through contractually based arrangements including licensing, to formal

joint ventures. However, within the joint venture format, many management possibilities still exist. For example:

- What should be the proportion of ownership by the interested "parents"?
- Should the joint venture be a new stand-alone venture, or can it be "carved out" organisationally from "pieces" of the parents' existing structures?
- How should it be staffed, with new managers or secondees from the parent organisations?
- What form of governance and control should be adopted - relative autonomy via an overseeing board or a more directly "operational" link to executives in one (or both?) the parents?

The most important factor to consider in reviewing policy towards a particular alliance is the intent underlying its establishment. In many cases, it may be that some aspects of the alliance carry potential for counter-competitive or collusive activity. However, it could be considered that on balance, the introduction of new technologies or new entrants into the market via the alliance is a more than offsetting factor, provided the objectives or intent of the alliance are effectively fulfilled. For example, this was clearly the case in the Honda-Rover alliance and the Corning optical fibre alliances. In other cases potentially positive results may founder as a result of faulty implementation. This may well have been the case of AT&T/Olivetti, where the alliance clearly had the potential to strengthen Olivetti's position as a viable competitor in personal computers, with a strong position in the economically crucial North American market, based on AT&T's support there. In practice, however, this alliance did not prosper. The reasons appeared to relate to unclear management objectives and structures, and cultural incompatibility between the alliance partners. As a result of this, some years of alternative independent development were "missed" by both parents. For

**Figure 10: Strategic alliances: critical success factors**

	Success more likely	Success less likely
<b>Background variables</b>	New markets / geographies Explicit criteria for partner choice	Same markets / geographies Partner choice serendipitous
<b>Strategic focus</b>	Development challenges Alliance seen as dynamic and long term	Business as usual Alliance intent fixed
<b>Management structures</b>	Simple Autonomous Equal rewards Learning orientation Strong commitment at senior level	Complex Seconded for short period Unequal rewards Product orientation Ambiguous signals

Source: Author

example, key skills and capabilities in North American marketing and sales which might otherwise have been built up by Olivetti - say by organic growth or other means - were not developed during the high growth phase of the market in the mid 1980s. As a result, therefore, of trusting this development to AT&T's role in the alliance, Olivetti was left without a comfortably viable North American market presence.

Because of the significance of the link between intent and management execution, it may well be, in cases involving different trade-offs in assessing the balance of public interest, that it is important to develop and maintain some insight into the management structure and processes being adopted by the parents and within the venture. It may be helpful to consider as a guide the following management principles gleaned from case studies performed within the current work. Inputs from public presentations on this topic by Corning, generally acknowledged to be one of the most effective operators of alliances internationally, were particularly helpful in compiling this list:

- Partner compatibility, mutual trust and commitment  
Both must be interested deeply in the success of the alliance and benefit from that success ("no winners, no losers")  
Perhaps paradoxically this can be helped by equal enterprise shares ("50/50") rather than one partner taking a majority
- Partners should make comparable business contributions to the venture  
For example, both bring key skills or capabilities, not "just money"
- Strong management, with autonomy, focused on the success of the new enterprise - not on their individual parent's success  
If "seconded" into the enterprise from one or other parent, this should be permanent - a "one way ticket" - rather than for a limited period

Finally, most successful proponents of alliances agree that since no one can ever foresee in advance all the issues that will affect an alliance and its success over time. Patience, flexibility and mutual understanding are vital management success factors!

The discussion in this section is summarised in Figure 10.

## CONCLUSIONS

Strategic alliances now cover businesses in almost all economic sectors. Even in parts of the economy which have not had much alliance activity, such as services, international groupings are forming with tremendous speed.

The main drivers of this are increasing globalisation of markets and competition. But two additional key factors are emerging. First, the power, speed, and low cost of networking computer systems permits a degree of business coordination never before possible (e.g., hotel or airline reservation systems). Second, new market opportunities are rapidly emerging with the convergence of previously distinct business segments (e.g., media, telecoms and IT to create multimedia).

In fact, the 'logic' of alliance behaviour is changing. Whereas in the past, the purpose of alliances was often to share the burden of high capital or R&D costs in industries like automobiles and aerospace, many recent alliances are service orientated with strong marketing and development agendas.

Because of this, and because the geographic spread of alliances is broadening to include multicultural deals with companies from different linguistic and historical background, alliances are frequently much more complicated and difficult to manage. The challenge for European managers to collaborate successfully with firms not only in Europe, but also with non-western firms, is particularly great.

Meanwhile, strategic alliances continue to challenge the assumptions of free market economics. Partners may well be rivals in similar product-market segments; partners in one business may be rivals in another. These complex webs of interlocking relationships will in all probability continue to grow in importance and pose even greater conundrums for both managers and policy makers.

## Typical forms of transnational investments by EU firms outside the EU

Despite an acceleration over the past 2-3 years, foreign direct investment by EU firms in the developing regions of the world still only represents a very small share of total EU foreign direct investments. Transnational involvement of EU companies outside the EU can, however, take very different forms, not all of which involve financial transfers in the form of direct investment. Among the other less- or non-equity forms of transnational expansion, are international strategic alliances, licensing agreements and subcontracting. Some of these correspond to expansion moves by EU firms in regions that cannot easily (or competitively) be served through exports, while others actually correspond to "relocation moves" of EU firms in non-EU countries.

This study seeks to quantify the extent to which the EU firms transnational development strategies may have reduced production and employment in Europe by "relocating" production activities in other parts of the world, by:

- analysing the various forms that strategic "relocation" and other co-operation moves involving EU firms in non-EU countries have take in recent years;

- analysing the sectoral differences, if any, in the typical forms taken by transnational investment by EU firms in non-EU countries;
- identifying the main differences in the pattern of these strategic moves by region of destination.

The following five forms of transnational expansion are considered in the analysis:

- Greenfield investments
- Mergers and acquisitions
- Joint ventures
- Licensing and franchising agreements
- Subcontracting arrangements.

There is no one-to-one relationship between the above classification and different motives for the transnational moves. In all of the above cases, the transnational expansion move by the European company can correspond both to the relocation of an activity previously undertaken within Europe, or to an international expansion move (aimed at serving foreign markets). In both cases, however, there can be spill-over effects

**Table 1: Main reason for selecting one form of transnational investment over another**

Form of expansion	Main advantages	Conditions under which strategy is to be preferred
Greenfield investment	Parent company has full control of the new operation Gives access to resources that may not be available locally	In case of entry in new markets (i.e. where the product/service is not yet available, or imported) There is no risk of over capacity
Acquisition / merger	Acquire capacity more easily Benefit from EOS in procurement, management, administration, finance Strong cultural/national behaviour Need to maintain some control over new operation	Market is regulated There are risks of overcapacity
Joint ventures	Less expensive than M&As or greenfield investments Useful if there are barriers to entry or if minimum critical size is required More flexible than M&As or greenfield investments	Typically preferred by SMEs Common in capital intensive sectors & sectors where there are EOS in R&D
Licensing arrangement	Lower risk Increased flexibility	No need for control of operation Preference for flexibility
Subcontracting	Gives purchaser complete flexibility to switch suppliers High risk business	Very competitive market upstream

Source: Author

on activity and employment in Europe, which will also be assessed here.

## FORMS OF TRANSNATIONAL EXPANSION

This section briefly reviews the regional and local factors which influence the relative attractiveness (and profitability) of different forms of transnational investment.

Table 1 presents the different forms of investment that can be chosen and reviews the conditions under which each strategy is likely to be preferred to any of the other transnational investment strategies considered.

### Greenfield investments

Greenfield investments are a good way to expand in foreign markets when either one or a combination of the following conditions are met:

- there is no risk of excess capacity either in that market or at world level;
- there are no cultural or regulatory barriers that make it difficult for a foreign company to operate in this market;
- the production activity requires certain skills or inputs that are not currently available within the local economy, and which have to be imported (whether technological equipment or human skills).

An important characteristic of this forms of investment strategy is that the parent company retains full control of the operation.

### Mergers and acquisitions

In contrast to greenfield investments, mergers and acquisitions (whether 100 % or majority acquisitions) present the following advantages:

- they give easy (and rapid) access to new production capacity;
- there are less risks of overcapacity than with a greenfield investment;
- the acquisition can give the parent company access to technology and production experience within the country of operation;
- the acquisition can facilitate R&D, enable sales maximisation or result in an immediate expansion of market share (in other words, enhance market power).

Moreover, in the case of an acquisition the investing company often benefits from tax advantages, at least in the first years following the investment.

One of the main advantage of mergers between two companies on an existing market is that they can generate savings from economies of scale (in production, transport, procurement, or from spreading of fixed costs), from economies of scope (from producing more than one product together) and from the rationalisation of administration and/or management. When taking place within a single country or region, mergers also permit savings in stock management, reduce downtime risks and eliminate duplication.

In the case of transnational mergers, economies of scale in production and transport are typically less important but the other factors (economies of scale in procurement, economies of scope,...) still play a role. From the point of view of the acquired company, being merged into or acquired by a (foreign) company can also be a means to secure inputs that were difficult to obtain due to a shortage of foreign exchange for imports, or that were subject to important price fluctuations. This latter factor explains several acquisitions in Africa, for instance, and in the basic metals sector. Of course, in all cases, increasing in size or simply changing ownership may enable the new company to raise capital more easily or to reduce interest costs, in addition to obtaining better prices from suppliers.

### Joint ventures

Here, joint ventures are taken to include any arrangement in which the operation of two or more firms are partially but not fully functionally integrated. The existence of equity stakes is thus not necessary, so that both contractual ventures and strategic alliances are covered. Ad-hoc agreements are excluded, however.

Joint ventures present many of the same advantages as M&As, generally at a lower cost. Joint ventures have the additional advantages that they allow to spread risk even further, can be more limited in scope and more flexible in nature, and that they make it possible to build a multiplicity of links with other companies as necessary. Hence, joint ventures tend to be preferred over M&As when the risk associated to an acquisition in an unfamiliar environment looks too high compared to the price of the acquisition.

The disadvantage of joint ventures over acquisitions, however, is that the parent company has less control over the new venture. Joint ventures are also typically more difficult to manage than mergers, because of lack of clear authority, of relatively high costs of coordination and sometimes conflicting objectives and interests. Non-equity ventures also tend to reduce the commitment of the participants to the success of the venture. This has negative spill-over effects on their duration and on their overall success rate.

Joint ventures tend to be preferred by SMEs who do not have the critical size or the financial means to undertake an acquisition nor are willing to take the risks of a setting-up a greenfield operation. In contrast, large companies will generally prefer to take a minority (or majority) stake in a new business, in order to have better control of the new operation.

Both greenfield investments and M&As represent an investment by the acquiring firm, and are thus included in the statistics of foreign direct investment flows that are available through various sources. In contrast, joint ventures do not necessarily have an equity component and, when they do, the "financial" involvement is typically less than in the case of an acquisition.

### Minority acquisitions

In economic literature, the view is that a firm will prefer to detain a majority stake in a company when control over a resource commitment is highly valued and the firm perceives that it can absorb the transaction costs of acquiring and monitoring that control. In practice, however, the preference for one form over another (i.e. for a majority versus a minority acquisition) depends on the nature of the business and the capabilities of the firms in presence, rather than on broader geographic, cultural or other aspects.

Because the spill-over effects on employment and activity in Europe depend on the relative importance of the foreign venture rather than on the share of ownership of the parent company, in this study we will not differentiate systematically between minority and majority acquisitions.

### Buyer/seller arrangements

Licensing and franchising agreements and subcontracting arrangements, are often referred to as "buyer seller" ventures. Such agreements do not imply equity transfer and often involve companies at different stages in the value-added chain. To some extent, they are thus alternatives to backward vertical integration.

Depending on the nature of the buyer/seller agreement, the rights, risks, responsibilities and potential returns for the investor vary.

There are essentially two broad types of buyer-seller ventures: licensing and franchising agreements and subcontracting arrangements.

**Table 2: Intensity of transnational involvement by EU firms in selected sectors**

Licensing agreements involve the transfer by the licensor (called here the "parent" company) of a right to use a specific piece of proprietary technology (for instance a patent) relevant to the production of a given product. Although the licensee (the user of the license) is usually responsible for the production, the agreement generally gives the parent company some control over the use which is made of the license to ensure that his own competitive position is protected. Such control may apply to the sourcing of inputs (from the patent company or one of its subsidiaries), to the production methods, to the use made of the technology and/or to the markets than can be served. The usual payment for a license is a fee or royalty based on the volume or value of the output which

embodies the information and knowledge provided by the license.

Franchise agreements are in many ways the extension to the services sectors of license agreements in manufacturing. Franchise agreements typically specify extremely detailed requirements and conditions, for example with respect to quality control, which the franchiser expects the franchisee to observe. Franchise agreements are common in the hotels, restaurants and catering sector (hotel chains, McDonalds, etc..) as well as in the retail trade sector (specialised cosmetics stores such as the Body Shop, toy stores, etc.). As in the case of licensing, the terms of the franchise agreement will normally allow the contractor some control over the deployment of the transferred

rights. Payments typically consist of a lump sum payment from the franchisee to the franchiser plus a fee based upon unit sales.

Subcontracting agreements cover loser types of contractual relationships between the contractant (or "parent" company) and the contractor. These are arrangements according to which the buyer (in our case the EU firm) specifies what he needs from the supplier, and accepts or rejects the product once manufactured according to whether or not it meets the agreed specification. Some subcontracting relationships thus involve a detailed and on-going interface between customer and supplier, which can include the provision of information and/or financial assistance by the contractant, advice on methods, pricing, component sourcing, testing procedures, costing etc.

Subcontracting agreements are typical of the textiles & clothing sector and of automotive and aerospace component manufacturing, amongst other.

### REGIONAL DIFFERENCES IN THE PREFERRED FORMS OF TRANSNATIONAL DEVELOPMENT

The transnational expansion of companies from industrialised countries into other regions of the world has taken many forms, with no obvious dominance of one form over another. When considering the typical transnational strategies by region, however, distinct patterns emerge which are illustrated in Figure 1. Whereas in North America the main form of transnational expansion by EU firms in the past has been majority acquisitions, followed at a distance by joint ventures and greenfield investment, in Japan there have been very few acquisitions - whether majority or minority acquisitions - and the bulk of the transnational development has been through joint ventures. In developed Asia, the dominant form of involvement has either been through majority ownership and greenfield investment, or through subcontracting and licensing agreements. The situation in the less developed world is still different, with Latin America (where the history of building relationships is older) generally following the same pattern as developed Asia, Africa seeing a dominance of majority ownership and Eastern Europe seeing a dominance of non-equity forms of involvement, followed by majority acquisitions.

The lack of a consistent pattern of transnational development across all the world regions reflects the fact that, both in the developed and in the developing countries, there is a multiplicity of empirical factors which influence the type of strategy that ought to be chosen by a given firm. Moreover, as most of these factors are dynamic, not static (for instance, changes in the regulatory environment, in the rate of growth of the market, in political or socio-economic factors), the transnational expansion strategy that will yield the highest returns will itself tend to change over time.

In general, one can say that strategic alliances (joint ventures) and majority acquisitions have dominated transnational development strategies of EU firms into the industrialised countries. Indeed, where such alliances involve companies at similar levels of development or companies originally involved in different markets, they often bring technological cross-fertilisation as the technologies originally developed by one industry are increasingly applicable to other sectors. In some cases, the joint ventures and other forms of strategic alliances also reflect a need to break anti-monopoly laws (as in the US), or to consolidate manufacturing production to gain competitive advantage in regional (essentially local) markets.

In the developing countries, the key market factors which influence the preferred form of investment are:

- the present size and distribution of firms in the economy;
- the ownership structure of firms in the market;
- the degree of technology intensity of the sector.

Many developing country markets are, indeed, characterised by:

- a high degree of state involvement in industry (there are very few public limited companies accessible to outsiders);
- a relatively small number of medium-and large-size firms (most are small family owned businesses);
- a high concentration of ownership amongst the interesting target companies (groupings of family controlled companies which control a relatively large share of industry are common in some developing countries).

Greenfield investment has thus been an important form of transnational expansion by companies from the industrialised countries into the developing countries. One exception is the technology intensive industries where joint ventures dominate. There is, in fact, a high concentration of joint venture agreements involving firms from both the developed and the developing countries in sectors such as electronics and electrical engineering, fabricated metals, chemicals, automotive and industrial supplies, as well as in the food, machinery and tools sectors. In the less technologically advanced developing countries, however, joint ventures have been confined to a few industries such as the pharmaceutical, agri-food or mining sectors.

Although industry structure factors would give the preference to greenfield investments in most sectors and to joint venture agreements in the more technology intensive sectors, in practice there are other factors which have come into play and have influenced the selected form of transnational involvement. In Asia, for instance, take-overs have tended to dominate because of the difficulty in gaining access to the market through other means. In Latin America, the possibility for foreign companies to make debt/equity swaps and the privatisation programme has shifted the balance in favour of M&As. The same applies to the countries of central and eastern Europe where the privatisation programmes under-way have put a lot of companies on the market for potential EU and other acquirers.

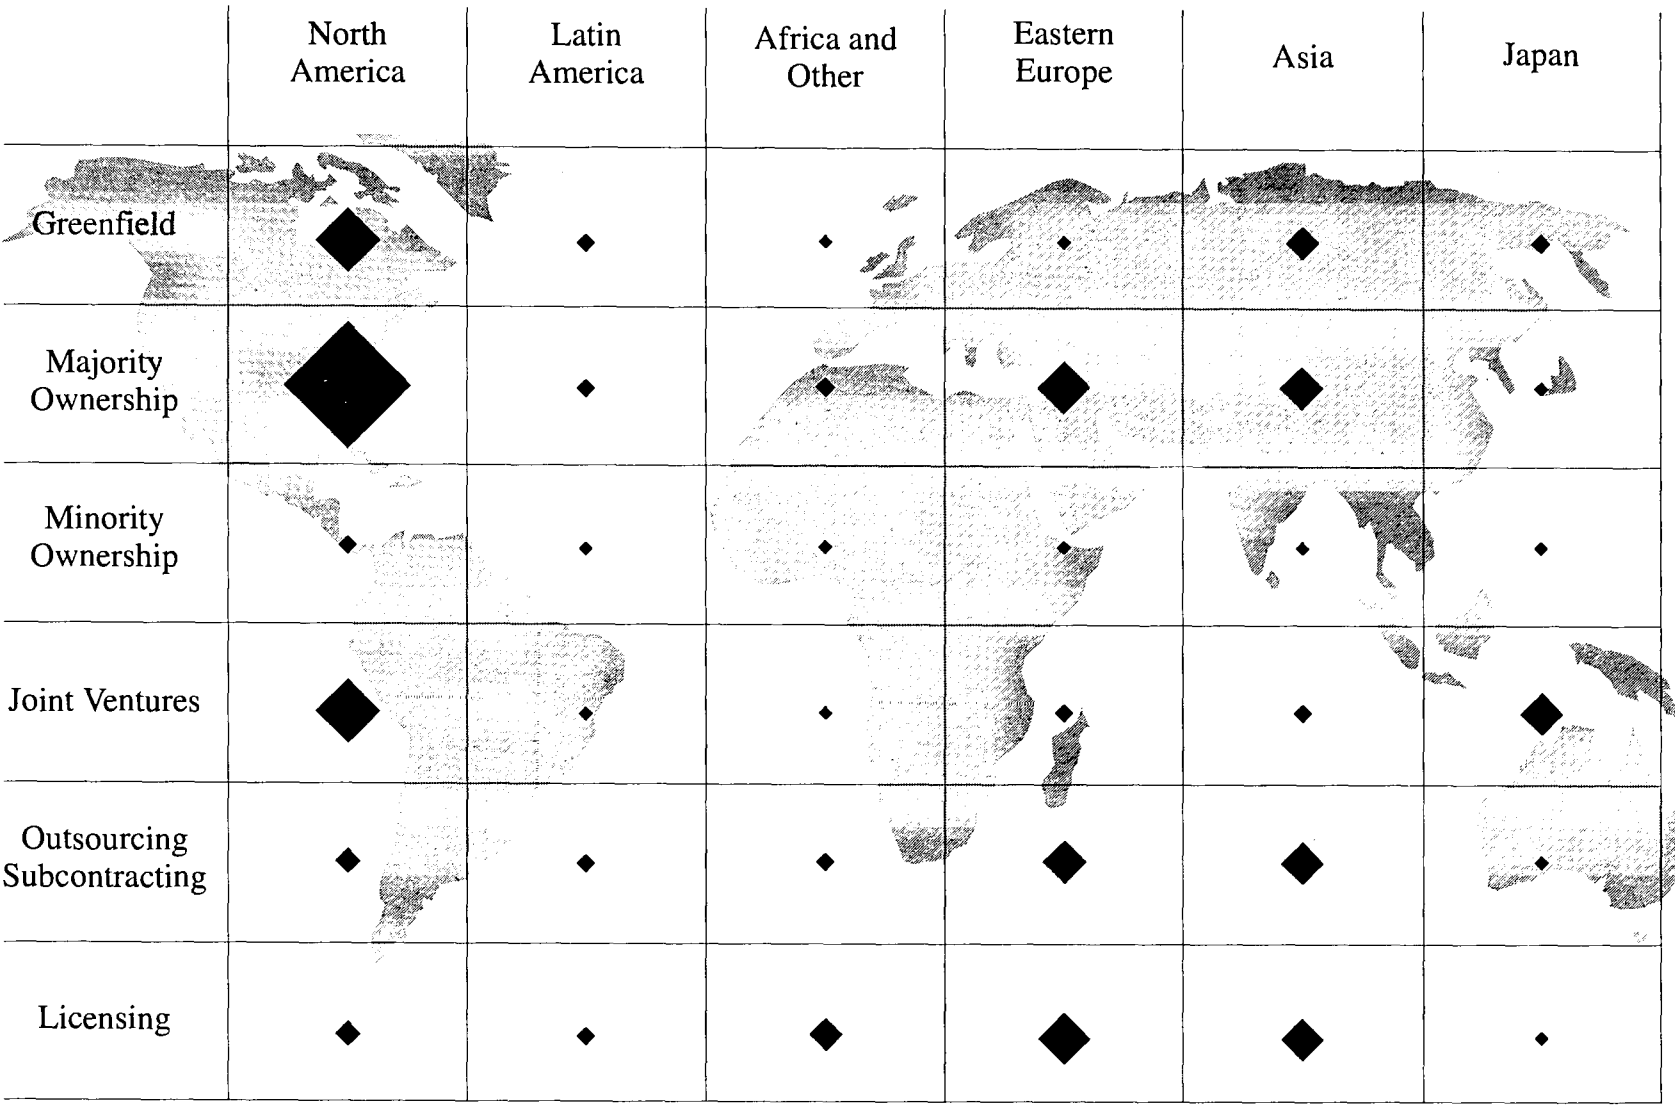

### SECTORAL DISTRIBUTION OF EU FIRMS' TRANSNATIONAL INVESTMENTS

Figure 2 shows the sectoral distribution of the world's top 100 non-financial transnational corporations, based on foreign assets held in 1990. Figure 3 illustrates the degree of internationalisation of these top 100 transnational corporations, by showing the proportion of these firms' total assets that are not in the home country, while Figure 4 shows similar figures for employment (i.e. the share of these companies' employment which is not located in the home country).

Based on the total value of foreign assets, the sectors which dominate the ranking of the top 100 transnational companies are petroleum refining, motor vehicles & parts, electronics and chemicals, in that order.

This distribution partly reflects the relative size of these sectors in world markets and the degree of concentration in each of these sectors. Among the 16 sectors which have representatives in the list of top 100 world transnational companies, those which are most "internationalised", i.e. those which have the highest share of foreign assets as a percentage of total assets, are printing and publishing, followed by rubber and plastics processing, pharmaceuticals, and food and drink (Figure 3). With a few exceptions, the share of foreign employment in total employment is similar to the share of foreign assets in total assets (see Figure 4), the exceptions being the trading sector, the food and drink and the electronics sectors, where the share of foreign employment is higher than the share of foreign assets. In contrast, in the printing and publishing sector the proportion of foreign employment is less than the share of foreign assets in total assets, indicating a tendency to main-

Figure 1: Regional patterns in the preferred form of transnational investment

Source: DRI Europe

tain the "labour intensive" activities (journalists, writers, marketing) within the domestic economy.

In summary, the observed differences in the forms taken by transnational investments across sectors and regions typically reflect:

- differences in industry structure or in the degree of concentration of companies in the market (if a market is small and there is already one large supplier or potential supplier, the potential benefits of market entry by a new firm are low);
- the degree of reliance on local sources of inputs - be they material inputs, human capital or physical capital;
- the degree of government involvement in that sector;
- regulatory barriers and differences in attitudes towards foreign firms in the country of destination.

The next section analyses the forms taken by EU transnational investments by sector. The analysis below covers the ten manufacturing and resource-based sectors in which the transnational activity has been particularly important.

### Energy

Because of its heavy reliance on local input sources, the energy sector - and, more specifically, the petroleum refining sector - is one of the world's most transnational industries. About 45 % of the total assets of the world's top 12 petroleum refining companies are held abroad.

During the 1980s, the stock of FDI in energy in the developing countries grew rapidly - in fact, it grew faster than in any other sector - due to the combined effect of intense merger activity and a search for safe investment locations. This partly reflected the high degree of uncertainty which prevailed in oil markets, which caused many oil companies to diversify geographically to spread risk. Some oil companies also diversified horizontally, for the same reason, taking stakes in mining for instance (such as British Petroleum). Most of this investment was directed towards Africa and the Middle East.

In more recent years, however, foreign investors' interest in the energy sector has shifted to central and eastern Europe, in particular to the former USSR where EU companies are developing activities in petroleum exploration and exploitation.

In this sector, low equity forms of transnational investment are commonplace for new investors (such as Germany or Japan), to reduce risk. In petroleum refining for instance, successful transnational operations have been established in many developing countries through turnkey and engineering contracts. UK investors, however, which have a long history of investing in the energy sector, generally have a majority or full ownership.

### Mining and metals

Mining is also a sector in which transnational investment reflects the need to have access to a natural resource. The EU metal producers have long been involved in transnational activities, both to ensure long-term access to mineral supplies for processing into the EU market and to serve growing local market demand.

Although the sector itself is highly internationalised, the relative importance of transnational activities in mining and metals is small compared to sectors such as petroleum refining, chemicals or automotive (see Figures 2 to 4).

There has been a considerable slowdown in transnational activity in mining and metals production in past years. Greenfield investment has considerably declined, partly due to the nationalisation process in developing (and ore producing) countries which took place during the 1970s and which led to substantial disengagement of EU firms from the capital of

the local mining companies. EU companies have also been hardly hit by the recent economic downturn and by the structural excess capacity problem. Instead of developing their transnational activities, EU companies are now concentrating on restructuring domestically, focusing on core activities and reducing overall production capacity.

In parallel to the decline of FDI in the sector, other forms of international involvement have increased in importance. These include minority equity investments in local firms, the provision of management or technical assistance, the supply or the sharing of technology or know-how through licensing agreements, joint ventures and even international subcontracting.

In more downstream segments, mergers and acquisitions have been a popular form of involvement of EU firms in non-EU regions, especially in North America. One example is Pechiney's acquisition of US's American Can. By acquiring the American can manufacturer, the French aluminium producer has become the world leading producer of aluminium food packaging. Some mergers have also taken place amongst locally owned and foreign-owned companies in developing countries (for instance in the Philippines), for regulatory reasons.

As the trend is now for developing countries to attract foreign investors by introducing open and stable foreign direct investment regimes, one can expect to see renewed interest in transnational activity in mining by foreign investors, in particular in the newly liberalised economies of central and eastern Europe.

The strategic moves towards central and eastern Europe will, however negatively influence activity and employment within the EU. The lower labour and energy costs, the availability of raw materials, the lower environmental constraints along with the existence of a potentially huge consumer market in central and Eastern Europe are attracting EU producers into this region. Activity in upstream sectors will not be much affected by such relocation moves, as mining activity is already quite marginal within Europe. Activity in immediately downstream sectors is, by contrast, potentially at risk. This applies in particular to the metal products industry, a sector which is characterised by a high labour intensity and a moderate technological intensity.

### Basic chemicals

The chemical sector is one of the sectors in which the importance of transnational operations is greatest. In fact, not only are the world's largest chemical companies very dispersed geographically (with over half of the assets of the world's major companies held abroad), but, from the point of view of the recipient countries, chemical companies are among the most important foreign investors.

In most cases analysed, the establishment by EU firms of facilities outside Europe has responded to the need to serve local (distant) markets, as opposed to relocation moves. Usually, the local market absorbs the entire output of the subsidiaries, such that there are no or only limited negative spill-over effects on domestic production in Europe.

Generally speaking, European chemical firms have pursued one of three main types of internationalisation strategies:

- Greenfield investment has by far been the favourite strategy. Recently, greenfield sites operating in the basic chemicals segment have been flourishing, particularly in Asia where demand is expected to grow particularly rapidly over the coming years.
- In a number of cases, European basic chemical companies have preferred to rely on joint ventures to establish a presence in new markets. The main reason underlying these joint ventures has been to share the prohibitive start-up

Figure 2: Sectoral distribution of the largest world and European transnational companies

Source: 1993 World Investment Report

and development costs which are typical to this sector. Most of the existing joint ventures were concluded with local partners who bring a good knowledge of the market and can help circumvent possible regulatory or market entry barriers.

- The third "typical" transnational development strategy in the chemical sector has been through acquisitions. Some of these operations have involved large enterprises and have therefore been highly publicised (e.g. Hoechst's purchase of Celanese, Rhône-Poulenc's acquisition of Rorer). In other cases, the size of the targets of M&A activity have been smaller, the acquisition being part of a more global expansion strategy (for example, the recent acquisitions by EU firms in Mexico are to be seen as part of a supply chain for the whole NAFTA area).
- Although the three above strategies dominate, a number of chemical firms have invested outside the EU via licensing agreements. These kinds of agreements are often part of a wide joint venture agreement whereby the EU companies also license the technology to local partners.

Eastern Europe has only recently become a favourite target for investment from all major European chemical groups, in particular the three German giants Hoechst, BASF and Bayer. In this area of the world, all kinds of investment strategies have been employed: for instance, in 1992, Hoechst acquired through its controlled Schwartzkopf a cosmetics manufacturer in Poland, established a joint venture in advanced ceramics in the Czech Republic and purchased holdings in two gas companies in Croatia.

The multinational nature of the European chemical industry implies that a sizeable proportion of its workforce and of the supporting services are located outside the EU. None of the segments of the chemical industry are very labour intensive,

however. The spill-over effects of chemical activities on the rest of the economy are nevertheless important, with DRI calculations suggesting that, of the total employment creation which is induced by a given rise in final demand for chemical products, more than half takes place outside the sector itself (i.e. is induced employment).

The negative effects on EU employment of the transnational strategies of firms in the basic chemical sector are most important. In this subsector indeed, a combination of high production costs (mainly feedstock and capital costs) and tight environmental regulations threaten to make European enterprises uncompetitive compared to other world regions. This creates incentives for EU companies to relocate production abroad. Two compounding factors are the weak rate of growth of domestic demand in Europe and the persistent situation of overcapacity. Our research, however, indicates that the fundamental reason underlying the interest of EU basic chemicals producers in Asia is that this is a fast growing demand market. Hence, if the strengthening of world market demand continues and the overcapacity problems are eliminated, the recently set-up production capacities in Asia will mainly serve the local (Asian) market, leaving room for a renewed expansion in production and employment in Europe.

### Pharmaceuticals

The pharmaceutical sector is also a highly de-localised industry, though for other reasons than the other chemical sub-sectors.

Greenfield investment has been the dominant form of transnational involvement in the pharmaceutical sector, followed by strategic alliances. The necessity for the industry to think globally and to serve its markets from a local base has indeed made the use of greenfield investment and of M&As the preferred strategies in this sector. This also results from the highly

segmented nature of national pharmaceutical markets, due to differing regulations and licensing rules. Also because of the high degree of market segmentation, the set-up of independent distribution networks is usually a condition for operating in this sector. Most transnational operations of the world's largest pharmaceutical companies thus operate as stand-alone units within the local economy.

To date, EU pharmaceutical companies have expanded in this way in most regions of the world, in particular in Latin America (Mexico, Brazil, Colombia), as well as Japan and Asia. The pharmaceutical sector is, in fact, the only sector in which European companies hold a sizeable share of the Japanese market.

The impact of transnational activity on downstream and upstream activities is fairly limited, because the pharmaceutical sector is not highly labour intensive and because most transnational investment moves have responded to the need to establish a local presence to operate in fragmented markets, rather than to a relocation of EU production.

### **Mechanical and electrical engineering**

In the engineering sector, non-equity forms of investments such as licensing, OEM agreements or subcontracting have been widely used as they are particularly suited to small and medium sized firms. In general, the pattern of involvement abroad is the following:

- EU mechanical engineering enterprises have preferred joint ventures to M&As or greenfield investment to penetrate foreign markets. This is true mainly in those countries where the industrial culture is very different from the western culture. Contrary to the situation with US or Japanese producers, JVs involving European companies are usually applied to small-scale collaboration experiments involving standard parts of machinery.
- Apart to reinforce their sales and distribution chain, firms in the sector have made more limited use of greenfield investment or mergers and acquisitions to expand internationally. The acquisition of established local manufacturers has nevertheless been the main avenue for international expansion by firms such as Mannesmann. The German producer, one of the world's leading mechanical engineering firms, has made use of M&As in order to reinforce its position on foreign markets where it was already present (notably in the US).
- Recently, outsourcing has become a favourite strategy to cut production costs in this sector. Outsourcing agreements usually apply to the production of components with a low labour content, which are then fabricated in high volumes through highly automated production processes. Another form of transnational investment which is growing in importance is licensing. This supply policy is commonly used for parts and components which are not crucial for the accuracy of the machinery. Contrary to outsourcing, licensing typically involves a long-term relationship between the licensor and licensee.

Whether it is relying on subcontracting or OEM agreements, the activity of the transnational mechanical engineering producer must remain closely linked to that of the parent company as the products or equipment must precisely fit the requirements of the transnational corporation. Thus, whatever the contractual form taken by the operation, the subcontracted firm must to some extent be integrated into the parent firm's value chain through the integration of some corporate functions (product development, R&D, etc.).

To date, the transnational activity of EU mechanical engineering producers has only limited effects on downstream and upstream activities within the EU. The share of supporting services which are supplied by domestically based EU firms

to support their foreign subsidiary is presently estimated at 1 %. This figure is not likely to increase in the coming years.

In the long term, both the direct and the indirect effects of transnational expansion moves in this sector are likely to be important as many of the larger firms have plans to slowly expand their activity outside the EU market. The increased reliance on outsourcing and licensing agreements will have a detrimental effect on employment in the component industry. As to the indirect employment effect, based on the French I-O matrix, DRI has calculated that for every 10 jobs that are created within the mechanical engineering sector following a rise in demand for capital equipment, 8.2 jobs are created up-stream in the supplier industries. Some of these may be at threat if EU production is replaced by imports.

One of the factors that will limit the reach of this phenomenon is that outsourcing and licensing agreements can only apply to parts that are relatively standard, i.e. that are neither too sophisticated nor unique to the machinery. On the other hand, to the extent that part of the value added from the machinery continues to be produced within the EU, as is the case with "simple" transnational investment moves (whether it is the assembly, the production of highly sophisticated components or the R&D), the transnational activities of EU firms can also have a positive, albeit likely limited, impact on employment in Europe. This could result from increased exports, as is the case at present with the Italian mechanical engineering sector. Most of the job creation in Italy indeed originates from SMEs who have to satisfy growing demand from customers located in Southeast Asia and Latin America.

### **Consumer electronics**

Consumer electronics companies are highly involved in transnational operations because of the need to be close to the end-users and because of the extremely competitive world market, which provides continuous pressure to reduce production costs. In the past, consumer electronic products were manufactured close to their end market. As the competitive climate heightened while standards and norms were being harmonised, European firms started to relocate their production facilities to lower wage regions in order to reduce production costs. As a result, there has been a surge in EU investment in consumer electronics in South East Asia, the region in the world which offers both high market growth and low labour costs.

Mergers and acquisitions have undoubtedly been the most widely used form of expansion, in particular in the industrialised world. Today's European multinationals have increased in size by absorbing competitors, both in Europe and abroad (e.g. the takeover of RCA in the USA by Thomson, Nokia's acquisition of the German SEL). Medium-sized companies have also followed this path in order to create a more comfortable market niche (e.g. Seleco's acquisition of Elbe in Spain).

Greenfield investment has also been popular, mainly in the less industrialised countries. All the major multinationals have established production facilities abroad to serve the foreign markets and profit from low labour costs. The scale of the phenomenon in the consumer electronics sector is larger than in other manufacturing sectors: Philips for instance transferred the headquarters of its Audio division from Holland to Singapore, a move justified by the fact that about 80 % of the division's workforce is now based in South East Asia.

Whereas in the industrialised region joint ventures are motivated by the need to build on synergies and reap economies of scale (EOS) in R&D, in the developing countries they have chiefly been put into practice for marketing purposes.

In comparison to EU firms, Japanese consumer electronics producers have relied more on greenfield investments to expand internationally. All the major Japanese consumer elec-

Figure 3: Share of foreign assets in total assets of the top transnational companies by sector

Source: 1993 World Investment Report

tronics producers have or are about to set up production facilities in Europe, in the US and particularly in South East Asia. Nearly all of their output is for export, both to Japan and to the rest of the world.

Similarly to the situation in the mechanical and electrical engineering sector, it is important in the electronic industry to integrate the activity of the foreign operation into that of the parent company, as the foreign operation often manufactures parts of the final product and not the complete product itself. This is why formal OEM arrangements, including licensing or subcontracting agreements are also common in this sector.

The expansion of EU companies into Asia rather reflects a desire to be present in a growing market. The firms which have invested there have set up production facilities which were originally essentially aimed at serving local markets, through greenfield investment. Increasingly, however, these production facilities supply other markets. Thus, for example, Philips produces audio equipment in Malaysia and Taiwan, and in-car entertainment in Singapore; Thomson manufactures television sets and components in Singapore, Thailand and Malaysia.

A similar pattern of investment can be found in Latin America, where all major multinationals (both European and extra-European) have established production facilities (e.g. Philips in Brazil, Thomson in Mexico). Marketing joint-ventures have been arranged in most countries in the region, but the original investment was also greenfield.

Eastern Europe has recently become a major target by European consumer electronics manufacturers, attracted by cheap labour and good medium term growth perspectives. Philips for instance has established a video-cassette recorder manu-

facturing operation in Hungary to serve the entire European market.

The intense transnational activity of EU consumer electronics firms has important spill over effects on activity and employment within the EU, in particular in the upstream segments of the business. The relocation of several EU consumer electronics firms in non-EU regions to benefit from lower costs of production has thus had spill-over effects on related industries, in particular on OEM production in Europe. This negative impact has, however, been partly offset by the fact that Japanese and Korean manufacturers have opened consumer electronics manufacturing plants in Europe to avoid trade barriers, and have themselves have attracted Japanese and Korean component manufacturers into the EU.

The consumer electronics sector also offers a good example of the potential effect of relocation on supporting services, i.e. on employment other than blue-collar employment. The already mentioned case of Philips, which moved its Audio division headquarters to Singapore, is emblematic in this sense: the share of relocated production has become so important that it has inevitably pulled with it the accompanying services that had traditionally remained in Europe.

#### Electronic components and computers

Although electronic component manufacturers do not stand out as being important foreign direct investors, EU producers have nevertheless been very active internationally through other means. The sector is indeed the second largest international subcontracting industry after textiles and clothing manufacturing.

The computer industry is much more international than the electronics production, with a share of foreign assets in total assets close to 50 % for computer manufacturers and less than 30 % for the top 11 electronics producers. These, how-

ever, typically rely on non-equity forms of transnational development, such that the above figures based on assets do not give a fair view of the high degree of internationalisation of the sector.

Generally speaking, transnational investment strategies in the electronic components and computer industries were originally driven by the necessity for companies to serve (new or fast growing) local markets. Cost reduction considerations represent a secondary albeit far from negligible factor for companies to locate productive activities outside of their domestic market. They have, however, been a major factor in the computer industry.

Between 1986 and 1993, the total number of strategic alliances, including joint venture agreements involving companies in the electronic components sector, increased dramatically, with a major shift away from EU-US agreements towards EU-Japan and EU-Asia agreements. This reflects a fundamental difference in the strategies pursued by US and EU firms respectively, with the former having a tendency to move PC production to the Far East, whereas the Europeans have continued to assemble PCs locally: this strategy allows European producers to configure products nearer to the customer, to respond quicker to market changes and to minimise inventories of high value added (and thus expensive) components. This does not give them access to mass markets, however.

Because of the huge cost associated to the research and the development of new components, collaborative agreements are increasingly common in this sector. The production plants resulting from these collaboration agreements are typically highly automated and rely on the availability of a highly skilled workforce. Such collaborative ventures are therefore more likely to be located in the US, in Europe or in the Far East, i.e. in regions combining the advantages of high skills and fast growing consumer markets.

In comparison, there has been very little transnational investment by EU firms in this sector taking the form of greenfield investment or acquisitions, and there are only a few cases of joint venture agreements. The integration strategy which is most frequent in this sector from the part of EU firms is the one in which components are built wherever it is cheaper to produce them, before being re-imported for assembly into the final product.

The manufacturing location for electronic components is determined by the size of regional markets, the availability of skills and the economics of production. This latter factor explains the recent shift in the location of electronics production from the US and Europe towards the Far Eastern NICs. The high production growth rates in the region (close to 30 % annually) are also explained by the fact that in some of the countries of the Pacific Rim, governments are making the electronic component industry (and in particular the semi-conductor industry) a cornerstone of their industrial strategy.

Being a major growth area, the Pacific Rim has naturally come to be a preferred location for EU electronic component manufacturers. It is important to note, however, that foreign involvement by Japanese and US firms in those countries far exceeds that of the European companies.

Favoured by lower wage rates, the east European countries hope to be able to account for a significant share of the world electronic components' production in the future. The location of such productive activity will be mostly driven by the need to serve locally key customer industries (automotive, electrical engineering, and others) which have set up or are expanding production in the region. Today, however, the emerging economies of the region do not yet meet the conditions that are necessary to the success of electronic component producers. One stated problem is the lack of flexibility of the east European workforce. Production equipment is indeed evolving apace, requiring suitably trained employees, capable of being

retrained almost continually and of acquiring new skills and responsibilities.

As in the case of the consumer electronics industry, the impact of the relocation of the electronics components industry on employment in Europe has been partly offset by moves in the opposite direction by US and Asian companies which have set up production facilities in Europe to avoid potential import barriers. Nearly half of the EU microprocessor requirements is currently supplied by non-EU firms based in Europe. The spill-over employment effects of electronics and computer manufacturing are relatively low, as total employment in the sector represents less than 2 % of total EU employment.

### Motor vehicles

Whereas chemical companies dominate the list of the largest foreign direct investors from the industrialised into the developing countries, automotive producers dominate the list of companies undertaking joint ventures in the developing countries. At world level, automotive firms have expanded abroad in search of lower labour costs and to get around trade barriers.

Practically all forms of transnational operations have been put into practice by the European carmakers over the past decades. In comparison, US and Japanese investors have until recently shown a distinct preference for greenfield investments to expand into new markets.

- Joint ventures with local partners have been the preferred strategy used by European motor vehicles manufacturers to expand abroad. This form of investment presents the same advantages as greenfield investment, but at the same time enables the EU firm to share the risks and costs associated with the new market entry while benefiting from the partner's experience of the local situation.
- Greenfield investment has, in contrast, been less used in this sector due to the high cost and the risk involved in setting up wholly owned operations outside Europe. Where it did happen, the greenfield investment was typically aimed at supplying local and regional markets. In some cases, however, as with the production of engines and other components, a growing share of production is now being exported to Europe.
- Mergers and acquisition have mainly characterised transnational moves within Europe. The present (growing) degree of concentration of the sector largely reflects sustained M&A activity throughout the eighties, which has left no independent small to medium carmaker in Europe. The industry is now making increasing use of outsourcing and subcontracting agreements both domestically and internationally, particularly in the field of components (engines, gear boxes, etc.). All original equipment (OEM) manufacturers commonly outsource components from foreign countries.
- Licensing agreements have been set up by all the major carmakers in many developing countries to supply the local market. These agreements mainly consist in assembly operations on kits imported from abroad.

The main reasons for the transnational expansion of EU automotive producers are: the need to sell to distant markets; the need to circumvent often restrictive trade regulations; and, the need to reduce risk associated to exchange rate fluctuations.

Trade regulations have also played an important role. Local production or assembly can indeed shun protective tariffs and other entry barriers. Another reason for international expansion has been the fluctuations in exchange rates, and, more particularly, the appreciation of the Japanese Yen which has made it imperative for Japanese producers to establish a presence

abroad to retain market share. The same applies to a lesser extent to European investment into dollar-driven economies.

European car manufacturers are involved in all kinds of transnational activities in practically all regions of the world. At present, the "hottest" geographical area for the car industry is South East Asia, and in particular China. This huge and rapidly growing market is a primary target for all European carmakers who are striving to find outlets for production outside the mature European market.

The few greenfield investments by EU companies outside Europe have mainly been located in the US. Here, BMW has established a production facility, followed by Mercedes-Benz which is building a plant for 4-wheel-drive cars. Both firms invested in the USA because it is the world's largest market for luxury and 4-wheel-drive vehicles.

Latin America has long been a primary target for the European car industry, given its market size and low labour cost structure. The world's largest carmakers have been investing in the region, in particular in Brazil, Mexico and Argentina. Most of the investment took the form of joint ventures (e.g. Renault in Colombia, Peugeot in Chile, Fiat in Brazil) or greenfield investment (e.g. Volkswagen and Renault in Mexico), along with few licensing agreements for assembly in smaller countries (e.g. Daimler-Benz in Uruguay, Fiat in Venezuela). A common feature of the car industry's investment in Latin America has been the government's pre-requisite of local content, which was set at quite a high level (generally at least 80 %). Recently, European investment in the region has been propped up by the NAFTA agreement between the USA, Canada and Mexico. The latter country has been the target of intense investment activity from European companies aiming to use it as a springboard for the North American market, in virtue of its low labour cost nature.

Expansion by EU automotive producers into the promising Eastern Europe market has taken three main forms. Many EU carmakers have been active on the acquisition front: the best example is provided by the purchase by Volkswagen of the Czech car manufacturer Skoda. The second strategy adopted to penetrate the East European market has been the joint venture: here, we can recall the operational venture between Fiat and the Polish carmaker FSM, which is now producing the new Fiat 500 for the European market. Last but not least, several west European manufacturers such as Opel, Volkswagen and Mercedes-Benz have set up production units in former east Germany after the fall of the Berlin wall. Additionally, thanks to its proximity to the west European market and to its low labour cost, east European component producers have often been involved into outsourcing agreements for standard components.

In the coming years, the transnational activities of European carmakers outside the EU will have important effects on the automotive components industry. The trend towards outsourcing components is expected to strengthen over the coming years, as increased competitive pressures within the world automotive industry will push for cost reductions, which will be achieved also a via a lowering of component costs.

The impact of the international activity of EU car manufacturers on employment in Europe is already quite evident. Although in past years the prime reason for building a plant abroad was to supply the local (regional) markets, a growing number of producers are now relocating some of their production units outside the EU with the aim of serving both the local and the EU markets. For example, Fiat is manufacturing the Fiat 500 in Poland after having produced the Duna model in Brazil for some years. Both models are sold on the European market. The impact of such international investment strategies on direct employment in the car industry within

Figure 4: Share of foreign employment in total employment of the top transnational companies by sector

Source: 1993 World Investment Report

the EU is clearly negative, and will continue to be so as the relocation trend is set to continue in the near future. On the other hand, the vast majority of supporting services upon which European car manufacturers rely will remain located within the EU. There are no signs that this situation might change because of increased transnational activity of European carmakers.

### Food, drink and tobacco

In the food sector, differences in consumer tastes and habits, along with trade barriers and often high local content requirements (for practical as much as for regulatory reasons), have frequently required transnational companies to adopt multi-country strategies to penetrate new markets rather than rely on exports. For a number of reasons which have to do with the nature of the products, such as the fact that they are difficult and/or costly to transport over long distances, different customers' tastes and preferences across countries and that the control of local distribution channels is essential, food and drink companies have typically expanded internationally through joint ventures and acquisitions of local firms, as opposed to greenfield investment or even subcontracting.

Companies from this sector who engage in transnational investment strategies are thus seldom "relocating" their activities, but rather seeking to expand sales by reinforcing their presence in distant markets. Among the factors that influence the form of international investment in the food and drink sector are:

- the nature of the regulatory environment in the target market (existence of standards, entry barriers, import tariffs, packaging and other regulations);
- the need to have access to distribution networks in the country of location of the investment, and eventually also in neighbouring countries;
- cultural differences making it important to adjust supply to the structure of local demand and to consumer preferences;
- the fact that in most segments demand grows only slowly, such that expansion can typically only be at the expense of a competitor, through an increase in market share.

Transnational investments by EU, US and Japanese food producers have mainly taken the form of mergers and acquisitions. The largest food multinationals have increased their market share by acquiring rivals and growing in size. This expansion, which was once limited to their home market, has recently boomed at the international level, as "going global" has become the motto for the 1990s.

Large food companies prefer to invest in wholly or majority-owned subsidiaries because this allows them to assure a consistent product quality around the world. Once acquired, however, in most cases the foreign subsidiary operates as a stand-alone unit within the foreign market. Indeed, by acquiring an existing firm the parent company obtains immediate access to local distribution channels and locally known brands.

The sector also provides some examples of joint ventures, which are, however, much less numerous than the two previous forms of investment. In some cases these have been set up with competitors in order to share the costs of an investment. Most joint ventures are, however, between western firms and local producers and/or the authorities, in order to reduce risk and avoid market entry barriers.

It is important to note that the majority of transnational investment moves in the food sector have been undertaken by large multinationals such as Nestlé and Unilever. The smaller and less financially endowed groups usually limit the scope of their activity to the European market and achieve higher market share by specialising in their strongest lines of business.

The extra-EU operations of the European food industry have only minimal spill-over effects on upstream and downstream activities in Europe, for two main reasons. First, food products can not be transported over long distance. Secondly, and consequently, the vast majority of transnational operations aims at supplying local markets, thus the entire output of these production units remains in the country/region of location of the investment. A few luxury food products (e.g. caviar), alcoholic beverages and tobacco products are an exception to this rule, as they can be easily shipped and are more or less universally appreciated.

One market segment in which there is a real threat to employment and manufacturing activities within Europe, however, is cigarettes manufacturing. Cigarettes are a standard product which does not require high technology in production. The recent expansion of cigarette makers, both European and American, into eastern Europe entails the risk of increased exports to western Europe, with consequent negative effects on production and employment within the EU. At present, most cigarette makers are already responding to the weakening in domestic demand by restructuring their operations in western Europe, rationalising production lines and closing down obsolete units (e.g. Philip Morris in Belgium). This trend is bound to be reinforced as a result of the building up of modern production capacities in eastern Europe.

### Textiles and clothing

Textiles and clothing companies do not appear as major international investors based on FDI figures. The sector is nevertheless highly internationalised, as indicated by the importance of textiles & clothing trade to and from the industrialised countries. In this sector, largely because of the small average size of companies and because of the need for flexibility, non-equity forms of investment dominate, such as OEM, subcontracting and licensing agreements.

In the clothing sector, the bulk of transnational activity takes the form of international subcontracting, followed by licensing, which is mostly found in the more fashion oriented products. Many EU clothing companies are indeed gradually turning the corner from manufacturing to purely distributive activities, and source their purchases in low cost countries. This procedure enables them to benefit from price advantages and to enjoy reduced commitment to a given subcontractor or licensee.

Textile producers are also commonly involved in transnational activities. These often take the form of an international sourcing of raw materials, but also (and increasingly) of semi-finished textile products. In this area, subcontracting is the most important form of link between EU textile companies and their non-EU counterparts. Subcontracting is mostly found in such activities as spinning and weaving, but does not usually involve equity ties. The subcontractor commonly remains independent from the contractor company. Licensing is also found in textile producing activities, but mostly in brand name textile production or in man-made fibre production in conjunction with plant construction or turnkey ventures. In developing countries, licensing has permitted EU textile manufacturers to generate returns from their technology, while the licensee has to assume most of the financial and marketing risks associated with the agreement. In the developed countries, by contrast, licensing and sometimes even cross-licensing is quite a common transnational strategy for EU firms as it enables the partners to share the costs of R&D and of marketing.

There are considerable differences in the form that relocation activity takes according to geographical area. For outward processing trade (OPT) operations, which require quick response and are based on just-in-time strategies, delivery times are a crucial factor in the choice of the country of location of activity. Proximity of the subcontracting country is therefore seen as fundamental. OPT operations are commonly developed

between Germany, France and the Benelux countries on the one hand, and the east European countries and countries of the Mediterranean rim on the other hand. Mediterranean countries and Africa are, in addition to the above-mentioned relocation forms, privileged locations for establishing own production facilities. The importance of OPT operations is largely explained by labour cost differences, as the production of garment is a highly labour-intensive process.

The general cost structure of textile and clothing production does not permit EU firms to compete against low-wage countries which have furthermore benefited from advantageous trading conditions under the auspices of the Multi-Fibres Arrangements. The relocation of some segments of textiles and clothing production has thus been essential to the survival of other business segments in Europe. The EU textile industry has thus benefited from the development of OPT operations by EU clothing firms which continue to source most of their input materials within the EU.

Unfortunately, this positive point has to be seriously tempered by the ongoing process of relocation of upstream activities, reflecting clustering patterns in production. The case of the Italian Marzotto and Miroglio is illustrative in this matter: these textile and clothing producers which had relocated their garment assembly activities in low-wage countries (in particular in the Mediterranean rim) a long time ago have recently continued their relocation process by moving textile production capacity in the Maghreb.

## CONCLUSION

The above analysis has shown that, although the typical forms of transnational involvement do vary significantly by sector, for each sector region couple one can indeed identify a specific pattern of transnational investment.

In most sectors, the transnational investment strategies of EU firms outside Europe have been driven by the desire of establish a presence or expand in a new (and/or fast growing) market. This trend has been further reinforced in recent years by the effects of the recession which prompted manufacturers to look for new outlets for their products. The overall importance of transnational investments by EU companies outside Europe is however, still relatively low, and there is a distinct trend towards lower equity, less riskier, forms of transnational involvement.

Investments aimed at re-exporting to Europe indeed only represent a small share of all transnational moves by EU firms, and they are generally quite limited in scope. Their spill-over effects on European employment levels are thus moderate. EU investment abroad is also still somewhat conservative in form: it is concentrated in mature sectors and in countries with which the EU Member States have historic ties. This also holds for EU investment in eastern Europe.

Finally, the employment effects (in Europe) of the EU firms' transnational involvement strategies are small in most sectors (the two exceptions being textile and apparel, and consumer electronics), if only because the sectors in which EU firms have the strongest presence abroad - or which are most internationalised - are not those with the highest labour content. There are, nevertheless, some important spill-over effects of these investments in up and downstream sectors, both positive and negative (see Table 2).

# The world's largest industrial groups

*This article compares the relative performance of the world's 200 largest industrial companies by region and by sector in terms of turnover, profit and other key indicators, then describes in more detail the past trends in the key financial indicators of Europe's top 200 companies by sector. All the data underlying this analysis comes from the Commission's database on large enterprises (DABLE), with all figures presented in current ECU. The data covers the period 1987-93, and relies on official figures from the companies' annual reports. Complete 1994 figures for Japan were not available at the time of writing, as the Japanese 1994 fiscal year only ends in March 1995. The data presented below thus only goes to 1993.*

## THE WORLD'S TOP 200 COMPANIES

### Overall performance

The total turnover of the world's 200 largest industrial companies was just over 3 500 billion ECU in 1993, 1 100 more than in 1987 (Figure 1). The rate of growth of turnover of the world's largest companies was, however, higher in the first part of the period (+8.5 % per year on average between 1987-90) than in the second part (+4.5 % per year on average between 1990 and 1993). This slowdown in turnover growth after 1990 results from both the deceleration in overall economic growth in the USA and Europe over that period, and

from less intense M&A activity by the top firms. In Europe, the number of cross-border acquisitions, which hovered around 1 840 in 1989-90, fell to 1 612 in 1991 and to just over 1 400 in 1992 and 1993. The average value of cross border acquisitions involving European companies also decreased over the period, to a little over 30 billion ECU from close to 50 billion ECU in 1989-90. The number of cross-border acquisitions started increasing again in 1994, when companies emerged from the previous period of corporate retrenchment characterised by 'survival' strategies.

The influence of the business cycle - with Europe at the bottom of the business cycle in 1993, whereas the USA was on the way to recovery and Japan was only beginning to slow down - is highly notable on Figure 1. Whereas the EU companies accounted for a rising share of the total turnover of the largest top 200 world companies until 1992 (from 37.3 % in 1987 to 39.3 % in 1990, then stabilising at that level until 1992), this share fell back significantly in 1993, to 35.5 %. The share of turnover of the top USA companies has, in contrast, decreased continuously since 1986, falling from 44.1 % in 1986 to 40.8 % in 1987, 37.3 % in 1990 and 34.3 % in 1993. In fact, the number of USA companies in the top 200 ranking has also been falling since the mid-1980s, whereas the number of Japanese companies risen continuously, from 36 in 1986 to 52 in 1993.

**Figure 1: The 200 largest industrial groups in the world**  
Turnover growth at current prices

Source: DABLE

**Figure 2: The 200 largest industrial groups in the world  
Net profit / turnover**

Source: DABLE

Given this increase in both the average size and the number of Japanese companies in the world top 200 ranking, it is not surprising to find that these have also significantly increased their share of total turnover by the world's largest 200 companies, from 17.2 % in 1987 to close to 25 % in 1993.

Looking at the trend in turnover in more detail, one finds that there was a turnaround in the USA companies' relative position in 1993. The weak relative sales performance of the large USA companies, which was very notable until 1992, actually ended in 1993: in 1993 there were 65 USA companies in the top 200 ranking, two more than the year before, and their share of total turnover had increased from 34 % to 34.3 % (Table 1). In contrast, there were only 71 European companies (from either the EU or the EFTA) in the top 200 in 1993, compared to 76 the year before.

There are four factors which will push for a reversal of the downward trend in the European companies' relative performance in 1994 and 1995. First and foremost, the acceleration of economic activity in Europe at the end of 1993 has given a boost to the top companies' turnover. Secondly, M&A activity in Europe, which had fallen back in 1991, 1992 and 1993, has since been on an upward trend: in 1994, the number of intra-European cross-border acquisitions increased again, to 1 536 according to 'Acquisitions Monthly', and the total value of the deals was up by 50 % from the 1993 level. Thirdly, economic growth in Japan slowed down in 1994 and 1995, implying a comparatively slower growth of the turnover of the top Japanese companies. And, fourth, the depreciation of the US dollar against the ECU comparatively reduces the US companies' share of total turnover when measured in current ECU.

In 1994 and 1995, thus, both the number and the share of turnover of the largest European companies are likely to have increased again from the levels shown in Figure 1.

The analysis of the trend in the profit ratio of the top companies by region over the period 1987-1993 also shows an interesting pattern, even if somewhat worrisome as far as the European and Japanese companies are concerned (Figure 2). In 1993, the financial performance of the major European companies continued to deteriorate, albeit at a slower pace than in 1992. This slower deterioration reflects the progressive improvement in the economic situation in Europe throughout the year, with both production and sales resuming an upward trend in the last months of 1993, and the result of the cost-cutting efforts of many of the European companies. One will, however, have to wait until 1994 to see an improvement in European companies' net profits and in their net profitability, the latter being measured by the net income to turnover ratio. This will be much needed since, as illustrated in Figure 2, the net profitability ratio of Europe's top companies has fallen consistently from its level of 4 % in 1988 to just over 1 % in 1993. As the rate of utilisation of production capacities has been on an upward trend since the middle of 1993 and as real interest rates in Europe remain high, it is essential for companies to restore their profitability in order to have the means to finance new investments.

The downward trend in profitability in Europe is not a unique phenomena, however. The largest USA companies also experienced a decline in their average profitability ratio in the late 1980s/early 1990s, but a turnaround took place as early as in 1992 thanks to the strengthening of economic activity in that country. In 1993, the average profitability ratio of the largest USA companies was back to 4 %, the peak level observed in Europe in 1988-89.

The average profitability ratio of the top Japanese companies has followed a trend very similar to that of the top European firms though falling as low as 0.5 % in 1993. Exchange rate movements and the timing of the business cycle also explain the observed downward trend in profitability of the top Japanese firms.

Considering the trend in profitability in the USA, it is unclear the extent to which the increase in competition at world level which resulted from globalisation and deregulation in many country markets has squeezed the "structural" profit margins of the world's largest firms, though this may have played a role in Europe and in Japan.

The long term borrowing to total assets ratio of the largest USA firms has been falling regularly from its peak of 21.7 % in 1990-91 to just above 20 % in 1993. The same indicator for the Japanese firms increased consistently over the period considered and is now close to the USA level, at 19.8 %. In Europe, a high self financing ratio and comparatively low indebtedness level of the larger companies, along with low investment levels, has made it possible to keep the long term borrowing to total assets ratio stable. At 14.5 %, this ratio is well below the level in either the USA or Japan. This, however, is both a positive and a negative point for EU businesses: on the one hand, the low level of indebtedness makes European firms financially sturdier than their competitors, but on the other hand this does reflect a structurally (too) low level of investment in fixed capital by the European firms.

**Table 1: The top 200 companies at world level**

Turnover by sector**

Source: DABLE

As profit margins were being squeezed in the early 1990s, many European companies engaged in a second wave of rationalisation and restructuring. This 'survival strategy' has taken the form of divestment of non-strategic units, some (generally limited to only a few sectors) acquisitions of business units seen to represent a good potential for economies of scale or synergies, and cost reductions, in particular labour cost reductions. A good indication of the magnitude of the efforts undertaken is provided by the fact that, contrary to what usually happens in business cycles, the average labour productivity in the top firms did not fall when production and sales started to weaken, but rather increased throughout the recession. This trend was observed in all three regions considered (the USA, Europe and Japan), indicating that labour shedding was both significant and spread out.

Other expenditure items which were cut as part of the cost saving efforts were fixed investment in new capacity and some renewal and modernisation investment, as indicated by the fall in the share of investment in turnover in many sectors of the European economy. One exception was expenditure on R&D, which continued to grow in a number of critical sectors in Europe, in particular in the pharmaceuticals and electrical equipment sectors. Thus, despite the recession in a number of technology intensive sectors, the larger EU companies are still spending a comparatively higher share of their turnover on R&D than their competitors. There are nevertheless three sectors in which the European R&D efforts remain well beyond those of their world competitors: these are computers and office equipment, instrument engineering and advanced materials (part of which are in the rubber and plastics sector, and part in the stone, clay and glass sectors).

The restructuring moves which were undertaken by most of the top firms in the early 1990s have started to bear fruit. In the USA, the financial situation of the larger companies started to improve as early as in 1992, whereas in Europe this was the case as of 1993 (Table 2).

This can be seen in particular through the reduction in the number of companies from those regions which reported losses in those two years (Table 2). Not surprisingly given the very low average profitability ratio of the Japanese firms, the number of Japanese firms in the top 200 reporting a loss continued to increase in 1993, reaching 13 or nearly one in four of all Japanese companies in the world top 200.

The breakdown of turnover of the world's top 200 industrial groups by sector in 1987 and 1993 is illustrated in Figure 3. In 1993, the larger automotive producers accounted for 20.3 % of the total turnover of the world's top 200 firms, followed by the electrical engineering and petroleum refining companies.

This ranking is quite different from that observed in 1987. Between 1987 and 1993, indeed, the weakening of oil prices limited the growth in the turnover of the larger oil and chemical companies and made these firms lose their first place in the ranking. The motor vehicles and parts sector thus became the sector with the highest turnover within the world's top 200 ranking, despite a relatively poor sales performance over the period 1990-1993. In fact, nearly all the sectors listed in Figure 3 increased their share of turnover in the world top 200 ranking, with the exception of the chemical sector and "other" industries. In many of the above cases, intense M&A activity by the top firms boosted the combined turnover of the companies within these sectors. It is interesting to note

that even the iron & steel sector saw its share of the total turnover of the top companies increasing, despite the very weak sale and production performance of the sector as a whole. The ferrous metals industry, which has seen many concentration moves since 1986, had more firms in the top 200 list in 1993 than in 1987 and the combined turnover of these firms had increased from 95.3 billion ECU to 167.3 billion ECU in 1993.

The larger companies from all three regions reported a lower rate of return on sales (ROS) in 1993 than in 1987, with only a few exceptions. The trend in profitability between 1992 and 1993 was, however, very different by sector and by region. In the USA, the improvement in the financial situation of the larger firms in 1993 was felt by the companies from nearly all sectors. Notable exceptions were the computer and office equipment sector, where increased competition at world level triggered a price war which squeezed margins for all producers, along with apparel and paper manufacturing, two industries highly vulnerable to competition from imports. The USA autos sector, however, continued to improve its financial performance and moved back to profit, posting a return on sales of 2.3 % in 1993 following figures of -0.7 % in 1992 and -2.9 % in 1991.

In Europe, five sectors reported losses in 1993. These were computer and office equipment, aerospace, metals, motor vehicles & parts and rubber and plastics. In the case of the aerospace sector, the total loss of the top European producers in 1993 was nevertheless much lower than that recorded in 1992, indicating that the restructuring measures undertaken by the top companies in the sector have started to bear fruits. The highest profit makers (measured by the rate of return on sales (ROS)) in Europe were the printing and publishing sector, followed by tobacco products manufacturing and chemicals (including pharmaceuticals).

Within Europe, the largest groups in terms of turnover are from Germany, France and the UK, in that order (Table 5). Together, the top companies of those three countries accounted for close to 70 % of the total turnover of Europe's top 200 firms in 1993, the same share as in 1987. Two other countries which also host a large number of Europe's top firms are Italy and the Netherlands, along with Switzerland. The Netherlands is, in fact, home to a number of Europe's largest oil and chemical companies (Royal Dutch Petroleum, Unilever, Akzo, DSM), as well as to other giant corporations such as Philips (electrical engineering), Hoogovens (metals) and Heineken (food and drink). Switzerland hosts two of the world's best known companies, Nestlé and ABB, as well as several large chemical firms such as Ciba-Geigy, Sandoz, and Roche, amongst others.

As in 1993, the largest profit earner in the world was a European company, Royal Dutch Shell. The second European company ranked by profit, however, only ranked 13th in the world ranking: this was Glaxo of the UK, now the world's largest pharmaceutical company. In total, there were only 6 European companies amongst the top 25 largest profit earners in 1993, two less than in 1992 (Table 3).

Most of the companies in the list of largest profit earners are from the oil, chemicals and food and drink sectors, alongside a few equipment producers such as Toyota Motor. Toyota was, in fact, the only Japanese firm in the list.

It is interesting to compare the list of largest profit earners with that of the most profitable companies at world level. First of all, there were no Japanese companies amongst the 25 most profitable companies at world level in 1993: Fuji Photo Film, which ranked 23d in 1992, has since disappeared from the top 25 ranking. Secondly, only eleven of the world's biggest profit earners rank amongst the 25 most profitable firms: these are all the pharmaceutical companies in the list of largest profit earners, along with a few diversified chemical

companies such as Johnson and Johnson and B.A.T. Industries, along with the giant soft drinks company Coca Cola, and the electronics giant Intel. PepsiCo, which is the 20th biggest profit earner in the world, does not rank amongst the list of most profitable companies, contrary to its rival Coca Cola. None of the oil companies which dominate the ranking of the largest profit earners are amongst the "most profitable" firms, as the average profit ratio in the petroleum refinery sector is generally low.

Below, we look at the overall performance of the world's top 200 firms by main sector of activity. The next section will then focus on the relative performance of the largest European companies, both by country of origin and by sector.

## Sector profiles

### *Petroleum refining*

The world energy sector is dominated by a few large companies, most of which have important transnational operations and some of which are still owned or largely controlled by government. Healthy economic growth in the second half of the 1980s combined with low energy prices hence lower incentives to conserve energy led to a healthy growth in turnover of the top energy companies. As a result, the number of energy companies in the top 200 world ranking and in Europe's top 200 list increased during the decade of the eighties, then stabilised in the early nineties. In 1993, there were 30 petroleum refinery groups in the list of the world's 200 largest firms.

Because oil prices have remained low for a number of years, however, and there have been comparatively fewer mergers/acquisitions in this sector than in manufacturing, the share of total turnover generated by the larger European oil producers in the total output of the world's largest petroleum refineries has remained broadly stable between 1987 and 1993, at around 37.5 %. Over the period, the turnover of the top firms increased by 5 % per year on average, reaching 670.4 billion ECU in 1993.

The USA companies seem to be the ones which suffered the most from the recent economic downturn: although their situation in 1993 improved significantly over 1992, with an 8.8 % increase in the combined turnover of the top 10 USA refineries increased by 8.8 % (which compares with a figure of 3.1 % for Europe), their share of the total turnover of the world's largest 30 petroleum refineries is, at 38.8 %, well below the 1987 figure of 46.6 %. The most impressive increase in relative market share over the period has been that of the Japanese and Korean producers, whose top companies posted a 29 % growth in turnover in 1993 over 1992. These companies now account for close to 16 % of the total turnover of the top oil producers.

In 1993, there were six Japanese and two Korean companies in the ranking of the 30 largest petroleum refineries: the larger of these were Nippon Oil, which ranked 11th, and Japan Energy which ranked 15th. The largest Korean refinery, Sunkyong, ranked 16th.

Exxon of the USA, which was already at the top of the list in 1992, remained the leader in 1993 with a turnover of 83.6 billion ECU. It was closely followed by Royal Dutch Shell at 81.3 billion ECU. The difference in turnover of the two groups has thus shrunk again from the 6.5 % difference of 1992. In fact, in 1990, it was Royal Dutch Shell which led the world ranking both in this and in all sectors.

As indicated above, the total turnover of the larger USA refineries increased much more rapidly than that of the larger European firms, between 1992 and 1993, largely because of the faster economic growth in the USA in that year. A direct result of this is that the difference between the average size of the top USA and European oil groups has shrunk. In 1993, the average USA oil company had a turnover of around 26 billion ECU, compared with a figure of 28 billion ECU for

the average EU oil refinery group. In comparison, the Japanese and Korean top producers are still much smaller, at 13.2 billion ECU or about half the size of the EU companies.

### Iron and steel

Between 1987 and 1993, the total turnover of the world's largest metal producers increased at an average annual rate of 9.8 %, which brought their share of total turnover from 3.9 % to 5 %. This rapid growth reflects in part the increase in the number of companies in the list (from 13 in 1987 to 15 in 1993) and, mainly, intense ownership restructuring activity amongst the top firms: as competitive pressures were rising, both because of the arrival of Central and Eastern European producers on the market and because of the weakening of demand, the top western producers engaged in major restructuring efforts, diversifying away from basic metals production and moving upstream in their product lines.

The heightening of competition at world level is highly notable in Figure 5, even though this only shows the regional market shares of the top 15 producers and not the market shares of all producers in the sector (hence, East European production is not accounted for in Figure 5). Between 1987 and 1993, thus, the share of the European producers' turnover decreased moderately, by one percentage point, while that of the USA fell from 13.9 % to 4.6 %. This, in fact, prompted the USA to tighten restrictions on imports of steel into the USA in that year, which created some disruptions on the trade front.

The financial performance of the larger iron and steel manufacturers has deteriorated significantly over time, such that in 1993 all three regions reported a negative ROS in this sector (-1.3 % in Europe, -0.7 % in the USA and -1.0 % in Japan). As a matter of fact, amongst the largest 10 world

ferrous metals producers only two reported profits in 1993. These were VIAG of Germany and Broken Hill Proprietary of Australia. The largest deficit was reported by the French company Usinor Sacilor, at 920 million ECU, a ROS of -8.1 %.

Figure 5 also shows the relative dominance of the Japanese producers in this sector.

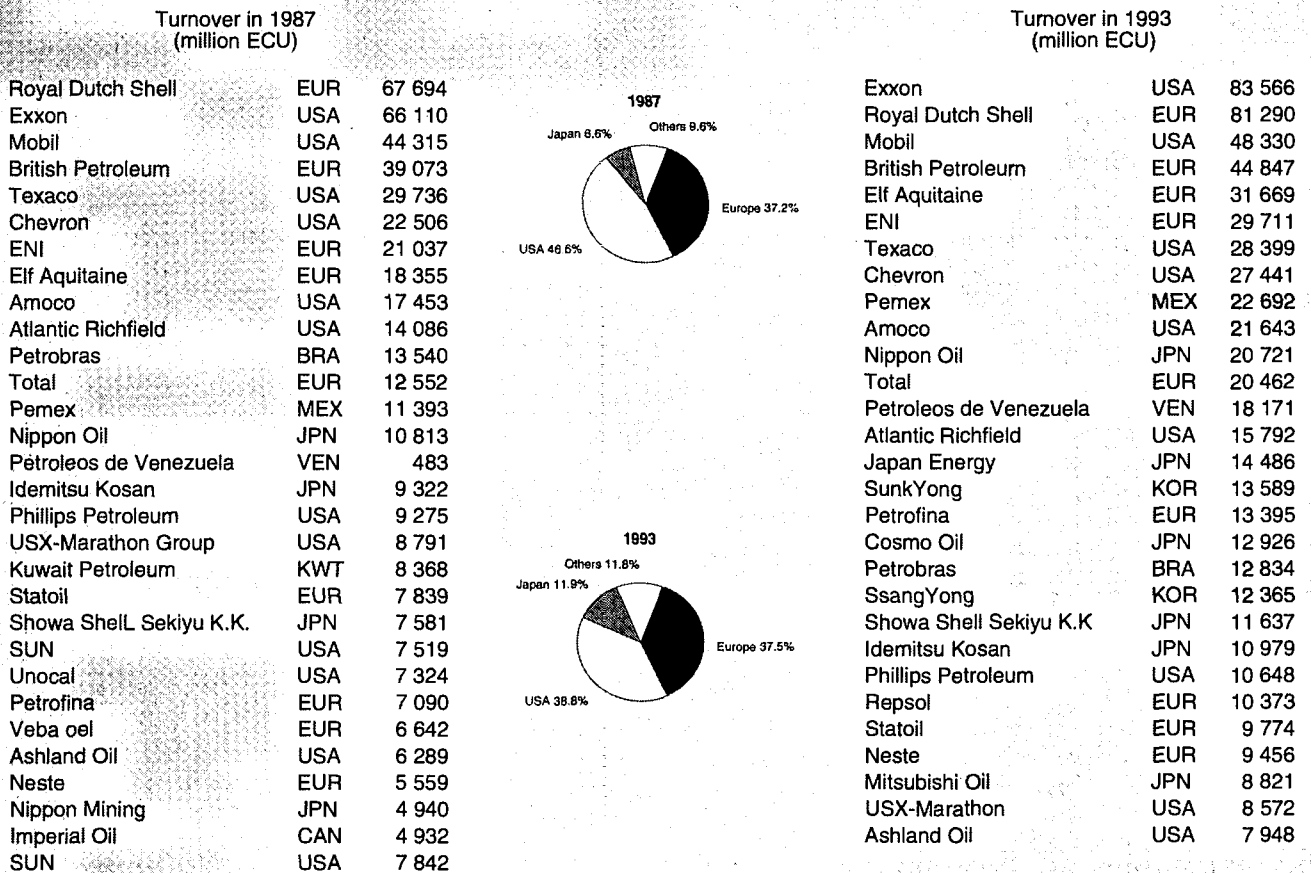

Among the 15 world largest basic metal producers in 1993, seven were from Japan. The first two Japanese producers ranked in 1st and 3d place respectively. Thyssen, the largest European metal producers, ranked second at world level, as in 1987, whereas Usinor Sacilor receded in 5th position behind VIAG of Germany.

Although they dominate the world ranking and their share of total turnover by the top firms remains high, the largest Japanese producers were not sheltered from the recession which badly hit their client industries. The steady appreciation of the Japanese Yen throughout the period also contributed to dampen the companies' financial situation, bringing all five major producers into the red in 1993. As demand prospects remained dull, a number of them announced large job cuts spread over 1994-96, similarly to the situation in both the USA and Europe.

### Chemicals

The total turnover of the world's largest chemical companies (including the pharmaceutical producers) increased by 30 % between 1987 and 1993, a 4.5 % average annual rate of growth, less than the average for all the top firms. As a result, the share of turnover by the top firms which was accounted for by the largest chemical producers decreased, from 9.7 % in 1987 to 8.7 % in 1993. The trend in turnover between 1992

Figure 4: Petroleum refining

Source: DABLE

**Figure 5: Iron and steel**

Source: DABLE

and 1993 was, at 5 %, not significantly different from the average over the previous 5-year period.

The regional shares of total turnover did not change significantly, however, with the European companies still accounting for about 55 % of the total sales of the largest world chemical producers.

The trend in the overall chemical sector masks very different performances across markets, however, as the pharmaceutical companies distinctly out performed the companies from the

basic chemicals or other specialty chemicals sector. Sales by the world's largest pharmaceutical producers thus increased at a steady rate throughout the period, while those of the basic chemical producers were much more vulnerable to the downturn.

The average financial performance of the world's largest chemical producers was also exacerbated by the overcapacity problems which plagued financial results in the basic chemicals segment and resulted in a fall in the prices of a number of key products.

**Figure 6: Chemicals**

Source: DABLE

**Figure 7: Electrical and electronic engineering**

Source: DABLE

### Electrical and electronic engineering

The electrical and electronic engineering sector is a highly globalised industry at world level, dominated by a number of R&D intensive large companies. In 1993, among the 200 largest world enterprises ranked by turnover, 28 were from the electrical and electronic engineering sector. Nine of these were from Japan or Korea, nine from western Europe and 10 from the USA. The Japanese companies have grown faster than their competitors over the past years despite the constant appreciation of the Yen, as indicated by the growing share of the total turnover of the larger Japanese firms in this sector. Between 1987 and 1993, this share increased from 29.2 % to 35.4 % at the expense of both the European and the larger USA companies (Figure 7).

Between 1987 and 1993, the combined turnover of the larger firms in this sector increased by 8.9 % per year on average. The fastest growth rate was recorded by the Korean and Japanese companies, whose combined turnover grew at an average annual rate of 11.7 % over the period. In contrast, the turnover of the larger European electrical and electronic engineering producers grew at only 5.9 % per year on average, and slowed further, to less than 1 % in 1993 compared to a rate of 3.9 % for the larger Japanese and Korean companies in the same year. Hence, despite numerous acquisitions and major efforts to improve competitiveness and market share by streamlining costs and relocating part of the production to low-cost countries, the larger European electronic equipment manufacturers continue to lose ground in world markets.

The efforts made by the larger European firms are most visible in the rising share of R&D expenditure in turnover. In 1993, Europe's largest electrical and electronic equipment producers invested 6.9 % of their turnover in R&D on average, compared to a figure of 5.5 % for the larger USA companies and 4.8 % for the leading Japanese producers. Although these efforts

may bear fruit in the longer term, in the short term this does not seem to have given European companies a distinct comparative advantage.

The growing competition in this market partly takes the form of a race for innovation, and partly of intense competition on prices. As a result, the profit margins of the larger producers in both Europe and Japan have progressively been squeezed over time. In Europe, the ROS fell from 2.5 % in 1989 to 1.4 % in 1993, whereas in Japan, it fell from 3.1 % in 1989 to 0.6 % only in 1993. Only the USA companies seem to have been able to maintain a high profit margin in this sector. This reflects the fact that most of the larger American companies in the list are manufacturers of equipment for industry as opposed to equipment for consumers, the latter being a sector with a much lower average profit margin.

The three firms which lead the 1993 ranking are Hitachi and Matsushita Electric of Japan, followed by General Electric of the USA. The first European company, Siemens, ranked fifth based on turnover, while Philips Electronics, the second largest European producer, ranked 7th. Between 1987 and 1993, there were relatively few changes at the top in this sector, the three leading firms being exactly the same. Two of the companies which were classified in this sector in the 1993 edition of the Panorama have since been re-classified into the computer and office equipment sector: these are NEC and Toshiba.

### Computers and office equipment

The world computer and office equipment market is dominated by only two players: the USA and Japan. Europe's Olivetti, which ranked 8th at world level in 1987, has since disappeared from the list of world top 200 companies based on turnover, and thus does not appear in Figure 8 in 1993.

**Figure 8: Computer and office equipment**

Source: DABLE

The total turnover of the largest firms in this sector was more or less evenly distributed between the top USA and Japanese companies, the sectoral leader being IBM of the USA, followed by Toshiba and NEC of Japan. IBM's position as world leader remains unchallenged, however, as its turnover of 53.6 billion ECU was still a comfortable 44 % higher than that of number two Toshiba.

Between 1987 and 1993, the combined turnover of the largest companies in this sector increased by 8.5 % per year on average, to 215.5 billion ECU in 1993. Newcomers in the list of largest manufacturers since 1987 are Apple Computer, along

with Xerox and Canon which increased their presence in this market from being more traditional electrical equipment suppliers.

**Motor vehicles and components**

The triad's dominance of the world automotive and parts market is beginning to be challenged, with Hyundai Motor of Korea having made its entrance in the list of the world top 200 industrial companies. Hence, whereas until the late 1980s the three main producers, the USA, Japan and Europe more or less evenly divided the world automotive market amongst

**Figure 9: Motor vehicles and components**

Source: DABLE

Figure 10: Aerospace

Source: DABLE

themselves, in 1993 Korea's Hyundai accounted for 1.1 % of the combined turnover of the 24 largest producers. The rise in the Japanese companies' market share is the other notable trend in Figure 9, this share having risen from 25.2 % in 1987 to 32.7 % in 1993. Between 1987 and 1993, the total sales of the larger firms in this sector increased by 7.5 % per year on average, the trend being distinctly faster in the first part of the period than in the second, and this for two reasons: first, demand itself slowed down in most regions after 1990, whereas secondly intense M&A activity amongst the top firms reduced the number of players and created more global firms. This was especially the case in Europe, where the number of producers in the world top 200 decreased by one (from 10 to 9) but the average size of these players grew significantly, from 16.8 billion ECU in 1987 to 24.6 billion ECU in 1993.

All the figures relating to the financial performance of the major European automotive producers in 1993 point to the difficult period that the industry is only now emerging from. The average ROS of the top European automotive producers was -1.0 % in 1993, compared to a figure of +0.4 % in Japan and +2.3 % in the USA. The company having posted the largest loss was Volvo (with a ROS of -3.1 % in 1993), followed by Volkswagen (-2.7 %). Two other EU companies (Fiat and Peugeot) reported small losses while the others reported a low profit. This is itself quite an achievement, given that the combined turnover of the main European automotive producers fell by 3.5 % in the year to 1993. Both investments in fixed capital and in R&D decreased in that year though the European R&D ratio in this sector remains well ahead of that of its two main competitors (5.2 % in 1993 in Europe compared with 4.1 % in the USA and 3.9 % in Japan).

General Motors remains the world's largest automotive producer, with a total world-wide turnover of 114.1 billion ECU, well ahead of the number two Ford Motor, whose turnover amounted to 92.7 billion ECU in the same year. The largest European producer, Daimler-Benz, ranked 4th with a turnover of 50.5 billion ECU, less than half that of General Motors. Although there have been a few changes in position at the top, the largest 10 automotive producers in 1993 were the same as in 1987.

#### Aerospace equipment

The world aerospace equipment market remains dominated by the top USA producers, who accounted for 74 % of the global turnover of the world's 11 largest aerospace producers in 1993. Their share has been falling progressively over time, however, as the three main European producers British Aero-

space, Deutsche Aerospace and Aérospatiale were reinforcing their presence in the world market. The European's relative expansion experienced a setback in 1993, however, as the difficulties experienced by many airlines in Europe combined with unfavourable exchange rate movements led to a major slowdown in European sales expansion: in that year, the total sales value of the three above-mentioned European companies only grew by 1.9 %, which compares with an average annual growth in turnover of the largest 11 companies of 4.6 % per year on average over the period 1987-93.

The very strong competitive pressures to which the sector is subject due to the continuous depreciation of the dollar are also notable through the comparison of the average profit ratios of the USA and European producers. Despite on-going cost control and restructuring efforts, the top European producers experienced a combined loss equivalent to 1.6 % of their 1993 turnover, which compares with a figure of +3.4 % in the USA that same year. The fact that the aerospace sector is one of the few sectors in the USA which actually reported a higher ROS in 1993 than in 1989 is highly significant in this respect.

Although they have been growing in size both through internal growth and ownership restructuring, the largest European aerospace producers remain smaller on average than their USA rivals. The average size of the largest three European aerospace manufacturers was 10.1 billion ECU, compared with a figure of 12.3 billion ECU for the USA.

#### Food, drink and tobacco

The food, drink and tobacco sector is one of those sectors which increased its share of the total turnover of the world's largest 200 companies, despite the fact that this is by nature a slow growing demand sector: between 1987 and 1993, the combined turnover of the world's largest food companies grew at an average annual rate of 7.7 %, i.e. faster than that of traditionally more dynamic sectors such as the automotive or aerospace industries.

The reasons for this comparatively faster growth are two fold. First, the sector is less cyclical than the equipment sectors, hence it suffered less from the downturn of the early 1990s. Secondly, this reflects the external growth strategies pursued by many companies in this sector, in particular by the European companies which grew through cross-border acquisition following the launch of the Internal Market programme. In 1993, for example, BSN, Grand Metropolitan and Cadbury Schweppes all acquired plants in India and China. BSN also expanded into Eastern Europe, through the acquisition of the largest dairy products plant in Hungary.

The largest world producer in this sector in 1993 was Philip Morris of the USA, with a turnover of ECU 43.2 billion, followed by two European food companies, Unilever and Nestlé. Philip Morris was particularly aggressive on the cigarette market, pursuing a strategy of price cuts to boost market share, and succeeding at it. Philip Morris also merged Kraft General Foods Europe and Jacobs Suchard in that year, creating a global multinational in Europe. These three companies already lead the ranking in 1992, in the same order. In total, among the top 22 firms in this sector in 1993, seven were European, two Japanese and 12 were from the USA. This compares with seven European companies, one Japanese, 14 USA and one South African company in 1987.

Profit margins in the food, drink and tobacco producing sector have traditionally been relatively high, but even so they have shrunk significantly between 1989 and 1993, both in Europe and in Japan. Again, only the USA companies saw an improvement in their profit margins over the period considered, thanks to their relatively strong internal market and to the limited degree of competition from imports in this low-trade intensity sector.

## EUROPE'S TOP 200 FIRMS

### Overall performance

In 1993, the total turnover of Europe's largest 200 largest companies amounted to 2 028 billion ECU, i.e. about 42 % of EU's GDP. Table 16 lists Europe's 200 largest manufacturing and services companies by country in 1987 and in 1993 respectively. Important acquisition moves by some of the larger Swiss companies (many of which are involved in the pharmaceutical sector) combined to exchange rate effects increased the Swiss companies' share of the total turnover of Europe's largest 200 companies. Similarly, acquisition moves by France's larger companies boosted the total share of Europe's turnover accounted for by the largest French producers. In contrast, the other countries' share of turnover shrank, the most important effect being observed in the UK, where the top companies' share of turnover has now fallen to 19 %,

from 23.1 % in 1987. Although the UK economy strengthened in 1993, one year before the other European economies, a number of UK companies were acquisition targets for non-UK firms, while the petroleum refineries which dominate the UK list of top companies reported a poor sales performance in that year. Thirdly, exchange rate movements in 1993 played against the UK companies' financial performance when measured in current ECU.

Compared to the rest of the world, the breakdown of Europe's largest companies by sector is much more varied - implying that many sectors which are highly concentrated in the rest of the world have not yet reached the "critical size" in the EU (Figure 13). Petroleum refining companies for instance, which account for nearly one fifth of the total turnover of the world's top 200 firms, account for less than 13 % of the global turnover of Europe's top 200 companies. And indeed, excessive fragmentation is one of the factors frequently quoted as negatively influencing the relative competitiveness of Europe's petroleum refineries compared to their competitors in the USA or Asia.

In the motor vehicles sector also, the relative fragmentation of industry in Europe (mainly of the automotive components part of the industry) is reflected by the fact that the "large" European automotive producers only account for about 10 % of the total turnover of Europe's top 200 firms, whereas the equivalent share at world level is more than 20 %.

The sectoral distribution of companies in the top 200 list in Europe is broadly similar in 1993 to that observed in 1987, with one notable exception, which is the telecommunications sector. This sector's share of the total turnover of the top 200 European companies more than doubled thanks to rapid growth in demand and sales, and to cross-border ownership restructuring following the liberalisation and deregulation of the sector in Europe. The automotive sector, in contrast, saw its share of the total falling by two points due to a poor sales performance over the second half of the period.

Table 6 present Europe's 25 largest profit earners, the most profitable and the richest firms, along with Europe's 25 biggest employers. As in the rest of the world, the list of most profitable companies is dominated by companies from the pharmaceutical industry, alongside a few electrical equipment producers. Amongst the biggest employers we find a very diverse mix of companies, many of which are fully or partially government owned, and some of which may not keep their place in this

ranking in future years as they are on the list of companies to be restructured or privatised.

Below, we look at the relative performance of EU firms in each of these sectors over time.

**Table 7: Petroleum refining

## Sectoral performance

### Petroleum refining

The total turnover of Europe's 12 largest petroleum companies represents 13.2 % of the total turnover of Europe's 200 largest firms, but the employment share is much lower, reflecting the fact that petroleum refining is not a labour intensive activity.

1993 was again not a very good year for petroleum refineries which saw profits tumble as a result of weak demand and oil prices. Even those companies that were able to maintain their turnover in 1992-93 saw profits squeezed by the dollar effect.

Of Europe's 12 largest petroleum refining companies, nine are in the world's top 200 ranking. The last three, RWE-DEA, Veba Oel and OMV are from Germany and Austria. Ten of these were already in the 1992 ranking of top 200 European companies, the two newcomers being RWE-DEA and OMV. The combined turnover of the top 10 companies increased by 3.4 % between 1992 and 1993, despite a fall in turnover by four of the 12 companies. The largest fall in turnover was posted by Repsol. This follows a period of fairly rapid growth in turnover, by 28.7 % between 1987 and 1992, or 5.2 % per year on average. Between 1987 and 1993, the fastest rates of turnover growth were recorded by Petrofina (+89 %), followed by Elf Aquitaine (+72.5 %), Neste (+70 %) and Total (+63 %). In contrast, the growth of the two leaders, Royal Dutch Shell and British Petroleum, was very low (+20 % and +14.8 % respectively).

### Iron and steel

The total turnover of the top 10 European metal producers increased by 36.7 % between 1987 and 1993, an 5.3 % growth in annual terms. Much of this reflected growth through acquisitions, however, as overall market demand growth was subdued, especially in the early 1990s.

Growing competition from the East European producers further squeezed the total sales of the larger western producers and partly accounts for the slow growth the European companies' turnover in the second part of the period.

The European basic metals sector is still dominated by national champions, and the recent cross-border acquisitions undertaken by a few of the major firms have done little to change this picture. Among the top 10 iron and steel producers, thus, there is nearly one per EU Member State: three are German, one is French, one is Italian, one is Belgian, one Dutch, one from Luxembourg and one Swiss. The only Member States

not represented in this list are Spain, Ireland and Denmark, along with Sweden and Finland.

Another interesting feature is the fact that, more than in most other sectors, there have been major changes at the top over the 6-year to 1993. Whereas Thyssen and Usinor-Sacilor still lead the ranking, many changes have occurred beyond the second position. Krupp Stahl's acquisition of Hoesch has brought it to third position, whereas Ilva, British Steel and Arbed now occupy the 4th, 5th and 6th place respectively. None of these ranked in the list of top 10 basic metal producers 6 years earlier.

All basic metals producers have been shedding workers in past years, and the trend continued in 1993. Thyssen Stahl, the leading German producer, cut its workforce by close to 25 % in the two years to September 1993. Usinor Sacilor also reduced its workforce through early retirements, outplacements or actual job cuts, by 7 % in 1993.

### Chemicals

In 1993, there were 15 chemical producers among Europe's 200 largest companies, which together accounted for just over 10 % of the combined turnover of these 200 firms. Among these 15 companies, four were German, three of which (Hoechst, Bayer and BASF) occupied the top three positions in 1993. The Swiss pharmaceutical producers also rank high in the list, with Ciba-Geigy in 4th position and Sandoz and Roche in 8th and 9th position respectively. The remaining companies in the list are French (Rhône Poulenc and l'Oréal), Italian (Montedison), British (ICI, SmithKline Beecham and Glaxo), Dutch (Akzo Nobel) and Norwegian (Norsk Hydro).

The total turnover generated by the 15 largest European chemical companies increased by 30 % over the six-years to 1993, an average annual rate of growth of 4.5 % in value. Turnover growth was much faster between 1987-91 after which growth around to reach a trough in 1993.

Although there have been many changes in the ranking of the top European chemical producers, 11 out of the 15 larger producers in 1987 were still among the top 15 in 1993. The four which disappeared from the top 15 ranking were Solvay, DSM, l'Air Liquide and the BOC Group. These were replaced by three pharmaceutical producers, the latter having been much less vulnerable to the downturn in the early 1990s than the basic chemicals producers.

l'Oréal, Henkel, Rhone-Poulenc and Ciba-Geigy are the four companies which posted the best performance in terms of turnover between 1987 and 1993, growing by more than 40 % in total (100 % in the case of l'Oréal), often through acquisition. The companies which showed the worst performance

**Table 8: Chemicals

BOC Group	2 742	L'Oreal	6 066

Source: DABLE

were Norsk Hydro, BASF and Akzo Nobel, whose turnover increased by less than 15 % in total over the six years. ICI experienced a 31 % fall in its turnover, following the separation its pharmaceutical unit, since called Zeneca.

#### Mechanical engineering

The European mechanical engineering sector is much less concentrated than its Japanese and US counterparts, such that the largest EU producers in this sector rank fairly low in Europe's Top 200 companies' ranking. Mannesmann, Europe's largest mechanical engineering producer, only ranks 80th in the list of largest world companies based on turnover.

Between 1987 and 1993, the sector had mixed fortunes, as a period of fast growth in the second half of the 1980s was followed by falling investment in fixed capital. Whereas the total sales of Europe's top 9 mechanical engineering producers increased by close to 45 % between 1987 and 1993, or 6.4 % annually, the total turnover generated by these 9 firms actually fell between 1990 and 1993. The best sales performance was posted by Mannesmann (whose turnover grew by 80 % in total over the six years to 1993). Three companies joined the list of top firms in 1993, AGIV, Tomkins and Linde. Finmeccanica, the Italian group, reported a decline in sales in 1993 due to the recession in civil aerospace and cuts in defence spending. To reduce its large debt, the group also sold off many of its subsidiaries, so that it does not appear in the 1993 top list, contrary to the situation the year before.

#### Electrical and electronic engineering

As in the chemical sector, the rapid growth of the electrical engineering producers over the eighties and early nineties has masked highly diverse performances by market segment, which had major implications on the relative ranking of firms in this sector. In Europe, thus, there have been notable changes in the rankings of the top 10 firms due to contrasted performances of companies involved in the production of electrical equipment for consumers (a segment which has been faced to growing competition on world markets and where European firms have been losing market share) and electrical equipment for industry (which includes telecommunications equipment and other electrical equipment for industry).

Siemens, which had already overtaken Philips as the European leader in this sector in 1990, has since largely confirmed its position thanks to a 25 % growth in turnover between 1990 and 1992, compared an average turnover growth of Europe's 10 largest companies, of only 9.4 %. In 1993, Siemens' turnover grew by an additional 9 %, to 42 billion ECU, about 4 % faster than the industry's second largest producer in Europe, Philips (+5.2 % growth in turnover in 1993). At the global European level, Siemens now ranks as the fifth largest company based on turnover, whereas Philips only ranks 15th.

The third and fourth largest European firms in this sector are respectively ABB and Alcatel Alsthom of France. Among the top 12 European companies, two are German, three are French, four are Swedish (some of these with shared ownership, like

Source: DABLE

ABB which is Swedish/Swiss), two are from the UK and one from the Netherlands. AEG, Thorn EMI and Nokia are newcomers in the top 200 European companies' ranking.

Between 1992 and 1993, the best performer in terms of turnover was ABB, which is rapidly expanding its presence in Europe and world-wide through acquisitions. The second best performance was posted by Ericsson of Sweden, which reported booming sales of mobile phone equipment: thanks to this, the leading world producer of mobile phones in 1993 more than doubled its pre-tax profits in that year.

The semi-conductor producers in the list also reported significant increases in output and sales in 1993.

Most of the French companies reported negative growth in turnover in 1993 when measured in current ECU, with Alcatel's turnover down 0.4 % and Thomson's turnover down 1.6 % from 1992. Thomson CSF engaged in a process of production rationalisation through the reduction of the number of production sites in France, to reduce costs, while Alcatel Alsthom suffered both from increased investment expenditure weighing negatively on costs, and from the fact that it has fallen behind in the race for innovation in the mobile phone business.

#### Motor vehicles and components

The combined turnover of the largest 12 European motor vehicles and components producers amounted to 244.5 billion ECU in 1993, a 4.9 % decline (in current ECU) over 1992. Out of the 10 largest automotive producers, only two reported positive growth in turnover in 1993: Daimler-Benz and Volvo.

All others reported either a stagnation in sales (this was the case of Ford, for instance) or a decreased in turnover - sometimes exacerbated by the restructuring of activities and divestment from non-strategic product lines. The biggest drop in turnover in 1993 was reported by Fiat (-20.4 %), followed by Opel (-17.8 %).

The difficulties experienced by the companies in this sector as a result of mounting competition at world level and weak demand have already been emphasised earlier. Most of the top 12 European producers, reported losses in 1993, the biggest ones, in relative terms having been posted by Fiat, Volvo and Volkswagen. Fiat and Volkswagen are, interestingly, the two European companies which are most dependent on their domestic market for sales, such that they suffered more than others from the decline in market demand which was particularly important in Italy and Germany. BMW posted the highest rate of return on sales in 1993 (+1.8 %), followed by Robert Bosch (+1.1 %) Renault and Daimler-Benz (both at 0.6 %). In all cases, this was achieved through major internal re-engineering and labour shedding.

Daimler-Benz is now the second largest European company based on turnover, and ranks 10th world-wide, up one place from 1992 in both lists. Fiat, which was second in the European ranking in 1990, has since fallen back to 13th position. The involvement of several of the large automotive producers in other markets, such as aerospace for Daimler-Benz, however makes comparisons of relative performances based solely on turnover somewhat misleading.

Source: DABLE

The decrease in turnover by Fiat and Peugeot in 1993 follows previous falls of -1.4 % and -1.6 % respectively between 1990-92. Saab Scania, which sold a big part of its car division to General Motors a couple of years ago, has since disappeared from the top 10 list.

#### Food, drink and tobacco

The total turnover of the top 15 European agri-food producers increased by 52.6 % in total between 1987 and 1993, a 7.3 % average annual increase.

Although most of the sector's production is accounted for by small and medium-sized firms, there are a number of major European giants operating in this sector which have posted both healthy growth in turnover and high profitability over the past years. As these major groups adjusted their strategies in the late 1980s to prepare for the Single European Market, there were significant changes in the list of companies which feature in the top 15 ranking.

UK companies nevertheless continue to dominate the list, with 11 companies out of 15 in Europe's top 15 list. The remaining four companies are French (2), Italian and Swiss respectively.

Unilever of the UK/Netherlands remains the unchallenged leader in this sector, closely followed by Nestlé of Switzerland. The next in line, BAT, has a turnover which is less than half that of the two European leaders in this sector.

#### Services

The above sections mainly looked at the relative performance of Europe's top manufacturing companies over the period 1987-93. Below, we briefly review the trend in turnover of Europe's key services companies, in those sectors which are most concentrated: the distribution of energy, telecommunications services, transport services and wholesale and retail trade.

The sector accounting for the largest share of turnover is the utilities sector, with 12 companies accounting for a turnover of 131.7 billion ECU. The next largest sector in terms of turnover is the telecommunications services sector, with a 1993 turnover of the top 8 companies of 118.7 billion ECU.

#### Energy

Table 13 presents the top 12 European utilities, ranked by turnover. The largest is EDF of France, with a turnover in

**Table 13: Energy

Source: DABLE

1993 of 27.7 billion ECU, followed by the German utility RWE AG. As the deregulation of this sector is not complete yet, all the companies on the list of top European utilities are still essentially national companies. Hence, it is not surprising to find the French, German, Italian and UK distributors at the top of the list.

#### Telecommunications

The liberalisation of the European telecommunications services market and the transformation of the key national players into companies capable of competing at global level has changed the relative ranking of the top 8 companies operating in this sector in Europe, without fundamentally changing the nature of their business. Between 1992 and 1993, the ranking remained unchanged, however.

Between 1990 and 1992, the combined turnover of the 8 companies in the 1992 top European companies' list increased by 8.1 %, just over 4 % per year on average. The period was characterised by the consolidation of Deutsche Telekom, and the privatisation of parts of British Telecom. In 1993, the turnover of the larger companies increased by an additional 4.6 %.

The fastest growth in turnover between 1992 and 1993 was reported by Cable & Wireless of the UK, whose sales grew by 22 % from 1992.

Deutsche Telekom also pursued an external growth strategy and comforted its leading position with a 14 % increase in sales in 1993. The two Italian telecom operators (STET and Telecom Italia) and the Spanish company Telefonica de España reported a fall in turnover of the order of 4.5-5 %, as a result of currency movements. The rationalisation of Italy's telecom utilities only started towards the end of 1993.

#### Transport services

Unsurprisingly, the list of top 10 transport companies in Europe is dominated by airlines. Among Europe's top 10 companies, six were airlines, three were railways and the remaining (P&O) is a shipping company.

Between 1987 and 1993, the total turnover of the top 10 European transport services providers increased by 51 % in total, a 7 % increase in annual terms. There were major changes at the top due to the liberalisation of European skies, the privatisation of some key operators and the reorganisation of companies in this sector along a European dimension.

The on-going rationalisation and restructuring which are under-way in this sector as market liberalisation proceeds will undoubtedly lead to further changes in the ranking of top firms in this sector over the coming years.

#### Distribution

Europe's largest distribution companies are listed in Table 17. In 1993, Metro of Germany outranked Tengelmann (also of Germany) as the largest European distributor in 1993, with a total turnover of 30.7 billion ECU.

Although cross-European concentration movements have taken place in this sector in the late 1980s and early 1990s, the size of the top players is still mainly determined by the size of their national markets. The exception is Spar International of the Netherlands, which ranks third at European level. Among the list of top 10 European distributors, four are German, four are French, one is from the UK and one is Dutch.

A comparison of the turnover generated by these top firms in 1987 and 1993 respectively shows major changes both in

**Table 15: Transport services  
Turnover**

(million ECU)	1987		1993

the average size of the groups and in their relative position. Carrefour of France for instance experienced a major growth in turnover over the period and moved to 5th position, by-passing Leclerc (also of France) which had posted a 60 % growth over the same 6-year period.

The relative concentration of the distribution sector in the Netherlands is evidenced by the fact that this country has four companies in the top 50 list, three of which are in the top 20. Belgium only has two distribution companies in this list, Delhaize Frères and GIB, ranked respectively 21st and 32d. In 1993, there was only one company from Spain and there is no Italian company in the list. The Spanish company was ICA Handlarnas and ranked 41st.

## Industrial transition of employment - Converging trends in the EU

### INTRODUCTION

The European Union undertook major integration efforts during the eighties which have slowly affected employment trends in the Member States. Going far beyond macro-economic adjustments, labour demand has become more homogeneous in the EU as regards the sectoral composition of labour, the growing need for skilled workers, the trends towards female employment etc. Even if employment structures are still different, there seems to be convergence in the basic qualitative trends. The internationalisation of the economies and the societies in Europe is obviously affecting labour markets more seriously than diverging unemployment rates indicate.

This chapter will discuss the scope and the determinants of European labour market integration in more detail. It is based on the work which was recently undertaken by the ERECO Employment Network on behalf of DG V of the European Commission establishing a medium-term forecast of employment for the European Union<sup>1</sup>. This study applies a bottom-up approach investigating, among other aspects, the changes in the sectoral, regional, and skills dimension in the Member States. However, the focus of this chapter will not be on the medium-term future but on the major labour demand trends of the eighties and early nineties. The first part will show the macro-trends of employment characterising the general labour demand conditions. In the second part the shift in various employment dimensions as characterised by sectors, occupations, gender etc. will be discussed. The third part will assess the scope and implications of labour demand convergence.

### MACRO-TRENDS IN EMPLOYMENT AND PRODUCTIVITY

Out of 8.1 million new jobs which were created in the European Union during the "golden" eighties, 4.7 million were lost in the following recession up to 1994 (Figure 1). This was a cold shock to European labour markets which pushed unemployment rates up to the levels of the mid-eighties. In addition, the extension of the EU brought in further areas of severe underemployment. German unification started with a shakeout of 3 million workers. The Scandinavian countries went through a serious adjustment crises with rapidly increasing unemployment rates. In the middle of the nineties, the job situation in the EU again has a long way to go until full employment levels can be approached. The ERECO forecast up to 1997 expects a recovery of labour demand. However, the dynamics of job creation will not go beyond compensating for the losses which occurred during the recent recession.

Of course, the macro-changes of employment are scattered broadly among the EU Member States. During the 1984-91 period the most dynamic expansion occurred in western Germany, Spain, the Netherlands and Luxembourg where labour demand grew by approximately 2 % annually. All other Member States experienced slower growth. The 1991-94 recession affected labour demand most seriously in Italy, Spain and Portugal. These countries lost between 2.5 and 3.5 % of jobs per year. In Germany, France and the UK the number of jobs decreased by nearly 1 % per annum. Only Ireland, Greece and the Netherlands were able to expand labour demand, at rather low rates of less than 1 % however. Among the new

Table 1: Hours worked

Member States, Austria had a positive employment performance. By contrast, the intensity of the job crises in Finland and Sweden was not far from the crisis in eastern Germany. Employment in these countries decreased by 4 to 4.5 % annually.

In terms of working hours, labour demand was much weaker than expressed by the number of workers. One third of the employment growth of 8.1 million during the 1984-91 period can be attributed to the expansion of part-time work and the reduction of weekly working hours. The total number of hours worked by employees and self-employed workers increased by 0.7 % while the number of workers grew by 1.2 % annually. If the trend towards reduced working hours has not changed considerably during the recession - in some countries it has even accelerated - it can be assumed that total hours worked decreased by 1.6 % annually between 1991 and 1994. Over the whole period of 1982 to 1994 the sum of hours worked decreased by 0.1 % annually while the number of workers increased by 0.3 % (Table 1).

Productivity - measured as value added in constant prices per hour worked - was boosted by an annual rate of 2.6 % in the 1982-94 period (Figure 2). Thus GDP growth was achieved by efficiency improvements rather than the extension of employment. During the second half of the eighties, productivity was largely supported by a long-lasting investment cycle contributing not only to the expansion of production capacities but to the modernisation of the capital stock with new technology. Moreover, the increase of capacity utilisation supported productivity growth. By contrast, in the recession of the early nineties, productivity growth was stimulated by cost-cutting measures, industrial restructuring which squeezed less productive capacities out of the markets, and by the introduction of new organisational concepts which directly address the efficiency of labour. Labour-saving rather than capital-augmenting measures were thus the driving forces of productivity increase.

The ranking of productivity levels has not changed significantly since 1982, even if growth rates were different between the Member States. The highest productivity growth was achieved in Ireland, Spain, and Portugal with annual rates above 3 %. Germany, the Netherlands and Denmark were

slightly below 3 % and France, Italy and the UK close to 2 %. High productivity growth can also be assumed for the next years due to increasing cost pressure from international competition, industrial restructuring and relocation of production facilities worldwide.

## EMPLOYMENT BY SECTORS

During the eighties the EU moved rapidly towards the post-industrial phase of economic development. In 1994, 55 million people were working in the private service sector (market services) as compared to 46 million in manufacturing, mining, construction, and agriculture<sup>2</sup>. In addition, 28 million were employed in public services. All together 64 % of all persons employed were working in service companies or institutions.

The dynamics of this well-known trend can be seen from Chart 3 which represents the absolute changes of employment between 1982 and 1994 by sectors for 12 EU countries, excluding eastern Germany. According to these figures, gains and losses of employment were highly concentrated on few sectors. Service sectors, like business and other private services, taken together under the heading of "Other market services" expanded most dynamically. The majority of manufacturing sectors stagnated while metal production, mining, transport equipment industries, and textiles and clothing shrunk. The biggest employment loss occurred in agriculture.

The rapid growth of service sector employment can be attributed to both private and public services. Since 1982 approximately two million jobs were created in the business services sector. This is the size of the whole chemical industry in Europe. Retail and wholesale distribution added a further 1.6 million jobs. Health and veterinary services grew by almost 1 million. Lodging and catering services contributed about 1 million new jobs. Public services including parts of health and education services, expanded by more than 3 million. The contribution of banking and insurance, transport, and communication services was much smaller.

Almost none of the manufacturing sectors was able to provide additional job opportunities. The only exceptions are rubber and plastics products, and the paper and printing industries which include publishing services. However, these manufacturing branches contributed only very little to employment

Figure 1: Employment in the European Union

Source: Eurostat, Ifo estimates

growth. Of course, the positive performance of services in relation to manufacturing is enhanced by the creation of part-time jobs in the service sectors. The pattern of change, however, is not altered if labour input is measured by hours worked.

Important technological branches like the electrical industry, chemical industry and office/data processing machinery did not provide any additional jobs. Employment in the machinery and transport equipment industries was reduced. Significant job losses occurred in textiles and clothing industries, mining, and metal production. For manufacturing as a whole the employment balance was negative with a loss of 3.7 million jobs in the 1982-94 period. Of course, this has to be attributed to recession to a large part. But even in the 1982-91 comparison a negative employment balance appears for manufacturing.

### De-industrialisation of Employment

During the recent recession the trend towards de-industrialisation probably was fostered not only due to cyclical phenomena but also due to long-lasting restructuring of the industries. The production process in manufacturing was reorganised in many fields. Peripheral functions were outsourced to service providers and production activities were relocated. Partly the increase of service sector employment therefore has to be explained by outsourcing from manufacturing and other sectors. But this is only half the story. The decline of manufacturing activities and the rise of services is also due to the limited competitiveness of classical industrial production in European locations. It is due to the retardation in the development of new technologies, the sluggish application of new organisational concepts, the growing problems of a high-price and high-quality strategy on product markets. EU companies are not only facing the overwhelming cost advantages of competitors in south-east Asia and eastern Europe. They are also facing technological competition from these countries, based on a well-educated labour force and rapid economic transition, at least in the Asian countries. Complex types of industrial production therefore can increasingly be organised in developing countries. The advantages of European workers in comparison to the labour force in these countries, based on education, training and technical know-how, are shrinking. Not only markets but production is becoming global.

This process which started during the eighties is in full swing. The creation of the Single European Market has opened new possibilities for relocation of production within the EU. The opening of eastern Europe and of China is establishing new conditions for the competition for working places worldwide. Industrial working places are threatened in particular. The services are less affected as they partly operate on local markets. Moreover, services are playing a key role in restructuring industrial production.

### Functional Relocation of Employment

The de-industrialisation of labour extends far beyond the sectoral dimension. The shift of employment from production-oriented functions as exercised by craft and related workers and plant and machinery operators toward service functions as done by professionals, technicians and related occupations reflects the same process occurring within sectors. New production technologies and the re-organisation of labour both aim at substituting unskilled labour by transferring simple functions to machinery and software and more complex activities to skilled workers. In addition, low-wage countries are successfully competing for a bigger share of industrial mass production, which relocates production-oriented activities.

With the globalization of industrial production, labour in Europe is increasingly specialising on skilled activities like business management, research and development, technical and legal consulting, marketing, production management, design etc. The competitive advantage appears to be significantly higher in these fields of economic activities than in the production of industrial commodities itself.

This is fostered by increasing investment in human capital on the one hand and constant wage relations between skilled and unskilled labour on the other. In combination, these two factors contribute to the relative decrease of efficiency wages for skilled workers. Taking advantage of the growing supply and the relative wage reduction of skilled labour, companies are developing new concepts of labour organisation which increasingly make use of the skills available. Exploiting the skills potential by delegating competence to lower levels in the occupational hierarchy is one of the possible strategies followed by countries like Germany which dispose of a broad

Figure 2: Annual % change of employment

Source: Eurostat, ilo estimates

**Figure 3: Productivity (1)**

(1) Value added at 1991 prices per hour worked  
Source: ERECO employment network

provision of skills. Other countries, like the UK, where the skills profile is much more concentrated on higher skill levels, are specialising on the production of upgraded services. This is supported by the low wage levels in relation to other industrialised countries.

These trends resulted in additional jobs in the occupational groups of professionals, managers, technicians and related occupations. In contrast, employment of plant and machinery operators, assemblers, craft workers and in elementary occupations, including agricultural workers, was declining. The national patterns of occupational change, however, are far from homogeneous. Variety rather than homogeneity best characterises the occupational structures of the EU.

**FEMALE EMPLOYMENT**

Female employment has slowly but broadly increased from a share of 38.3 % in 1982 to 40.5 % in 1991. The shifts in labour demand toward service industries and professional and service functions increasingly compensated for the existing disadvantages, even if female employment levels still lag behind those of males. Female employment is predominantly located in the occupations of clerks and service workers, while male employment is most commonly found in the occupations of craft and related trades and plant and machine operatives. The overall degree of contrast between the occupational structures of male and female employment is still striking. However, the specialisation of women in services, clerical work and

**Figure 4: Employment by sector, 1982-94 (1)**

(1) EU12 excluding Eastern Germany  
Source: ERECO employment network

increasingly in professional occupations is emerging as their major competitive advantage on labour markets.

Female employment opportunities appear to be promising in the higher level occupations while the future of male employment looks gloomy. A large number of male jobs remain in those sectors and occupations which have already declined in the past and will continue in the future.

### QUALIFICATION OF THE WORKFORCE

Available evidence has indicated that EU Member States show considerable variation in educational attainment. For instance, in the northern Member States much higher proportions of their workforce have received some form of post-compulsory education. At the EU level it is difficult to make a comparison of change over time due to lack of data, but if a comparison is made of the countries for which data are available, the evidence does point to an increase in the level of educational attainment. While those in employment at the beginning of the nineties were still more likely to have the minimum compulsory level of education or less, the number with either a second level/second stage or third level education has increased. If data are viewed in isolation for the ten Member States for which data are available, the picture of educational attainment looks favourable. Though a large number of those in employment have less than the minimum level of education, a large share have attained a post-compulsory level of attainment (either second level/second stage or third level).

Administrators, senior officials, and managers, professionals, and technicians/associate professionals - higher level occupations - comprise an occupational elite. The level of conceptual knowledge embodied within the occupations is considerably in advance of that incorporated in the task repertory of any other occupation. The success of the EU economy is ultimately dependent upon its ability to realise further improvements in the quality of its labour force. The need for such a transition is obvious. In global terms most regions of the EU represent high wage economies, the maintenance of which, during the eighties, has been dependent upon the development of high value-added product market segments successfully underwritten, to date, by innovative product design and production systems coupled with high labour productivity. The strategy has not been without risks, however. Recently,

South-East Asian producers have rapidly captured a sizeable market share, in the EU and elsewhere, with a product market strategy based upon the production of high quality/high value added goods with very low labour costs. Though there are concerns about wage flexibility in the EU, few are willing to relinquish the high wage levels and the standard of living they have supported. This places an onus upon the development of a workforce able to compete in the global product and labour market. A highly educated and skilled labour force is instrumental to obtaining this goal. Regardless of arguments about high skill levels which will optimise long-run employment and output, a high wage economy is dependent upon the ability to reproduce and improve the quality of its labour force over time.

### CONVERGING TRENDS

From a theoretical point of view it remains an open question whether integration of economies leads to divergence or convergence of industrial structures. On the one hand, diverging trends can be expected if the resources owned by the individual regions remain highly specialised. Natural resources, labour-force skills, technical equipment, and other long-term determinants of regional specialisation contribute to regional competitiveness more powerfully when economies are integrated. Local producers can realise economies of scale and thus improve their position on widening markets. On the other hand, however, the distribution of resources is changing in the long run. In particular, technical know-how and skills are distributed more equally among regions. Modern production technologies are spreading and reducing regional differences. Insofar as such trends are present, industrial structures can be expected to converge. Labour division between regions is less organised along the lines of different products and resources. The "globalized" type of production networks reduces the differences in industrial structures.

This is exactly what can be observed in the European Union since 1982. As indicated in Chart 4, the sectoral employment structures of the individual Member States converged towards the common EU pattern<sup>3</sup>. The only exception is France where the sectoral employment structures have become a little more different. In all other countries sectoral employment structures converged towards the average EU profile. The large countries

Figure 5: Convergence of sectoral employment structures

(1) Standard deviation of sectoral employment shares from EU shares, calculated for 25 NACE-CLIO sectors  
Source: Eurostat, Ifo Institute

of the EU were closer to the EU average than the smaller countries already in 1982. This is, of course, the result of their greater weights. The only exception is Spain. Smaller EU countries are characterised by a greater extent of deviation but also by a greater extent of convergence.

The greatest step was taken by Greece. The average deviation of sectoral employment shares, which was 4.8 percentage points in 1982, declined by 1.1 percentage points up to 1994. The country diverging most extensively from the EU average is now at the same distance as Portugal. Spain was the other country which experienced great convergence. This is indicated by the decline of average deviation by 0.7 percentage points, or one fourth of the 1982 distance. The changes in the other EU countries were less pronounced. On average, all 12 EU Member States reduced their differences in sectoral employment structures by 12.5 % in the nine year period observed.

Much of the convergence of sectoral employment structures has to be attributed to the declining share of employment in agriculture and the growing shares of services - other market services and non-market services in particular. These were the strongest changes in employment structures which applied to many EU countries. By contrast, the differences of sectoral employment structures of manufacturing are less than those of services, and changes between 1982 and 1994 were smaller. Among the few exceptions in manufacturing is the textiles and clothing industry, the decline of which contributed to overall convergence. In services, the general expansion of employment shares of other market services was important.

The further steps towards the European Monetary Union can be expected to foster both increasing specialisation of the EU countries on specific types of production and growing integration. The structural effects, therefore, remain unclear. The elimination of exchange rate variations among EU Member States will intensify direct competition of European pro-

ducers via product quality and costs. This may lead to a higher degree of regional specialisation. Simultaneously, it will ease economic integration and the creation of European networks of production. This will result in a more homogeneous distribution of sectoral activities. The experience of the last ten years informs us that the integration component is stronger than the specialisation component. This might also apply to the future. Moreover, economic integration is strongly supported by the structural funds which can be expected to increase their activity during the following years.

1. Vogler-Ludwig, K. et al. (forthcoming): Medium-Term Forecasts of Employment by EU Districts and Sectors of Industry. Study on behalf of the Commission of the European Communities.

2. Figures excluding eastern Germany and the new Member States.

3. The indicator of convergence or divergence is based on employment structures for 25 sectors in the 12 EU Member States. The sectoral classification is taken from national accounts statistics (NACE-CLIO, as indicated in Figure 3). The indicator takes the average deviation of sectoral employment shares in one Member State from the corresponding sectoral EU shares as the measure of divergence. The reduction of the average deviations between 1982 and 1991 indicates growing similarity between the Member State and the EU average. An increase indicates growing disparity.

## The new Member States: Austria, Finland and Sweden

On January 1, 1995 three wealthy, industrious countries joined the European Union. As a result of the entry of Austria, Finland and Sweden, the Union's territory has grown by 36 per cent, its population by 6 per cent and its GDP by 7 per cent. These three new Member States agree on freer trade, tighter budget constraints, stricter environmental rules and greater openness in decision-making.

### INTRODUCTION

Whereas Sweden and Finland experienced a severe recession period from 1991 to 1993, Austria has had only one year (1993) with a negative growth rate since 1981. Of the three new member states, unemployment is the largest in Finland, at 19 %, compared to 7.9 % in Sweden and 4.4 % in Austria.

Sweden and Finland have sharply devaluated their currencies and have thereby gained export advantages, but domestic demand is only reviving slowly as the respective governments must wrestle with high unemployment and very large budget deficits. After three years of deep recession, the Swedish and Finnish economies returned to growth rates of between 2.0 %

and 2.5 % in 1994. The Swedish budget deficit amounted to more than 13 % of GDP in 1994, compared to the 6.3 % average in Western Europe. The budget deficits of Austria and Finland were estimated at 3.8 % and 7.5 %, respectively.

The entry of the three countries to the EU increases the area of the internal market by 36 %. France remains the biggest country in the EU, followed by Spain, Sweden, Germany, Finland and Italy. Austria is one of the smaller Member States, in size roughly comparable to Portugal.

GDP in the EU of fifteen countries (EU-15) is approximately 7 % higher than that of the EU-12. With the EU population increasing by 6 %, this means that the average per capita GDP is higher in the larger EU. Per capita GDP remains the highest in Luxembourg (168 % of the new EU average), followed by Denmark (140 %), Germany (126 %) and Austria (122 %). Whereas the per capita GDP of Austria and Sweden (at 114 %) are above the new EU average, Finland's per capita GDP is 12 % below. The three countries contribute 2.7 % (Sweden), 2.6 % (Austria) and 1.2 % (Finland) to the EU-15 GDP, which may be compared to Germany's share of nearly 28 %.

**AUSTRIA**

In 1990, more than 40 % of Austria was agricultural land whereas non-forest land amounted to 32 000 sq km, 38 % of the total area. The five major cities are Vienna, Graz, Linz, Salzburg and Innsbruck. Almost 20 % of the 7 991 000 inhabitants of Austria live in Vienna.

Austria's contribution to the EU budget is likely to amount to 1.5 % of GDP (34 billion schilling), including both direct transfers to the EU and compensatory payments to Austrian farmers. Approximately one-third is paid back in the form of adjustment payments to farmers because of the immediate effects of the Common Agricultural Policy. The net external transfers will be around 0.5 % of GDP, raising the current account deficit to over 1 % of GDP in 1995.

Austrian consumers are the big winners, not only thanks to falling food prices but also because of the many service costs which will be brought down through decreasing protectionism. The Austrian National Bank joined the European Monetary System on the 1st of January, 1995, and the Exchange Rate Mechanism on the 9th of January. The schilling was already rigidly pegged to the D-mark, so these moves will have no noticeable effect.

(1) Estimates  
Source: OECD**Economic indicators and trends**

The recession in Germany had its effects on the Austrian economy, as Germany is Austria's biggest trading partner. However, Austria is slowly recovering; the economy expanding by 2.6 % in 1994 after a decline of 0.3 % in 1993.

The economic recovery began sooner than was originally expected, spurred by consumption, rising production in the construction industry and the stabilisation of industrial output. As a result, the recession was much milder than expected, with GDP falling by only 0.3 % in 1993. Driven by higher exports and supported by tax cuts, output growth resumed in 1994.

In 1993, exports were depressed by stagnant foreign markets and losses in competitiveness caused by an increase in the real exchange rate of the schilling. Manufacturing industry and tourism were hit particularly hard, as private investment fell the most in these two sectors. In other, more sheltered parts of the economy, activity was more resistant to the forces of recession, as profits fell less and employment stability prevented consumer spending on services from weakening significantly.

With major foreign markets in Western Europe recovering from the recession, and the negative impact of strong wage growth in the past and the real appreciation of the schilling fading, economic activity appears to be picking up, led by rising exports. Recently, foreign orders, merchandise exports and industrial output have all recovered markedly.

Real GDP growth should stabilise at around 3.0 % in 1995, driven both by domestic demand and the international economic recovery. However, this growth rate will be lower if corporate investment is delayed as a result of insufficient export performance due to the appreciation of the schilling.

Inflation, although decelerating, was above 3 % in 1993, due to higher public prices in the public sector and in services, notably in sectors where demand remained strong and competition among suppliers weak. Inflation is expected to decline towards a 2 % annual rate.

**Current account**

The current account has been more or less in balance in the past ten years, with the large trade deficit being offset by a surplus in services, dominated by tourism. This was also the

case in 1993, despite Austria's relatively strong exposure to economic cycles and large losses in competitiveness in 1992 and 1993.

Despite slower wage growth, disposable incomes will increase as a result of the income tax cuts and decelerating inflation. Private consumption should thus recover gradually and, as domestic demand picks up, the current account may weaken slightly, although the deficit should stay around 0.5 % of GDP.

### Employment

Employment reacted only modestly to lower output, as job cuts in industry were largely offset by gains in services. Wage moderation also contributed towards employment stability, which implied a slowdown in productivity growth. Unemployment is projected to fall only slowly, given the scope for further productivity increases and the cyclical responsiveness of the labour force.

Apart from helping to contain rising unemployment, wage moderation is also holding back inflation. Residual inflation inertia in the sheltered sectors will be reduced by intensified competition as a result of the EU membership.

### Public finances

Public finances deteriorated considerably in 1993, mainly as an effect of automatic stabilisers. In 1993, the budget deficit amounted to 98 billion schilling (approximately 4.6 % of GDP). The 1994 budget forecast a market improvement compared to 1993 and the deficit was estimated to fall to 83 billion schilling (3.8 % of GDP) in 1994. Austria has one of the lowest deficit to GDP ratios of the EU countries. Nevertheless, the budget deficit is likely to increase as a result of the considerable contributions to the EU budget.

The public debt was roughly 1 200 billion schilling at the end of 1994. Despite sharply falling interest rates, the proportion of foreign-currency denominated debt could increase further since interest rates in the countries to which Austria is the most indebted, such as Japan, Switzerland and the US, continue to be significantly lower.

### Monetary policy

After the collapse of the Bretton Woods System, the Austrian National Bank adopted the hard-currency policy. According to this policy, the schilling/D-mark exchange rate is quasi-fixed. Instead of direct control over the money supply (the task of the Deutsche Bundesbank), the intermediate aim of Austria's monetary policy is the exchange rate. The freedom to set interest rates independently of Germany has to a large degree been forfeited, but there remains some room for independent interest rate moves. Since this policy gained credibility, the interest rate differentials between Austria and Germany have diminished significantly. When fundamental indicators in the Austrian economy are performing better than those in Germany, the Austrian money-market rates may even undercut German ones for a long time without affecting the exchange rate. The current situation shows that with lower inflation and brighter budget deficit prospects, Austrian interest rates may remain substantially below German rates. The long-term stability of the Austrian monetary policy will continue. EU membership will not alter the policy of the Austrian National Bank and continuity is guaranteed.

### Fiscal policy

Austrian fiscal policy has been mildly expansionary, which led to a further rise in the budget deficit during 1993. Revenue

Source: World Tables 1994

losses from a general income tax cut and the abolition of two different business taxes were only partly offset by increases in corporate and payroll tax rates. The decline in the budget deficit in 1994 was mainly due to receipts from asset sales and a bringing down of reserves. The Austrian government's fiscal policy, as well as the elaborate system of subsidies that shelters such sectors as construction, need to be changed.

### International trade

Germany, with a 40 % share of Austrian exports, is the most important trading partner by far. The reforming countries of Central and Eastern Europe account for 10 %, the highest proportion of any OECD country. Austria's most important Eastern European trading partners are Hungary and the Czech and Slovak Republics. Austria's trade balance with respect to its Eastern European partners is positive as these countries account for around 7 % of the Austrian imports. Since the opening up of the eastern European economies, trade with these countries has grown rapidly

Exchange-rate induced terms-of-trade gains and the fall in domestic demand for goods of high import content have had a positive influence on the current account. However, in 1993, this was more than offset by lower net receipts from tourism, resulting yielding a small current account deficit.

### Important sectors and companies

Austrian industry is dominated by small- to medium-sized enterprises (SMEs): only 110 domestic shares are currently listed on the Vienna Stock Exchange. The banking sector accounts for 25 % and the energy sector for 17 % of the total market capitalisation of roughly 330 billion schilling.

Austria has one of Europe's least transparent economic structures; the country is among the richest in Europe, yet it has no companies the names of which are widely known, beyond its borders, except among specialised audiences. In 1994, only six Austrian companies made the Financial Times list of Europe's Top 500 companies, and all but one of these six companies come from the very large public sector, which illustrates that the country's economic strength rests on the large number of SMEs. Many of these businesses are highly sophisticated and specialised.

The largest company, Bank Austria, was created through the merger of Österreichische Länderbank and Zentralsparkasse und Kommerzbank. The latter is the city of Vienna's savings institution and dominates the savings market. The two largest Austrian companies remain controlled by the public: Bank Austria is owned by the city of Vienna, and Creditanstalt by the federal government, but full privatisation is expected. For years the country's subsidised, and often inefficient, state-owned industries have been sheltered from international competition. The government has been forced to join the growing club of privatisers.

Austrian banks are working hard to put themselves in a position to act as intermediaries in the transformation process of Eastern Europe. They too, however, face dramatic changes as a result of the greatly needed but desperately slow process of restructuring the country's overbanked and overbranched financial system as well as the government's privatisation programme. In the top of the list for rationalisation is the savings bank sector, especially GiroCredit. The result of rationalisation activities has been increasing concentration among the larger savings bank groups and growing competition between them and the commercial banks.

Both OeMV and EVN are partially privatised. OeMV, an integrated oil and chemical producer, is expanding its petrol station network in Central and Eastern Europe. The only one in the private sector of the six largest companies by market capitalisation is Wienerberger Baustoffindustrie, a building materials group which has grown rapidly through acquisitions to become the European leader in bricks and roof tiles.

### Competitive power of Austria

Vienna is considered to be a potential hub of a growing Central European economy and an important conduit between the East and the West, not the least in the area of financial services. The competitive advantage of Austria, apart from its central location in Europe and favourable standing with its neighbours, lies in the country's highly developed infrastructure. Furthermore, Austria is one of Europe's leading nations in such aspects as availability of skilled labour and senior managers, worker motivation and overall security.

**Table 11: Austria: six largest companies by market capitalisation, 1994**

Source: Financial Times FT500, January 1995

Despite some optimism in some service sectors (most notably tourism), there is widespread scepticism about the future international competitiveness of the manufacturing sector. Austria has technological and structural disadvantages compared to other OECD countries. However, these are not fully supported by Austria's high per capita GDP. During the 1980-1990 period, the Austrian economy was characterised by improving cost competitiveness. As mentioned previously, however, large losses in competitiveness were experienced in 1992 and 1993. In the 1980-1990 period, the annual increase in productivity in the manufacturing sector was 4.8 %, whereas relative unit labour costs rose by 0.9 % per year, compared to increases of 3.2 % and 1.5 %, respectively, for the EU as a whole.

## FINLAND

More than half of the area of Finland is covered by forests, whereas lakes make up 9.5 % of the area (32 000 sq km) and cultivated land amounts to 8.0 % (27 000 sq km). The largest cities in Finland are Helsinki, Espoo, Tampere and Turku, and approximately 20 % of the Finnish population are inhabitants of one of these.

Finland is recovering from the most severe recession that any industrialised country has suffered through since the second world war, and it is doing so relatively fast and without being heavily indebted. The Helsinki stock market, enjoying a bonanza of foreign buying, was Europe's top performer in 1994. Finland will be a net contributor to the EU budget, but consumers should benefit from lower food prices as trade barriers fall, whereas Finland's highly subsidised farmers will face a painful adjustment to the EU's lower prices. The country is signing up for the EMS, but intends to float the Finnish Markka for the time being.

## Economic indicators and trends

In the 1990-1993 period, the Finnish economy was hit by the coinciding international recession, the collapse of trade with the neighbouring Soviet Union, a credit boom that collapsed, and the burden of a large and expensive welfare system.

In 1994, however, exports led the Finnish economy into recovery. For the first time in three years the upward trend in

exports is being sustained, not only by strong price competitiveness, but also by a genuine pick-up in the markets. The decline in domestic demand, which depressed economic activity in 1992 and 1993, has come to an end and both investment and consumption were higher in 1994.

## Current account

The deficit in the current account began to decrease in 1990 and turned into a surplus in 1994. With a current account surplus, the debt may increasingly be financed on the domestic market. Moreover, a stronger Finnish currency will reduce the markka value of foreign-currency debt. Finland's net foreign debt rose to 59 % of GDP in 1993. However, it is expected to decrease during 1994 and 1995, leading to a net foreign debt estimated at 41 % of GDP in 1995.

## Employment

Despite several promising signals, the bright outlook continues to be clouded by high unemployment. The unemployment rate increased from 3.4 % in 1990 to 18.3 % in 1994, putting Finland alongside Spain and Ireland at the top of the European jobless league. Whereas demand for labour is gradually regaining strength (in sectors most important from the employment point of view, i.e. services and construction, the trend in employment is stable and may take an upward turn in 1995), unemployment will persist as the most important social problem over the next few years.

## Public finances

The difficulties in public finance will be alleviated slightly as the economy recovers and expenditure of a cyclical nature decreases. The budget deficit was officially projected to decline from nearly 10 % in 1993 to about 7.5 % in 1994. The fall in public investment will be reversed thanks to stimulatory measures. Public expenditure will thus increase, despite the small decrease in public consumption. The pick-up in activity is expected to improve government finances in 1994 and in 1995.

The public debt has risen fast, from 15 % of GDP in 1990 to around 70 % in 1994. In 1994, the government's net borrowing did not rise as much, and amounted to about 14 % of GDP. The debt is expected to increase only slightly in 1995.

## Monetary policy

Monetary policy appears to have entered a phase of stabilisation. Although short term interest rates may hold some further downward potential, it is expected to have any major impact on economic activity. The inflation is expected to remain very low. The only major source of upward pressure is the value-added tax that was introduced in 1994. Whilst the central bank has occasionally intervened to prevent the appreciation of the markka from being too rapid, monetary policy continues to be geared towards assuring that consumer price rises (excluding changes in indirect taxes and officially administered prices) do not exceed the announced target level of 2 % by 1995.

### Fiscal policy

The 1994-1995 period will highlight the role of the fiscal policy in redressing unemployment. The main focus of fiscal policy remains budget consolidation, with the objective of reducing real central government expenditure to its 1991 level by 1995.

### International trade

In 1993, the EU and EFTA countries accounted for almost 65 % of Finnish imports and for about 64 % of exports. Germany was Finland's single largest trading partner, representing 13.1 % of exports and 16.3 % of imports, followed by Sweden. Major Extra-EU trading partners include the US and the Commonwealth of Independent States (CIS). Trade with the USA was more substantial than with the CIS, although 8.1 % of Finnish imports originated therefrom. At its peak in the mid-1980s, the Soviet Union accounted for 26 % of Finland's trade. Today, the CIS is Finland's fifth largest trading partner.

The volume of exports rose at a record rate of 16.6 % in 1993. The exports were not boosted by economic expansion in traditional export markets but by price competitiveness (stimulated by the depreciation of the markka) and by inroads into new markets. Exports to the Far East, the developing countries and Russia nearly doubled. The favourable impact of recovering exports to Russia began to be felt towards the end of 1993, mainly in the foodstuffs, textile and clothing industries. Exports directed to the EU and EFTA increased

by slightly below 10 %. However, the recovery in Finland's traditional export markets will be the most important factor in determining the prospects for Finnish exports in the next few years.

As domestic demand picks up, the growth in imports will accelerate and the rapid growth in industrial production will stimulate imports of producer goods. Furthermore, the gradual recovery in investment and consumption will also be immediately reflected in imports.

### Important sectors and companies

The economy continues to exhibit distinct dual trends. From 1992, industrial production increased, whereas most services and construction decreased. Despite overall industrial production growth, the developments were not uniform among the various sectors of the industry. In 1993 and 1994, production in the forest, metal and engineering industries increased substantially, stimulated by exports, whilst the output in other industries on average remained at the 1992 level.

Agricultural production increased by nearly 8 % in 1993. Employment in Finnish agriculture accounts for only 7 % of the working population and 2.5 % of GDP. The number of farms is expected to fall to 70 000 within ten years from 120 000 today, whereas the average farm size will rise from 20 to 30 hectares.

Wood products account for 36 % of Finnish exports and their success has done much to promote the country's export-driven economic revival over the last two years. The four largest listed forest industry groups are Repola, Kymmene, Enso-Gutzeit and Metsä-Serla. These groups are expected to expand through acquisitions rather than investments in existing plants. For example, Enso-Gutzeit has recently agreed to buy a 35 % stake in Veitsiluo to, the country's fifth largest pulp and paper group. Whether Finnish groups seek to expand at home or abroad is not clear, 26 % of the forest industry's production capacity is already based abroad. Most of this capacity is located close to the big markets and sources of recycled material in Europe.

The largest Finnish company is Nokia, which over the past three years has transformed itself from a sprawling conglomerate into a dynamic telecommunications company. Nokia is the world's second largest supplier of mobile telephones after Motorola of the US. The company now represents more than

25 % of the value of the Helsinki Stock Exchange. Foreign investors hold more than 50 % of the shares in Nokia.

Production in the service industries declined by nearly 3 % in 1993. However, private services are expected to grow. Telecommunications and transportation will also increase further along with the growth in industrial production.

The Finnish privatisation programme has been a cautious one. As the government in most cases retains more than 50 % of the shares of former state-owned companies, the process is more appropriately characterised as one of broadening of ownership. Over the past 12 months, stakes have been sold in Outokumpu (the mining and metals group), Rautaruukki (steel), Valmet (paper machinery manufacturing), Kemira (the chemicals group) and Veitsiluoto (pulp and paper). Altogether there are some 12 industry groups on the government's privatisation list, including Neste (oil and petrochemicals), Enso-Gutzeit (the pulp and paper group), Finnair (the national airline) and Imatran Voima (energy).

### Competitive power of Finland

Finland offers a high level of technological competence and a high level of education. This is illustrated by the fact that, in the world competitiveness survey for 1994 of the World Economic Forum, Finland headed the list in education and was second in production technologies ranking.

In the forest industry, Finland also offers special know-how. The investment programmes of the late 1980s are only now giving the industry a real competitive advantage.

Moreover, Finland has a stable, well-functioning society. In the world competitiveness survey, Finland ranked fourth in overall security, just behind Singapore, Japan and Austria. After its devaluation in the first half of the 1990s, which raised Finland's price competitiveness, the value of the markka has risen since 1994. Despite the stronger markka, price competitiveness remained good. Price competitiveness is also sustained by the moderate wage agreements of recent years.

### SWEDEN

Of the total area of Sweden, 8.7 % is covered by lakes, whereas cultivated land and woodland make up 6.7 % and more than 50 %, respectively. The three major cities are Stockholm, Göteborg and Malmö, in the metropolitan areas of which more than 30 % of the total Swedish population lives.

The traditional focus of Swedish social democracy has been the welfare system. Over the past 20 years, Sweden's economy as a whole has been losing competitive and productive power. Although a recovery from the three-year recession during the early 1990s at last took hold, the combined effects of the slump and the costs of the country's big public sector left the state with a large budget deficit, the fastest growing public debt in the industrialised world and more than 13 % (if one excludes government training schemes) of the workforce unemployed. Nevertheless, just as Austria and Finland, Sweden will also be a net contributor to the EU budget. However,

Sweden entered the EU on the condition of a budget compromise consisting of a net contribution of only 50 million ECU in 1995, 150 million ECU in 1996, that will rise to 750 million ECU only in the year 2000.

### Economic indicators and trends

Sweden's current economic recovery, after three years of recession, has been driven by the success of its export industry. With the domestic economy still struggling to emerge from the recession, it is the exporting companies that have stimulated growth in the Swedish economy in 1994. The export boom has especially been fuelled by the devaluation of the Swedish krona and the recovery in international markets.

The overall Swedish performance is more steady than spectacular, and the big gains on the Stockholm exchange of 1993 were not matched in 1994. The current recovery of private consumption is expected to strengthen in response to rising household income and a declining household saving ratio in 1995 as consumer confidence improves.

Presently, three issues dominate the Swedish economy: the budget deficit, the resulting increase of the public debt and the unprecedented levels of unemployment.

Growing exports as well as a moderate recovery in the domestic economy are expected in 1995, which has led the government to forecast a gross national product growth of 3.4 % for this year. The Swedish finance ministry foresees stable private consumption despite the reduction in household income due to tax increases and spending cuts, and a fall in the "open" employment, further below 8 %.

### Current account

Although the growth rate of exports is likely to come down from recent levels, export performance is set to remain good. And even though the recovery in domestic demand may be accompanied by rapid growth in imports, the current account could move into a surplus of nearly 2.3 % of GDP in 1995, compared with a deficit of 3.1 % in 1992 and a surplus of 1.1 % in 1994.

### Employment

In 1994, the total unemployment was 346 000 or 7.9 % of the workforce. The increase in economic activity may create new jobs in 1995. The unemployment fell modestly in 1994, influenced by employment movements were and changes in the labour supply. Much of the fall in unemployment, however, was due to a rise in the number of people in government training schemes. When those in government training schemes are added to the total unemployment figure, it rises to about 13 % of the workforce. In the past two decades, net job creation has almost entirely been in the public sector. This is a structural weakness in the Swedish economy.

### Public finances

In 1994, the budget deficit equalled 201 billion kronor, or 13.3 % of GDP. Public spending has grown and accounts for some 70 % of GNP, the highest level among the industrialised countries. Some structural reduction in the budget deficit is foreseen for 1995 and, as the result of cyclical improvements, the general government deficit may fall to 10 % of GDP. However, unless the budget deficit is quickly brought under control and borrowing is stabilised, the danger of continued high interest rates, resulting in a return to recession, will remain.

Borrowing in order to finance the budget deficit has pushed up the public debt. In 1994, it amounted to 81 % of GDP. Through a series of tax increases and spending cuts, the Swedish government is now trying to stop the further growth of the debt.

Since the autumn of 1993, the Swedish central bank has been cautious in relaxing the stance of monetary policy in order not to jeopardise its medium-term inflation target of 2%. Although short-term interest rates may come down, long-term interest rates remain high given the rapid accumulation of the public debt.

government to be more disciplined in reducing the country's large budget deficit and fast growing debt. These expected tougher government actions are likely to bring down interest rates, which will stimulate investment and help create new jobs. A climate of greater investor confidence in Sweden should bring about both increased domestic investment and a rise in much-needed foreign investment in the country.

## Fiscal policy

The revised 1994 Swedish budget that was presented in April 1994 increased the target for medium-term deficit reduction from 80 billion kronor to 100 billion kronor (equivalent to around 7.0% of GDP) with the consolidation process being implemented faster than previously envisaged. However, specific proposals for improving public finances in the coming five years will be presented in the course of 1995. Market sentiment is very sensitive to the pace of fiscal consolidation, implying that policy credibility could be lost if the required reduction of the budget deficit is postponed. This underlines the importance of making the medium-term fiscal strategy more credible.

## International trade

Europe is by far the largest market for the Swedish multinational companies. In 1993, the EU accounted for more than

50 % of both exports and imports. The single most important trading partner is Germany (14.4 % of exports, 17.9 % of imports) followed by the UK, Norway, Denmark and Finland. The US, accounting for 8.4 % of Swedish exports and 9.1 % of Swedish imports, is Sweden's major Extra-EU trading partner.

### Important sectors and companies

The pulp and paper sector is Sweden's largest net export earner, and the EU is by far the largest market for the overall forest industry. About 30 % of the industry's existing capacity is located outside Sweden, but within EU borders. During the late 1980s and early 1990s, Swedish forest industry groups invested heavily in the UK, Germany and France in order to settle near their main markets. In the present expansion phase, there are signs that a greater proportion of investments is concentrated in Sweden itself.

Sweden's pulp and paper groups enjoyed a 1994 that was much better than they expected. Profits grew as rising prices and strong demand drove up capacity utilisation and sales. The weak krona, cost reductions and lower debt burdens also contributed to the upturn. As an EU member state, the Swedish

forest industry will have a direct influence on the EU policy in the continuing environmental debate, an issue of considerable commercial importance to the companies in this sector. However, EU membership will carry a cost for the forest industry groups: to help fund the estimated 20 billion kronor (2.2 billion ECU) yearly cost of Swedish EU membership, a series of new corporate, energy and environment taxes has been introduced.

Sweden's regiment of big companies has largely survived the domestic recession of the early 1990s and the international slump to preserve its impressive record on the European and international stage. Sweden's representation in the European Top 500 companies by market capitalisation has risen to 24 in 1994, against 21 in 1993, with seven new entries or re-entries outweighing four departures, two of which were accounted for by a take-over (Nobel Industries bought by Akzo of the Netherlands) and a break-up (Pharmacia breaking free from Procordia). Moreover, the country can claim another half company in the Swiss-Swedish engineering giant ABB Asea Brown Boveri which is the 34th largest company on the FT 500.

The growth in exports has been reflected in improved rankings for companies such as Electrolux, the home appliance maker, Atlas Copco and SKF, two stalwarts of Sweden's cyclical engineering sector, and the forest industry groups Stora, AssiDomän and MoDo, the latter two newcomers on the FT 500 for 1994. Stora was Europe's biggest pulp and paper group in 1994. Residential construction saw another year of sharp decline in 1994, but capacity pressures in export sectors should lead to a recovery in business investment.

Excluding the privatised AssiDomän, perhaps the most eye-catching Swedish performer was Hennes & Mauritz, the clothing retailer. With its profitability (nearly 50 per cent return on capital in 1993) it became a star of the Stockholm stock exchange.

Tourism is one of Sweden's fastest growing sectors and, although the sector is a relatively young one, ranks as the country's third largest industry, generating a yearly turnover of an estimated 98 billion kronor of which 21.4 % comes from foreign tourists.

The investment-exodus of the late 1980s has led to an alarming shift in industrial output. Increasingly, Swedish multinationals export basic components to units in EU member states where more sophisticated phases of production are completed. Exports still account for about 50 % of Sweden's industrial production, but the proportion of basic industries, such as steel or pulp and paper, has increased while engineering industry's share has waned. This has devastated many small and medium-sized companies that survived as suppliers and helps explain the plunge of industrial production to about 18 % of GNP from 27 % in the early 1980s.

### Competitive power of Sweden

Sweden dominates the corporate scene in the Nordic countries. However, Denmark and Norway both enjoyed economic growth of more than 4 per cent in 1994 and have not been held back by large budget deficits as Sweden has. According to the world competitiveness survey for 1994 of the World Economic Forum, Sweden headed the list for total expenditure on R&D as a percentage of GDP and was second in management (business efficiency, management development).

Two important factors have transformed the competitiveness of Swedish industry. The first is the devaluation of the Swedish krona in the 1990s, which restored the ability of manufacturers to compete in the European market. The second change is a significant rise in industry's productivity over the past few years. In the long term, the second factor is more important as the krona may rise in value, and the effects of increased productivity are expected to last.

## CONSEQUENCES OF THE ENTRY OF AUSTRIA, FINLAND AND SWEDEN

Apart from the effects on the three new Member States, four categories of consequences for the EU can be distinguished: economic, social, legislative and other consequences.

### Consequences for the three new Member States

The direct consequences for Austria, Finland and Sweden are limited because the countries have already adopted EU rules and legislation to a great extent. On January 1, 1994, the European Economic Area (EEA) Agreement came into force, effectively expanding the single market into five countries of the European Free Trade Association (EFTA): Austria, Finland, Ireland, Norway and Sweden.

The EEA is quite similar to the EU internal market with its four freedoms (freedom of movement of goods, capital, persons and services), but there are some important exceptions. Processed and unprocessed agricultural products are largely outside the scope of the EEA. Trade in such products continued

to be subject to national market arrangements. Moreover, as the EEA does not involve a customs union, border controls and the disadvantage of being a third country with respect to the EU increased the prices of Austrian, Finnish, and Swedish exports and reduced their competitiveness. Furthermore, although the three former EFTA countries enjoyed most of the advantages of the single market, they had no real influence on the rules and regulations which underpin it, which was a great disadvantage.

For Austria, Finland and Sweden, the EEA Agreement was only a temporary arrangement as they foresaw joining the EU in January 1995, subject to the outcome of national referenda.

EU membership will make labour more mobile and, sectors of the economy that were traditionally protected more exposed to competition and thus more efficient. EU membership will also reduce technical trade barriers such as different standards and test certificates. But most important of all, the countries will have better chances of attracting foreign direct investment. For example, Austria could become an EU centre for production and services because of the strong historic ties to the transition economies of Central and Eastern Europe. EU entry is expected to translate into roughly 3.8 billion ECU in additional output in Austria (i.e. 2-3 % of the GNP) within six years. Sweden expects EU membership to add 0.8 percentage points to annual economic growth between 1995-2004. The net economic benefits of joining the EU for Finland is estimated to equal 4.2 % of GNP, whilst national consumption is expected to increase by 5.5 %.

### Economic consequences in the EU

The enlargement will affect the EU's trade policy. Austria, Finland and Sweden will join the voices that argue for free trade and budget discipline, partly because they are all going to be net contributors to the EU budget. Therefore, a more liberal regime is expected. The Nordic countries are also expected to support the UK, Denmark, the Netherlands and Germany with regard to their desire of tighter control on state aid.

### Social consequences in the EU

The new Member States will bring more votes for environmental protection, for open and democratic decision-making and for high social standards. Austria, Finland and Sweden support the principle of subsidiarity, the principle of decentralising decision-making from Brussels where appropriate. Expansion, therefore, seems to be an achievement for defenders of arguments in favour of wider, rather than deeper, integration. However, Austria, Finland and Sweden are determined to strengthen the EU's social policy.

### Legislative consequences in the EU

Being EU members, and thereby able to influence policy and regulations on market conditions and standards, is of great importance for various sectors vital to the three countries, such as Sweden's wood and telecommunications industries.

The paper and pulp and forest industries are important for both Finland and Sweden. Therefore, Swedish and Finnish multinationals will try to influence EU directives, particularly where, as in the case of waste paper recycling, there is a direct impact on the amount of virgin fibre going into the paper system.

Austria entered the EU on the condition that it receive important concessions until the year 2001, at the earliest, with respect to the control of the flow of heavy trucks passing through the Austrian Alps. Furthermore, Austria will probably exert considerable influence on the Common Agricultural Policy (CAP) henceforth. Influencing the formulation of this policy is important to Austria as the food processing industry, Austria's largest industry, and the small farms will be sig-

nificantly affected by the CAP. The CAP is also of importance for Finland, as food-related industries account for about 10 % of Finnish production.

### **Other consequences**

The enlargement will imply less inward and more outward expansion, especially towards the East. Austria, Finland and Sweden support early EU membership for the Central and Eastern European countries. Enlargement might begin with the Czech Republic, Poland and Hungary, followed by the Slovak Republic, Bulgaria and Romania, and the Baltic states.

Enlargement further implies institutional reform. Striking deals will inevitably become more difficult as the Union grows. This means that more effort must be made to streamline the process, to reduce the bureaucracy, whilst at the same time providing maximum flexibility for the decentralisation of decision-making. The current trend appears to be towards a minimum set of rules and obligations, with no Member State having the right to stop others able and willing to move at a faster pace.

Written by: Netherlands Economic Institute

## Media services

*The communications and audio-visual sector produces a modest turnover, compared to industrial segments of the economy, or telecommunications. It is however a very important field for Europe, because of its visibility among citizens, and also because it constitutes the reference market for multimedia services, on which much hope is conceived as a future driving force of the community's economy.*

*It is also a complex area, since it includes segments as varied as, the press and book publishing, cinema theatrical exhibition, television, cable and satellite programming, and other audio-visual domestic entertainment, broadcast or edited, such as radio home video and video games.*

*Moreover, the economic state of each sector is very contrasted per national market: total spending in one area depends largely on the state of appropriate equipment infrastructures (this is particularly obvious for cable or satellite, for which penetration rates are very different, say in the Netherlands, from southern European countries) and also on cultural factors (such as the tradition of heavy press consumption per capita in the UK).*

### THE MARKET IN 1993

#### Press and publishing

In terms of sheer turnover, the press is still the single biggest segment of the communications sector. In 1993, the total press and book publishing activity for the five bigger countries in Europe exceeded 70 billions ECU. Its revenues are derived in comparable proportions from two main sources: sales to the public and advertising.

As the older branch of the communications sector, the publishing business has undergone several waves of mergers and acquisitions, and is now very concentrated around a few national players.

#### Television

Since the beginning of the eighties, the main evolutions in the television field were spurred by the rise of the private, commercial sector which caused increasing financial difficulties for public broadcasters (mainly because governments refuse to increase licence fees). For instance, German public broadcasters have recently declared major deficits and staff reductions: at ARD, 1.4 billion DM by 1996 with the loss of 800 jobs; at ZDF, 94 million DM and 400 jobs (Source: TV World October 1994).

There is also a trend towards weakening of the audience base for the generalist, terrestrial channels, mainly due to the development of the "thematic" chains. They remain however the preferred medium for mass audiences. In that regard, they are insured the best share of the television advertising market, even in the context of a declining audience.

In the last part of the decade, another important phenomenon arose: this is the mutation in transmission media, from ter-

restrial to cable for part of Northern Europe, and now, even more rapidly, to direct satellite broadcasting.

The number of satellite only channels went from none in 1980 to almost as many as there are terrestrial channels in the mid-nineties.

There are now over 35 millions European households receiving television through cable and satellite. This amounts to a penetration rate of about 28 % of TV homes.

In that regard, Europe is still behind the US, which counts a cable subscription rate of over 60 % among TV households, but the reach of new television transmission systems is no longer a marginal, secondary market.

Cable and satellite reception infrastructures is one of the fields for which the national and regional situation is the most contrasted in Europe: the percentage of homes receiving non-terrestrial television amounts to over 40 % in Northern Europe, while it is still under the 5 % lever in southern Europe.

The satellite transmission market for television services in Europe is clearly dominated by one of the only private operators: The SES, (Astra satellites) based in Luxembourg. Astra reaches over 47 million homes in all of Europe and the EFTA countries.

Germany is clearly the biggest market for consumer-based traditional and new media alike: it has the largest installed base and highest penetration rates for cable and satellite equipment. Belgium has the highest cable penetration rate in Europe, followed by Germany and the Netherlands.

For pay TV services however, it is France (with Canal+) and the UK (with BSkyB), among the "big" countries, which are the most developed.

The total revenues derived from television are going to be coming increasingly from pay services, mostly subscription based. The potential for growth of pay television is still high in Europe. Global television-derived advertising revenues continue to grow at a mature pace.

The pay-TV market is dominated by three media groups, each of them selling a package of channels, centred around a premium movie service. They all have an international scope.

#### Other audio-visual services

##### Cinema

National box office results largely depend on the film exhibition industry. This industry has undergone in Europe two major trends in the last decades: modernisation of exhibition infrastructures, with the development of multiplex theatres, and concentration of the business around large corporate structures.

##### Home video

Home video has grown considerably in Europe, with penetration rates reaching high levels. This medium now concerns

over 90 million households in Europe. But the program consumption (purchasing and renting of pre-recorded tapes) is far from having reached the American level, even for the same equipment penetration rate. Nevertheless, the economic weight of the home video commercial activity Europe is now already larger than that of the cinema.

#### Radio market

Radio has been successful in retaining audiences and advertisers in an increasingly competitive and technologically complex media environment. This is particularly true in France and Germany, where radio advertising markets are rather striving.

Radio advertising in Europe is experiencing double digit growth in 1993 for the best stations. The CLT has a major

share of European commercial radio activity, and is expanding its base of radio stations throughout the Community.

Concerning technology advances in the sector, it is worthwhile to mention the existence of pre-operational digital audio broadcasting in the UK, Germany and France.

#### EUROPEAN MEDIA AND THE GLOBAL MARKET

In spite of the different measures taken by community and national regulation bodies, the trade deficit between the US and Europe in the audio-visual sector, or at least the program trade (including the film industry, television broadcasting and home video) is increasing: the deficit grew from 2.38 billion ECU in 1990 to an estimated 2.91 billion ECU in 1995.

This deficit now represents over 5 % of the total media services market value in Europe. Measured in absolute terms, it is

not likely to decrease with the advent of new technologies, such as digital compression, which will multiply the number of channels. But European production progresses as well in this context, if not in the same proportions as do the amount of imports.

There are only a few European multimedia groups of international scope (see Table 11). A number of them are already present on the television market.

## FORECASTS BY SEGMENT

### Press and publishing

The medium term outlook is very grim for advertising revenues in the press: they are going to be lower in 1997 than in 1993 in most countries considered, especially in Southern Europe

and in France, changing at average annual rates going from -4 % to less than +1 %. As for the book publishing area, forecasts go from over -3 % to less than +2 % change yearly. Sales of press and publishing products to the public are more likely to maintain themselves than advertising revenues for which forecasts are negative in every country except the United Kingdom.

### Television

Evolutions of the television market much depend on whether free, terrestrial television or pay television is considered: growth perspectives are about 10 times higher in the latter field within a medium term timeframe, leaving more room for new channels than in the saturated traditional fields. Overall however, revenue growth for the sector will remain healthy.

### Other audio-visual services

#### Cinema

Thanks to substantial restructuring of the sector in several European countries ( the United Kingdom, Spain...) theatrical exhibition revenues will maintain themselves. Being a mature activity, they won't grow and theatrical exhibition will increasingly play a showcase role for the other audio-visual markets ( home video, cable and satellite rights..).

#### Home video

The global trend in European home video is towards a 20 % increase within the 5 year period, averaging nearly 5 % growth a year. Revenues are increasingly coming from sales, while they were dominated by rentals up until 1992.

## TRENDS AND NEW TECHNOLOGIES ON THE MEDIA MARKETS

### Segmentation of new services

The new "media services" in development can be divided into a few families of services defined by technical and access criteria:

- Multimedia publishing (editorial content published on CD-ROM or CDI);
- New services using analog technologies (pay per view, interactive television, teletex type services); interactive television is an upgrade to analogue TV or for digital TV, typically to permit viewer participation in quiz shows, or for home shopping;
- On demand television services (using cable, ADSL...) such as video on demand, made possible by digital television broadcasting;
- Telematic, on line computer information services.

### The new media markets

The new media markets are developing with the introduction of computer, telecommunications techniques and players into the field of traditional leisure industries such as publishing and television. These services can be based on three types of terminal: television, computer or specific, dedicated terminal.

**Perspectives for new television services in Europe**

*Pay Per View*

The potential in Europe for increased consumption and spending for pay television services is high (the average American home spends several times what the average European home on pay television). Moreover, the advent of digital technology will enable operators to enrich their pay TV offer, to diversify their marketing techniques (tier paying, multiplexing of channels, pay per view or pay per play...) and to lower their transmission costs.

The commercial potential of pay per view is real, but, as the American experience proves, relatively limited in a multiple channel environment. One big stumbling block is the avail-

ability of movie rights, which is often limited by the grip in this field of existing broadcasters and pay television services. This analysis is also true for Video On Demand. This implies alliances between the program service operators (cable operators, pay services operators) and the program providers (American Majors, European movie right holders like the Kirch group).

Another problem with pay per view is the response time. The less time a customer has to wait after ordering programme, the better the utilisation rate, according to US results. This will depend upon how many channels the cable operator has reserved for pay per view. Also availability of exclusive special event programming like boxing fights boosts utilisation. Films are more difficult because studios will not concede a pay per view release window ahead of video release.

Experiments as well as commercial pay-per-view services are already in place in several European countries: The Multivision pay-per-view service was launched in France 1994 by the consortium formed around Telcarte (France Telecom, represented by VTCOM, Lyonnaise des Eaux, CLT and TF1). In the Netherlands, Philips, PTT Netherlands allied with the American Graff pay per view has launched a service in 1994.

*Digital television services*

Digital TV enables the consumer, among other things, to reap the benefits of compression by receiving a large number of television channels and using interactive services such as video on demand or interactive information data bases. To date, the biggest issue in digital television is the set top box or rather

the commercial functionalities of the set top box. The European Digital Video Broadcasting Group has defined specifications for digital satellite and cable which have become ETSI norms and ITU recommendations. DVB brings together manufacturers, broadcasters, transmission providers and others to consider requirements for new TV systems. There is therefore agreement on transmission / reception standards. The debate on proprietary and open systems relates only to conditional access systems for pay TV. A key objective of the DVB discussions was to define technical approaches which would per-

mit a single integrated receiver / decoder to receive encrypted services from more than one broadcaster. Two approaches were defined, i.e. Simulcrypt and the Common Interface. These approaches are not mutually exclusive and could be implemented together in the same decoder.

Another crucial element in the success of future digital services is definitely the user interface, navigation system available for the subscriber of a multi channel, multi-service offer (also restrictively named "Electronic TV Guide".) Several European players in the broadcasting, telecommunications and computer fields are working on the development of such software.

Digital television will be introduced in Europe by satellite and cable by end-1995 ahead of terrestrial delivery, since the DVB group is still defining the specification for terrestrial. One likely candidate to the pioneer position in this field is Canal+, allied with Bertelsmann in the Canal Satellite service, which is planning a digital satellite broadcast of several channels and services beginning in 1995-1996. BSkyB, has also announced the launching of digital satellite broadcasting services. The American groups Viacom (MTV, etc...), which already has a digital broadcast feed, and Turner should also be in the race.

This new area promises to be competitive, and European players seek partnership in order to better resist possible non-European entities, which can be more advanced in the design of digital television services.

#### Wide screen 16:9 TV

High Definition Television (HDTV), the new standard of television reception, promises to be the major development of the twenty-first century. Widescreen (16:9 format) and improved definition television receivers have recently entered the market: in 1994, total European sales of 16:9 widescreen TV sets reached 150 000 units (100 000 in France only, as 16:9 broadcasting started there first).

#### Video on demand

A lot of the commercial or technical problems to real "on demand" services are not solved yet, as shown in the American experiments (in Orlando, for instance). Real video on demand services will not be implemented commercially and on a wide scale in Europe before 1998. Their launching will be prepared by multi channel, multi services packages, and pay per view services...

The countries best prepared to digital services are those where the cable and satellite penetration is high (Germany, Belgium, the Netherlands) and where there is already a real multi-channel environment. The presence of a strong alternative program provider (as Canal+ in France and BSKyB in the UK) is also an asset.

So far, only a few video on demand trials have been announced: one, instigated by British Telecom, should be using ADSL and an Oracle media server, and the Deutsche Bundespost is also planning trials in Germany.

#### On-line information services and data bases

It has been much heralded that the advent of digital technologies will blur the line between traditional broadcast media and the computer and telecommunications industries. This predicament has now become true, as shown by the birth of a new category of media, that we can globally call "on-line services". These services distribute to the consumer's home information, entertainment, educational and professional services. They are also a meant to convey personal communications.

There are three main categories of on-line information services to the home:

- Broadcast, TV based, interactive teletext (through terrestrial or satellite distribution): produced and distributed in partnership with broadcasters (France 2 France3, Pro7 with Burda, Swiss Television, RAI, etc...). This type of activity, possible within an analog environment, is picking up quickly after having been long neglected. Teletext services are widespread in countries where the majority of TV receivers are equipped with a teletext decoder (like the Netherlands, and Belgium). They are likely to be further developed in a digital environment, where the television set can be an outlet for services much like those currently proposed by Teletel in France, or by the American on-line services.
- on-line dedicated terminal-based services (Teletel). The Minitel technology is likely to be replaced in the long term by standard platforms.
- on-line, computer based services (Compuserve, Bulletin Board Services). They are growing fast in the US. In Europe, their success in the consumer market will depend on the computer and modem penetration rates. These services are gaining ground in Europe. They first appeared as subsidiaries of the American services, simply duplicated for the European market instead of being custom-made for the European national and multilingual audiences. But recently, European actors are emerging to compete with Compuserve, America On Line and Microsoft Network on their own market: the European consortium formed by Matra, Burda and the CLT is launching Europe On Line, and in France, the video game and on line service company Infogrames is planning to introduce Infonie, another computer based service.

## Impact of the globalisation of markets on financial instruments available to the European capital goods industry

The European capital goods sector is of crucial importance, accounting for a third of total industry value-added and a similar share of total extra-EU exports.

The sector is made up of a wide range of different products, technologies and markets. Despite this diversity, a number of key threads run through these industries: interdependent amongst themselves, generally capital intensive and highly cyclical, they have a significant role to play in infrastructure development and are vital to the Union's workforce and economy.

### The growing concerns for EU capital goods competitiveness in a global market

An increasingly global demand and supply structure has led to an intensification of world competition for European producers, both on home ground and on export markets.

For this reason, large capital goods groups, as well as SME's, the latter traditionally more dependent on domestic markets or at best on intra-European export markets, will have an increasing need to respond to the global challenge if they are to survive in the long term. The same is true of some of

the smaller or less developed European export economies, which do not currently have adequate export support structures for their national capital goods producers and exporters.

In recent times, however, there have been concerns over a decline in the trade balance in certain European sectors of capital goods and hence, the future competitive position of European exporters. In particular, a decrease in competitiveness has been noted with respect to the rapidly growing Asian and Pacific rim economies and producers. As underlined in the EU White Paper on growth, competitiveness and employment, this is a matter of special urgency since the clear key to the future is to push European export capabilities in the fastest growing markets outside the Union.

### Financing - an increasingly major tool in the global expansion and competitiveness of a capital goods firm

Greater communication levels, globalisation and competition have meant that success is depending less and less on pure product and price strategies, and more and more on the related services which provide the right fit between capital goods and their markets.

One of the most important of these services is that of financing which plays an increasingly crucial role in the outcome of a capital goods sale or project. In 1993, Officially supported export credits accorded to European capital goods exporters represented some ECU 16 billion.

**Indications that EU loss of competitiveness in capital goods exports may be linked partly to financing difficulties**

In recent times, however, there have been worrying indications that the decrease in capital goods competitiveness may be

Source: LEK

linked in part to the unavailability of appropriate financial instruments to support the global expansion of EU capital goods producers. In this respect, it is interesting to examine OECD statistics on the evolution of Officially Supported Export Credit operations between 1989-93. Figure 1 below shows that the EU share of total credits awarded (credit periods over 1 year) has reduced in favour of the USA and Japan.

The problems of financing can be seen not just in relation to the most global of capital goods industries, the largest capital goods contracts and the most important players. Smaller European capital goods firms experience special difficulties in answering the global challenge, one of the key problems being limited levels of awareness of and access to adequate financing and insurance, particularly as many of the fastest growing capital goods markets are in countries where payment is slower and risk levels high.

Two key issues arise out of the above observations:

- What is the effectiveness of financial instruments currently available to European capital goods exporters?
- How is globalisation affecting the evolution of demand and supply for export finance in the European capital goods sector and how will this impact our future competitiveness?

**Basic structure of export finance for capital goods exporters**

The export finance role commences at the point of contract finalisation and covers capital goods manufacturers' credit and insurance needs during the production and post-shipment phases. The pre-contract stage of financing needs remains principally the domain of the corporate financier and is usually provided by the regular domestic bank of the capital goods exporter on the basis of a long-term relationship. This is illustrated in Figure 2.

Large capital goods groups and exporters of "heavier" goods, principally use buyer or supplier credits, resorting to less developed, and often costlier, instruments such as forfeiting when traditional forms are unavailable. Capital goods SMEs tend to have shorter term, more limited financial needs (at

least in absolute terms) and experience greater difficulty in covering their requirements, with frequent recourse to costly overdrafts and letters of credit.

For medium and long term financing of exports, the OECD Consensus and Helsinki Rules have helped provide a harmonising framework, though insurance and short term finance are not covered.

In the case of credit insurance, despite European moves towards harmonisation and initial discussions at an OECD level, a level playing field is far from being established. For example, there are significant variations in maximum levels of insurance coverage available both within Europe and between the EU and its extra-EU competitors, in particular, the US and Japan. This can be seen in Table 1.

There are also substantial differences in the overall supply structure of credit insurance. This is summarised in Table 2.

**Current handicap for European capital goods exporters: availability, quality and cost of financial instruments**

An analysis of the availability, quality and cost of export financial instruments currently available to capital goods exporters within the Union around a series of key factors indicates that European firms do not always benefit from appropriate export finance and risk hedging systems or at least are penalised compared to certain extra-EU exporters. This is particularly true for certain exporters (smaller firms, certain EU countries) and certain domains of export finance such as insurance. The main issues are listed in Table 3.

**Challenges for the future: effects of increasing complexity and globalisation of the capital goods market on EU export finance demand and supply**

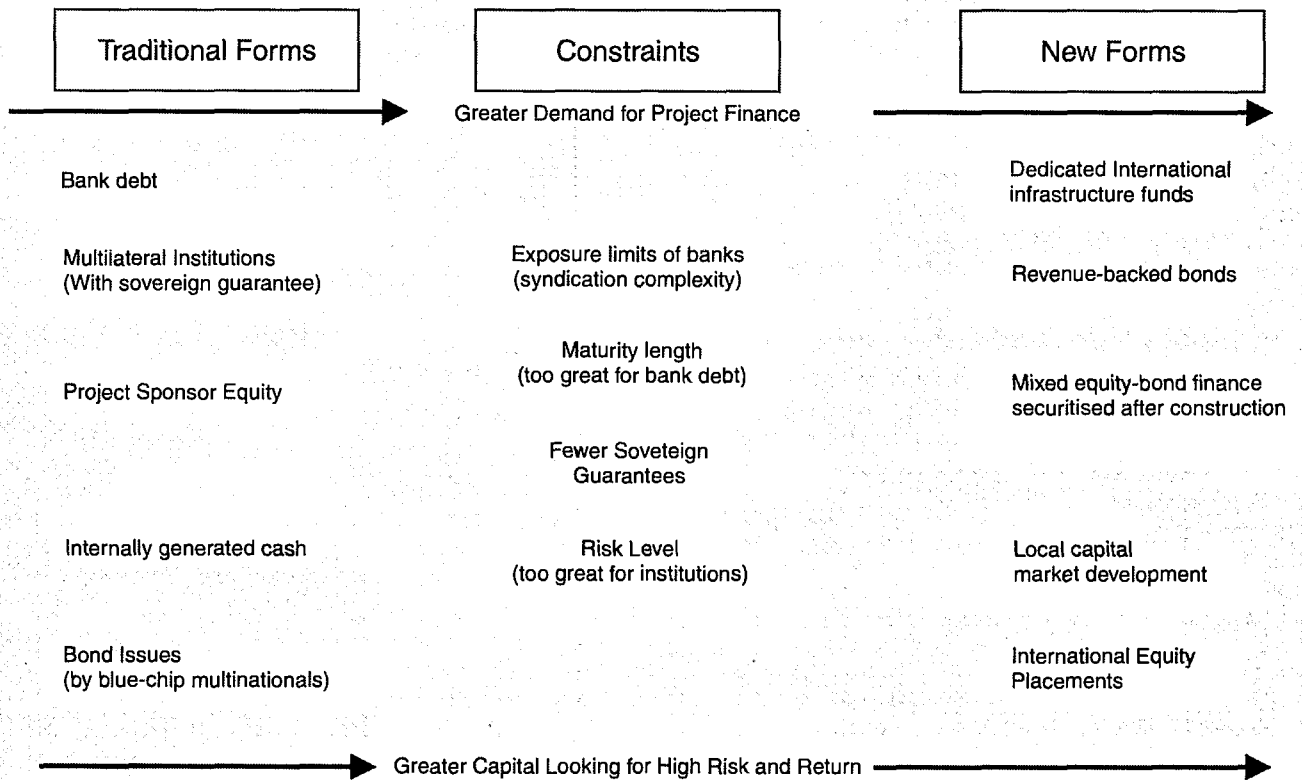

Over and above the current situation, there are a number of challenges for the future: the increasing globalisation and complexity of the marketplace are pushing European capital goods exporters to more sophisticated solutions in the bidding process. This in itself is leading to more and more complex re-

**Table 3: Main issues concerning financing and risk hedging**

Financing	Issue
- Interest rate: OECD consensus	Unavailability or limited availability in certain EU countries
- Interest rate: non-supported	Lower interest in US / Japan Important where consensus does not apply, e.g. short-term finance often used by smaller players
Risk hedging	Issue
- Exchange risk	Additional cost of hedging dollar-denominated contracts in sectors such as aerospace
- Credit insurance:	
- In most EU countries, maximum cover of goods is less than 100% of loan	Cost of residual risk to most EU capital exporters (unlike US counterparts)
- Most EU insurers offer specific goods risk insurance, not unconditional guarantee	Raises risk to be carried by EU capital exporters (unlike US counterparts) Limits possibility of financing through loan securitisation (e.g. aerospace sector)
- Quality of ECA service	Insufficient in certain EU countries (e.g. speed of response in claims delivery)
- Premium rates	Wide range in EU - affects overall cost of financing Triad competitors may be cheaper, but difficult to evaluate

Source: LEK

**Figure 3: The evolution of project finance sources**

**Table 4: Summary of main export credit issues for EU capital goods exporters**

	Principal issues	Relative importance to companies interviewed	Current actions / scope for EU action
<b>Export financing</b>			
- OECD consensus rates	Unavailability or limited availability in certain EU countries	Crucial in certain countries	Outside scope
- Market rates	Lower interest rates in US / Japan	Important where consensus does not apply (e.g. short term finance / 15% downpayment) SMEs probably more affected (greater recourse to short term credit)	Outside scope
<b>Credit insurance</b>			
- Exchange risk	Additional cost of hedging dollar denominated contracts	Critical for certain capital goods sectors such as aerospace	Outside scope
- Maximum % of insurance cover available	Cost of residual risk for many EU exporters	Critical	EU draft directive in discussion; also OECD working party"
- Nature of insurance provided	Most EU insurers offer specific risk insurance (US and Japan provide unconditional guarantee)	Critical	EU draft directive in discussion; also OECD working party"
- Quality of ECA service	Speed of response and certainty of coverage	Crucial in some EU countries	EU draft directive covers some of these issues
- Premium rates	Speed of delivery of final product and claims Wide range in the EU	Often mentioned but difficult to prove / evaluate effect	EU draft directive in discussion; also OECD working party"
- Limits on insurance of foreign content	Triad competitors appear to be cheaper Loopholes often exploited to reduce EU directive limits further	Growing importance with EU multi-sourcing	Possible review of loopholes to prevent advantages to Triad competitors
- Local content	OECD financing/insurance limited to 15%, but some extra-EU competitors may exploit loopholes	Less important than other issues? Difficult to prove	Scope for EU action unclear
- Project finance	Need to develop EU project finance possibilities	Important issue for the future	Unclear. Possible liaison with OECD to extend payment terms

Source: LEK

quirements for financial engineering, the impact of which can be seen in two major effects:

- Increase in funding requirements for large, long-term projects
- Greater risk exposure in fast-growing developing capital goods markets

### Increase in funding requirements for large, long-term projects

An increasing number of large infrastructure and other projects, where construction and financing time frames are protracted, is having a significant impact on the nature of demand for EU capital goods exports and the type of deal structures involved. Large capital goods often form a direct and integral part of infrastructure projects (e.g. railroad equipment for high speed train lines, turbines for power plants, electric cables for telecommunications networks). In addition, exporters of smaller capital goods benefit indirectly but substantially as subcontractors to the needs of larger capital goods and other players involved in these projects.

Many of the more recent infrastructure projects represent substantial sums involved, as in the case of the massive Hub River power project in Pakistan, valued at \$1.5 billion. The project took eight years in the negotiation and financing, and very nearly did not come to fruition owing to the tremendous complexity of the deal, the number of players and the levels of risk involved.

### Greater risk exposure in fast-growing capital goods markets

The saturation of certain EU capital goods markets has meant that manufacturers are looking not just to extra-EU countries but to developing regions for the greatest potential. The railway equipment market is an illustration of a European capital goods market which is relatively mature (except in certain segments such as high speed or urban trains), but shows enormous potential in markets such as India and China.

An illustration of the exposure of EU capital goods exports to high risk regions is provided in the accounts of the main Export Credit Agencies (ECAs). For example, the medium and long term insurance coverage of Coface - of which in

excess of 90 % relates to capital goods/infrastructure-type exports - is spread as follows: 31 % Africa, 31 % Asia, 18 % Middle East, 5 % Central and Eastern Europe, 9 % S. and N. America, 6 % Western Europe. In the case of Hermes, more than 50 % of its capital goods long-term coverage was accorded to non-developed or developing countries in 1993.

The effects of increasing market globalisation and competition and the development of long-term projects in high risk regions will have a key influence on the evolution of export financing needs. Two areas of particular challenge for European capital goods exporters of the future were identified in the course of this analysis:

- Increasing role of project finance
- Issues around multi-sourcing

### Project finance

The increase in long term infrastructure projects in higher risk regions, together with the reduction in sovereign guarantees (partly a result of increasing privatisation), has led to an increasing and evolving role for project finance in export credit for capital goods. New types of financing approach (e.g. Build Operate Transfer or BOT) and new high risk/high return funding sources are continually being developed.

European banks and ECA's are increasing their involvement in project finance though practical experience varies from one member state to another. In particular given the aggressive approach of certain extra-EU competitors in this area, this is likely to be a key issue for capital goods exporters seeking to develop in the emerging export markets of the future.

### Multi-sourcing

Market globalisation and stiff competition are increasingly leading exporters to bid in multi-national consortia or de-localise production in search of greater efficiency. European geographical fragmentation and lack of harmonisation in ECA insurance schemes prevent EU exporters, however, from obtaining adequate and cost-effective pan-European financing for the foreign content of contracts. This will increasingly affect the competitiveness of European Union capital goods competitors when bidding against US or Japanese companies which are covered by a single entity.

The growing importance of offset agreements and local content in major contracts - particularly in sectors such as the aeronautical or rail construction industry - is also having an impact on financing needs and creating problems of financing and insurance coverage.

### Financing of EU capital goods exports: cost of inaction for future competitiveness

The competitiveness of European capital goods clearly depends on a number of factors, which range from product quality, to value-added services to price and other elements. There is a need to ensure however that, at the very least, a level playing field exists for EU actors in the increasingly key area of export finance. While these export finance issues exist for European capital goods companies, the stakes remain high precisely because the global capital goods market is evolving rapidly and competitor countries and companies are responding to the export finance challenge:

- Rapid changes in the nature of demand mean that the successful companies of the future are those which are able to adapt now, with adequate support from new forms of financial engineering;
- For those European companies which are not able to adapt (whether SMEs or other firms), there is unlikely to be a second chance;
- Strong competitor countries such as the US are currently taking action to improve their export finance system for

American companies; In the US case, particular emphasis has been made by the Clinton administration on expanding exports into "Big Emerging Markets" and helping SMEs;

- Competitors from newly emerging Asian economies already pose a real problem for the future and these countries will increasingly develop sophisticated financial systems.

For this reason, inaction or insufficiently rapid progress, is likely to create a major and potentially irrevocable handicap for European capital goods industries, with all this implies in terms of loss of market share, loss of markets and loss of jobs for small and large companies alike, as well as the indirect impact on the sectors which these companies serve.

However, despite some clear action steps that have been taken at a national, European and OECD level, there is clearly still some way to go. In Table 4 below, the main outstanding issues for European capital goods exporters are reviewed in the light of their relative importance to companies interviewed (Column three). The final right hand column specifies current actions and scope for future action in each of these areas, since clearly not all these issues lie within the bounds of EU influence.

### Conclusion

At the European level, there is therefore a need:

- To work towards an efficient and globally competitive export finance structure for all European capital goods exporters

However, as stated above, not all the outstanding issues in export finance for capital goods exporters lie within the bounds of EU influence, for example, those relating to interest rates and exchange costs.

Many of the outstanding issues on which the EU has potential influence relate to insurance of export credit risks. These issues affect different EU member exporters differently (e.g. percentage levels of coverage, quality of service).

Insurance harmonisation is, therefore, a goal, but only if it enables EU capital goods exporters to remain competitive at an extra-EU and worldwide level. One implication of this is the need for co-ordination between current OECD initiatives and potential EU moves to harmonisation.

- To work towards improved access to efficient export finance systems for EU capital goods exporters with particular needs, such as SMEs

The EU should play a central role in the enhancement of export finance structures for smaller European capital goods players, which dominate certain sectors of the industry and represent a substantial part of the workforce.

This may include assistance towards improved communication on availability of export credit instruments, on commercial/political risk management and on availability of insurance for SME's. It should involve discussion with both SME representative bodies, trade associations and financial institutions on specific needs and improved access to appropriate and cost-effective export finance.

In acting towards the above goals, the EU will be taking one step further in the development of its industrial policy by preparing capital goods exporters for the challenges of the global marketplace.

## Traffic Management and the use of Information Technology

### INTRODUCTION

The industry sector covered by the International Union of Public Transport (Union Internationale des Transports Publics - UITP) includes all aspects of personal transport and mobility in urban and regional (inter-urban) contexts namely:

- The management of Collective Transport and intermodal facilities.
- The Public Transport investment including passenger terminal & rolling stock.
- The derived services such as:
  - Infrastructure management (e.g. rail track management)
  - Management of value added services (e.g. multi-operator cards & passes)
  - Transport demand management (all modes)
  - Traffic flow management which require a combination of information technology and telecommunications (in one word: "Telematics")

The present chapter of PANORAMA OF EUROPEAN INDUSTRY covers specifically the recent developments in the traffic management. It includes Road Transport "Telematics". The European Road Transport Telematics Implementation Co ordination Organisation (ERTICO) which includes the public authorities, the infrastructure operators, car manufacturers and public and private operators. ERTICO aims at developing a consensus between public and private sectors on common specifications and standards. UITP participates as a founding partner in ERTICO.

### 1 - TOWARDS IMPLEMENTATION OF PAN-EUROPEAN NETWORKS

The Treaty on the European Union signed in Maastricht (Article 129 C, paragraph 2) that came into force on 1 November 1993 has expanded Community powers. It sets up the necessary new institutional framework to allow for the development of Trans-European Networks including in the field of surface transport.

At several consecutive European summits, the heads of state and governments have been stressing the need for the completion of a Trans-European Road Network (TERN) before the year 2010 in order to facilitate European growth, enhance the competitiveness of the economy and develop the labour market.

The Commission's White Paper entitled "Growth, Competitiveness Employment and the Challenges: Ways Forward into the 21st Century" presented to the European Council in December 1993, presents the trans-European network completion as a tool for relaunching economic growth.

All modes of transport are concerned: surface transport, shipping and air transport. This programme is estimated to cost a total of 400 billion ECU by 2010.

The accelerated implementation of an advanced surface transport infrastructure in Europe is nevertheless difficult to reconcile with the need to consolidate national public finances required for monetary Union. This is why the private sector needs to be involved more widely, particularly through public-private partnership schemes, in the financial engineering and management of such networks.

### 1.1 - MAIN ROAD CORRIDORS

In its decision of 29 October 1993, the Council of Ministers has, fixed the outline of the Trans-European Road Network to become the official network of the European Union. This includes:

- The construction or upgrading of the missing links.
- The development of traffic management systems.

Concerning its completion, the construction of 12.000 km of motorways is expected to be initiated by 2002 at the latest. These new sections will either complete the network, replace existing low quality roads or run in parallel with existing but congested roads. It also aims at integrating peripheral regions.

In order to assure a pan-European dimension to the Trans European Road Network, links to third countries are considered of major importance. As a first step, appropriate links to the former EFTA countries are considered, but connections to Central and Eastern European countries also have to be defined. Within the Directorate General for Transport, an "Action Group" called Network and Mobility (NEMO) was created to revise the initial TERN outline by extending the network to include Austria, Finland, Sweden and also Norway and Switzerland, and connecting it to Central and Eastern Europe.

Criteria used for the definition of the initial outline of the Trans European Road Network include technical indicators such as:

- Quantitative assessment of a major transeuropean route (Density of total traffic, density of heavy traffic, connection of economic centres and metropolitan areas)
- Quantitative assessment of the route's importance to international traffic (cross-border links, connection with third countries, density of goods and tourist international traffic, anticipation of demand trends)
- Qualitative assessment of the route (continuity of network - missing links and time saving, continuity of services and standards - safety and comfort)
- Regional accessibility and integration of peripheral regions (Connection of regional capitals, area accessibility in terms of time and distance, access to major urban centres)

**Table 1: Major road links per country.(major road links are mostly motor ways but not in all cases-e.g. Ireland)**

	Area (1000 km <sup>2</sup> )	Population (millions)	Road links		Densities		2004

Source: DGVII

and operation of some 65,000km of "technically advanced links"(mostly motorways), which will ultimately constitute 90% of the system. Today 70% of the network is already operational. In approximately ten years an additional 20,000 km of motorways and high quality roads are expected to be operational. More than 40% of these additional roads will be built in peripheral countries of the Community.

The motorways will be built on new alignments or by upgrading existing links. Some existing sections handling heavy traffic and some urban by-pass roads will be widened. Some expressways and upgraded roads will complete this motorway network.

Table 2 presents per country the total length of the existing and planned links of the revised TERN in comparison to each country's surface and population.

The Trans-European Road Network connects the major European Urban Centres and helps to serve all the regions of the Union. The main corridors of international traffic will constitute one third of the network while the other two thirds are regional or national and are to be considered as alternative roads to the main corridors. Map n°2 shows the main corridors of international traffic.

## 1.2 - THE MAIN RAILWAY CORRIDORS

The Treaty of Maastricht prepares not only the ground for the development of a Trans-European Road Network, but allows also the elaboration of railway networks and in particular the High Speed Network. In this field a proposal for high speed network was prepared by the Community of European Railways (CER) and submitted to the European Commission by the end of 1989. The Council of Ministers created a high level Working Party for "High speeds", chaired by the EC and including governments, railway companies, industry and other parties. This group drew up a "European master plan of high speed links". This plan was approved by the Council of Ministers on 17 December 1990. The High level working Group has continued working since then. Studies have been carried out to elaborate on the cost effectiveness of the different links, their feasibility and their physical and social compatibility with the Community environment. A second report is under elaboration in 1994. This second report will contain

the results of studies undertaken on the socio-economic impact of the network on the Community, the approach to be adopted regarding environmental constraints and possible interaction with other modes. The High level Working Group pleads also for a pan-European harmonisation of the characteristics of the high speed rail links.

Similar to the Trans-European Road Network, the currently emerging European high speed rail network includes new lines built specially with high speed traffic in mind, upgraded lines adapted to speeds of up to 250 km/h and connecting lines worked at lower speeds.

It is incorporated in the Trans-European Railway Network as shown in map n°3.

The total cost of the high speed network is estimated at approximately 200 billion ECU. Within this total, the cost of the key links is set at 70 billion ECU

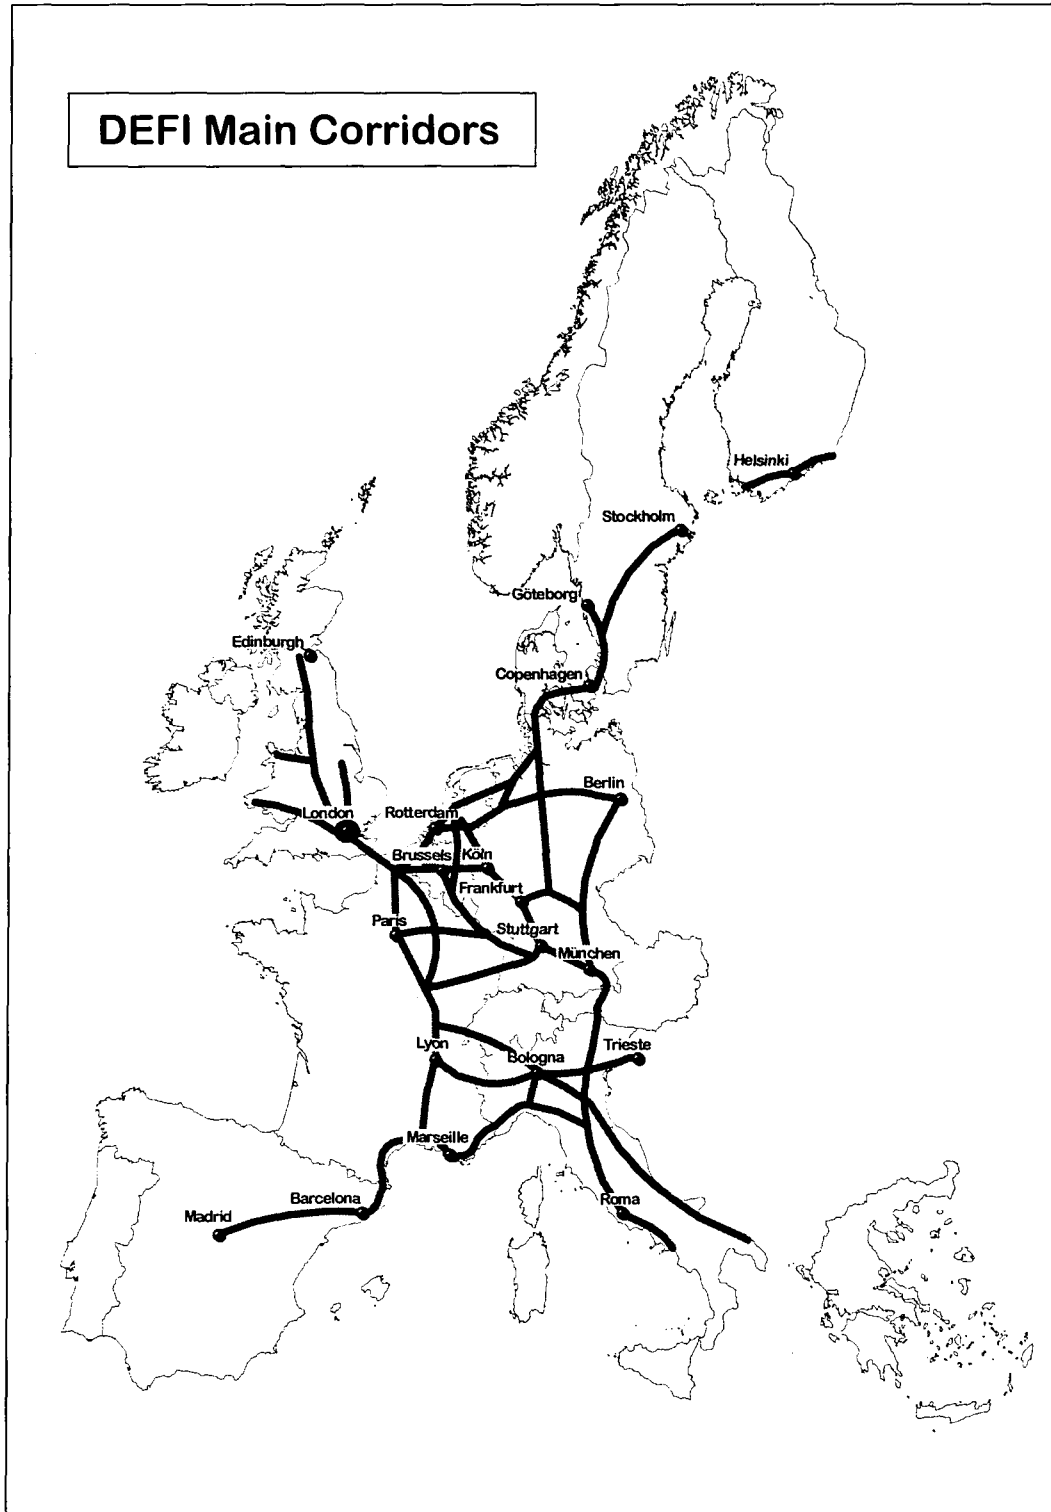

## 1.3 - FINANCING THE TRANS-EUROPEAN INFRASTRUCTURE

Following the decision of the European Council in December 1993, a group of personal representatives of the Heads of State or Government was established to assist in implementing efficiently, consistently and speedily the trans-European networks in transport (all modes) and energy. The European Investment Bank (EIB) participated in the group's work especially in relation to the financing aspects. The Group was chaired by Mr. Henning Christophersen, vice-president of the European Commission, and is therefore more commonly known as the "Christophersen Group".

The specific approach has been to identify and assist in accelerating specific projects of common interest considered to contribute in a valuable way to the implementation of the trans-European networks.

Projects were selected on the following main criteria:

- common interest for the trans-European networks, such as cross-border sections;
- large scale, bearing in mind the type of the project and the relative size of the Member States directly concerned;
- economic viability and scope for private involvement;

Source: CEC DGVII

**Table 3: The 14 priority projects proposed by the Christophersen Group (end 1994)**

Priority Project	Investments Total cost(MECU)	Status 1995-1999(MECU)	
1. HST/combined transport Berlin-Verona (Brenner Axis)	20 830	4 190	ready
2. HST Paris-Brussels-Köln-Amsterdam-London	15 754	9 466	constr.
3. HST South (Montpellier-Madrid-Vitoria-Dax)	12 870	4 380	prom

14. West Coast Main Line	880	733	prom
<b>TOTAL (approx in billion ECU)</b>	<b>91</b>	<b>40</b>	

*prom = promotional phase, design = in design phase, ready = ready for construction, constr. = already (partially) under construction.*  
 Source: DG VII

- contribution to Union objectives such as economic and social cohesion;
- respect of other Union policies, notably on environmental protection;
- maturity.

The Group has identified for each project obstacles to implementation, and assessed their importance and provided recommendations to overcome these obstacles. Some "horizontal" measures (applicable to the majority of the projects) to be taken at the State level and at the Union level have also been put forward.

In an interim report, the Christophersen Group presented to the Corfu European Council a preliminary set of 34 infrastructure and five traffic management projects as being of priority nature. The European Council in Corfu endorsed the priority nature of 11 mature projects, addressing mainly the high-speed rail network in Europe and the missing links in the peripheral countries.

According to the Christophersen Group, transport is the sector where most difficulties arise in achieving the objectives. This is due to the scale of investments, the often modest financial profitability of projects (although for most of them the economic profitability can be significantly higher), and to the very considerable variations in Member States' regulatory framework and traditional approaches to infrastructure development. Consequently, the Group considers that their approach

of identifying priority projects and promoting them will prove useful, especially in this sector.

After Corfu the Group continued working and included some projects proposed by the newly joining countries and projects concerning the connections to third countries.

The Group concluded that in all 14 transport projects are of priority and at an advanced stage of development and decided to submit the amended list to the Essen summit of the European Council.

In addition to the priority projects for physical infrastructure, the Group stressed the important role of traffic management systems, saying that networks without management will fail to serve their purpose. Moreover, the Group emphasised the mutually beneficial influence of the Information Society and other economic sectors such as transport that can help consolidate the strategic position of European industry and in particular transport telematics.

The Group also stressed the specific importance of those physical infrastructure projects which incorporate traffic management using wherever telematics applications and invited the Commission to proceed with an action plan.

The total investment for the 14 priority projects for the period until 1999, including the existing investments in 1994 and earlier for the projects already being implemented has been estimated to grow up to 45 BECU representing 49% of the total investment of 91 BECU.

**Table 4: Trans-European Transport Network  
 Estimated Community Contribution  
 Until 1999**

TOPIC	TOTAL COST ESTIMATE (BECU)	UP TO 1999 (BECU)	POSSIBLE EC CONTRIBUTION (BECU)
14 priority projects	91	40	1.8
Other important projects	51	27	0.5
Traffic management services	34	10	0.4
Interoperability	40	15	0.15
<b>TOTAL</b>	<b>216</b>	<b>92</b>	<b>2.85</b>

Source: DG VII

The following chart represents the estimated evolution of the yearly total investment for the 14 priority projects as a percentage of the total investment of 91 BECU.

## 2 - TOWARDS IMPLEMENTATION OF EU-WIDE TELEMATICS

### 2.1 - THE ISSUES

The EU wants to guarantee Trans European Road Network users fast and safe travel associated with a high and consistent quality of service on the motorways. The intention is to upgrade the whole Trans European Road Network to the highest technical level in order to achieve this.

Taking into account the ever increasing traffic problems on the major road axes, and in particular on urban by-passes, the Trans European Road Network is a prime focus for the development of a modern transport telematics infrastructure and services for traffic management and the communication of all kinds of information to the users.

The guidelines for the development of trans-European transport networks (proposed in April 1994 by the European Commission and currently under discussion among the institutions of the European Community) places the road network within the multi-modal context (i.e. in relation to the conventional

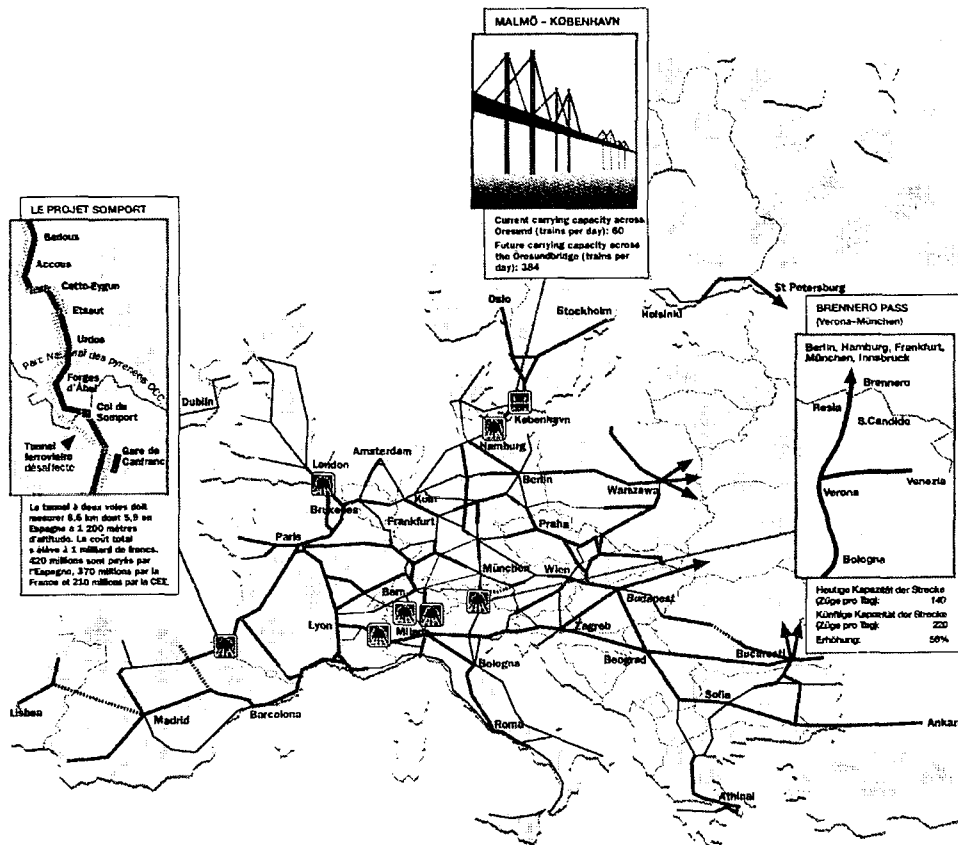

and high speed rail networks, combined transport, inland waterways, sea and air travel.).

Road transport telematics aims at playing an important role in the improvement of road safety, the search for a better balance between rail and road transport and the implementation of a sustainable transport policy (user specifications for infrastructure and facilities harmonised and continuous) as far as possible. Although the trans-European Road Network is already partly inter-operable, there is still need for improvement: certain common specifications on the typology of inter-urban roads, sign posting, road marking, traffic management systems and the services offered need still to be adapted and/or gradually implemented to meet user needs.

Traffic management requires a consistent and convergent approach and includes:

- Monitoring of the network:
- Monitoring of traffic, detection of incidents, surveillance of exceptional events, weather conditions, presence of hazardous loads, etc.
- Data gathering:
- Collection and processing of traffic data
- Traffic control:

Map n° 3: Trans-European Railway Network

Source: UIC

Figure 2: RDS-TMC radio (voice only)

Source: ERTICO TELTEN Report

- Flow of traffic, speed limit regulations, surveillance of bridges & tunnels, access control to congested zones, etc.
- Traffic information for the user:
- Information on traffic flows, real time information on road events, travel planning, general information, etc.
- Added value services:
- Such as dynamic guidance, selection of the best route, automatic toll payment without stopping, etc.

## 2.2 - TELEMATIC SYSTEMS

Since 1989, Community Research and Development programmes such as DRIVE, PROMETHEUS, ATT, etc. have been developing new techniques and technologies in the domain of traffic management. The feasibility and applicability of these developments have already been demonstrated in large scale pilot experiments with a view to formulating a European traffic management policy.

It is the intention of the EU to build on the results of these R & D programmes and to continue work in this field under the fourth Research and Development framework programme during 1995 - 1998, directly connected to the common transport policy and to focus on full-scale demonstration projects.

Development of telematic systems is now sufficiently well advanced for a start to be made with concerted full scale deployment on the Trans-European Road Network including the following systems/technologies:

- *Pre-travel information systems.*

Accessible at home, in the office or in the car; such systems, which should include all modes of transport, would enable users to prepare their journeys in Europe in a more rational way. Exchange of road information beyond borders is still exceptional, and users are often poorly informed about traffic and the state of roads during international travels. Interconnecting the national and regional information centres of the different European countries is essential. Therefore, a true network of road information centres need to be established.

- *Dynamic route information and route guidance systems;*

These systems provide visual traffic information on a screen or through variable message signs. Some in-vehicle units even

have the capability of guiding the driver to a given address, selecting the shortest route in distance or in time, scenic routes or other possibilities.

- *The Radio Data System - Traffic Message Channel (RDS-TMC) system.*

This system, an enhancement of the existing RDS, is based on digitally coded transmission of information messages which can be decoded on board the user's vehicle in his own language, independent of the country he is in.

It is already capable of providing a quality information service on a European scale. This system appears to be the first application for the provision of traffic management services using in-vehicle units.

With the DEF1 project, the European Union is aiming to establish a quick and concerted development strategy of RDS-TMC on a basic network of several thousand kilometres, to be progressively expanded in a later phase. Map n° 4 shows the main corridors envisaged for early RDS-TMC application.

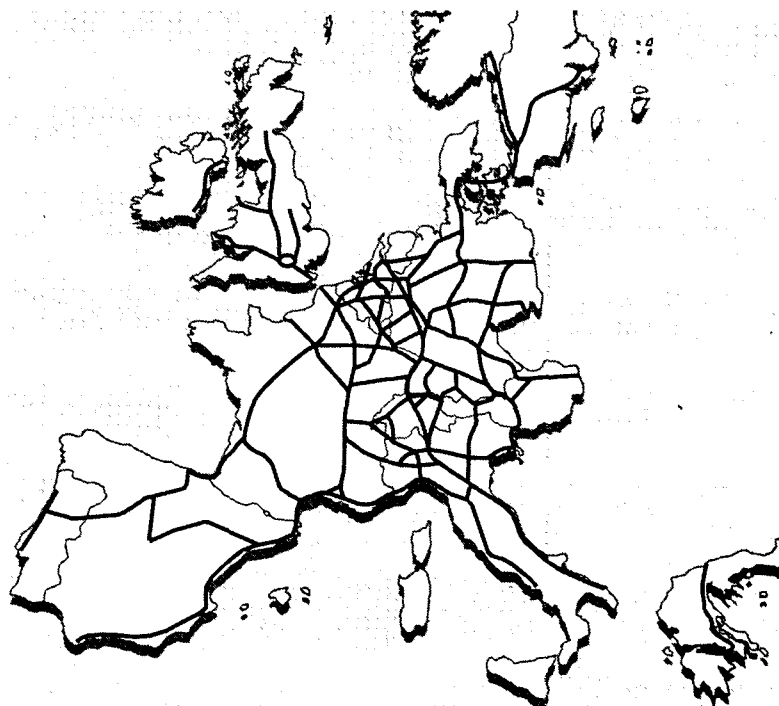

- *Satellite based positioning and guidance.*

Such a uniform system, based initially on the Global Positioning System (GPS) satellite configuration to be extended in a later phase to the European Global Navigation Satellite System (GNSS) configuration using International Maritime Satellite organisation (INMARSAT) III satellites, will accelerate the deployment of driver guidance systems, fleet and heavy goods vehicle management systems and monitoring systems for emergency vehicles, hazardous goods transport, buses, taxis, etc.

- *Automatic toll systems.*

New generation automatic non-stop debiting systems allowing for the payment of tolls or charges for the use of certain infrastructures, without imposing any constraint on speed or lane choice are already available from the shelf. These systems will encourage the development of alternative forms of financing and of the coverage of the costs of using the infrastructure and its facilities through user tolls. They will also make it possible to manage traffic during peak periods by adjusting the tolls for specific times of the day and for specific days.

Source: CEC DGVII

### 2.3 - THE HIGH LEVEL GROUP ON THE INFORMATION SOCIETY

The "Recommendations to the European Council concerning Europe and the Global Information Society" prepared by the High Level Group on the Information Society<sup>1</sup> - 26 May 1994, better known as "the Bangemann Report", sets out an operational programme and measures to be taken for the promotion of the development of the infrastructure in the information domain.

This includes, amongst others:

- Measures accelerating the liberalisation of the Telecom sector;
- Creating, as a primary objective the interoperability of services and applications following the successful example of GSM digital mobile telephony, market players could establish Memoranda of Understanding (MoU) to set the specifications requirements for specific application objectives. This type of mechanism would adequately respond to market needs. These requirements would then provide input to the competent standardisation body;
- Standardisation bodies could then respond with a reviewed European standardisation process in order to increase its speed and responsiveness to market needs;
- Support the openness of the European market and assure its counterpart in markets and networks of other regions of the world. Adequate steps should be taken to guarantee equal access;
- Intellectual Property Rights (IPR) protection must have a high priority;
- Individual privacy must be guaranteed. - Without the legal security of a Union-wide approach, lack of consumer con-

fidence will certainly undermine the rapid development of the information society;

- Financing of the Information Society should be entrusted to the market forces and the private sector.

The report also sets out ten application domains amongst which Transport takes an important part. It considers the establishment on a European scale of telematic solutions for advanced road traffic management systems and other transport services ( driver information, route guidance, fleet management, road pricing, etc. )

The High Level Group advises the European, national and regional administrations, user groups and traffic operators to set up a Steering Committee in order to define a common open system architecture for advanced telematic services with common user interfaces.

This would be to the benefit of drivers, local communities (especially in heavily congested areas) and industry by reducing traffic, increasing road safety, lowering environmental costs, and energy and time savings.

The aim of the High Level Group would be to implement by 1996 telematic systems for road traffic management in 10 metropolitan areas and 2.000 km of motorway. 30 metropolitan areas and the Trans European Motorway Network should be covered by the year 2000.

### 2.4 - CONFERENCES & TECHNICAL EXHIBITIONS

From 30 November 1994 until 3 December 1994, at the initiative of the European Commission and in co-operation with ITS America and VERTIS Japan, the first world congress on applications of Transport Telematics was organised by ER-TICO in Paris. It assembled nearly 2500 participants from the five continents. 400 papers were presented in more than 100 sessions. The proceedings represent 7 volumes totaling

Figure 3: Dual mode route guidance systems based on RDS-TMC

Source: ERTICO TELTEN Report

3500 pages. In parallel with the congress an exhibition covering a total space of 3000 m2 of which 800 m2 were taken by the European Commission for showing the results of the ATT Research and Development programme run by DG XIII C6. The rest was devoted to car and telematic manufacturers, operators and governments showing not only future developments but also a growing reality proven by 20 demonstration cars.

During the G7 conference in Brussels on 25 and 26 February 1995, the EU organised an Information Society showcase exhibition. The exhibition showed the latest state of the art in all Information Technology applications. It had an tremendous impact on the media (Radio, TV, Press) and showed to the public the latest developments.

These conferences and exhibitions allowed to show some already "off the shelf" available products:

- *In-car navigation and Information Systems:* Digital road maps stored on CD-ROM were shown inside the car, scrolling automatically as the vehicle moves. The current vehicle position is obtained by GPS and shown on the map.
- *Advanced Urban Traffic Control Systems:* A modern traffic control centre using IT and telecommunication to provide better control of traffic signals, rapid detection of traffic incidents, better information to drivers and improved reliability for bus services, as operational in Southampton, was demonstrated.
- *Dynamic route guidance for vehicles:* Mobile communications can be used to help vehicles to navigate around congestion. Moreover, the vehicle itself can be used as a traffic probe.
- *GSM based Mobile Services:* Every road user will be able to tailor his GSM terminal to his individual needs, such as for emergency and breakdown services, vehicle theft protection, making parking reservations during the journey, and route guidance.
- *Motorway Traffic Information:* Drivers can now have up-to-the-minute information about traffic speeds on motorways. Speed detectors placed on bridges over motorways radio back current traffic speeds to the control centre, which broadcasts them to the subscribers. Users see either on a

PC or a portable unit a map of the motorway showing where the traffic is slow.

- *Advanced Public Transport Systems:* Vehicle positioning systems and mobile radio communications on buses can provide information to traffic controllers on bus location and whether they are on time or ahead of or behind schedule.
- *Navigation and language independent traffic messages.* Showing a navigation system that offers visual and voice route guidance plus the Radio Data System Traffic Message Channel (RDS-TMC)

### 2.5 - A TIMETABLE FOR IMPLEMENTING EU WIDE TRAFFIC MANAGEMENT

The Telematics on the Trans-European Road Network (TELTEN) project, performed by ERTICO with a grant from DG VII (transport), has undertaken to produce a scenario for deploying traffic management using wherever necessary telematic applications on the Trans European Road Network. Deployment should be in accordance with rational and logical criteria. The TERN concept itself dictates the primary criteria, namely:

- Ensure interoperability of systems (the capability of devices to communicate and interact with each other under two aspects: system to system and user to system)
- Ensure continuity of services (in time and in space).

Application of the subsidiarity principle means that different systems will co-exist in time and it is also obvious that not all drivers will regularly use the telematic tools at their disposal.

Three deployment steps have been identified:

- Step 1: Provide a base infrastructure and some forms of actions and services in localised areas (providing solutions to traffic and safety problems where they are most acute) while ensuring interoperability of solutions through common standards (the minimum base that will lay the ground for future expansion). The risk of creating a patchwork is outbalanced by the opportunity to initiate the process.
- Step 2: Provide a base infrastructure and a base set of services on a "core network" of the TERN (the part of the

**Table 5: Telematic systems deployment by country**

Country	Step 2 kilometres	Step 3 kilometres
Belgique/België	450	1 320

<b>EU (15)</b>	<b>11 010</b>	<b>64 276</b>

Source: ERTICO TELTEN Report

TERN where traffic management can be most effective for traffic reasons), ensuring interoperability of solutions and continuity of services.

- Step 3: Provide all traffic management measures and services on the whole TERN.

Step 1 is already under way

Steps 2 and 3 will be undertaken gradually between now and 2010. The length of the motorway sections involved is given in Table 6.

## 2.6 - MARKET POTENTIAL

The estimated cost for the implementation of the telematics infrastructure is 13 billion ECU, building up as follows: (Table 4)

The total market for **in-vehicle equipment** is expected to be around **18 Billion ECU** cumulative from 1997 until 2010. Consumer demand will grow even further as traffic density rises and the quality of services improves, therefore providing greater market opportunity.

The most likely developments for early implementation are:

- RDS-TMC information as an additional feature in car radios might spread rapidly and achieve a high rate of penetration, but with limited revenues and margins.
- Dynamic Route Information systems may find a limited market but they fill only a small gap between RDS-TMC radios and systems including guidance and therefore will probably only occupy (regional) niches.
- Automatic non stop tolling systems will be wide spread from 1997 especially in countries with no history of motorway tolling

Forecasts are given as an example for two main groups of products:

- "RDS-TMC radio" which is a relatively cheap and simple product, supplying regionally specified traffic information by voice that is available at any time.
- "Dynamic Route Information" providing visual traffic information on a screen, with or without route guidance function.

Car radios with integral TMC will be sold from 1996. The initial extra price for the TMC decoder is approximately 100 ECU (for the first 1 million units). Price decreases by 25% if cumulated outcome doubles and the market is oligopolistic or if there is a large number of competitors causing cost reductions to be passed on quickly in price decreases. The annual hypothetical market potential is seen as almost equal to the "hypothetical market potential" (1.3 x new car registrations), with a very slight increase in the first years because of abnormal sales due to the novelty of the product. Diffusion is steep, and the penetration rate rises to 62% in 2010 and 70% in 2020 (i.e. 1.3 x 18 million and 19 million new car registrations respectively). Revenues remain in a moderate range of 200 to 300 MECU a year. They grow fast, but also peak early because of price decreases and intense competition. In 2010 they will total 243 MECU with cumulative sales of around 3.8 billion ECU. Revenues are not to be seen completely as additional revenues to the electronics industry, because substitution is likely with other car-radio features such as quadrophonic speakers, CD-players etc. (Many consumers have definite ideas what a product should cost and therefore will replace other features by RDS-TMC).

- RDS-TMC car radios should become a success, in the mid-range providing most drivers with improved information, but additional market potential for the industry is very restricted. If only one third of revenue represents substitution for other features, the additional cumulative market would be 2.2 billion ECU from 1997 until 2010.

The introduction of systems of this kind will be in 1995/96. The initial price will be high (about 2,000 ECU for the first 50,000 units) which will be the main barrier against adoption. Diffusion will therefore start among the segment of very frequent business travellers and of drivers of prestige cars. An additional barrier is that drivers may perceive loss of autonomy. The system has no direct connection with routine purchases of car radios, resulting in a lower frequency of decisions providing an opportunity to purchase the system. Hypothetical market potential is equal to purchases of new cars, because consumer decisions tend to relate to purchases of new cars and system replacement will not be frequent. There is a strong dependence on factory installation in cars (high costs for later installation). Despite decreasing prices, the system remains unattractive for second cars, cars used only in urban areas or rural areas; therefore, market penetration will not exceed a certain level.

Until 2002 diffusion is slow. Sales are likely to pick up rapidly as prices decline and factory side installation spreads to lower classes of cars. Penetration increases to 45% to 50% of the market (of 18 million new car registrations) between 2010 and 2015. So, in this scenario the system is successful, but with late diffusion. After 10 years revenues will reach almost 2 billion ECU per year and then will remain at this level.

**Table 6: Distribution of costs for implementation of telematics infrastructure**

	Kilometres	Estimated cost	Cumulative cost
Step 1	7 000	2 billion ECU	2 billion ECU
Step 2	11 000	3 billion ECU	5 billion ECU
Step 3	64 000	8 billion ECU	13 billion ECU

### 3 - THE "CITIZEN'S NETWORK" FOR LINKING THE TERN TO URBAN TRANSPORT

The Motorway Working Group has also recommended the establishment of a European strategy for optimising mobility on major trans-European axes bearing in mind both the regional dimension and integration of other modes. It has recognised the need to consider not only interurban axes but also urban roads and alternative transport. The white paper on common transport policy also stressed the importance of developing a "citizen's network" that would ensure rapid and convenient travel not just on the Trans-European Road Network as defined above, but also on the feeder and distribution systems that serve them.

Taken into account the fact that telematic solutions in increasing the capacity of road networks will always be more limited than the increase of traffic, fundamental measures based on demand management strategies will need to be applied.

However, before such measures can be taken, and in order to maintain the citizen's mobility at least at the existing level, actions need to be undertaken in order to make available the only alternative: an inter modal Collective Transport system including easy intermodality between the private car and Collective Transport networks. This comprises:

- Improved passenger terminals,
- Rail links,
- Park&Ride facilities,

Nowadays some Public Transport operators are already taking initiatives to integrate in their network operation other modes such as: taxis (Dutch Railways - NS), rental electric cars & electric scooters (La Rochelle, Strasbourg), car rentals (Zürich), etc.

The Commission has also announced for 1995 a green paper on the Citizens network which will stress the importance of effective public transportation as part of a strategy to keep our cities viable and concentrate on measures to overcome barriers to an increased attractiveness of public transport. A green paper on external costs will inform on the cost of pollution, accidents and land use not borne by the road users and recommending the increase of road transport costs to limit congestion and ensure a fair balance between private and collective transport costs.

For the European Union to undertake a programme to apply modern telematics to the interurban motorway network, without addressing the critical problem of onward travel to the user's final destination - that may often count for the majority of time spent travelling, even for longer journeys - would only partially cover the problem.

It is obvious that the complementary nature of collective transport, generally leading directly to the city centre (and/or the commercial and business centres), to private car transport needs to be considered. The problem is similar for air transport conveying passengers to an airport outside the city.

Therefore, it is necessary as a matter of high priority to undertake further research to identify the means of tackling the problems of city connections.

The problems to be addressed are:

- The development of user-friendly fare collection systems and the adherence to integrated payment systems
- The use and evolution of AVM systems
- The development of vehicle location systems (satellite based or not)
- The promotion of Passenger information systems and the integration of inter modal (public transport and private car) information in order to encourage modal shift

The encouragement and disburden of inter modal interchanges

This involves not only the development of improved traffic control systems (as already foreseen on the Trans European Road Network), but also the integration of collective transport within the system, and in particular to ensure the most efficient use of road space in urban environments.

Consequently, for the EC to launch an action to cover the problem of the citizen's network for urban penetration as a complement to the successful TERN actions, could be a way of tackling this problem.

### 4 - CONCLUSIONS

1. The E.U. approach concerning the development of the pan-European transport networks is estimated at an overall cost of 400 billion ECU till the year 2010

2. The development of the Trans-European Road Network, includes the construction and/or modernisation of approximately 65.000 Km of motor ways and the implementation of Telematic systems for traffic management. E.U. wide telematic systems for road traffic management include principally:

- Dynamic route information and route guidance systems
- Radio Data System - Traffic Message Channel (RDS-TMC)
- Automatic toll systems

3. The development of the Trans-European Railway Network including mainly the creation of a high speed trans-European network is estimated at a cost of 200 billion ECU

4. The link between the envisaged Trans-European Networks which are essentially inter-urban networks and the urban transport allowing for the penetration in the urban centres is an indispensable complement in order to maintain European cities viable.

Our thanks go to Mr. Robert Libbrecht of ERTICO for compiling the article, to DG XIII, Mr. Fotis Karamitsos, for his personal input, to DG VII for making available their brochure on the Trans European Road Network, and the NEMO I report, to Mr. Pierre Decoster from ERTICO for his help and making available the TELTEN reports. Thanks also to Mr. John Fawkner from UITP and Mr. David Bowerman from ERTICO for their help.

# World information output in engineering sciences and technology

### INTRODUCTION

Scientometric approaches have long become a standard tool for handling a family of input and output R&D indicators. On the other hand, all industrialized countries are devoting increasing amounts of resources, both public and private, to improving their competitive position. While manpower and financial expenditures are the classical measures of research inputs, the count of publications, citations, patents and manifold related techniques provide an insight in various aspects of performance and efficiency. Approaches linking inputs to R&D (measured as resources allocated) with measures of outputs from R&D purport to indicate the contribution of R&D to economic growth and to economic and social entities. Publication-derived indices may be used to assess inventive activity in general and not at all only in the fundamental research, they are able to assess entire disciplines or research fields, and allow for cross-country and cross-disciplinary comparisons.

There is a substantial body of public literature and internal reports in these respects, containing a broad range of methodical approaches and findings. A part of the scientometric, or sometimes rather technometric analyses tackle the applied research, its performing establishments, the industrial research strongpoints, or the areas of science and technology which are inherently bound to successful industrial activities. Even technological capability as a very broad concept can be monitored by a wide variety of potential R&D indicators. Engineering scientific and technological research is apparently one of the key resources of new ideas for industry, its position is traditionally strong and level often excellent throughout the European continent, but little factography is generally known about its true international size, trends and profiles in output terms. There is also a growing awareness of the need to examine the interconnections between different research and socio-economic characteristics of national systems in order to explain the observed lasting differences in innovative and growth performance.

### THE DATABASE

The following assessment is a result of long-term systematic searches in *The Engineering Index* database for the years 1986-1994, a total of 1.5 million bibliographic items. The *Index* is published by The Engineering Information Inc. in New York. The literature covered is found in about 4500 journals, 2000 conferences per year (starting in 1989), publications of societies and organizations, technical reports, directories and monographs. *Compendex* and *Compendex Plus* are the machine-readable versions of the *Index*, which is now available also as CD-ROM products. The database, covering as many as 200 thousand records annually, is the best recognized world compilation of engineering and technological literature. In the area of engineering S&T and applied research, this database is perhaps ten times more comprehensive than the *Science*

*Citation Index*, currently the much too globally implemented tool for performance indicators in science and technology policy. International socio-economic figures were extracted and introduced in the model matrixes from the latest edition of *The World Bank Atlas*, published by the International Bank for Reconstruction and Development.

### MAIN RESULTS

36 fairly self-explaining scatter diagrams, discriminant scatterplots, dendrograms, bar diagrams and time series are presented in four series: **Socio-economic relationships and country groupings**: Standard double-logarithmic regression model and 95% confidence limits are applied to examine the publication scores of EU countries against the population size, national or individual wealth. While positive and highly correlated associations (Figs.1-4) confirm basic scientometric and econometric models, the seemingly negative effect of both the absolute and relative engineering publication activity on the countries growth rates in GNP per capita (Figs.5.6) would require some interpretation. In the pairs of Figures 7a and 7b to 10a and 10b, both the discriminant function analysis and the joining (tree clustering) methods help to group the EU countries by their engineering S&T publication effort, again versus a set of major demographic and socio-economic indicators. **Cumulative distributions** for major engineering S&T fields provide very simple comparisons on the global (Figs.11-16), regional (Figs.17) and EU (Fig.18) scales (as in other cases, limited size of this chapter did not permit to elaborate for individual European or world countries). **Growth trends** for major engineering S&T fields in the whole world, five leading regions and the EU (Figs.19-26) are structured similarly. **Treatment criteria**, allowing to distinguish (with overlaps) whether the performed activities belong to theoretical research, experimental research, or applications (other categories are: general, numerical & statistics, management, economy, history), are shown for the whole world cumulatively (Fig.27) and in trends (Fig.28), in regional distributions (Fig.29a) and markedly different regional profiles (Fig.29b). The last discriminant diagrams (Fig.30a) and similarity tree diagrams (Fig.30b) for the complete set of Central & East European countries (respective surveys are available for all EU and 27 non-European countries) indicate the proximity/distance in the countries engineering S&T research orientation - a vital information for international collaboration, joint projects, educational exchange, or even the brain-drain.

# Building business: evidence from Europe & North America on growth, competitiveness and jobs

*Debate on competitiveness is usually framed in terms of evidence at the macro-economic level for industries or national economies. But policies for competitiveness only work if they assist the achievements of individual businesses. It is at this level that competitive achievement and competitive capability should be tested.*

*Proposals for policies to improve the competitive capability of businesses must make assumptions about what aids profits and growth. Models focusing on costs and productivity are sometimes presented as alternatives to those driven by "intangible" factors such as innovation or quality.*

This article summarises a statistical study designed to examine the drivers of competitiveness from evidence on individual business operations in a wide range of different markets. The study examines a number of measures, tests their relative importance, and investigates the situations where they have the greatest impact.

The study uses "hard" measures of competitive achievement for businesses, including:

- pre-tax, pre-interest return on capital employed (ROCE);
- growth of share in the business' target market;
- growth of value added, which is the contribution a business makes to GDP.

The study also examines the creation of full-time equivalent jobs, because of the importance of the latter to EU policy.

The study links measures of competitive achievement to competitive capabilities which economists often describe as "intangible" as they are difficult to quantify in macro-economic studies. Such measures include relative quality of products and services, innovation, marketing efforts, R&D investment and intellectual property. They are measures which can be quantified at a "micro" level, by managers in individual business operations.

The source of information for the study is the 1994 edition of the PIMS database, containing over 3 000 business years of data from European enterprises, and more from North America. Each observation in the database is a business unit, although normally not an entire company, covering a minimum period of four years.

## MAIN CONCLUSIONS

The three major conclusions are:

- "Intangible" factors are more powerful drivers of medium-term business growth than the "tangible" factors that were measured;
- Innovation and intellectual property are the strongest drivers of competitive achievement. There are clear statistical links between R&D, management capability, intellectual prop-

 European market barriers appear to benefit quality niches and local monopolies

Source: PIMS 1994

**Figure 2: Capital intensity, productivity and profits**

erty, innovation, customer preference and market focus, and rising market share, growing value added and jobs created.

- Relative costs and productivity affect growth and profits. However, labour productivity gains which are achieved by “capital deepening”, i.e. substituting capital for labour, usually destroy both jobs and profits.

The business performance data that were used show that responsive management, measured by “speed to market”, is a significant factor in innovation, and that clarity of distribution objectives helps turn innovation into growth.

Customer preference, or quality, are more important as drivers of growth and profits in North America than it is in Europe. This demonstrates the merits of an effective Single Market and strong competition policy. Expect it to become the pattern in Europe as the Single Market develops.

The data also show that the biggest boost to value added and employment growth is to be found in “challenger” businesses, which are growing from weaker market shares rather than from dominant positions. Previous research based on the database (Patten 1986) shows that such businesses with high

current investment in marketing and R&D “intangibles” usually lose money over the medium term.

The statistical evidence for these conclusions is summarised in the sections below.

**POLICY IMPLICATIONS**

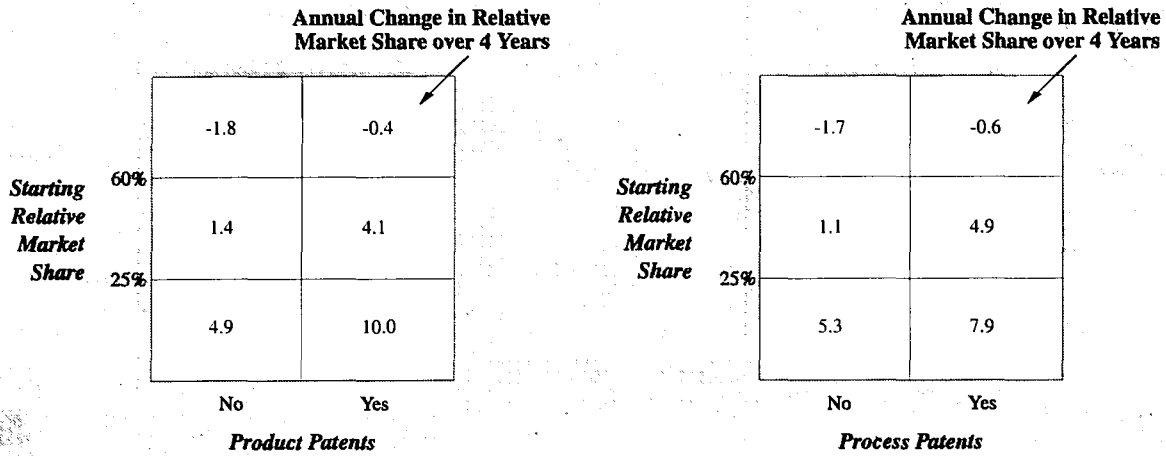

The main implications for policy are:

- Adequate protection of intellectual property advantage is a key issue in encouraging businesses to invest in innovative research;
- Accounting and tax treatment of “intangible” investment, particularly R&D and innovation costs, differ significantly between EU countries and are often less favourable than treatment of investment in fixed assets. These direct disincentives to businesses to invest in ways which aid competitive achievement should be reduced;
- The importance of “speed of response” may preclude direct fiscal intervention by way of public policy mechanisms to support specific innovations, simply because another stage in the innovation process involving decision by public agencies would impose delay. However, mechanisms which reduce the costs, the risks, or the time lag of innovation for

**Figure 3: More low productivity business in Europe**

**Figure 4: Intellectual property and share gain**

Source: PIMS 1994

“challenger” businesses are worth considering, particularly where there is a reasonable chance of achieving competitive advantage in growth markets as a result;

- Policies concerned with the power of producers versus distributors should pay attention to the effects on the ability of innovators to respond to customer needs and should not limit the ability of innovators to focus on specific segments of their markets.
- Incentives for “capital deepening”, i.e. substituting capital for labour, in slow-moving or declining sectors should be removed wherever possible.

**Defining Competitiveness**

There has been a great deal of debate on appropriate measures of competitiveness. This study uses two types of indicators to track competitive success. Each of these is measurable at the level of the individual business unit.

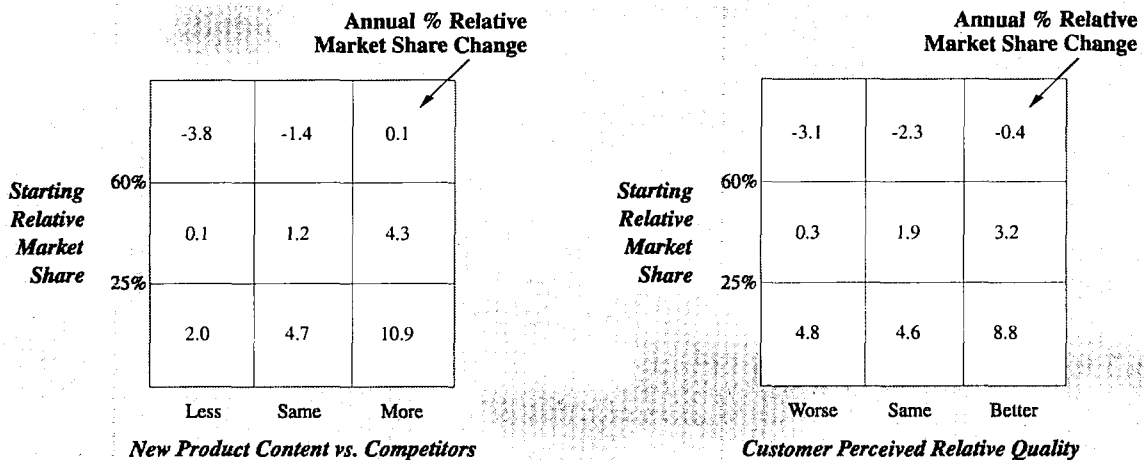

- Competitive achievement measures:
- How profitable is the activity, in terms of return on capital employed (ROCE)?

- How successful is the activity in achieving share growth in its target market, relative to its leading competitors?
- Is the activity successful in creating value added which its customers are prepared to pay for?

These are indicators of the competitive position of a business in two markets, the market for capital to finance its growth, and the market for the products and services it supplies. Value added growth also measures the business’ contribution to growth in the national or international economy. In addition, the study looks at another measure of achievement, which lies behind many of the EU’s policy proposals on competitiveness, namely: how successful is a business in creating jobs ?

- Competitive capability measures, which include:
- How well does a business satisfy the expressed needs of its customers relative to other suppliers, quantified as “customer-perceived relative quality”?
- How effective is a business in developing new products and services, measured as the percentage of its revenue from new offerings ?

**Figure 5: Innovation, quality and share gain**

Source: PIMS 1994

**Figure 6: Intellectual property, innovation and quality**

Source: PIMS 1994

- What intellectual property advantages does a business have ?
- How do business costs and prices compare to those of the competitors ?

In addition to these relative measures of competitive capability which help define the competencies of a business in relation to others, absolute measures of capital and labour productivity are also examined.

Most of the evidence referred to has been validated in multivariate regressions in order to establish precisely how the various effects relate to each other. However, the maximum number of relationships presented simultaneously here is two. Each statistical chart has been individually tested for significance.

In many of the exhibits the effect on one variable (such as business ROCE or change in share) of two others (e.g. current relative market share and relative quality) is presented. In Figure 1, for example, the left-hand diagram relating to North America indicates how ROCE (on the ordinate) increases with relative market share (on the left axis) and with relative quality (on the right axis). The data for Europe in the right-hand diagram show a more complex pattern.

**COMPETITIVE STRENGTH AND PROFITABILITY**

**Evidence**

Profit margins and return on capital employed (ROCE) for the 3 000 businesses in the database are strongly, and positively, related to:

- business share of the target market, relative to the share held by the top three competitors (relative market share)
- customer rating of product or service performance, relative to competitors (customer-perceived relative quality)
- asset productivity, measured in terms of value added to capital employed
- employee productivity, measured in terms of real value added per person.

These main “profit drivers” were among the first to be identified from the database when research based on it began twenty years ago. None of the relationships appears to have weakened as the database has grown. If anything, the statistical significance of quality in relation to ROCE may have increased during the 1980s as businesses have become more skilled at measuring quality performance.

Each of these relationships applies with reasonable consistency across:

- businesses in growing and declining markets;
- businesses in Europe and North America;
- businesses in consumer, industrial and service markets.

However, there are some statistically significant differences from these broad trends:

- in growing markets, where high quality and strong market share more than reinforce each other, this leading to very high profit levels for strong share and quality leaders;
- in consumer markets, where businesses with low share positions are unable to turn high relative-quality positions into good returns on capital, because they fall short of the minimum required scale in consumer marketing.

There are also competitive effects which appear to be specific for Europe. During the 1970s and 1980s, a number of businesses seem to have used dominant positions in local markets to make extraordinary profits, despite lacking customer-perceived quality advantages (Figure 1). It also appears to be the case that businesses in Europe with small market share are better able to gain returns from high quality “niche” positions. Possible explanations for these effects are:

- Market barriers, particularly prior to the Single Market, permitted local geographic monopolies to survive;
- Differences in customer taste and distribution in Europe are more likely to allow “niche” positions to be rewarded than do the more homogeneous markets in North America.

Relationships between productivity and profit are similar in Europe and North America; on neither continent is it likely that an investment intensive business will achieve high returns to capital, particularly if value added per employee is low. Capital intensity reduces profits because heavy investment, particularly fixed investment, changes the dynamics of competition. The positive impact of productivity on profits is understandable (Figure 2).

However, European businesses are much more likely to display low labour productivity. On average, European productivity is around 20 % below that of comparable North American businesses. There appears to be a significantly larger group in the European sample with value added per employee below 35 000 US dollars (1980 prices) even among the businesses which are relatively capital intensive (Figure 3).

The study does not offer a definitive explanation for the reasons behind the distinctively higher labour productivity in North American business, even when allowing for greater capital input. However, there is clear evidence from the sample that American business both invests significantly more in inputs to intellectual property, and achieves more by way of innovation. As is seen in the next two sections, this almost certainly underpins a higher sustainable rate of business growth and, in addition, higher growth in business value added. One would therefore expect productivity in North America to gain from this effect.

### MODELS FOR COMPETITIVE GROWTH - EVIDENCE

An enterprise which is able to gain shares on the target market at the expense of other suppliers is clearly "competitive". The study investigates the performance of businesses in terms of Relative market share, defined as the share of a business within its target market divided by the share sum of its three main competitors. Success in increasing relative market share is perhaps the ultimate measure of competitiveness, provided it is not attained at the expense of reduced profits.

In examining the evidence, it is necessary to take account of the fact that in most markets high-share businesses see their market positions decay. In identifying the impact of specific competitive capability factors, it is essential to take account of whether a business is defending a strong share position or starting from a weaker one. Each charts in this section thus present starting relative market share on the ordinate (high share businesses at the top, low-share businesses at the bottom), whilst the abscissa represents the competitive factor, the impact of which is being tracked. In each cell, the average movement of relative market share for the businesses contained is displayed.

Exclusive know-how is strongly correlated with share performance. Businesses with patented or proprietary products perform substantially better in gaining or retaining market

share than those without. But even with this key advantage, high-share businesses still lose out. Intellectual property related to performance reveals similar, but less dramatic, effects (Figure 4).

Innovation, measured by the share of revenue from new products in a business, and the margin by which this figure is ahead of or behind that of the competitors, is strongly related to share gain. Relative innovation advantage is the only factor that was found which allows high-share businesses to hold or even advance their positions. But high share businesses which face more innovative rivals are particularly vulnerable to rapid loss of market share (Figure 5).

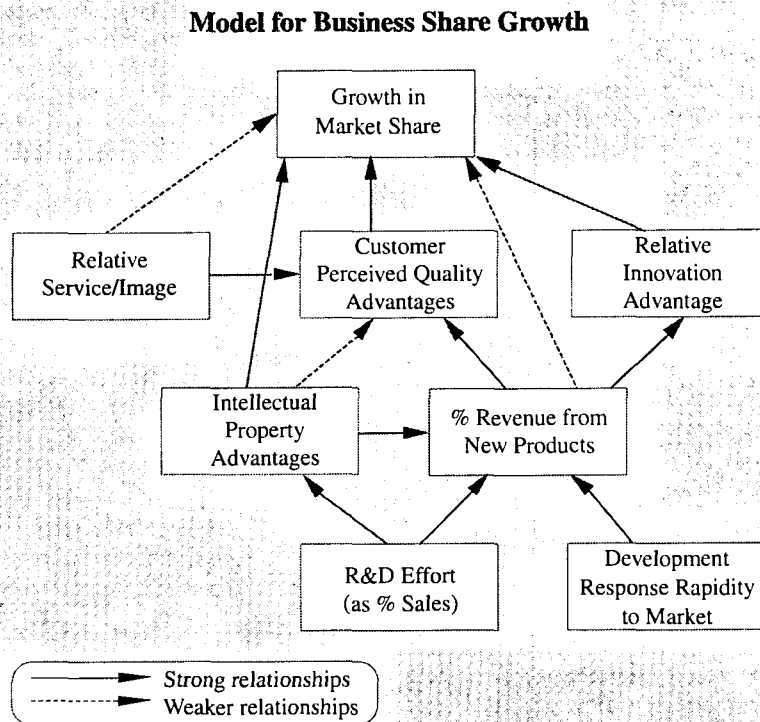

There is clear evidence that quality, i.e. the quality of products or services perceived by the customers relative to those of competitors, leads to stronger share gain for low- and medium-share businesses, and helps high share businesses to resist share loss. The data suggest that this relationship may have become stronger during the 1980s, either because markets have become more sensitive to quality, or because buyers and sellers are now better at measuring it. The absolute level of new product introductions also has a positive impact, distinct from the relative innovation effect above.

Other measures of relative quality, such as relative service and image, have significant effects on share, as do various measures of relative marketing effort. Sales force and promotion have clear positive effects on the ability of small share businesses to grow, but little measurable effect for most large-share businesses. Somewhat surprisingly, advertising, the basis for some measurements of "brand value", shows no such effect.

When one takes a closer look at some of the drivers of market share change identified above, at the factors which affect and link intellectual property advantage, innovation and relative quality, one finds a set of relationships which are "intuitively right" but which are seldom demonstrated statistically. There are clear and significant links between:

- R&D effort, speed to market and innovation achievement;

Figure 7: Model for business share growth

Source: PIMS/IMI

**Figure 8: Focused distribution helps turn advantages into share gains**

Source: PIMS 1994

- R&D effort and the possession of intellectual property advantage;
- intellectual property advantage, innovation and quality (Figure 6).

These relationships demonstrate most of the relationships necessary in a causal model linking management capability and R&D effort, through intellectual property and innovation, to quality supported by marketing on to market share growth (Figure 7).

The individual links in this model can be demonstrated despite the fact that neither in this database, nor in the DABLE database of company performance, is it possible to detect a sufficiently strong relationship between R&D and growth, on which to base policy.

Relative price positioning has surprisingly little impact on medium-term share gain in most cases, perhaps because it is usually either supported by a differentiated product or service offering, or quickly matched by competitors. The only situations in which it appears to be significant is where market leaders attempt to sustain high price premiums, and then lose share quite quickly. This is particularly evident where new competitors enter a market and attack the premium suppliers.

The evidence on relative costs is stronger, but similar. High-cost market leaders risk substantial share loss.

**EFFECTS OF MARKET STRUCTURE - EVIDENCE**

The type of market structure within which a business operates may affect the way in which the forces outlined above work in practice. Scope and complexity, measured by relative range of products or customer types, tend to be broad in high-share businesses. Allowing for this, there is evidence that increased product or customer complexity lowers the ability of businesses to gain market share.

Distribution complexity also affects the rate at which businesses turn competitive capability into share gain. Where businesses must divide their marketing approaches between distributors and direct sale, their ability to turn patents and innovation into share growth is weaker (Figure 8).

The blunting of competitive edge through mixed distribution strategies seems to apply both to the effects of quality, and those of intellectual property. Related evidence also suggests that distributor power, measured as the mark-up achieved between producer and user price, also slows down the conversion of quality advantage into share gain.

**Figure 9: Intellectual property and value added growth**

Source: PIMS 1994

Figure 10: Jobs and market growth - less flexibility in Europe

Source: PIMS 1994

VALUE ADDED AND EMPLOYMENT CREATION

Evidence

Gains in market share indicate that a business is able to win the preference of an increasing proportion of its potential customers for its products or services. But if one wishes to measure what a business contributes to overall economic growth, one must look at its value added. This is the link between "micro-" and "macro-" economic measurement.

The evidence shows that business value added growth is driven by broadly the same factors as market share. Intellectual property is certainly just as strongly related to value added growth as it is to share gain (Figure 9). Businesses with patent advantages are better able to raise value added even if they are already strong in their markets.

Quality proves to be a stronger driver of growth in North America than it does in Europe. Innovation, however, shows an effect on value added different from the impact that is visible with respect to market share; whereas new product content of sales is a powerful driver of value added growth for low-share businesses, it has little impact in medium- and high-share businesses, both in Europe and in North America. This effect occurs despite the fact that, as was demonstrated

in the previous section, a higher rate of innovation helps secure or defend market share for these businesses. The implication of this evidence is that "challenger" or lower-share businesses are more likely to turn innovation into economic value than existing market leaders.

Having identified the impact of these "intangible" factors on competitiveness and growth, can one assume that the same factors will help employment? A large part of the European Commission's work on competitiveness, as well as that of national governments, has been directed at employment creation, so this is clearly a crucial question, and one which can be addressed at the business unit level.

The findings suggest that employment growth is as strongly correlated with market share growth of businesses within their markets as it is with market growth itself. It also shows that the main competitive capability measures which drive market share growth (innovation, relative quality and marketing) also drive employment growth.

Relationships between business growth and employment growth display two significant differences between Europe and North America:

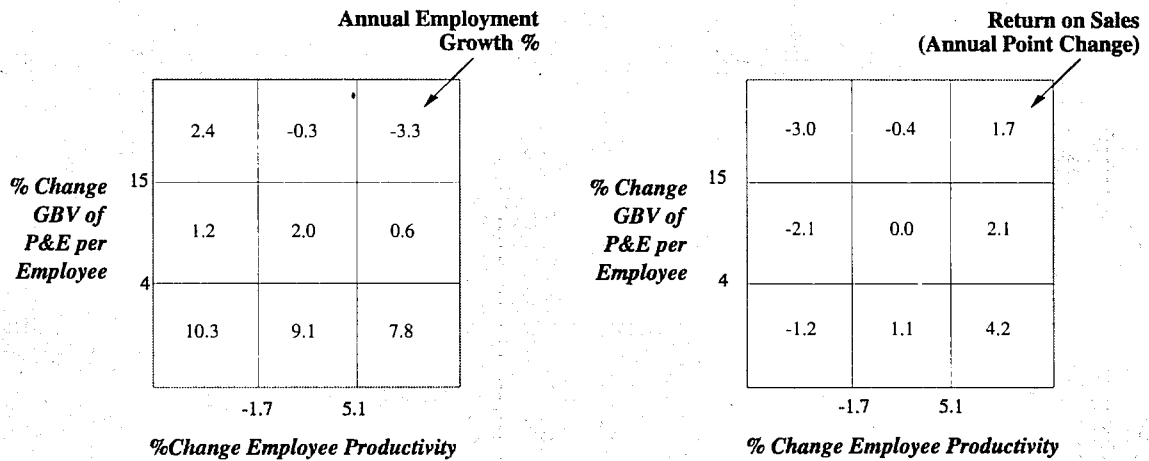

Figure 11: Jobs and market share change - less volatility in Europe

Source: PIMS 1994

**Figure 12: Productivity, employment and margins**

Source: PIMS 1994

- The distribution of market growth for businesses in the database clearly displays a more favourable pattern for North America, where there are more businesses in high-growth markets (Figure 10);
- Whereas the relationships between market growth, share gain and employment growth are similar where there is growth, North American businesses are much more likely to cut employment in response to sustained market decline or share loss (Figures 10 and 11). European businesses in the sample have tended to hold on to labour in downturns.

Not surprisingly, productivity improvement restricts or reverses employment growth in businesses. What is perhaps unexpected is the evidence that productivity gains achieved through substituting capital for labour, in the absence of significant business growth, not only reduce jobs, but also profits. This is related to the phenomenon that was visible in the section on competitive strength. Increasing capital intensity may reduce costs, but it usually changes the dynamics of competition in a market to ensure that little of the cost saving is retained by the business (Figure 12).

In practice, one finds that "capital deepening", i.e. significantly increasing the fixed capital per employee in a business, can

only be sustained without deteriorating margins if real output is increasing. The strong relationship between output growth and productivity growth makes it important to strip the effect of cyclical upswings (on costs and prices) from the relationships that have been examined. If one does this, the evidence is even more startling. Productivity gains achieved without real output growth are usually associated with declining profits as well as declining employment (Figure 13).

**Conclusions**

The evidence that has been brought forward shows that "intangible" measures of competitive capability are the most important determinants of competitive achievement. We have identified clear statistical links between:

- R&D effort in businesses and the "amount" of innovation they achieve, and the creation of intellectual property advantage;
- speed to market and success in sustaining innovation;
- innovation, intellectual property and the ability of businesses to achieve customer quality preference for their products and services;

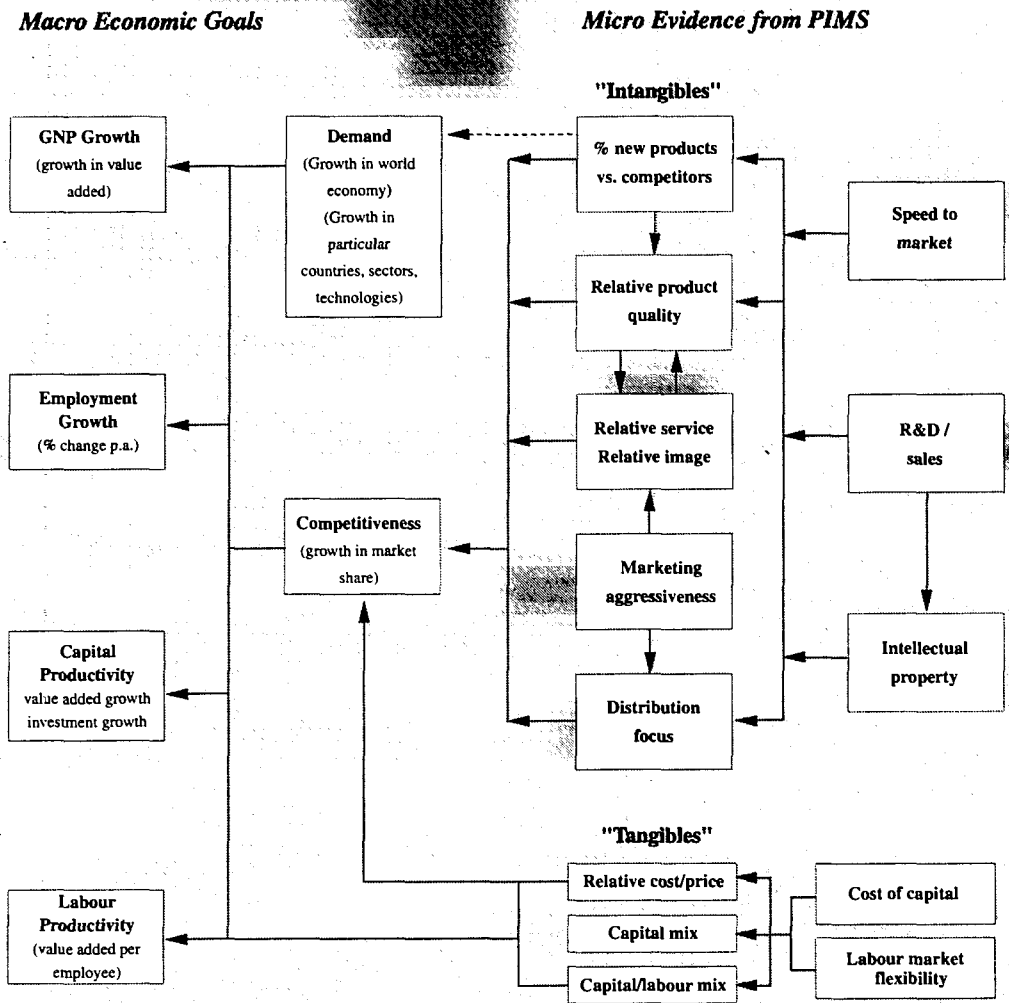

**Figure 13: Value added productivity and sales growth**

Source: PIMS 1994

Figure 14: Conclusions

Source: PIMS/IMI

- innovation, intellectual property, relative quality advantage and focused marketing effort with the success of individual businesses in growing in their markets, increasing value added and adding to employment.

The relationships, linking "micro" business measures to "macro-" economic performance, may be summarised in the following diagram (Figure 14).

Written by: Tony Clayton, PIMS Associates, London, UK; and Charles Carroll, Irish Management Institute, Dublin.

## Classification of 500 cooperatives, mutual benefit societies and associations

### OBJECTIVES

This document is the synthesis of a study carried out by SOFICATRA in 1993 and 1994 at the request of the DG XXIII of the European Commission.

The objective of the study was to create two classifications:

- the first consisting of the 500 largest Cooperatives, Mutual Benefit Societies and Associations (CMAs), in order to list and identify the 500 largest bodies in the CMA world
- the second consisting of the 500 most dynamic Cooperatives, Mutual Benefit Societies and Associations in terms of employment growth, in order to bring to light, on this occasion, those CMAs which are expanding, creating employment and which will probably become the largest CMAs in the future.

### WHY TWO CLASSIFICATIONS?

The world of the CMA is probably not well known and is difficult to define, because it is very diverse as regards its legal forms and methods of operation and above all it is very heterogeneous and disparate within the different countries of Europe.

It was decided to create two classifications because it is a matter of defining how the Social Economy is performing: in fact, it is based neither on the characteristics of the CMA within a country, nor on the management of legal statutes.

The representativeness of the classification is that of a self-proclaimed profession, in so far as the classifications include only those CMAs which answered the questionnaires sent to them.

In this context, it would be futile to attempt to extrapolate the full geography of the European Social Economy from these two classifications.

It is advisable merely to regard them as two tables which are both impressionistic, because they consist only of points connected with one and the same world, and impressive, because this is the first time so many participants of the same kind have been brought together.

### METHODOLOGY

At the start, SOFICATRA contacted 534 CMA federations in the 12 countries of Europe requesting them to select from among their members:

- those CMAs with more than 500 equivalent full-time staff (not including unpaid voluntary work) - in order to create the classification of large CMAs;
- those CMAs which they felt were particularly dynamic and where employment had very likely risen during the last five years.

So as to use only CMAs whose size was consistent with visibility from the European viewpoint, we deliberately restricted ourselves, in the case of the second classification - the most dynamic CMAs - to those employing more than 50 equivalent full-time paid staff in 1993.

Moreover, we have distinguished two types of CMAs:

- the CMAs themselves which are entities established as companies or which are established in a legal form which groups together all the activities quoted;
- the CMA groups which do not exist as a legal entity, but where, because of similar activities or other major synergies, the turnover and employment figures are often artificially consolidated "legally and fiscally".

We have essentially worked on the basis of the CMAs, but have also published the classification which includes groups, for information only.

We note that only 18.5 % of the 534 federations actually answered our questionnaire, which meant we had approximately 1 700 sets of data about CMAs able to be contacted for the purpose of appearing under at least one of the two classifications.

Source: SOFICATRA study

These 1 700 sets of data account for one third of all the questionnaires sent out, i.e. a total of 5 314.

The other two thirds of the information comes from: data banks; other studies; meetings, information and lists of participants during symposia; an informal network which was built up gradually throughout the study.

A questionnaire was posted to these 5 314 CMAs, followed up by a fax, and in the last instance a telephone call. These procedures meant that over 2 000 replies were received (a 39 % return rate) uniformly distributed among the twelve EU countries.

**Figure 2: Total number of jobs created by all CMAs by country**

(net jobs created between 1987 and 1992)

Source: SOFICATRA study

If only those CMAs employing over 500 people (the large ones) and those with more than 50 people which have experienced employment growth during the last five years (the dynamic ones) are taken into account, almost 1 000 of the questionnaires returned fulfil at least one of these two conditions for taking part in the study.

### MAIN RESULTS OF THE SAMPLE AS A WHOLE

A perusal of the 950 positive questionnaires received (returned by those CMAs which meet the criteria of size and/or growth) provides us with particularly interesting data concerning their internationalisation, financing and the number of jobs created during the last five years.

#### Internationalisation

More than 10 % of the CMAs which replied already have a significant export business with the following characteristics:

- three small to medium-sized countries stand out as exporting more than the average: Ireland, Denmark and Spain;

**Figure 3: Number of entities in the classification of the most dynamic CMAs**

Source: SOFICATRA study

- three large countries export less in our sample: Germany, Italy and the United Kingdom.

Furthermore, out of the total of 950 questionnaires, 637 future development projects are mentioned.

We have been particularly surprised, and very pleasantly so at that, by the number of projects already formalised: 637 projects from 950 questionnaires returned, which corresponds, in fact, to 0.66 projects per CMA.

These projects seem to be mainly directed towards other countries in the Community, since:

- only 58 projects (less than 10 %) would be carried out within their own country;
- 532 projects would require a partner in another EU country;
- 47 projects are even directed towards countries outside the EU.

The CMAs most anxious to expand are mainly from the United Kingdom, France and lastly Spain. They are particularly trying to set up in Germany, France and the United Kingdom, in that order.

Lastly, there are also many CMAs with an existing partner or "subsidiary" in another country in the EU or outside it. Out of the 950 questionnaires returned to us, we found there were 815 existing partnerships, i.e. almost one partnership per CMA.

However, in this case, it is seen that some CMAs have existing partnerships in many countries within the EU whilst the majority have not yet become established in any country.

The main countries with existing partnerships are chiefly the large ones, since the three leading countries where partnerships exist are France (86 partnerships in France), Germany (82) and Italy (77), whilst the countries with the fewest partnerships are more often than not smaller ones such as Ireland (45), Greece and Luxembourg (42).

The United Kingdom's position in the very middle, well down in terms of its size, should be noted, seemingly showing that with a figure of 64 partnerships it is still lagging behind the other large countries when it comes to opening new businesses, which fact is confirmed by the low export rate we had found in an earlier question. This relative isolation of the CMAs in the United Kingdom would also explain the large number of future development projects originating in and intended for the United Kingdom (in order to make it less isolated).

#### Financing requirements

One of the questions in the questionnaire concerned the possible financial requirements of the CMAs. They were asked to state the following amounts:

- their owners' equity (or equivalent) at the end of 1992;
- their medium- and long-term debt at the same date;
- their future financing requirements on the same date.

Very precisely 174 CMAs indicated an amount in the box covering financing requirements, which is equivalent to one CMA in every five of the sample of 950 questionnaires returned; however, account must be taken of the fact that the question was particularly indiscreet, since it not only asked whether there was a future financial requirement, but also asked that an estimated figure of this requirement be given.

If the financing requirements of these 174 CMAs are related to the number of CMAs which indicated their owners' equity (626 CMAs) or the amount of their medium- and long-term debt at the end of 1992 (484 CMAs), the financing requirement rate of 18.3 % of the CMAs rises to 27.7 % and even 36 % (the number of CMAs expressing financing requirements in relation to those with existing long-term debt).

Moreover, in the United Kingdom, where the practice of distributing accounts is much more widespread, the percentage rate of CMA's indicating a future financing requirement in relation to those with existing long-term debt is 52.7 %.

Taking the average rate of 36 % of CMA's expressing financing requirements, the realities of the situation are found to be very different, such as:

- a rate of 28 % for the cooperatives;
- a rate of 22 % for the mutual benefit societies;
- a rate of 54 % for the associations.

If the very large CMA's (the large banks and mutual benefit societies) which distort the average are excluded, the following profile of a CMA looking for future financing requirements can be drawn up:

- it employs around 300 equivalent full-time staff;
- it achieves a turnover of almost 78 million ECU;
- it had owners' equity of 15 million at the end of 1992;
- it had long-term debt of 7.5 million ECU (the equivalent of 50 % of its owners' equity);

**Figure 4: Average annual percentage of jobs created by country**

Source: SOFICATRA study

- in order to cater for its expansion it sought additional permanent funds of approximately 5 million ECU, which represents around 20 % of the total capital employed of the average CMA.

### Net creation of jobs

Based on the 950 questionnaires and eliminating the groups (to avoid duplications) and the CMAs which did not supply us with data for the two years (1992 and 1987), we are left with 604 CMAs.

Between 1987 and 1992, these 604 CMAs very precisely created a net total of 119 196 jobs, which is equivalent to each CMA creating 196 jobs on average.

These 604 CMAs must also be divided into two different categories:

- 487 CMAs which created a gross total of 136 259 jobs, i.e. 279 jobs per CMA;
- 127 CMAs which shed 17 063 jobs over five years, which is equivalent to an average of 134 jobs per CMA.

This net figure of one hundred and twenty thousand newly created jobs is distributed differently according to the countries involved for which the average number of jobs created per CMA is not uniform, since it ranges from 6 for the Danish CMAs to 605 for the German CMAs.

This average net figure of 196 jobs created per CMA must be related to the original number of jobs in these CMAs which was close to 2 000 equivalent full-time staff in 1987.

This annual job creation figure of almost 2 % per annum has therefore made it possible to create one hundred and twenty thousand jobs in five years, of which the breakdown by country is shown in Figure 2.

The jobs created therefore appear to be distributed to the advantage of three countries which account for almost 80 % of the 120 000 new jobs created over the five year period:

- the United Kingdom, which sweeps up almost 40 % of the total;
- Germany, which, despite a low response rate to our study (less than 10 % of the 950 questionnaires), obtains almost 30 % of the newly created jobs;
- the Netherlands, which is close to 10 %.

The biggest loser, at least in our sample, is France, which returned almost 30 % of the questionnaires to us but where

it seems that job creation has not followed, because it represents only 7.5 % of our sample's total.

Taken as a whole, it is nevertheless interesting to note that in all the European countries without exception, the CMAs which replied to the questionnaires have, on average, created a significant number of jobs (10 % over 5 years), whereas they account for an average of 2 000 people and at the present time it is more usual for an organisation of this size to cut its workforce rather than increase it.

The following suggestions can be advanced to explain this undoubted expansion of the role of the CMAs in the economies of Europe:

- the CMAs are engaged in activities now partly abandoned by the State, which is withdrawing from direct involvement in a series of sectors; in fact, the State would appear to be experiencing the same phenomenon as witnessed among the large industrial groups, namely outsourcing all of its non-strategic activities and, consequently refocusing on its core functions;
- the activities of the CMAs are, in the main, better distributed and cover fields which, generally speaking, are much more buoyant than the average in terms of consumption. These buoyant segments would appear to include the following:
  - savings and insurance, which, as a reaction to insecurity, tend to increase in times of economic crisis;
  - health and paramedical activities, which benefit from the extension of the average life span and the larger percentage of older people in the age pyramid;
  - training and culture, which will assume an increasingly important role in our economies;
  - all activities connected with assisting the many persons who have become marginalised (the unemployed, injured, handicapped, homeless, etc.) whose numbers, unfortunately, are constantly on the increase.

The CMAs have now learned to use modern techniques totally efficiently, for example: mass communication for Non-Governmental Organisations; marketing is also found to be expanding as regards internationalising activities; business combinations and mergers are also to be seen in almost all sectors, but mainly in banking, insurance and agriculture.

Probably all these factors individually contribute in part to the development of the cooperatives, mutual benefit societies and associations such as we have seen in the questionnaires returned to us.

### CLASSIFICATION OF THE 500 MOST DYNAMIC CMAs

The aim of classifying the 500 most dynamic CMAs is to provide a current picture of those organisations which are growing the fastest and which, in a way, thus foreshadow the profile of the organisations of the future.

We have chosen a parameter devised by an American, D. Birch, to select these CMAs.

This index is half-way between:

- the number of jobs created which favours the large CMAs more because it is easier to create 500 jobs from a starting figure of 10 000 than it is from zero; and
- the percentage increase in employment which favours the small CMAs too much because it is easier to produce a 10 % increase when there are 100 employees than when there are 1 000.

The index used by D. Birch harmoniously reconciles the two aspects of job creation since it satisfies the following formula: (Employment 92 - Employment 88) X (Employment 92 / Em-

**Table 2: Ranking of the largest CMAs according to employment**

- in order to cater for its expansion it sought additional permanent funds of approximately 5 million ECU, which represents around 20 % of the total capital employed of the average CMA.

### Net creation of jobs

Based on the 950 questionnaires and eliminating the groups (to avoid duplications) and the CMAs which did not supply us with data for the two years (1992 and 1987), we are left with 604 CMAs.

Between 1987 and 1992, these 604 CMAs very precisely created a net total of 119 196 jobs, which is equivalent to each CMA creating 196 jobs on average.

These 604 CMAs must also be divided into two different categories:

- 487 CMAs which created a gross total of 136 259 jobs, i.e. 279 jobs per CMA;
- 127 CMAs which shed 17 063 jobs over five years, which is equivalent to an average of 134 jobs per CMA.

This net figure of one hundred and twenty thousand newly created jobs is distributed differently according to the countries involved for which the average number of jobs created per CMA is not uniform, since it ranges from 6 for the Danish CMAs to 605 for the German CMAs.

This average net figure of 196 jobs created per CMA must be related to the original number of jobs in these CMAs which was close to 2 000 equivalent full-time staff in 1987.

This annual job creation figure of almost 2 % per annum has therefore made it possible to create one hundred and twenty thousand jobs in five years, of which the breakdown by country is shown in Figure 2.

The jobs created therefore appear to be distributed to the advantage of three countries which account for almost 80 % of the 120 000 new jobs created over the five year period:

- the United Kingdom, which sweeps up almost 40 % of the total;
- Germany, which, despite a low response rate to our study (less than 10 % of the 950 questionnaires), obtains almost 30 % of the newly created jobs;
- the Netherlands, which is close to 10 %.

The biggest loser, at least in our sample, is France, which returned almost 30 % of the questionnaires to us but where

it seems that job creation has not followed, because it represents only 7.5 % of our sample's total.

Taken as a whole, it is nevertheless interesting to note that in all the European countries without exception, the CMAs which replied to the questionnaires have, on average, created a significant number of jobs (10 % over 5 years), whereas they account for an average of 2 000 people and at the present time it is more usual for an organisation of this size to cut its workforce rather than increase it.

The following suggestions can be advanced to explain this undoubted expansion of the role of the CMAs in the economies of Europe:

- the CMAs are engaged in activities now partly abandoned by the State, which is withdrawing from direct involvement in a series of sectors; in fact, the State would appear to be experiencing the same phenomenon as witnessed among the large industrial groups, namely outsourcing all of its non-strategic activities and, consequently refocusing on its core functions;
- the activities of the CMAs are, in the main, better distributed and cover fields which, generally speaking, are much more buoyant than the average in terms of consumption. These buoyant segments would appear to include the following:
  - savings and insurance, which, as a reaction to insecurity, tend to increase in times of economic crisis;
  - health and paramedical activities, which benefit from the extension of the average life span and the larger percentage of older people in the age pyramid;
  - training and culture, which will assume an increasingly important role in our economies;
  - all activities connected with assisting the many persons who have become marginalised (the unemployed, injured, handicapped, homeless, etc.) whose numbers, unfortunately, are constantly on the increase.

The CMAs have now learned to use modern techniques totally efficiently, for example: mass communication for Non-Governmental Organisations; marketing is also found to be expanding as regards internationalising activities; business combinations and mergers are also to be seen in almost all sectors, but mainly in banking, insurance and agriculture.

Probably all these factors individually contribute in part to the development of the cooperatives, mutual benefit societies and associations such as we have seen in the questionnaires returned to us.

### CLASSIFICATION OF THE 500 MOST DYNAMIC CMAs

The aim of classifying the 500 most dynamic CMAs is to provide a current picture of those organisations which are growing the fastest and which, in a way, thus foreshadow the profile of the organisations of the future.

We have chosen a parameter devised by an American, D. Birch, to select these CMAs.

This index is half-way between:

- the number of jobs created which favours the large CMAs more because it is easier to create 500 jobs from a starting figure of 10 000 than it is from zero; and
- the percentage increase in employment which favours the small CMAs too much because it is easier to produce a 10 % increase when there are 100 employees than when there are 1 000.

The index used by D. Birch harmoniously reconciles the two aspects of job creation since it satisfies the following formula: (Employment 92 - Employment 88) X (Employment 92 / Em-

**Figure 5: Number of dynamic CMAs by country**

Source: SOFICATRA study

**Figure 6: Breakdown by sector of the 500 dynamic CMAs**

Source: SOFICATRA study

ployment 88). This index produces positive results if there is job creation, and negative results if there are job losses.

It is thought that to achieve a Birch index of 100 in five years is a real success story since this means a company has to: grow from 20 people in 1988 to 57 people in 1992; start with 50 people in 1988 and be around 100 people in 1992; number 585 in 1992, from a total of 500 in 1988; start with 1 000 people in 1988 and reach 1 092 people in 1992.

We have taken only the Cooperatives, Mutual Benefit Societies and Associations into account and have not considered "groups", which come under a separate category.

A detailed analysis of the classification of the 500 CMAs producing the highest Birch indices shows that:

- In comparison with the other criteria which we could have used to classify dynamism representatively, this is the only one which gives associations a share similar to what we perceive to be the real situation: in fact, a criterion such as the rate of variation in turnover between 1992 and 1988 meant the associations got the smallest share (less than 4 % of the sample) because they are smaller and their budget is often only the sum of their wage costs and operating costs (few raw materials purchased); consequently, by choosing the Birch index it is possible to compare the three categories of organisation together, highlight their differences, without obliterating or excessively stifling one of them;
- The top CMA in our classification has a BIRCH index of 12 766 (creating 8 850 jobs, since it moves from 20 000 to 28 850 jobs);
- The CMA in 500th place creates 4 jobs (up from 171 in 1988 to 175 in 1992) which we feel is still a significant performance for someone at the bottom of the table;
- The average Birch index for the classification stands at 405, which as far as the CMAs in our classification are concerned, is equivalent to the following performance:
- a CMA of 20 people in 1988 creates 80 jobs to stand at 100 in 1992;
- a CMA of 100 people in 1988 creates 150 jobs and totals 250 in 1992;
- a CMA of 1 000 people in 1988 creates 300 jobs to total 1 300 in 1992.

In practice, working on the basis of the average CMA in our classification of the 500 dynamic ones, it is seen that the BIRCH index of 405 corresponds to employment rising from 837 people in 1988 to 1 084 people in 1992. This trend therefore implies the creation of 247 jobs per CMA over 5 years and is equivalent to annual employment growth of 6.6 % per annum.

From the total sample of 500 dynamic CMAs, total employment rises from 405 000 units in 1988 to 525 000 units in 1992.

#### Analysis of dynamism by category

When analysing the first 500 of the classification according to their different categories (Cooperative, Mutual Benefit Society or Association), the following emerges:

- In terms of the number of entities within the classification, the cooperatives account for 44 %, the mutual benefit societies 20 % and the associations 36 % (the number of representatives in the three categories is shown in Figure 3);
- The profile of the entities within each category is very different, however, in so far as:
- the 221 cooperatives rise on average from 867 jobs in 1988 to 1 156 jobs in 1992;
- the 102 mutual benefit societies are large, since they start off with 1 263 jobs in 1988 and finish with 1 842 jobs in 1992;
- the 177 associations are modest in size - 380 people in 1988 - but rising to 515 people in 1993;

Although at the beginning the average size of the three categories differs considerably, the rate at which new jobs are created varies little according to category and therefore according to the size of the entity, since employment increases by an average of 6.6 % per annum, as against: 6.2 % per annum for the cooperatives, 7.6 % for the mutual benefit societies, 5.9 % for the associations.

The corollary of this is that, as the growth rate is similar within the three categories, the average number of jobs created between 1988 and 1992 will be proportional to the size of the entities: 289 jobs per cooperative, 579 jobs per mutual benefit society, 135 jobs per association.

**Figure 7: Employment growth rate according to sector**

Source: SOFICATRA study

**Analysis of dynamism by country**

Figure 4 clearly shows the comparative annual job creation rates of the entities in the sample.

It can be seen that the countries enjoying the best growth rates are Ireland, Italy, the United Kingdom, Spain and Germany, which are all above the 7 % figure for new jobs each year !

At the other extreme, the three least dynamic countries in terms of job creation are Belgium, France and Denmark, whose job creation rates are 50 % lower.

An analysis of these results seems to show that there is apparently no significant relationship between the job creation rate and the size of the country, or even the size of the entity. Instead it is apparently necessary to turn to explanations of a sectorial nature, or to analyse the age of the entities or the world of the CMAs or even to compare the compulsory levy rates in order to create a framework for justifying these differences.

If the breakdown of the 500 CMAs is analysed according to country, it can be seen that the United Kingdom and France each account for one quarter of the entities in the classification, a third quarter being shared between Germany, Italy and Spain with all the other countries accounting for the last quarter.

Compared with the large CMAs and the sample as a whole, the countries which are over-represented in terms of the dynamism of their operators are mainly the United Kingdom and Spain. The countries whose operators seem considerably less dynamic than the average are France and Germany.

In terms of average size the dynamic CMAs also vary significantly, depending on the country, compared with the all-country average of 1 100 persons in 1992:

- three countries produce entities well above this average: the Netherlands with 3 070 people on average, Germany with 2 198 jobs per entity, Denmark with 1 304.
- the CMAs of three small countries fall below half of the average employment figure: Luxembourg with an average of 183 employees, Greece with 202 employees and Portugal with 466 employees.

**Analysis of dynamism by sector of activity**

A breakdown of the 500 dynamic CMAs by sector provides the following information:

- one CMA in six belongs to the primary and secondary sectors (18.2 %) with the agricultural and agri-foodstuffs sectors predominating representing more than 13 % of the sample;

**Figure 8: Average employment per CMA - Higher than average sectors**

Source: SOFICATRA study

**Figure 9 : Number of jobs created by sector  
(job creation between 1988 and 1992)**

Source: SOFICATRA study

- another sixth of the entities comprises CMAs involved in commercial activities (essentially wholesale, to a lesser extent retail trade and marginally as middlemen);
- a quarter of the activities are in financial services and insurance (including financial subsidiaries);
- one CMA in ten operates in sectors closely related to general government (compulsory social security, research, education, etc.);
- the balance, i.e. almost one CMA in three, carries on an activity linked to health and community services (homes, day nurseries, home care, services to the disadvantaged,...).

The employment growth rate varies very considerably according to the activity involved:

- one sector beats all the records and outclasses the rest with a growth rate of almost 12 % per annum, namely business services, which in particular bring together computer and consultancy activities;
- the CMAs in three sectors show employment growth of approximately 8 % per annum (i.e. 1.4 % above the average), namely wholesale and retail businesses as well as

general administration departments (such as social security, education, research, etc.);

- the CMAs in two sectors have experienced below average employment growth: credit institutions, with slightly above 5 %, and health, with an annual rate of under 4 %.

As was already the case with categories and countries, the CMAs differ in size considerably according to the sector of activity involved.

Figure 8 shows the sectors in which the CMAs account for more employment than the general average (1 100 jobs in 1992).

Classification of the sectors according to the total number of jobs created differs considerably from that made according to the employment growth rate, in so far as this growth rate is, in this instance, weighted by both the number of CMAs and also the size of the CMAs. Therefore, the following movements are noted:

- the many large insurance and credit institutions, situated at the bottom of the first classification, are pulling themselves up to the top positions, which allows each of their sectors to create over 20 000 jobs,
- the corporate services activities, of which there are but a few, are relegated towards the bottom of the classification, together with health and agriculture; these three sectors each create far fewer than 5 000 jobs over the 5-year period.

All these factors for analysing the results provide an initial approach to the average dynamic CMA, but nothing quite matches a more precise description of the CMAs which are included in the classification.

### PROFILES OF DYNAMIC CMAS

By taking the top 50 in the classification of the 500 most dynamic CMAs, and thus analysing the "front runners", it is noted that:

- there are 25 cooperatives, 17 mutual benefit societies and 8 associations (which are therefore considerably under-represented);
- in order of country they are as follows: 15 CMAs are classified for the United Kingdom, 12 for Germany, 6 for Italy and 5 for the Netherlands. Ireland, Spain and France each have 3 CMAs, Denmark has two CMAs, with Portugal having the last CMA needed to make up the 50, which means that neither Belgium nor Greece nor Luxembourg has any CMAs among the top 50 most dynamic ones.

**Figure 10: Employment in the large CMAs by country**

Source: SOFICATRA study

**Figure 11: Employment in the large cooperatives by country**

Source: SOFICATRA study

- Dynamism seems to be consistent with a respectable size, in so far as out of the 50 most dynamic CMAs, 43 employ more than 1 000 people, and 5 CMAs even have more than 10 000 staff;
- Co-operative Wholesale Society (UK) ranked no. 1 because it creates 8 850 jobs (up from 20 000 jobs in 1988 to 28 850 in 1992);
- Rabobank Nederland (NL) comes 5th, creating over 5 000 jobs starting with 30 000 jobs in 1988;
- Hamburg-Mannheimer Versicherungsverein (Germany), in 7th place for adding 3 824 new jobs to the existing figure of 10 801 in 1988;
- Konsumgenossenschaft Dortmund-Kassel (Germany), which creates 1 867 jobs from 10 000 originally and comes in 22nd place.

As regards the associations, the British would receive the crown for being dynamic: out of the 20 top associations classified using the Birch criterion, no less than 15 are British; some partial explanations will be sought in the following directions:

- the British government has outsourced a whole series of care services, which have been taken over and developed by the private sector as associations;
- the economic situation has been particularly severe in the United Kingdom, hence a sharp increase in forms of poverty, exclusion and marginalisation;
- Anglo-Saxon behavioural habits are more open to the marketing of charitable work and the publication of the results of this activity.

Here are a few examples of associations, among which the most significant are:

- London Lighthouse (UK) which is the first association in the classification (12th place) to help AIDS /HIV positive sufferers with a staff of 6 in 1988 and 150 in 1992;
- The Fédération Nationale Léo Lagrange (France) which is the second association (19th place) which has seen its workforce grow from 447 to 1 275 in five years;
- The other associations, mainly in the United Kingdom, particularly aim at helping families with a sick child (Acorns Children's Hospice up from 4 to 86 staff), and at sheltering, educating and putting handicapped people back to work

**Figure 12: Employment in the large mutual benefit societies by country**

Source: SOFICATRA study

(Shaw Trust is up from 1 010 to 2 027 employees, and also Mac Intryre Care, up from 248 to 640 employees);

- Ass. Naz. Famiglie Fanciulli Subnormali (Italy) which pursues the same aims in Italy with 1 300 jobs in 1988, reaching 2 403 in 1992;
- Association des Paralysés de France (France) which is up from 5 336 to 6 272 jobs.

Among the thirty cooperatives best placed, are to be found:

- almost 15 cooperatives whose main activity involves being a commercial agency, mainly in agri-foodstuffs, but also in pharmaceuticals and more generally in bulk-buying such as, for example:
- Co-operative Wholesale Society (UK) which occupies first place in the classification with jobs up from 20 000 to 28 500;
- Kerry Co-operative Creameries Ltd. (Ireland) which occupies second place in the general classification, up from 2 615 to 6 279 employees;
- Eroski S. Coop (Spain) which distributes foodstuffs and which is up from 1 683 to 3 184 staff;
- Apothekers Co-operative (Netherlands) in 30th place, up from 1 381 to 2 398 people.
- in almost 10 cases, the cooperative owns a manufacturing or processing base in the agri-foodstuffs or stock farming sector, often together with an operation involved in marketing these products such as:
- Waterford Co-operative Society (Ireland) which is up from 1 166 to 3 224 people;
- Apofruit (Italy) whose horticultural produce business employs 792 people compared with 206 five years earlier;
- Vestjyske Slagterier (Denmark) whose main activity is animal slaughtering (5 777 as against 4 783 people).
- Surprisingly, in four out of the 25 leading cooperatives, mass catering is clearly expanding in Italy, creating more than 2 400 jobs from a starting figure of 2 456 in 1988:
- Coop Italiana di Ristorazione;
- Serist Servizi Tor Vergata;
- C.A.M.S.T.;
- Cooperativa di Lavoro "La Cascina".

Figure 13: Employment in the large associations by country

Source: SOFICATRA study

- in four other cases, enterprises are involved in banking, insurance activities or holding companies such as:
- Rabobank (Netherlands), lying in third position, alone creating more than 5 000 jobs;
- Confédération Nationale du Crédit Mutuel (France) which creates 1 000 jobs.

The mutual benefit societies sector is largely dominated by two countries, since among the 20 biggest job creators in this sector there are to be found:

- 10 German ones mainly operating in insurance activities:
- Debeka Krankenversicherungsverein a.G., up from 4 786 to 8 755 jobs;
- Hamburg-Mannheimer Versicherung, which creates 3 824 jobs;
- R + V Lebensversicherung a.G., which creates 3 569 jobs.
- 9 from the UK, where they very often take the form of building societies:
- Nationwide Building Society, up from 6 453 to 10 873 jobs;
- Norwich Union Life Insurance Society, which creates 2 692 jobs;
- Scottish Widows' Fund and Life Assurance Society, which creates 2 003 jobs;
- Standard Life Assurance Company, which creates 1 987 jobs.
- The leading French Mutual Benefit Society appears in 62nd place, i.e. M.A.C.I.F. (Mutuelle d'Assurance des Commerçants et Industriels de France).
- The leading Dutch Mutual Benefit Society is INTERPAIS N.V., occupying 67th position.
- A single Spanish Mutual Benefit Society: Asepeyo Mutua Patr De Accid De Trab. 151, up from 1 071 to 1 890 jobs.

#### Classifications available

Classifications of dynamic CMAs which are available on request are:

- a classification of the 500 most dynamic CMAs as per the D. Birch index;
- twelve classifications of the CMAs by country;

- three classifications according to whether they are cooperatives, mutual benefit societies or associations.

#### CLASSIFICATION OF THE LARGEST CMAs IN EUROPE

We have finally managed to take a census of 1 039 CMAs employing more than 500 equivalent full-time people. This information comes from our mail shots as well as from data banks which we have interrogated.

The motives and "cultural" behaviour behind the willingness to reply to financial questionnaires are fundamentally different from country to country.

We cannot therefore claim that the 1 039 sets of financial information which we received are exhaustive or even representative of the whole of the CMA population with more than 500 people which existed in the 12 countries of the EU in 1993.

Nevertheless, to our knowledge it is the most extensive study of its type carried out to date and therefore, bearing in mind our reservations, it can be considered as being the best and most faithful representation of the real situation in the world of the CMAs.

#### Analysis of the breakdown of employment in the CMAs

The 1 039 large CMAs have contributed a total of 2 077 356 jobs, i.e. an average of approximately 2 000 jobs per CMA. Let us recall that this relates merely to employment in the societies and that we have never taken into account employment in the group as a whole.

Based on the large CMAs only, the countries which take up most jobs are:

- France and UK with over half a million jobs each, i.e. one quarter of our sample each time;
- Germany with more than 430 000 jobs, i.e. over one fifth;
- Italy with 155 000 jobs;
- Spain, the Netherlands and Belgium with around 100 000 jobs in each country;
- Denmark with 60 000 jobs;
- Ireland and Portugal with over 20 000 jobs.

The 422 largest cooperatives account for 824 139 jobs which, in both cases, represents approximately 40 % of our total sample, which is a logical distribution, bearing in mind the fact that the cooperatives have 1 953 employees on average.

The countries are in relatively the same order as for all of the CMAs apart from Italy, which has a stronger presence, and France, which has fallen back:

- France, which now accounts for only 20 % of employment compared with 28 % for the bulk of the CMAs;
- Italy, whose share in employment moves from 7.5 % for the large CMAs to 14.2 % for the large cooperatives.

The 147 large mutual benefit societies represent less than 15 % of the CMA world, but the employment which they account for (338 338 people) pushes their share to 17 % of the sample because the average size of these large mutual benefit societies (2 302 people) is higher than the average for the CMAs.

The three large countries (France, the United Kingdom and Germany) are all better represented within the mutual benefit societies, since the three of them alone exceed nine tenths of the jobs in the mutual benefit societies of the sample, whereas these three large countries account for only seven tenths of employment for all the CMAs.

As far as the 470 large associations are concerned, it is seen that they are medium-sized consistent with the average CMA (1 946 employees) and that they represent 45 % of the sample both in terms of the number of CMAs and jobs. Again the three large countries (France, the UK and Germany) are over-represented.

### Analysis by country

The following are the main representative features of the various countries in our sample of large CMAs:

- France and Germany seem significantly more important within the large mutual benefit societies and associations than in the large cooperatives;
- The United Kingdom and Spain have a balanced presence within the three classifications;
- It is the large cooperatives above all which make up the bulk of employment in the large CMAs in Italy and in the Netherlands, whilst it is the associations which increase representation in Belgium.

The average size of the large CMAs differs significantly according to the country and these differences cannot be explained by the breakdown into CMA classifications:

- the large CMAs in the United Kingdom and the Netherlands on average employ more than 3 000 people, i.e. more than 50 % above the average of 2 000 jobs;
- the large CMAs in Italy, Portugal, Belgium and Luxembourg have less than 1 400 jobs, i.e. 30 % below the average;
- in the other five countries (France, Ireland, Germany, Denmark, Spain), the CMAs are of average size.

### Analysis of the breakdown of the CMAs by sector

Seven sectors of activity account for more than three quarters of the two million jobs of the large CMAs, namely:

- 337 402 jobs in the 146 credit institutions, each of which employs 2 311 people on average;
- 326 070 jobs in the 217 health institutions, which employ an average of 1 503 people;
- 265 124 jobs in the wholesale trade, retail trade or middlemen organisations, where 123 companies account for an average of 2 155 people.

Two other sectors each account for almost 200 000 jobs in our sample:

- other community services;
- insurance companies.

Two activities account for almost 100 000 jobs:

- agriculture and agri-foodstuffs;
- the construction sector.

### h. Descriptions of large groups and large CMAs

Among the 103 groups employing more than 500 people can be found:

- La Caisse Nationale de Crédit Agricole (France) with 73 750 people;
- The Co-operative Wholesale Society Ltd. (UK), comprising banking activities (Co-operative Bank Plc) which made over 3.5 billion £ in 1993 and has 40 200 employees;
- The Groupe des Banques Populaires (France) and its 25 805 jobs;
- Mondragon Corporación cooperativa (Spain), which is a diversified financial and industrial group employing 25 322 people in 1992 compared with 20 113 in 1987;

Figure 14: Average number of jobs per CMA by country

Source: SOFICATRA study

- The British United Provident Association (UK) or BUPA, with 10 000 people working in insurance and health-care;
- The Debeka group (Germany) with 9 000 people working in health insurance;
- Fagor (Spain) which creates 1 200 jobs, reaching a figure of 7 828 employees in 1992 particularly in the manufacture and marketing of domestic appliances;
- Eroski (Spain) with 6 938 people working in the distribution of foodstuffs and non-foodstuffs and which, like FAGOR, belongs to the Mondragon group;
- The Arco group (Belgium) whose banking and insurance activities employ 6 700 people;
- The commercial foodstuffs company, Kerry (Ireland) which started in 1974 from a small dairy cooperative and now, less than 20 years later, employs more than 6 250 people;
- The life assurance group IDUNA (Germany) which employs more than 6 000 people;
- Suiker Unie (Netherlands) whose industrial activities extend from the original sugar activity to include at the present time fruit and vegetables, spices and trade;
- Deutsches Jugendherbergswerk (Germany) where 4 000 people work in the travel sector and youth hostels.

As far as the CMAs themselves are concerned, we count 1 039 with more than 500 people. All of the top 100 CMAs each employ more than 4 000 people and if we had had knowledge about the groups in all these cases, we would certainly have counted even more jobs. The following can be quoted as among the large CMAs:

- the Rabobankorganisatie (Netherlands) which has created more than 6 000 jobs in 5 years, now has more than 36,000 and is continuing to expand in most of the large European countries;
- the commercial Co-operative FDB (Denmark) which owns different shop signs (Irma, Fakta, Merlin, Mac Coy) and employs almost 14 000 people. Its magazine, Samvirke, has 780 000 subscribers;
- the Konsumgenossenschaft Dortmund-Kassel (Germany) which basically markets foodstuffs and employs almost 12 000 people;

Source: SOFICATRA study

- the Schleswig Holstein commercial co-operative (Germany) has created more than 2 500 jobs in five years to give a total of 7 000 in 1992;
- Saracoop EG Pharmazeutische (Germany) whose wholesale and retail trade in pharmaceutical products employs more than 6 000 people in Germany;
- MD Foods Amba (Denmark) which exports more than half of its dairy products and employs 5 684 people;
- Vestjyske Slagterier (Denmark) which employs 5 777 people in its abattoirs and on its production lines;
- CEBECO Handelsraad (Netherlands) employs 5 500 people in the agri-foodstuffs sector (chemicals, garden products, fruit and vegetables, meat and eggs, etc.);
- Anchor Housing Association (UK) with 5 000 employees engaged in helping elderly persons to find accommodation and to look after themselves;
- Avonmore Foods (Ireland) employs 4 228 people in order to produce and market dairy products;
- Halifax (UK), the largest building society in the world with 5.5 million members and which is in the process of becoming a mutual insurance company;
- Groupama (France), the leading major French mutual insurance company specialising in agricultural insurance and reinsurance;
- Remploy Ltd. established after the Second World War to provide work for the disabled and the Association des Para-

Figure 15: Number of jobs in the largest CMAs

Source: SOFICATRA study

lysés de France which is the largest French association after the Red Cross;

- John Lewis Partnership Plc, which is a chain of department stores belonging to its employees;
- The MGEN (Mutuelle Générale de l'Education Nationale) which is the leading provident mutual association in France;
- Organisations such as the Max Planck Gesellschaft, the Fraunhofer Gesellschaft, the Marie Curie Memorial Foundation, which are active in the sphere of scientific research.

i. Main conclusions

After consulting 534 federations and various data bases, we sent out 5 314 questionnaires. We received over 2 000 replies, including 950 questionnaires which had been completed over several years.

This self-proclaimed survey of Cooperatives, Mutual Benefit Societies and Associations which decided to reply voluntarily to our call means we are able to draw four main conclusions:

- Two out of every three CMAs declare development projects which, in 80 % of the cases are in the EU countries;
- At least one CMA in three expresses a future financing requirement, which clearly shows that the lack of financial resources is one of the main factors slowing down expansion for numerous CMAs;
- The 600 CMAs which indicate an increase in their employment over the last five years have together created almost 120 000 jobs. In fact, this is equivalent to creating an average net figure of 30 000 jobs per annum. The CMA dynamic sample had 1 800 jobs in 1988 and 2 000 in 1992 (a 10 % rise in employment over 5 years, i.e. 2 % per annum);
- We have found over 1 000 CMAs with more than 500 people, which alone account for more than two million jobs in 1992.

On the basis of the replies we received, the world of the cooperatives, mutual benefit societies and associations therefore seems particularly dynamic in terms of expanding activities and creating employment.

By extrapolating from the results obtained, it is easy to imagine the inherent capacity for growth that the CMAs yet conceal, since the majority indicate that they still have numerous development projects which they would be unable to implement because of a lack of financial resources.

## SMEs and employment

### INTRODUCTION

For the last few years, Member States of the European Union have been expressing serious concern about the weak performances of the European economy. On the request of the Copenhagen European Council, the European Commission presented a White Paper on Growth, Competitiveness and Employment in 1993. The White Paper marked a turning point in the preparations of concerted action towards employment creation within the EU. The Commission has recommended the setting of a target to create 15 million jobs by the year 2000 to be able to halve the actual level of unemployment. In order to achieve this, a huge increase in economic growth is essential. However, that growth has to be accompanied by a high rate of employment intensity. Global competitiveness plays a crucial role in achieving such sustainable job-creating growth. The White Paper proposes a number of measures to be taken by the Community and the Member States to improve the economic environment for European enterprises and by doing so, increase their competitiveness.

Much attention has been given to the job-creating capacity of small and medium-sized enterprises (SMEs). A great number of international surveys and analyses on this phenomenon have been carried out by different institutions. Some argue that SMEs are the greatest potential job creators, whilst others question the sustainability of the jobs created because of the relatively low survival rate of new firms.

The purpose of this article is to provide an overall view of the relationship between SMEs and employment creation and the measures proposed and taken by the Community and Mem-

ber States. Firstly, the situation of employment in Europe will be described. Secondly, a brief outline of SME characteristics will be presented. Then we will examine the role played by SMEs in employment creation. Finally, we will conclude by looking at the measures proposed and taken by both the Member States and the European Union in the field of SME policy.

The information, in particular the statistical material, used in this article was mainly drawn from the following sources:

- The Third Report (volume 1 & 2) of Enterprises in Europe compiled by Eurostat (1994);
- The Second and Third Annual Report of the European Observatory for SMEs compiled by the European Network for SME Research (ENSR) (1994/1995);
- Employment in Europe 1994 compiled by the European Commission.

### EMPLOYMENT IN EUROPE

#### A high level of unemployment in the European Union

The most pertinent observation that can be made with reference to the employment situation in the European Union is the high level of unemployment across all Member States, particularly when compared with the Union's principal competitors.

Unemployment in the Union stood at 2.1 % in 1965. Since that time it rose consistently to a level of 10.8 % in 1985. Despite a considerable decrease in unemployment toward the end of the 1980s, unemployment has risen once more in the 1990s. The Union rate of unemployment increased from 8.3 % in 1991 to 11.2 % in 1994 (see Figure 1). Unemployment has also risen in Japan since 1990, but at a much lower rate than in the Union (2.5 %) due to Japanese companies' practice of job preservation. The rates of unemployment in the US and Japan in 1994 were respectively 6.1 % and 3.1 %.

#### Europe's employment rate now stands at less than 60 %

When considering the employment performance of an economy, the employment rate, (defined as the proportion of the population of working age in work), rather than the unemployment rate, often provides a more accurate reflection. A plurality of definitions exist for unemployment, itself a rather imprecise concept, such that a single accurate and comparable rate is practically impossible to find. For example, in the Union Labour Force Survey in 1992 the number of unemployed stood at 13 million whilst only 78 % of these people were actually registered as unemployed in the Member States. Comparisons of the employment rates indicate that Union performance on employment has not even come close to that of the US or Japan. The rate of employment in Europe has declined steadily since 1960 and is now less than 60 % of the population of working age, in sharp contrast to the US where

Figure 1: Community unemployment rate

Source: Employment in Europe

**Table 1: Breakdown of the change in employment according to size class in EUR16**

(%)	1988-1990	1990-1993	1993-1995	1988-1995
Micro	3.75	-0.5	-0.25	0.75
Small	1.75	-1	-0.25	0
Medium	1.25	-1.75	0	-0.5
Large	0.75	-1.75	0.25	-0.5

Source: European Observatory, Third Annual Report, 1995

it has steadily increased and now stands at over 70 %. The employment rate in Japan has remained stable in the 1990s despite poor output growth and equally exceeds 70 %. As for the EFTA countries, despite a higher rate of decrease in employment during the recession compared to the Union, the employment rate as a percentage of working age population remains significantly higher at 68 %.

**Low level of labour force participation of people of working age**

The European Union also differs from its main competitors with regard to the prospects for new entrants into the employment market - especially young people and women. Actual unemployment of young people stands (under 20 years old) at over 20 %, i.e. on average twice as high as that of adults (see Figure 2), in the EU compared to 13 % in the US and only 5 % in Japan. However, the situation confronting the Union is not only the high level of unemployment, but also the low level of labour force participation of people of working age, especially young people. Since 1960 the proportion of young people in or seeking employment has fallen sharply from 55 % to 30 % in the Union. The same trend, only to a greater extent, was observed in Japan, over the same period falling from 50 % to 20 %, but there has been little overall change in the US with the figure remaining around 40 % due to a higher participation of young women compensating for a lower participation of young men.

In May 1994 the Union unemployment rate of women stood at 13 % as compared to 10 % for men and is continuing to increase faster than that of men (see Figure 3). From 1960 to 1992 the rate of women's participation in the workforce increased from 30 % to just over 40 % only. In the US and Japan more equitable distribution of labour force growth has

been achieved between men and women. The participation of older people has also changed significantly in Europe in contrast to the US and Japan. In the Union there has been a substantial drop in the number of men over 65 remaining in the workforce compared to only a small decrease in the US and no change in Japan. Long term unemployment as a percentage of total unemployment reaches over 40 % in the EU as against 11 % in the US.

**Job creation performance of the European Union**

Between 1960 and 1990 for every 1 % rise in GNP in the EU employment growth of 0.12 % was achieved in contrast to the US, Canada and Australia where employment growth of between 0.56 % and 0.59 % was attained. In the Union the employment rate has followed the same path as the rate of growth of GDP - increases or decreases in GDP engendering respectively increases or decreases in employment. In the US the same general trend can be observed, but with larger fluctuations. There, the gap between output growth and employment growth has remained constantly smaller than in Europe enabling the US to sustain significant increases in employment for a given rate of GDP growth. However, if we look at Japan, a country that has experienced an even sharper overall drop in output growth than in the Union, employment numbers have continued to rise.

According to the European Commission the EU has failed to match Japanese increases in employment due to differences in the way that the given volume of employment is spread across the number of jobs and hours of work. Japan has attained a higher rate of employment through a narrower scale of distribution of revenues than the EU. It should be noted however, that the US has, in contrast, experienced a widening of the gap in the distribution of revenue through an increase in employment.

In general terms of employment growth the evidence clearly indicates that it is the same sector namely, services, in the Union, the EFTA countries, Japan and the US that has contributed the most to employment growth (see Figure 4). It should be noted that as SMEs account for much of the employment in the service sector in the Union the perception of SMEs as job creators is reinforced by this evidence.

**Decline in the Union's international competitiveness**

The high level of unemployment in the European Union is perceived as both the cause and result of the overall decline in the Union's international competitiveness. In national currency terms, there has been increase in Union nominal unit labour costs of nearly 7.5 % from 1970 to 1991. By contrast, the US has undergone a 4 % rise and Japan only 3 %. In addition, there are considerable differences between the Union, Japan and the US as regards employees' contributions and taxes on wages. In the Union these two charges together amounted to 20 % of labour costs in 1991, but in both the US and Japan they averaged only 10 to 15 %. Social security contributions are heavier on low incomes in eight of the Member States.

**Figure 2: Community unemployment rate - Total vs. Youth**

Source: Employment in Europe

**Table 2: Principal Member State actions in SME policy**

**Belgique/België**

- \* Introduction of a 'SME Barometer' to promote discussion on and generate ideas for SME policy.
- \* Increase in the availability and the amount of 'Overdracht Fonds' which facilitate enterprise transfer.
- \* Social security reforms e.g. reductions in employers' contributions.

**Danmark**

- \* Fiscal policy reforms - increase in public investment and tax reforms.
- \* Legislation on a state guarantee system available to private Development Companies (Udviklingselskaber) investing in promising SMEs.
- \* Introduction of a 'rebate card' offering start-up grants and advice to entrepreneurs.

**BR Deutschland**

- \* New legislation (Standortsicherungsgesetz) for SMEs allowing a reduction in corporate tax on profits.
- \* Reduction in income tax on business earnings and a provision for inheritance tax allowance.
- \* '30-Points-Programme' set up to consider the recommendations of the White Paper and to relaunch the 'Eigenkapitalhilfe Programm' to support start-ups.

**Hellas**

- \* Privatisation, tax and competition policy reform.
- \* Establishment of regional institutes providing support for medium-sized enterprises.

**España**

- \* Reform of the 'Reciprocal Guarantee System' to reduce the cost of guarantees.
- \* Introduction of subsidised loans available for investment purposes.
- \* Setting up of a 'Joint Venture Capital fund' by the 'Instituto de Crédito Oficial' for start-up firms.
- \* Easier SME access to the stock exchange, fiscal incentives and labour market reforms to increase flexibility.

**France**

- \* 'Plan Madelin' aimed at improving the economic environment of SMEs through fiscal reforms, easier access to credit, competition law reforms, easing of the burden of administrative procedures, promotion of inter-enterprise co-operation.
- \* Guarantee fund available to SMEs for investment purposes.

**Ireland**

- \* Network of 'County Enterprise Boards' established to support SMEs.
- \* Further development of the 'Business Expansion Scheme' to include tax relief on corporate gains.
- \* Introduction of a 'Seed Capital Scheme' to indirectly support start-ups with income tax advantages for entrepreneurs.

**Italia**

- \* Launch of 'Interventi per l'innovazione e lo sviluppo delle piccole imprese' with tax allowances and direct subsidies for SMEs. The eight sub-programmes of this scheme provide support for SMEs in such areas as R&D, loan guarantees etc.

**Nederland**

- \* Creation of a plan 'Meer werk, weer werk' to improve market flexibility.
- \* Improved access to subsidies for R&D costs.
- \* Development of apprenticeship schemes.
- \* Current investigation into the potential for easing taxation on SMEs.

**Portugal**

- \* 'Intercalary Programme' to facilitate SME access to finance, improve efficiency and foster growth.
- \* 'PEDIP II programme' - incorporates numerous aid measures for SMEs.
- \* Variety of support programmes to promote export and international trade.
- \* 'FRIE fund' to promote equity participation.

**United Kingdom**

- \* Establishment of 'Business Links' to foster co-operation and improve competitiveness.
- \* Improvement of 'The Small Enterprises Loan Guarantee Scheme' with an increase in the amount of loan available.
- \* Introduction of the 'Enterprises Investment Scheme' to improve access to equity funding.
- \* Provision for tax relief for those investing in unquoted companies.
- \* Creation of the 'Uniform Business Rate' which involves a reduction in the tax and social burden of SMEs.

**European Commission target of creating 15 million jobs**

Just to keep Union unemployment stable an annual rate of increase of 0.5 % in employment is needed to compensate for the predicted 0.3 % rise in population of working age and estimated 0.7 % increase in participation. This implies that 5 million jobs will have to be created between now and

the year 2000 just to prevent any increase in unemployment. In order to attain the European Commission target of creating 15 million jobs between 1995 and 2000 to halve the level of unemployment a constant annual rise in employment of 2 % will be required. Certainly an ambitious target as it means outperforming the US economy between 1974 and 1990 when an average annual increase of 1.9 % was recorded. It is en-

**Figure 3: Community unemployment rate - Men vs. Women**

Source: *Employment in Europe*

visaged that this target increase in employment can be achieved if the Union is capable of combining a sustained annual economic growth rate of 3 % with an increase in the employment intensity of growth of at least 0.5 %.

#### The economic prospects of the Union have improved in 1994

The economic prospects of the Union have improved in 1994. In May 1995 the Commission forecast economic growth rates of 3.1 % for 1995 and 2.9 % for 1996 for the 15 Member States. This, however, does not in itself guarantee the targeted increase in employment. It is further predicted that employment will stabilise in 1995 at 18 million unemployed (or 11.6 % of the active population). Economic and social policies must be geared towards the long term in order to restore public

**Figure 4: Sector contribution to employment growth, 1970 to 1991**

Source: *Employment in Europe*

confidence and create jobs. There is a danger that, in the absence of new structural measures for employment creation, economic growth will not translate into higher employment, but will only offset productivity gains. These challenges must largely be taken up by the Member States although the European Union can, and indeed, must play a role.

#### SMEs ON THE THRESHOLD OF THE NINETIES

##### Diverging definitions for SMEs pose the risk of incoherence

The recognition of the importance of the SMEs has been stressed by the creation of a great number of actions in favour of SMEs, at Community as well as at national level. These actions use different definitions based on different criteria such as employment, turnover, balance sheet total and the degree of financial autonomy. The maximum number of employees, for instance, falls within a range of 50 to 500. These differences can cause incoherence between community and national policies. In order to minimise the risk of incoherence, the Commission is preparing, on the request of the 'Research' Council of 29 September 1994, a recommendation to Member States and a decision preparing a single definition for SMEs. This recommendation would set the employment threshold of the definition at 250 employees.

For the purposes of this article, the definition used until now by Eurostat and the European Observatory will be applied, unless otherwise specified. Therefore, the enterprises referred to in this article - all private enterprises except those in agriculture, hunting, forestry and fishing - will be divided in the following categories:

- micro-enterprises: less than 10 employees;
- small enterprises: between 10 and 99 employees;
- medium-sized enterprises: between 99 and 499 employees;
- large enterprises: more than 500 employees.

Where necessary a more detailed subdivision will be used.

##### SMEs outnumber large enterprises in number of enterprises and employment

There are about 15 million enterprises in the Community, employing 92 million people. SMEs account for 99.9 % of the total number of enterprises and almost 80 % of the employment. The share of micro enterprises outnumbers all others in both number and employment terms: 93.3 % of all enterprises are micro providing 31.8 % of total employment. Small enterprises account for 6.2 % of the total number of enterprises and have a share in employment of 24.9 %. Medium-sized enterprises are the least numerous of the SMEs: 0.5 % generating 15.1 % of the total employment. The large enterprises, however, show a relatively large share in employment: 28.1 % provided by only 0.1 % of the total number of enterprises in the twelve Member States (see Figures 5 and 6).

##### No positive correlation between the share in total number of enterprises and total turnover

When comparing the share in turnover by enterprise size, the most striking observation that can be made is that there is no apparent positive correlation between the share in the total number of enterprises and the share in total turnover. It can be derived from Figure 5 that a significant number of micro enterprises account for only 23.4 % of total turnover, whereas a very small number of large enterprises generate a share of 30.6 % in total turnover. It also becomes clear that medium-sized enterprises outperform micro and small enterprises, considering that one fifth of total turnover is generated by only half a percent of all enterprises (see Figure 5).

## SMEs highly represented in a large number of sectors

As mentioned before, the majority of employment growth during the period of 1970 to 1991, occurred in the service sector. In order to estimate the effects on SMEs caused by growth or decline of the different sectors, one has to examine the share of SME dominance within these sectors. In nearly all sectors, the majority of the enterprises are SMEs. There is, however, a significant dominance of either SMEs or large enterprises in certain sectors. Figure 7 shows the dominance of micro enterprises in the retail distribution and personal services sectors. Micro and small enterprises together represent a dominant position in the construction and wholesale sectors. The extraction and manufacturing sectors, together with the transport and communication sectors, can be described as large enterprise dominant sectors. This dominance is mainly due to very large-scale activities. Although the producer services sector (that is, services not particularly oriented towards the general public, but towards businesses, such as communication, supporting services to transport, R&D and so on) is dominated by large enterprises, micro enterprises account for a relatively large part of that sector.

## Enterprise sizes differ remarkably among Member States

The average enterprise in the Community employs 6 persons (including the entrepreneur). However, there are remarkably big differences in enterprise size among individual Member States. Enterprises in the southern countries are generally smaller than the ones in the northern states. This can partly be explained by the effects of per capita GDP and population density. The average enterprise size is positively correlated to per capita GDP. The reason for this could be the fact that higher GDP leads to an increase of demand and thus of the enterprise size. Figure 8 shows that, generally speaking, countries with a relatively high per capita GDP (e.g. Germany, Luxembourg and The Netherlands) have a higher average enterprise size. There is also a positive relation between population density and enterprise size. Especially in the distribution and personal services sectors, a high population density (e.g. in Denmark, Luxembourg and The Netherlands) causes an increase of the local demand and thus of the size of enterprises providing services within a certain area.

**Figure 5: Breakdown of number of enterprises and turnover according to size class, EUR 12, 1990**

Source: Eurostat/EIM

## EU is more oriented towards SMEs than the USA, Japan and EFTA countries

In order to make a comparison between the European Union, the United States and Japan, size-class 0 (self-employed category) has to be omitted. This omission will of course mean that the data shown here below (see also Figures 9 and 10), will diverge from that already shown above. The share of enterprises in the size-class 1-10 employees, is 84.7 % in the former twelve Member States as opposed to 77.1 % in the US. This size-class accounts for respectively 24.3 % and 12 % of the share in employment. The share of small firms is 14.1 % in the Community and 20.5 % in the US, accounting for respectively 27.8 % and 26.9 % of employment. No remarkable differences were found in the medium size-class: 1 % of Community firms belong to that band against 1.7 % of the US enterprises. Their share in employment differs not so much either: respectively 16.5 % and 14.5 %. Both the Community and the US show the largest share of employment in large enterprises: the 0.2 % and 0.7 % share of enterprises provide respectively 31.4 % and 46.6 % of the jobs. The average enterprise size in the former twelve Member States is 12.3 employees (double the aforementioned size, due to the exclusion of the self-employed category) and 18.4 employees in the US.

Although there is a lack of comparative material for Japan, it is still possible to depict an overall structure of its size distribution. Like the US, Japan shows an emphasis on medium and large sized companies (see Figure 11). Japanese micro enterprises account for 70.4 % of the total number of enterprises which is a relatively small share compared to the Community and even to the US. The 12.8 % share of Japanese enterprises with 20 to 99 employees, however, outnumbers both the US 9.3 % and the European 12.5 %.

The 1988 statistics show that 98 % of the total number of half a million enterprises in the EFTA countries (excluding Switzerland) are SMEs, which is significantly less than the 99.9 % of the twelve Member States of the Community. The average firm size in the non-primary private sector is 12 employees which is twice the Community average. This can partly be explained by a higher level of labour costs and per capita income in the EFTA countries. It becomes clear that the EFTA countries are less oriented towards micro and small enterprises than the Community. Only 43 % of employment is generated by micro and small enterprises as against 55 % for the Community. The share in employment of medium sized enterprises shows no significant difference, whereas the large firms in the EFTA countries account for a relatively large share in employment.

## THE ROLE OF SMEs IN EMPLOYMENT CREATION

### Controversy about the job creating capacity of SMEs

The net job creation potential of SMEs has prompted much controversy both at EU and international level. Recently, their contribution to employment has been questioned. This has resulted in the production of a number of studies. One of the first initiators of the debate was Birch (1979), who stated that during the period 1969 - 1976 in the US, firms with less than 100 employees accounted for 82 per cent of job creation. As concluded in Employment in Europe, small firms do account for many of the new jobs created, but due to the lack of reliable and consistent data, it is difficult to quantify their importance in employment growth. Therefore, it is necessary to recognise that SME research is faced with a number of data deficiencies, which may lead to misinterpretation and inaccurate depiction of the role they play in employment creation.

### Statistical data on SMEs are often unavailable and incomparable

The issue of diverging definitions of SMEs in both Member States and the EU has already been discussed in part 2 above. SMEs are also faced with the disadvantage of the availability of data which varies between Member States. Although most of the official data is received from the national statistical institutes, there are occasions when missing information must be estimated or obtained from other data sources. Data can also differ in the nature of population and sector coverage, the reference years and methods of computation.

### Widespread criticism of the studies conducted by Birch

As mentioned above the first studies conducted on employment change were performed by Birch in 1979, exploiting data collected by the American credit rating company Dun and Bradstreet. His headline statement, claiming that more than two-thirds of all jobs created between 1969 and 1976 in the United States came from firms employing less than 20 persons, was widely scrutinised and subsequently widely criticised. The main criticisms levelled at Birch's work were as follows. Firstly, it was argued that Birch's use of net job change as a measure of employment change was inappropriate, gross new job creation (i.e. the number of jobs created and excluding the number of jobs lost) provides a more accurate picture. Secondly, there was some confusion as to whether his data was based on establishments and enterprises rather than enterprises alone. A third criticism was made by Armington and Odle in 1982 who found that due to the numerous assumptions made by Birch in his research they were unable to replicate his results. Finally, it was alleged that the data supplied by Dun and Bradstreet was not sufficiently "clean" for the analytical purposes to which they were put as, for example, firms remained on the data base even after they had ceased trading.

### More careful analyses in US and UK produce more reliable results

In order to address these criticisms levelled against Birch and in an attempt to produce more reliable results the US Small Business Administration conducted an extensive rework of the Dun and Bradstreet data. Their results showed that between 1976 and 1988 American small firms employing less than 20 persons accounted for 19.4 % of total employment and approximately 37 % of net employment change. Although this figure is well removed from Birch's figure of 82 %, this

undoubtedly reflects the more careful analysis over time conducted by the Administration.

The Administration further concluded that small firms contribute more to job creation than large firms when the rate of new job change is lower and, conversely, large firms perform better than their smaller counterparts when the rate of new job change is higher. This would therefore suggest that small firms are more consistent creators of employment irrespective of the prevailing macroeconomic conditions, whereas large firms respond essentially only to fluctuations in the economy.

We can draw some broad comparisons between the Administration's results and the situation in the United Kingdom thanks to a further analysis undertaken by Colin Gallagher et al., using the Dun and Bradstreet files. UK data and the same methodology as the Small Business Administration. Gallagher and his colleagues noted broadly similar results in the UK, with 54 % of the increase in employment between 1987 and 1989 generated by firms with less than twenty employees who accounted for 32 % of base year employment. This supports the conclusion that small firms provide a disproportionately high share of new job creation.

### Employment growth in Community SMEs

The European Observatory in its Third Report also noted positive results with regard to employment growth in Community SMEs from 1988 and 1995. During this period SMEs experienced an average annual increase in employment of 0.25 %, whereas LSEs displayed an average annual decrease in employment of 0.5 %. The data used for these conclusions has been drawn from Enterprises in Europe. By merging existing data, estimations could be made in order to fill the lack of material for some countries. The Observatory also uses the 'SME in Europe Accounting Scheme' which derives the development of employment by size-class from turnover developments and from wages and prices.

### David Storey concludes that small firms are more consistent job creators than large firms

In "Understanding the Small Business Sector" (1994) Storey concluded that small firms in both the US and the UK created jobs faster than large firms in the 1980s, and furthermore, that small firms are more consistent job creators than large firms because they are less affected by macroeconomic factors. However, he did stress that these affirmations were subject to several provisos. Firstly, the research that generated these conclusions was not wholly "clean". The data used for the first half of the 1980s lacked precision and were subject to political bias. It was only towards the end of the decade that reliable data became available. Secondly, although small firms have in the past proved to be significant job creators it would be entirely inappropriate to direct resources away from large firms and concentrate solely on their smaller counterparts. This argument is reinforced by the observation that, due to the extensive practice of outsourcing by large firms in the 1980s, SMEs cannot be always considered as independent motors for employment growth. Moreover, it is important to recognise that job creation in SMEs is often the result of productivity gains (often realised at the expense of employment) in large firms which through economic growth engender employment growth for SMEs in the service sector. As this is a natural process no policy implications are presented.

Throughout the 1980s so much attention was placed on quantifying the job creation potential of SMEs to the extent that the issue of the quality of the jobs created fell into obscurity. The research undertaken indicates that certain elements of jobs created in SMEs are less attractive in comparison with large firms. For example, wages tend to be lower, fringe benefits are less frequently offered and training is provided less often. However, it is important to note that, in certain areas, the quality of jobs provided by SMEs can be considered as higher than those provided by large firms as the individual

Figure 6: Breakdown of employment according to size class, EUR 12, 1990

Source: Enterprises in Europe

**Figure 7: Breakdown of employment according to size class and SME dominated sector, EUR 12, 1990**

Source: ENSR

employee of an SME may have wider responsibilities than in a large firm. Moreover, SMEs tend to be less unionised than large firms and there is often more workplace harmony and higher job satisfaction.

"The small firm sector is seen to be the way in which the local economy can create its own employment by pulling itself up by its own boot-straps"

Returning to the observation made by the US Small Business Administration that small firms are more consistent job creators than their larger counterparts who are more susceptible to fluctuations in the economy, we can find an explanation of this phenomenon in "Understanding the Small Business Sector". Storey states that "where major job shedding takes place, the small firm sector is seen to be the way in which the local economy can create its own employment by pulling

itself up by its own boot-straps". He notes that when a large employer shuts down redundant workers turn to the small firm sector for employment. The former unskilled workers turn to self-employed work as taxi-drivers, window cleaners, etc. and the skilled workers, computer experts, draughtsmen, etc., often set up independently in their own fields.

**Upward trend in the employment share of SMEs**

The European Observatory for SMEs in its Second Report advanced a number of arguments to explain the upward trend in the employment share of SMEs. Firstly, they point to the increasingly important role played by innovation in the 1980s and 1990s. SMEs have during this period benefited immensely from the process of innovation in infant industries, a sector that they dominate. The availability of new computerised technology engendered the creation of new SMEs. A second factor highlighted is the change in consumer taste experienced since the 1970s. Consumers have demonstrated an increased demand for specialised products as opposed to mass produced goods. SMEs can respond with greater flexibility to rapidly changing consumer preferences and ever shorter product life-cycles than larger capital intensive firms. It should be noted at this point that the increase in SME job creation may reflect the structural shift of employment from goods to services. The fast growing service sector creates more jobs in SMEs in particular due to their dominance in that sector (see Figure 7). A third argument presented in the Observatory concerns government SME policies, whereby government intervention in recent years to redress the perceived discrimination against smaller enterprises has brought more flexibility for SMEs through an easing of taxation and social obligations. Furthermore, it is maintained that the post-war baby-boom may well have led to the creation of new enterprises due to the associated increase in the labour supply accompanied by a stagnation in the growth of real wages.

Finally, it should be remembered that in any consideration of the job creation potential of SMEs, or of any size of firm for that matter, that it is not simply about the amount of jobs created or even the quality of those jobs created. To ensure that job creation ultimately leads to a reduction in unemployment, the jobs created must be capable of being filled by the unemployed.

**Figure 8: Average enterprise size, 1990**

Source: ENSR

**Figure 9: Breakdown of employment according to size class, 1990**

### The size distribution fallacy

As reported in *Employment Outlook* (OECD, 1994) a number of statistical biases tend to distort the contribution of firms, whether they be large or small, to job creation. One of the statistical problems is the size distribution fallacy. This issue is described in the study "Gross job flows in US. Manufacturing" (1994) by Davis, Haltiwanger and Schuh (henceforth Davis et al.). They examined the manufacturing employment changes in the US during the period 1972 - 1988. A distortion of the picture on sources of net growth is caused by the fact that as firms grow or decline they cross size boundaries. For instance, if an enterprise that employs 450 persons expands such that it takes on a further 100 employees it crosses the boundary from the medium size category to large size category. As a result, the LSE sector will gain 550 jobs with a new large sized enterprise, whereas the SME sector will have a loss of 450 jobs. Regardless of the fact that the overall net job gain is 100, such shifts distort the indication of whether job creation occurs through SMEs or larger firms. Davis et al. note that, especially during periods of sustained economic growth, upsizing of small firms into large ones is a common phenomenon. Conversely, during periods of slow employment growth, downsizing of large firms into small ones is likely to occur quite often, creating the appearance of a booming small-firm sector.

At this juncture it should be noted that some recent studies have shown that the work of Davis et al., while theoretically correct, may have overstated the effect of the size distribution fallacy. In his study "Small enterprises as job creators - Myth or Fact?", Davidsson shows that less than two out of one hundred enterprises in Sweden actually appear to cross size boundaries, which implies that the size distribution fallacy would only account for an error margin of 2 % in Swedish enterprises and thus be empirically virtually irrelevant. Unlike Davis et al., Davidsson included the smallest enterprises of the band of 1 to 4 employees. This allows a more precise view on job creation by SMEs, taking into account the importance of micro enterprises in the Community. Furthermore, a Canadian study on the manufacturing sector performed by Baldwin and Picot, using the same type of analysis as Davis et al., came to the conclusion that, irrespective of the weightings system chosen, small enterprises outperformed large enterprises in job creation. Finally, the European Observatory in its Third Report underlines the fact that the size distribution fallacy does not per se "benefit" SMEs, as the direction of

the bias is statistically accidental. Moreover, it developed a method which allowed to compensate for the size distribution fallacy, using a combination of several methods for analysing longitudinal data (see below).

### The need for a longitudinal database

A number of statistical deficiencies can be addressed with an analysis of longitudinal data on individual enterprises. Time series information will enhance the understanding of many aspects of the performance of firms. Following the individual employers through time results in the elimination of questions arising from the crossing boundaries by growing SMEs or downsizing large enterprises. However, Davis et al. argue that longitudinal studies that focus on the share of net job growth accounted for by small businesses grossly misrepresent the actual distribution of newly created jobs by size of the employer. In their opinion a more meaningful way to represent this distribution is to focus on the small-employer share of gross job creation. The Observatory states in its Third Report that the use of longitudinal datasets alone is not free from bias because they ignore natality and mortality of businesses. Nevertheless, the use of this instrument as one out of several analytic tools is recommended.

The development of a European Longitudinal database has been initiated by Eurostat within the framework of the evaluation of the impact of the Internal Market which will be presented in 1996. The main evaluation models of this pilot project are essentially based on job creation and destruction, competitiveness and growth. By following a sample of enterprises in the former twelve Member States, changes in economic performance can be measured at the level of individual enterprises. Furthermore, progress in the field of SME data collection has already been made by Eurostat. The Commission SME Project introduced by Enterprises in Europe intends to establish a biennial 'tabular data' component and 'SME indicators'. The collection of 'tabular data' concerns the figures on four variables: the number of enterprises, the number of persons employed, turnover and value added at factor cost. These figures are broken down by sector of activity and enterprise size in terms of employment. The 'SME indicators' component is still at an experimental stage. The aim is to create short term indicators on SMEs such as the number of enterprises set up or closed down and a short term indication of number of persons employed, turnover, value added and investment. In order to prevent an increase of administrative burden for SMEs by launching additional surveys, Eurostat seeks to collect data from national registers and surveys that already exist.

A longitudinal study on a sample of Dutch businesses over a period of 5 years, is presented in the Third Report of the Observatory. After comparing five different methods of analyses it is concluded that the most accurate way to assess job creation, is to use longitudinal data on enterprises and using average employment as the base year for the computations. By using this method plus a correction for the net crossing of the size boundary, the Observatory seems to have eliminated the size distribution fallacy and mastered other methodological pitfalls.

### MEASURES TO ASSIST SMEs IN EMPLOYMENT CREATION

#### The challenge facing the European Union

The challenge facing the European Union in the 1990s was highlighted in article 2 of the Treaty establishing the European Community as amended by the Treaty on European Union signed in Maastricht that defined the following objective:

"To promote throughout the Community a harmonised and balanced development of economic activities, sustainable and non-inflationary growth respecting the environment, a high degree of convergence of economic performance, a high level

of employment and social protection, the raising of the standard of living and quality of life, and economic and social cohesion and solidarity among Member States."

The European Commission has repeatedly emphasised that economic growth alone is not enough to create the amount of jobs required, and that urgent action is required by the Member States on jobs. Following the publication of the White Paper on Growth, Competitiveness and Employment, the European Council of Brussels made seven recommendations to Member States in 1994 as follows:

- to improve education and training systems, especially further training;
- to improve the flexibility within enterprises and on the job market;
- to reorganise work within enterprises;
- to implement targeted cuts in the indirect costs of the work force (compulsory contributions), especially for non skilled workers;
- to make better use of public money intended to combat unemployment;
- to adopt specific measures geared to poorly trained young people;
- to develop employment taking account of new needs.

### Commission action on employment for SMEs

With special reference to SMEs, the Commission's Integrated Programme in favour of SMEs and the Craft Sector (COM (94) 207) established in 1994 aims to improve the administrative and legal environment of SMEs, in recognition of the fact that SMEs are widely perceived as new job creators. To promote a sustainable growth in industry, one of the requirements, as noted by the Commission, is to "underpin the dynamism" of SMEs. The need for this Integrated Programme became apparent from both the economic assessment contained in the White Paper and from the Council Resolution of 22 November 1993. The Integrated Programme finds its legal basis in article 130 of the Treaty on European Union whereby:

"The Community and the Member States shall ensure that the conditions necessary for the competitiveness of the Community's industry exist. For that purpose, in accordance with a system of open and competitive markets, their action shall be aimed at ... encouraging an environment favourable to initiative and to the development of undertakings throughout the Community, particularly small and medium-sized undertakings ... "

The Integrated Programme aims to assemble all existing and new initiatives derived from the objectives outlined in the White Paper within a more coherent framework. Its innovative approach lies in its provision for closer partnership between all parties concerned with the development of SMEs - at Community, national and regional levels - in order to achieve greater convergence of measures proposed and adopted. The Programme therefore provides for two different types of measures:

- concerted actions i.e. measures to promote mutual consultation and co-ordination between Member States;
- contributions the Union intends to make to the development of SMEs with its own policies.

The concerted actions relate first of all to the improvement and simplification of the business environment with a view to reducing burdens on businesses and unlocking their potential to create jobs. To this end a committee to improve and simplify the business environment was set up in December 1994 with the task of identifying best practices in the simplification of business formalities and the improvement of the legislative framework of businesses. The second field targeted by con-

**Figure 10: Breakdown of number of enterprises according to size class, 1990**

Source: *Enterprises in Europe*

certed actions concerns support measures for businesses at national and regional levels. In this context, the Commission has proposed the creation of concertation forums to stimulate exchanges of best practices between Member States in terms of support provision for SMEs.

The Commission is organising two major conferences which will take place in June and September 1995 with participants from all Member States, government representatives, SME representatives and SME entrepreneurs. The conferences aimed at start-up and young businesses will deal respectively with measures to improve and simplify the business environment through an exchange of best practices and with support measures for SMEs.

The contributions of the Union to the development of SMEs relate to action taken specifically within the framework of enterprise policy and other Union policies. The Commission has presented several proposals for action concerning the improvement of the business environment which should benefit SMEs. In 1994 the Commission produced a number of recommendations addressed to the Member States with the intention of improving the legislative and fiscal environment of SMEs. By highlighting existing best practices in the Union the Commission hopes to inspire Member States who may be lagging behind and encourage them to adopt the appropriate measures. These recommendations concern the taxation of SMEs, the transfer of enterprises from one generation to the next and late payments in business transactions. With reference to improving the financing of SMEs a number of advances were made in 1994. Firstly, the interest subsidy mechanism for the European Investment Bank global loans available to SMEs was implemented in twelve Member States. This mechanism was introduced to reduce the cost of access to credit and to increase the amount of loans for job creating SMEs. Secondly, three SME specific projects with Community funding of 150 million ECU were approved last year within the framework of the European Investment Fund. These projects will assist SMEs in accessing bank loans through the provision of guarantees.

With regard to support measures for SMEs the Commission has introduced new instruments and programmes directly geared towards SMEs. In order to encourage collaboration between both large and small enterprises, the Commission has conceived European networks such as BRE (Bureau de Rapprochement des Entreprises) and BC-Net (Business Co-operation Network). The Commission also assists SMEs

**Figure 11: Breakdown of number of enterprises according to number of employees, Japan, 1991**

Source: *Enterprises in Europe*

through EURO INFO CENTRES, a business information network, EUROPARTENARIAT and INTERPRISE programmes for sub-contracting, and pilot schemes such as EUROMANAGEMENT, Venture Capital and Commerce 2000 aimed at improving SME management, financing and know-how.

The ADAPT Community initiative was conceived in conjunction with the SME Community initiative to address the need identified in the Integrated Programme to improve the quality of SME management. With Community funding of 1400 million ECU, it will assist the work force through vocational training and the development of new jobs and activities to adapt to industrial changes largely brought about by the implementation of the Single Market. The SME initiative, benefiting from an appropriation of 1 billion ECU, is designed to assist SMEs in the manufacturing and services industries. Support is provided in particular to under-developed or changing regions to enable SMEs to take up the challenge of the Single Market and become more internationally competitive through improvements in co-operation, financing and management of SMEs.

Finally, the Commission action plan following the Bangemann Report on the Information Society was adopted in September 1994. The plan makes specific reference to SMEs to raise their awareness - and thus their demand - for the new concepts, products and services brought about with the onset of the Information Society in fields such as telematics and teleworking.

### Progress to date

Within the last few years all Member States have undertaken reforms to their employment systems. For instance, current efforts abound on the part of the Member States to stabilise or reduce the cost of statutory labour charges as a proportion of GDP. Upon closer examination of recent Member State SME policy two distinct trends become apparent. Firstly, in all Member States the focus of recent attempts to stimulate job creation via SMEs has been in supporting start-ups and existing enterprises with financing and improved access to R&D. In the majority of Member States there is also an increasing emphasis in SME policy placed on alleviating current constraints. For example, tax reforms to facilitate enterprise transfer are widespread. Secondly, a wealth of new programmes, financial schemes and measures for SMEs has been introduced in order to foster growth, employment and com-

petitiveness. For a short summary of the main actions taken in SME policy in the Member States subsequent to the publication of the White Paper refer to Table 2.

However, in the Commission's view, the Member States have not gone far enough to meet the challenge of employment in the 1990s.

The White Paper emphasises the need to widen the access to the job market and to create a new spirit of utilising productivity gains to create new jobs as opposed to simply raising the income of those already in employment. Furthermore, progress must be made in the area of equal opportunities with higher participation of women. More attention must be accorded to promising new sectors with high potential for employment creation. The Commission stresses that the Union must maximise its capacity to create and maintain non-skilled and semi-skilled jobs and facilitate job creation by lowering the relative cost of non-skilled and semi-skilled workers. Studies show that reducing the social security contributions of low wage earners would engender a rise in employment of 2 %.

The Commission has called for a more coherent national and European framework for action to be put in to place in order to realise the job creation potential in 17 key areas. In this context four proposals designed to encourage local development initiatives were submitted to the Council of Essen. The proposals concern actions with regard to creating a local framework favourable to development and employment initiatives, to the implementation of a range of financial instruments for local development, to adapting training and education with a view to guaranteeing new jobs, and to renewing the legal framework. The 17 key areas identified as having a high potential for employment creation, in that they are sectors that correspond to the current and future needs of European citizens, are as follows: domestic services, child minding, new information and communication technologies, assistance for young people experiencing difficulties in social integration, improvement of housing, security, local public transport, revaluation of urban public spaces, local shops, tourism, audiovisual technology, cultural heritage, local cultural development, rubbish management, water management, protection and upkeep of areas of natural beauty, and control and regulation of pollution and polluting installations.

However, despite the recent efforts of Member States to modify their employment policies, a fragmented approach still pervades with complex national regulations still in force in many Member States. The reforms implemented to date still appear incomplete and hence the global effect is difficult to evaluate. Considerable progress is still required at enterprise level namely, simplification and harmonisation of market regulations across the Union, better provision of information for SMEs to benefit from the advantages of the Single market, promotion of the information society. To guarantee the adoption and implementation of further reaching reforms, greater public awareness and acceptance of the short term adjustments will also be necessary. Inter governmental co-operation has to be seen as one of the first priorities here. A detailed examination of the workings of the different national systems would enable the spread of best practice in employment creation.

### Future role of the European Commission

The Commission will continue to support the Member States in adopting the solutions proposed by the White Paper. Work will continue on the elaboration of a medium term plan for employment in co-operation with the Member States with the involvement of all Commission directorates concerned with employment. The Commission also proposes to extend its annual reporting on employment issues in order to evaluate the impact of current economic policies. Better comparative statistics on the structure of employment will be sought in

co-operation with the Member States. The European employment service EURES, set up to assist job seekers throughout Europe, will be developed. Furthermore, the Commission will continue to assess the usefulness of employment aid programmes and will also examine the impact of Union and national employment legislation on employment. In 1995 a series of new community initiatives (ADAPT, EMPLOYMENT, and the second phase of LEADER) will be launched.

## CONCLUSION

The need to improve structural employment growth and the competitiveness of European businesses is widely recognised. Many steps have already been taken at both Community and national level in order to increase the job creating capacity of European enterprises. A great number of support measures are aimed at small and medium-sized enterprises which account for the largest share of both the total number of enterprises and employment. The current absence of a single and clear definition for SMEs, however, can result in inconsequential and discriminatory implementation of these support measures. It is therefore important to determine a single definition for SMEs within a short period of time.

There has been a lot of debate about whether the contribution of SMEs to job creation is correctly estimated. Numerous international surveys have been dedicated to this issue. However, the European Observatory seems to have found a method using longitudinal data plus a correction of the net effect of crossing size class boundaries that avoids methodological pitfalls. It concludes in its Third Report that, "despite the validity of methodological criticism of studies alleging a dominant role for small enterprises in the job generation process, implying that the job creation prowess of SMEs is overstated, prevailing evidence shows that SMEs still out-perform LSEs with regard to job creation".

# Reviews and Forecasts: Industrial Sectors

## Overview

NACE 11, 12, 13, 14, 15, 16

In 1993, inland primary energy consumption in the EU totalled just under 1.2 billion tonnes of oil equivalent (toe), a level of consumption almost unchanged from the previous year. The EU was 50 % self-sufficient in energy supplies, mainly due to North Sea production of oil and gas, gas production in the Netherlands and coal production in the United Kingdom, Germany and Spain. The United Kingdom contributes over 33 % to EU primary energy production.

The primary energy mix is still dominated by oil, which accounts for almost 44 % of gross inland primary energy demand. Natural gas consumption is increasing fast. By the year 2000, gas is expected to account for about 23 % of EU primary energy requirements, from 16 % in 1993, overtaking coal to become the second largest energy source in the demand mix. Over this period coal's share is expected to drop from 20 % to 18 % of EU primary energy consumption. A rising share of coal consumption will be met by imports, as the coal industries of Germany, Spain and the United Kingdom are phased down.

The energy sector is at the heart of the current debate on environmental issues and policy. Strategies to reduce the threat of global climate change, and to reduce other harmful emissions depend largely on the level of energy demand, the fuel mix, and the quality of fuels burned. The implementation of some of the measures proposed to reduce harmful impacts on the environment could have significant consequences for the energy industry over the next decade.

### INDUSTRY PROFILE

#### Description of the sector

The activities covered by the energy industry in the EU are classified according to the following standard NACE classifications: extraction and briquetting of solid fuels (NACE 11); coke ovens (NACE 12); extraction of petroleum and natural gas (NACE 13); mineral oil refining (NACE 14); nuclear fuels industry (NACE 15); and the production and distribution of electricity, gas, steam and hot water (NACE 16). These activities are dealt with in the following specific chapters:

- Solid fuels (covering NACE 11 and 12)
- Exploration and production of crude oil and natural gas (covering NACE 13)
- Nuclear fuels (covering NACE 15)
- Refining and distribution of oil products (covering NACE 14)
- Electricity generation and distribution (covering NACE 161)
- Transmission and distribution of natural gas (covering NACE 162)

In addition, a description of the renewable energy industry (not defined by NACE) is given. For the purposes of this chapter renewable energy includes small-scale hydro, wind, biomass, tidal, and waste incineration. Large-scale hydro is included in the chapter on electricity generation and distribution.

The following conventions and definitions are extensively used. Energy consumption is referred to at two different levels

**Figure 1: Energy**  
Fuel shares of primary energy demand, 1993

Source: DRI Europe

- primary and final. Primary energy consumption refers to the sum of all energies either used by consumers or used as an input to the production of other energy forms. For example, the production of electricity requires the input of such fuels as coal, natural gas and heavy fuel oil. Gross inland energy consumption refers to primary consumption of fuels for inland uses, i.e. excluding marine and aviation transport fuels. Final energy consumption refers to the sum of all energy used by consumers, including electricity produced from other fuels, and thus excludes transformation and distribution losses.

Energy intensity is defined as the amount of primary energy consumed per unit of gross domestic product (GDP). Energy intensities vary from country to country and over time depending on the economic background, national energy policies and sectoral and industrial structures. For mature energy economies, such as prevail in the EU, they tend to decline over

time as energy efficient technologies enter the equipment stock, and as consumers invest in energy conservation.

It should also be noted that all references to the EU Member States refer to the 12 countries which were Member States in 1994. At the time of writing these chapters, Austria, Finland and Sweden had ratified their decision to join the EU from 1st January 1995, while the referendum in Norway had not yet been held. Should Norway have confirmed its intention to join by the time these chapters are published, this would add significant reserves and production of oil and natural gas to EU energy resources, and correspondingly reduce the EU's import requirements for these energy forms. Norway is also a significant producer of hydro-electricity for its own electric power needs.

#### Recent trends

In the 10 years between 1984 and 1993, EU gross inland primary energy consumption increased by 20 %, an average annual increase of 1.9 %. In 1993, gross inland primary energy consumption in the EU totalled 1190 million toe. In the decade to 1993, primary energy production also increased, but by only 17 %, with regular increases in oil and gas production partially offset by a decline in solid fuels production. There has thus been an overall increase of 30 % in net imports of energy into the EU between 1984 and 1993.

The mix of fuel consumption has also evolved, with natural gas and nuclear electricity substantially increasing their share at the expense of solid fuels and, to some extent, oil. The use of oil is becoming increasingly concentrated in the transport sector, which has shown growth, but this has been offset by its loss of share in the other sectors to gas and electricity. In 1993, oil represented almost 44 % of total gross inland primary energy consumption, with solid fuels, natural gas

and primary electricity each contributing 20 % or less. Renewable energy contributed 1.5 % of consumption.

Over the whole of the EU, energy intensity has declined over the past decade. This results from the stage of maturity of EU energy markets, where growth has been primarily in sectors with low energy intensity, while energy intensive industry has tended to decline. The main exception to this trend was in 1991 following German reunification, when the statistics reflect the predominance of energy intensive industry in the former East Germany.

Generally speaking, the countries which have shown the smallest decreases (or even increases) in energy intensity are those with rapidly growing industrial sectors (e.g. Portugal and Spain). Those countries showing significant decreases in energy intensity are those which have undergone extensive industrial restructuring (e.g. the Netherlands, Belgium and Germany, prior to reunification).

Comprehensive statistics on employment in the energy sector of the EU are not currently available, due to the great diversity of sectors of activity and organisations involved. However, the energy industry tends to be less labour intensive than other traditional industrial sectors, therefore the impact on changes in activity on overall employment levels is not significant, compared to the total level of employment in the economies of EU Member States.

#### International comparison

In 1993, gross inland primary energy consumption in the EU was just under 1.2 billion toe, approximately the same as in 1992. This level of consumption represents about 15 % of total world primary energy consumption, making the EU one of the most important energy markets in the world, after North America and Asia. The USA is still the largest energy con-

**Table 2: Energy**

Source: Eurostat

suming country in the world, accounting for about 24 % of total world primary energy consumption. Asia is the fastest growing area of energy demand in the world, including the relatively mature energy economy of Japan, but also the high-growth economies of China and the South-East Asian newly industrialising countries. Asia now represents almost 24 % of world energy demand, but has substantial potential for future growth since annual energy consumption per capita, at 0.8 toe, lags well behind Western Europe (3.3 toe) and North America (7.9 toe), and the economies of the region, with the exception of Japan, are booming.

### Foreign trade

The EU is a net importer of energy. Net imports reached 596 million toe in 1993, or 50 % of gross inland primary energy consumption.

Imports of oil, natural gas and coal have all risen over the past ten years as rising demand has outstripped production growth. The Middle East and Norway have been the principal sources of crude oil imports, Algeria, Norway and the former USSR are the most important natural gas suppliers from outside the EU, while coal imports are dominated by supplies from the USA, Australia and South Africa.

## MARKET FORCES

### Demand

#### Final energy demand by sector

The principal sectors of final energy demand are industry, transport and residential/commercial, (the power generation sector, included in gross inland primary energy demand is a transformation sector, whose output is included in final energy demand).

While all three main end-use sectors have shown growth in energy demand over the last 10 years, the mix of demand between sectors has been modified over this period. The residential/commercial sector has remained stable at around 40 % of the total, but the share of industry has declined as energy intensive industry has been restructured and growth has been concentrated in light industry. The transport sector has increased its share, in line with the increase in personal mobility allied with rising living standards, and increased freight transport by truck with the development of intra-EU trade. The transport sector has now overtaken industry to become the second most important end-use sector for energy.

Energy consumption in the residential and commercial sector is dominated by heating applications for which electricity, natural gas and petroleum products are the main competitors. Other energy uses open to inter-fuel competition are cooking, and provision of hot water, while lighting and appliances are almost exclusively powered by electricity.

There are many different uses for energy in industry, from space-heating and lighting, steam-raising in industrial boilers, drying and many specific process applications. In the latter

category, there is a shift towards electricity use as many new industrial processes are exclusively powered by electricity. The other fuels compete for more traditional steam-raising, heating and process uses, with natural gas gaining market share at the expense of coal and oil.

Transport is dominated by oil, since, as yet, no alternative fuels have made a significant penetration on the market. Consumer choice is thus focused almost exclusively on gasolines and diesel fuels refined from oil. In the long term, alternative fuelled vehicles, using electricity or compressed natural gas are likely to become more available, but are unlikely to make significant inroads into the dominant position held by oil.

#### Energy demand by fuel

Oil still accounts for 44 % of Europe's energy requirements, a level which is little changed since 1985. Loss of markets for oil in the residential/commercial and industrial sectors, where natural gas and electricity have become more competitive, have been offset by continuing growth in the transport sector, where the opportunities for fuel substitution are extremely limited. For this reason, many regions now have an oil demand which is relatively captive.

Natural gas now represents 20.5 % of EU energy demand, up from 18 % in 1985. Although the development of natural gas has been extremely uneven across the EU, with resource-rich countries, such as the Netherlands and the United Kingdom, developing important gas markets much earlier than other EU countries, natural gas is now becoming a major component of energy markets right across the EU. Portugal and Greece, the last countries to introduce natural gas, both have major plans to develop natural gas import and distribution infrastructure over the next few years to facilitate gas availability. It is worth pointing out that Spain will show the biggest volume increase of the newly gasified countries. The attractiveness of gas in the power generation sector means that the already developed markets in Northern Europe (Belgium/Luxembourg, France, Germany, the Netherlands and the United Kingdom) plus Italy will still see substantial future growth in demand for gas: these markets will account together for over three quarters of the volume growth in demand for gas over the next 15 years or so.

The share of nuclear and hydro-electricity in gross inland primary energy consumption has now reached almost 16 %, following the extensive programme of development of nuclear power in France in the 1980s. France now exports electricity to its neighbouring countries. The current share enjoyed by nuclear and hydro-electricity is not now expected to increase further, since the nuclear programme in France has been considerably slowed down, and other countries are making different choices for their power sector development programmes. There are also very few opportunities left in the EU for the development of new large-scale hydro-electric power plants.

Coal and other solid fuels (lignite and peat) account for 19 % of gross inland primary energy consumption, a share which has declined from 23 % in 1985. The increasing availability

**Table 3: Energy

Source: Eurostat

of natural gas, and regulations to limit harmful emissions, have contributed to a large reduction in coal's share of energy use in the industrial sector. It is now primarily used as a fuel input to power generation, where large-scale plants have been able to fit emissions abatement equipment. Future coal demand is expected to be increasingly concentrated in this sector.

### Supply and competition

The contribution of EU indigenous energy production to EU energy demand has remained virtually unchanged over the past 10 years at around 52 %, but there have been some modifications in the relative contribution of production of different forms of energy.

EU oil production has declined by 15 % in the 10 years between 1984 and 1993. The principal source of oil production in the EU is the United Kingdom sector of the North Sea, where output dropped in the late 1980s following loss of capacity after the Piper Alpha disaster, but production has now stabilised and is expected to regain an upward trend until the late 1990s, before declining after the year 2000. This will be a consequence of the recovery from Piper Alpha, and particularly because of technology advances and cost reductions in exploration and production.

EU natural gas production has increased by 30 % in the 10 years since 1984, as more exploration and development investment has been focused on natural gas, particularly offshore in the Netherlands and the United Kingdom, in response to the anticipated higher growth opportunities for natural gas demand than for oil.

EU coal and solid fuel output has also increased since 1984, up by 5 %. This is entirely due to German reunification which added significant production of lignite to EU output. The underlying trend is, however, one of decline. Hard coal production has dropped by 12 % since 1984, while lignite production has declined by 18 % since 1991. The reasons for this are twofold. Firstly traditional markets for coal are declining as industry switches to natural gas and electricity for environmental reasons. Secondly, the major coal-producing regions of the EU (Germany, the United Kingdom, Spain and France) are all restructuring their coal industries, since production costs for European deep-mined coal are above world coal-price levels. In addition, production subsidies, combined with guaranteed purchase contracts with the power sector, which have been the means to maintain indigenous production, are now beginning to be phased out, which will lead to cuts in production capacity.

Output from nuclear and hydro-electricity production has increased by over 50 % since 1984, mainly due to the contribution from new nuclear power stations in France.

Competition between fuels is well-established in the EU, for all applications for which fuel substitution is technically possible. The only exceptions to this have been the special purchase arrangements for coal into the power sector in the main coal-producing countries, whose governments have in the past sponsored contracts guaranteeing a price and a quantity of coal. These arrangements are now being phased out, and fuel choice based on competitive and economic criteria should now be generalised.

The degree of competition between suppliers of a particular fuel varies considerably. In the oil markets, there is a high degree of competition throughout the EU, as each country is served by a sufficient number of refining and marketing companies to ensure competition. In addition price transparency is the norm, and there are very few barriers to trade. The natural gas and electricity transmission and distribution industries have traditionally been the domain of state-owned public service companies with national or regional monopolies. However, this pattern is beginning to change. The United Kingdom has pioneered the opening up of these sectors to

competition, with its programme of privatisation and liberalisation, while the European Commission is continuing to promote the introduction of a framework for more competition in the rest of the EU, via proposals for Third Party Access (TPA) to electricity and natural gas transmission grids and other supporting measures. The coal supply industry is generally competitive for most sectors, with access to imported sources of coal becoming more available.

---

## INDUSTRY STRUCTURE

---

### Companies

There is a great diversity of companies involved in the energy production and distribution industries in the EU, including giant state-owned energy companies such as ENEL and ENI of Italy, EdF and GdF of France, or Repsol of Spain; large privately-owned multinational energy companies headquartered in the EU, such as Royal Dutch/Shell (NL/UK), British Petroleum (UK), Elf (F), Total (F) or British Gas (UK); non-EU based multinationals with significant activities in the EU, such as Exxon or Texaco (USA); large privately-owned national energy companies such as RuhrGas (D), RWE (D), or National Power (UK); and a multitude of medium-sized or small companies involved in producing, transporting or selling all the forms of energy discussed here.

The major trend in industry structure over the past 10 years has been the ongoing reduction in the role of the state. Privatisations of state ownership or shareholdings in energy companies have occurred in practically every country in the EU, and are still continuing.

### Impact of the Single Market

Although some specific elements of the Internal Market programme have had some impact on the energy sector, more far-reaching effects are expected to come from the completion of the Internal Energy Market, which is still under discussion. Both in the electricity generation and distribution sector and in the transmission and distribution of natural gas sector, the type of Third Party Access (TPA) mechanism that will be introduced will have a critical influence on the structure of competition, and on prices. At present, energy prices still vary significantly across countries, despite strong inter-fuel competition. These price differences reflect both differences in taxation across Member States, and the persisting fragmentation of markets along national lines.

Among the measures which were part of the Internal Market programme and which were of direct relevance to the energy sector were the opening up of public procurement markets, the harmonisation of excise taxes on petroleum products, and, mainly, a number of environmental policy measures, including the Large Combustion Plant Directive. In addition, some positive impact on demand was felt from the overall improvement in the economic situation. Priorities for the future include the completion of the Internal Energy Market, and a harmonisation of environmental and fiscal legislation, which currently varies significantly across Member States and are a source of market distortions.

---

## REGIONAL DISTRIBUTION

---

Energy demand in the EU is distributed according to the economic activity of each country or region. By and large, most regions have access to all the forms of energy supply available. Where this is not the case, there are projects being undertaken to ensure that new energy supplies will be made more widely available over the next few years. This is the case with respect to the development of new gas supply infrastructure to Portugal, Spain and Greece, and the connection of electricity networks in Greece and Ireland to those of other EU countries.

Apart from the production of nuclear electricity, technically possible in many locations, the regional distribution of production of other energy forms depends on the geological resource endowment of each region. EU oil and gas production is concentrated in the United Kingdom and the Netherlands, with smaller endowments in Denmark, France, Germany and Italy. Coal production is mainly in the United Kingdom, Germany, Spain and France.

---

## ENVIRONMENT

---

Environmental considerations have been at the forefront of energy policy-making for the past several years, both at EU level and within individual Member States.

For example, in the framework of the debate on global warming, the EU has committed itself to stabilising CO<sub>2</sub> emissions at the 1990 level by the year 2000, and has instituted a monitoring programme to assess the contributions of national programmes of Member States towards meeting this goal. The energy sector has a very important role to play in meeting this target, through improvements in energy efficiency and the promotion of fuels containing less carbon (such as natural gas or nuclear and hydro-electricity), at the expense of fuels with higher carbon content (such as coal or oil). The EU is debating whether the introduction of energy taxation, partially based on a fuel's carbon content, should be applied as a strategy to help meet the emission stabilisation goal. In the meantime some countries, such as Denmark and the Netherlands, have introduced this type of tax.

The EU has also moved to limit other sources of harmful emissions, particularly SO<sub>2</sub>. In 1988 the EU passed the Large Combustion Plant Directive (LCPD), which applied to all existing and new industrial plants above 50 MW (Megawatt) capacity. Its objective was for plants to achieve a phased reduction of SO<sub>2</sub> emissions from 1990 levels totalling 60 % by 2003, by limiting the amount of SO<sub>2</sub> present in flue gas emissions. To meet these targets, industrial plants and power generation facilities have been obliged to choose between burning lower sulphur fuels in their boilers, or to invest in flue-gas clean-up technology, such as FGD (flue gas desulphurisation). The LCPD will soon be due for review and revision.

Other EU initiatives to control emissions involve modifications to the specifications of petroleum products, and regulations to introduce technology to limit emissions of volatile organic compounds during the storage and distribution of petroleum products. These are discussed more fully in the chapter on refining and distribution of petroleum products. Here, reference ought to be made to the important tripartite EPEFEE (European Programme on Emissions, Fuels and European Technologies) joint Commission / automotive industry / oil industry programme.

---

## REGULATIONS

---

There is a well-developed regulatory framework covering the energy industry in the EU, both at the national level, and at the level of the EU. Regulations can have specific provisions for the energy industry covering such aspects as the environment, health and safety, competition and fiscality, as well as including the application of provisions affecting all industrial or business enterprises, such as planning regulations or the obligation to publish audited accounts.

Since the introduction of the Single Market within the EU, the thrust of EU policy towards the energy sector has included proposals for the development of a new regulatory framework which will assist development of a single energy market. There are two main aspects to this effort. On the one hand, the European Commission is enforcing existing EU legislation and treaty obligations, including the free trade provisions of

the EEC treaty as well as competition and state aid provisions. On the other hand, a strategy involving regulatory changes and new EU legislation has been in progress since the late 1980s. A three-stage approach is being implemented.

The first stage is largely completed. It involved the adoption of Directives on the transit of electricity and natural gas, and on price transparency in the gas and electricity sectors. Measures were also taken to harmonise technical rules and standards, and to define minimum levels for excise taxes and VAT on petroleum products.

The second stage is still under discussion within the European Commission, and has involved long debate with national governments and energy companies. It is supposed to include such measures as the removal of exclusive rights for electricity generation and for the construction of electricity and gas distribution infrastructures, the unbundling of the management and accounts of vertically integrated electric and gas utilities and the introduction of TPA to electricity and gas transmission and distribution networks serving large industrial users and some distribution companies.

The third stage has not yet been specified in detail, its scope being partially dependent on lessons learnt from the implementation of the first two stages. However it is expected to include, inter alia, the extension of electricity and gas TPA rights to all distributors and small consumers.

---

## OUTLOOK

---

As the major EU economies renew their path to growth through the mid 1990s, energy demand is also expected to pick up, albeit at a slower rate than GDP growth, as energy efficiency improvements and conservation investments continue to put downward pressure on the energy intensity of EU countries. Total final inland energy consumption in the EU is expected to be almost 12 % over 1993 levels by the year 2000, and to increase by a further 15 %, or 0.9 % per year, by 2015.

The future EU primary energy mix will be characterised by the continued dominance of oil, with its share remaining at over 40 % through 2010, although its share could dip marginally below 40 % by 2015. Oil will, however, remain the largest single contributor to the primary energy mix.

Natural gas consumption is expected to increase at the fastest rate of all fuels, at 2.7 % per year between 1993 and 2015 in primary energy demand, and at 2.0 % per year over the same period in final energy demand in the EU. This will result in natural gas occupying the second largest share in the fuel mix. In 2005, natural gas is expected to have a share of over 24 % of primary energy demand, rising to over 26.5 % in 2015. This rapid increase reflects the growing attractiveness of this fuel in terms of environmental and economic considerations, and its increasing penetration of the power generation sector.

Solid fuels consumption is expected to stabilise over the remainder of the 1990s, and then to increase after the year 2000, as stable international coal prices help coal regain its competitiveness in the power generation sector while oil and gas prices rise. Coal should thus retain its share of just under 20 % of EU primary energy demand.

On the production side, prospects are less favourable, relative to recent years. Oil production from the EU 12 countries is expected to decline quite sharply after the turn of the century as existing reserves are depleted, although this decline could be partially offset by the results of new exploration programmes. Natural gas production is expected to stabilise over a longer period, since gas reserves have hitherto been relatively less exploited than oil ones. However, a slow decline in output is expected to begin after the year 2000. With regard to solid fuels, hard coal production levels are expected to decline appreciably as state aid supporting high-cost mines is phased

out, while lignite production is also expected to fall as environmental considerations continue to induce fuel-switching to cleaner forms of energy.

A small increase in nuclear electricity production is expected by the year 2000 as those plants currently under construction in the United Kingdom and France come on stream. However after the year 2000, in the absence of major changes in policy by EU electricity generating companies, it is anticipated that retirements will outstrip capacity additions, and thus nuclear output will begin a period of decline.

# Solid fuels

## NACE 11

*Despite the contraction in the production of hard coal, the share of total primary energy requirements met by solid fuels was around 19 % in 1993, falling from 23 % in 1980. Reductions in EU production of hard coal have been largely offset by increased imports, and the inclusion of the former East Germany into the EU in 1991 gave a substantial boost to lignite production.*

*However, the outlook for the hard coal production industry is for a continued decline for at least the medium term. Governments are increasingly coming under pressure to reduce subsidies to uneconomic production, and this will lead to a reduction in production capacity. Improvements in productivity will help to improve the profitability of remaining EU hard coal production.*

*Consumption of solid fuels is also expected to decline. The main reason for this is an increase in gas use in the power generation sector due to environmental and economic pressures. This phenomenon will be the most marked in the UK, at the expense of indigenous coal production. In the longer term, the development of fuel prices may revive the attractiveness of coal in this market.*

---

### INDUSTRY PROFILE

---

#### Description of the sector

This chapter covers the extraction, as well as the associated washing, grading and ranking processes, of all types of coal, including:

- brown coal or lignite (NACE 112.2);
- black lignite and sub-bituminous coal (NACE 112.1); and,
- hard coal, including bituminous coal and anthracite (NACE 111.1).

It also covers the production of patent solid fuels (NACE 111.2) and lignite briquettes (NACE 112.3).

Although reference will be made to all solid fuels, the emphasis in this chapter is on hard coal, which represents 75 % of total solid fuels consumption on an energy equivalent basis. The chapter also covers to some extent the coking industry (NACE 12), which is closely related to the hard coal industry and which is not covered elsewhere in the energy section.

#### Recent trends

The production of hard coal in the EU has fallen steadily since 1987, largely as a result of cut backs in production capacity in the UK and Germany, but also reflecting the complete phase out of coal production in Belgium. This leaves just four countries with significant coal industries, France, Germany, Spain and the UK.

However, whilst the level of EU production has fallen, the level of imports has risen, and the impact on the share of indigenous solid fuels in gross inland consumption for 1993 has been a 3.5 % decrease since 1980. Until 1978, the two main suppliers of coal imports to the EU were the USA and Poland. As of 1993, the USA remains the leading supplier to the EU (31.4 million tonnes) followed now by South Africa (26.4 million tonnes) and Australia.

The key reason for the reduction in EU hard coal output is the divergence between the cost of EU production and the price in the expanding international coal market. This has required governments to subsidise hard coal production, either through direct grants or through imposing market restrictions

which guarantee a market for higher priced indigenous production. In the interests of promoting growth and free trade, and in accordance with EU legislation, governments have increasingly sought to reduce these subsidies, which has led to closures of high-cost production capacity.

The difficult situation for the hard coal industry was further exacerbated in 1986 by the fall in the price of oil and particularly heavy fuel oil, with which coal competes in its main market, power generation. Until this time, governments had been encouraging industry to switch away from high cost imported oil, by providing grants for the construction of coal fired boilers. However, the fall in the cost of oil reduced the incentive to switch fuels and the share of coal in industrial and commercial markets was eroded by more convenient fuels such as gas and heating oil. In addition, the abrogation in March 1991 of a 1975 Community restriction on the use of natural gas for electricity generation resulted in a shift towards gas-fired power stations. The depreciation of the US dollar compared to EU currencies in the late 1980s has rendered imported coal even cheaper.

In contrast, the production of lignite is largely carried out on a commercial basis, and is even more concentrated than that of hard coal. Only three countries (Germany, Greece and Spain) produce significant quantities of lignite, and Germany accounts for around 75 % of EU production on an energy equivalent basis. The production of lignite in the EU was dramatically increased as a result of German re-unification in 1991. Indeed at that time the former East Germany accounted for nearly half of EU lignite production, although its share has since fallen back due to the economic re-structuring of its industry and environmental concerns.

The impact of the re-structuring and cut-backs on employment in the hard coal and lignite industries has been quite severe. Employment underground has fallen by 68 %, from 387 100 in 1980 to 125 000 in 1993. This trend is continuing, and further large cut-backs in employment have been made in 1994 in both the UK and Germany, the largest producers in the EU.

#### International comparison

Most EU hard coal production comes from underground mines, and with relatively narrow and deep seams, and more complex geology, production costs are substantially higher than those of the world's major coal exporting countries. Coal output in EU countries is typically between 3 and 10 t/man-shift, whereas output for some open-cast mines can be in excess of 100 t/man-shift. Such a comparison however is inadequate because the production costs structure is totally different. Less than 10 % of European coal is extracted from surface mines, compared to 50 % in Australia, 60 % in the USA and 85 % in Canada. German production costs are particularly high with hard coal deposits at an average depth of 900m.

#### Foreign trade

The EU ranks with Japan as one of the two foremost importers of hard coal. Indigenous hard coal production accounted for 58 % of gross hard coal consumption in 1993, with the remainder being covered by imports. The share of imported hard coal has risen from around 20 % in the early 1980s, increasing from around 70 million tonnes to over 130 million tonnes in 1992. However, in 1993, coal imports fell 16 % from 1992 levels as a result of the recession and the high level of existing coal stocks.

Within the EU, only the UK and Germany export significant quantities of coal, and the vast majority of this is sold to other EU countries. Germany exports anthracite, and its main markets are in France, Belgium, Italy and the Netherlands. UK exports are almost exclusively steam coal and its main markets are in Denmark, France, Germany, Ireland and Spain. Both countries also export some coal to EFTA countries. Be-

Source: Eurostat

tween 1980 and 1993, intra-EU trade fell from 17.2 to 2.9 million tonnes, mainly due to the deterioration in the price competitiveness of EU coal versus coal originating from third countries.

The USA supplies the greatest volume of imports to the EU, providing 31.3 million tonnes, 27.5 % of total extra-EU imports in 1993. Imports from South Africa and Australia accounted for 24.3 % and 15.8 %, respectively. The remaining 32.4 % was made up largely by imports from Colombia, Poland, the former USSR, Canada and China.

The level of foreign trade in hard coal has risen considerably over the last decade. In total, world trade in hard coal stood at about 200 million tonnes in 1980, the majority of which was coking coal. Since then the market has grown to 384.2 million tonnes in 1993, with coking coal accounting for 173 million tonnes and steam coal representing 211 million tonnes. The key factors in the recent development of the market has been the growing demand in the EU and increasingly from Asia (Japan, South Korea, Taiwan and Hong Kong).

The development of a large international trade in coal has significant benefits for importing countries, since it provides a wider range of suppliers, including a growing spot market to meet short term requirements, and a competitive market in which suppliers have to face downwards pressure on prices.

International trade in other solid fuels is very limited, and given that the vast majority of lignite production is directly integrated with electricity generation, it is difficult to draw meaningful comparisons with industries outside the EU.

## MARKET FORCES

### Demand

#### Hard coal

By far the most important market for hard coal is power generation which, in 1993, accounted for 66 % of gross consumption. A further 20 % was accounted for by the production of coke. Most of the final consumption of coal is in energy

intensive industries, and where plants are typically large scale, such iron and steel, chemicals and cement.

The reason for the high concentration of demand is the high cost of combustion equipment and the greater difficulty of transportation (for coal) compared with liquid or gaseous fuels. Coal is therefore only an attractive option when economies of scale can be achieved, and where the cost of transportation can be limited, such as in the power station market. In small scale markets, e.g. commercial and domestic boilers, coal has difficulty competing with gas and heating oil due to their greater convenience and lower cost.

The concentration of coal consumption into so few end uses poses significant risk to the industry, since it ties the industry's prospects to the prospects of these consumers and to technical developments within them. In the power generation market, the rapid penetration of gas-fired power plants in some countries will increasingly limit the market share for hard coal. At the same time the changing industrial structure, away from heavy energy intensive industries such as iron and steel, has reduced the size of its main industrial market. In the iron and steel industry, the position of coal has been further undermined by the development of pulverised coal injection technology, reducing the need for coke and hence higher value coking coal, as well as the move towards a greater proportion of steel production coming from recycled scrap steel produced in electric arc furnaces.

#### Lignite

Lignite consumption is concentrated in the power generation sector, which in 1993 accounted for 78 % of consumption. Most lignite used in the power sector is burned in power stations located next to the lignite deposits. It is generally uneconomic to transport lignite over long distances.

The other significant markets for lignite are briquetting plants and gas manufacture in the former East Germany. However, due to the environmental impact of manufacturing gas from lignite, and the availability of natural gas following German re-unification, the quantity of lignite used for this purpose is falling.

## Supply and competition

Coal is the most abundant fossil fuel in the world and within the EU. European proven hard coal reserves are estimated to have stood at 29 billion tonnes at the end of 1993. At current rates of production, this means that hard coal reserves would last about 160 years. France, Germany and the United Kingdom are estimated to account for 93 % of Europe's hard coal reserves, with Germany alone accounting for 82 % of the European reserves.

Although the EU is reasonably well-endowed with coal, the majority of remaining reserves are deep deposits that require working at very great depths, sometimes in excess of 1 000 metres with heavy-duty, sophisticated equipment, both for technical and safety reasons. This has led to high production costs and has undermined the financial situation of the coal production industry.

Due to the high cost of transportation and handling, and its relatively low calorific value, historically coal industries have developed along national lines, and were built to serve the regional market which grew up around producing areas. The coal industry was therefore characterised by a low level of international trade, and regional industries were relatively isolated from competitive pressures from either other fuels or other coal producers.

During the 1970s the fact that coal production in Europe was becoming increasingly expensive was hidden by the rapid increase in the price of oil, and the consequent desire to improve security and diversity of energy supplies. In addition, governments saw a need to maintain coal production in order to support regional economies.

However, from the early 1980s onwards, with a growing availability of cheap coal from exporting countries, together with a desire to improve economic performance by reducing trade barriers, governments in the EU began to seek to reduce subsidies. This gained momentum during the 1980s as oil prices fell and coal became available from a wide range of countries, particularly OECD countries, which reduced concerns over supply security.

Whilst the ECSC Treaty, under Article 4(c), prohibits all "subsidies or aids granted by States, or special charges imposed by States, in any form whatsoever", the critical state of the Community coal industry from the early 1960s onwards led to the Commission establishing, in 1965, a temporary framework for State aid to the Community coal industry under the provisions of Article 95 of the ECSC Treaty. The continuing problems in the industry have led to successive Commission decisions establishing Community rules for State aid to the coal industry, the most recent of which is Decision No. 3632/93/ECSC. This Commission Decision, which will last until the expiry of the ECSC Treaty in the year 2002, establishes that aid may be considered compatible with the proper func-

tioning of the common market provided that it helps to achieve at least one of the following objectives:

- to make, in light of coal prices on international markets, further progress towards economic viability with the aim of achieving a degression of aids;
- to solve the social and regional problems created by the total or partial reductions in the activity of production units;
- to help the coal industry adjust to environmental protection standards.

The Decision also contains provisions designed to make existing aid schemes more transparent. After a transitional period not exceeding three years (therefore ending on 31st December 1996), aid would only be authorised if it was entered in the national, regional or local public budgets of Member States or channelled through strictly equivalent mechanisms. In addition, from the beginning of 1994, all aid received by undertakings has to be shown together with their profit-and-loss accounts as a separate item of revenue, distinct from turnover.

Member States intending to grant aid to coal undertakings during the period 1994 to 2002 are required to subject to the Commission in advance a modernisation, rationalisation and restructuring plan to improve the economic viability of the undertakings concerned by reducing production costs. For undertakings unable to achieve this, aid will only be considered if they are subject to a closure plan with a deadline occurring before the expiry of Decision No 3632/93/ECSC or, in exceptional social and regional circumstances, if the closure occurs after the expiry of the Decision.

European reserves of sub-bituminous coal and lignite are believed to have stood at about 68 billion tonnes. Some 83 % of these reserves were in Germany. Europe has 13 % of world reserves of sub-bituminous coal and lignite. Most lignite mined in the EU is extracted by surface or "open cast" methods, which allow higher productivity than underground mining and yield a fuel that is competitive with other fuels used for electricity generation.

## Production process

There are two principal methods of extracting solid fuels from the ground, these are open-cast or under-ground mines. Most coal in the EU is extracted from under-ground mines, whilst lignite is generally only economic if accessible using an open-cast pit.

Open-cast mining is possible if the coal reserves lie relatively close to the surface, and can be accessed by removing the over-burden of top-soil and sub-soil. This is usually carried out using large scale machinery and productivity can be very high.

Where deposits are much deeper, under-ground mining is necessary, requiring a shaft to be sunk and tunnels to be con-

structured in order for coal faces to be developed. For underground mines the degree of mechanisation will depend on the thickness of the coal seam, and on the geological conditions, i.e. the extent of faulting and the inclination of the seam. The two main technologies are longwall and continuous mining machines. Longwall technology can be used for thicker seams and where the coal seam is not highly faulted. Longwall cutters remove a coal seam by taking slices across the coal face, and then automatically advancing to make a new cut. Alternatively, continuous mining machines, together with a "room-and-pillar" extraction method, can be used when the seam requires more flexible methods.

Following extraction, most coal is then washed in order to remove non-combustible material extracted with the coal, and then graded.

Overland transportation of coal is usually by rail, although smaller quantities can be transported by road, and dedicated transport systems, such as slurry pipelines and conveyors which are sometimes used over very short distances. Coal delivery to power stations, where these are not located directly on the mine, is usually by rail, and may involve a dedicated rail link. Barges are used for transport on waterways, or in coastal waters, and international seaborne trade can involve ship sizes of up to 200 000 dwt.

### Research and development

Investment in the EU coal industry has fallen from 1 billion ECU in 1990 to an estimated 770 million ECU in 1993, and is expected to fall further to 670 million ECU in 1994. This has been mainly due to the reduction in the overall size of the industry. It has been high in areas of health and safety concerns.

Two key areas of technical research have been in mining technology and product upgrading. Research in mining technology is concerned with improvement of roadway support techniques (particularly in light of ever greater working depths), monitoring of ventilation, automatic steering of mining machines, and more efficient and safer transport systems for both personnel and materials. Research is also being made into remote control, data processing and modern communication systems, to examine whether and how they can contribute to increased safety, improved working conditions and more efficient mining operations.

Research into product upgrading concerns efficiency and environmental considerations of coal preparation, handling and coking. Both fundamental and applied research is being carried out by mining institutes, universities and laboratories, often on an international level, with ECSC financial support amounting to some 60 % of total costs.

After the first oil crisis, in 1974, interest grew in the conversion of hard coal and lignite into other materials as a way of reducing dependence on imported hydrocarbons. As a result, several pilot and demonstration programmes were launched by the EU into:

- gasification and liquefaction of solid fuels (including underground gasification);
- substitution of hydrocarbons by solid fuels with fluidised bed combustion, coal-liquid mixtures and combined cycles as key areas of research;
- utilisation of solid fuels within the framework of the EU JOULE 2 R&D programme into non-nuclear energy and rational use of energy which took over from Joule in 1992;
- energy production from fossil fuels based on advanced technologies, notably combined cycles, within the recent "Framework programme" (1990-94); and
- new and improved clean combustion methods for solid fuels such as fluidised bed combustion, underground coal gasi-

fication and use and treatment or enhancement of wastes arising as a result of the use of solid fuels, all within the new demonstration "Thermie" Programme (European Technologies for Energy Management) which was proposed by the Commission and ran from 1990-94. THERMIE II is now on the table as part of the "Fourth Framework Programme."

---

## INDUSTRY STRUCTURE

---

### Companies

The bulk of French coal production is the responsibility of the nationalised company, Charbonnages de France (CdF). A few small mines are operated by Electricité de France or are privately held. The Technical Association for Coal Imports (ATIC) co-ordinates coal imports. All coal and lignite mining in France is due to cease by 2005.

In Germany, the main coal mining companies are Ruhrkohle, Saarbergwerke, and Preussag, which produce hard coal, and Rheinbraun, Mibrag and Laubag for lignite. The lignite companies are mostly owned by electricity companies or have power plants associated with their mines. Indeed, Rheinbraun is a subsidiary of RWE, and owns a large share in Laubag, the remainder of which is owned directly by power companies. A new subsidy programme was announced at the start of this year which fixed the amount of money to be made available to the hard coal industry. The figure has been set at DM 7 billion between 1997 and 2000, and is likely to lead to further rationalisation. In addition, legal action has resulted in some liberalisation in the supply of coke and coking coal to the steel industry, which has allowed further imports and forced cut-backs in coking capacity.

The major producer of lignite in Greece is the publicly-owned Public Power Corporation (PPC). Additionally, there are some small privately-owned mines in northern Greece. Greek lignite is burned almost exclusively in PPC's power plants.

In Ireland, coal mining at Arigna Coelieris was stopped in 1990. However, the production of peat for use in power stations and other low grade heating applications still continues. The Electricity Supply Board consumes about 3 million tonnes/year of peat, and a smaller quantity is turned into peat briquettes.

Italy's modest lignite output is found in Tuscany and Umbria. There is also sub-bituminous coal production in Sardinia. Coal imports are made by ENEL, ENI and Finsider, the steel company.

In Portugal, solid fuel production is limited to one anthracite mine, the output from which is used to fire a mine-mouth power station. The mine is due to be closed at the beginning of 1995.

Coal in Spain is produced by a large number of companies, more than 100 in total. The leading company, Hunosa, is publicly owned, while most of the rest are held privately. Sales of coal to power stations are made under the auspices of a contract between Carbuñion, the association of coal producing companies, and UNESA, the association of electricity utilities. The coal industry in Spain receives significant subsidies, both directly from the government and via its contracts with the electricity industry.

Finally, in the United Kingdom, British Coal has seen very substantial rationalisation of its capacity over the last two years, and has now been broken into a number of regional companies which are being sold to the private sector. RJB mining is expected to take over the vast majority of remaining production, and the privatisation process should be completed by the end of 1994.

## Strategies

The strategies of companies in the EU solid fuels sector are largely shaped by the foreseen decline in indigenous output, caused by the EU drive for increased competitiveness within the context of the EU state aid policy. Producing companies will have to rationalise capacity and increase productivity in order to gain or maintain profitability.

In the UK, the privatisation and re-structuring of British Coal is intended to remove any further need for state aid to the industry. The main protection mechanism in place in the UK has been a large contract for coal sales to the electricity industry. For 1993/94 the volume of this contract was cut to 40 million tonnes and for 1994/95 it is already down to 30 million tonnes per year. Contract volumes will remain at this level for the next three years. These volumes are a reduction from 70 million tonnes per year prior to privatisation of the electricity industry.

In Germany, hard coal production capacity has also seen substantial rationalisation and productivity improvements. Production has been cut by about 33 % and employment by 43 % since the early 1980s. Further rationalisation will result from the recent reduction in subsidies, and this will include coking capacity. Lignite production has also been falling as a result of the economic re-structuring in the former East Germany, and in response to environmental pressures. This will require further cuts in production before stabilisation and will result in a further concentration of demand in the power sector.

Charbonnages de France has recently reached agreement with its employees on a programme which will lead to the ending of coal and lignite production in France. CdF is liable by law for the livelihood of its mining employees, and thus is investing in developing alternative employment for them. CdF will continue to operate its coal fired power stations, but will increasingly fire them on imported coal.

The Spanish coal industry has accepted to implement a re-structuring plan which will result in the closure of the uneconomic underground pits and, hence, a further reduction of the underground workforce.

In order to cope with the employment effects of the restructuring process and in order to reinforce the reconversion process in the mining regions affected by pit closures, the European Commission established the Community initiative, RECHARII (to last until the end of 1997), which is additional to other Community financial instruments.

### Impact of the Single Market

The coal industry in Europe has undergone profound restructuring and downsizing over the past 15 years. This process is continuing in an effort to improve the sector's competitiveness and reduce its reliance on state aid. This process has not, however, been mainly due to the creation of the European Single Market. A framework for European co-ordination of development and aid for the coal industry has existed since the setting up of the European Coal and Steel Community in 1953, and rules for state intervention have been periodically defined within the framework of this treaty (the latest rules were published in January 1994, and define the criteria for authorising state aid up to 2002).

Coal trade in Europe, both within the Community and with third countries, is not subject to any particular technical or fiscal barriers. The preponderance of high-cost coal within Europe's remaining coal-producing countries has meant that only very small quantities are traded, the fuel being largely uncompetitive outside national markets subject to state aid or protected contracts. Conversely, the Union is open to imports of coal from third countries.

Coal markets in the European Union, particularly in the power generation and industrial sectors, have been adversely affected by EU environmental legislation (particularly the Large Com-

bustion Plant Directive). Deregulation and privatisation of the power sector in certain countries, notably the UK, have also reduced the market for coal.

## REGIONAL DISTRIBUTION

Hard coal is currently mined in significant quantities in four EU countries: the United Kingdom (67.6 million tonnes), Germany (64.2 million tonnes), Spain (18.1 million tonnes), and France (8.6 million tonnes). Small quantities are also produced in Portugal and in Italy.

Lignite is mined in four EU countries: Germany (222 million tonnes), Greece (51 million tonnes), Spain (13 million tonnes), and Italy (1 million tonnes). The three biggest producers accounted for over 98 % of total output in 1993. In addition 6 million tonnes of peat is produced in Ireland. Lignite production in France was terminated in 1992.

Within each producing country there is a further regional concentration of production. In Germany lignite is produced in the former East Germany and the Rheinland district, and hard coal is produced in the Ruhr and Saar coalfields. In the UK the majority of production comes from mines in Nottinghamshire and Yorkshire, although other areas, particularly South Wales and the Northeast have been more important in the past. In Spain the main producing regions are Asturias and Leon, while in France hard coal mining is mostly concentrated in the underground mines in Lorraine and in the South of France.

Traditionally coal mining areas have also been areas associated with heavy industry, and the regional effects of reduced coal mining together with re-structuring of heavy industries has had a big impact on unemployment and regional development.

## ENVIRONMENT

As with any fossil-fuel, the production, transformation and use of solid fuels have an impact on the environment. Hard coal and lignite are used mainly for large scale power and heat generation, processes which offer cost effective environmental protection measures. In particular, major efforts have been undertaken since the mid-1970s to reduce particulate, SO<sub>2</sub>, and NO<sub>x</sub> emissions from coal and lignite-burning power plants, albeit at the expense of conversion efficiency and the relative cost of coal-generated electricity. As a result of the installation of flue gas desulphurisation and NO<sub>x</sub> removal units, significant reductions in the emissions of pollutants have already been achieved. Further improvements are expected over the balance of this decade with the development of a large number of pilot plants that employ advanced methods of clean coal utilisation such as fluidised bed combustion. These will help to maintain a market for coal in the power generation and large boiler sectors.

Compared to other fossil fuels, solid fuels emit the highest amount of CO<sub>2</sub> per unit of energy. In order to ensure that the greenhouse gas emissions from coal use are minimised, it is important that, wherever possible, the efficiency of coal utilisation continues to improve. So far this century, the efficiency of coal-fired power generation has doubled due to technological improvements. Further efficiency gains are expected as combined cycle systems are developed and widely deployed. CO<sub>2</sub> emissions from such plants are as much as 20 % lower than from conventional plants. Furthermore, the development of combined heat and power plants offers potential CO<sub>2</sub> emissions reductions of more than over 50 %.

## REGULATIONS

The coal and lignite mining industries operate under strict health and safety regulations. These particularly concern underground mines, where dust, methane, subsidence and water

**Table 8: Solid fuels  
Forecasts**

Consumption	265	232	225

Source: DRI Europe

all present considerable health and safety risks. Such regulations are generally developed and monitored by national institutions.

With respect to the EU, the key regulations are those concerning the issue of subsidies and environment. The issue of subsidies is covered by the ECSC Treaty (since 1952), which completely prohibits State aid under Article 4(c), and rules agreed subsequently. The most recent reform, Decision No 3632/93/ECSC, is detailed under "Supply and Competition" of this monograph. These new rules, agreed in an attempt to reduce the level of subsidies and open coal markets, allow aid provided it meets one of three criteria: it is intended to make the industry more efficient with the aim of achieving a depression of aids; it is intended to off-set social and regional problems; it is intended to help the industry meet environmental standards. Furthermore, after 1996, aid will only be allowed if it is recorded transparently in national and/or regional government accounts, and in the accounts of the receiving company.

The Treaty also encourages, under Article 55, the promotion of technical and economic research relating to the production and increased use of coal and to occupational safety in the coal industry. The ECSC Treaty will expire in June 2002, when the coal and steel sectors will be integrated into the EC Treaty.

The main environmental measure currently in place, and which impacts on the cost of coal combustion, is the Large Combustion Plant Directive (LCPD) which places emission limits on large scale boilers (over 50 MWt) as well as specifying maximum emission levels for each country. This legislation effectively requires the use of flue-gas-desulphurisation and NOx reduction plant to be fitted to all new coal plants, and for a reduction of emissions from existing plants by retrofitting flue gas cleaning plant or switching to non-polluting fuels, e.g. gas.

## OUTLOOK

Solid fuels face a declining share in both the domestic and industrial sectors. This is largely due to consumer preference, with competing fuels offering greater convenience, less local environmental impact and lower investment costs in capital equipment. This trend is not expected to be significantly altered by differential fuel prices.

Coal does, however, have a future in power generation where its share of the fuel mix should rise into the next century. Currently the share of coal is declining in this sector as countries respond to emission legislation, and low gas and oil prices offer lower cost electricity. However, as oil and gas prices are expected to rise more quickly than coal prices, the competitive position of coal should improve.

Competition from extra-EU coal exporting countries and the general effort to lessen national subsidies means that, by the year 2000, 65 % of hard coal consumption will be serviced by imports compared with about 42 % in 1993. Meanwhile, hard coal production should fall by around 34 % by the year 2000, compared to 1993. Although indigenous energy production can play an important role in terms of security of supply, the stability of the world market for coal with abundant supplies from a wide variety of geographical sources leads to the conclusion that, even in the long term, the risk of persistent interruption of coal supplies is minimal, although it cannot be ruled out completely.

Consequently, major developments are expected in the British, Spanish and German coal markets. In the United Kingdom, coal sales to the power generation market will probably fall below 30 million tonnes by the end of the decade, as a result of the expansion of gas-fired power. In Germany, the reduction in coal subsidies will reduce output, and in particular liberalise the coking coal and coke markets. Meanwhile, in Spain, a major restructuring of the industry is anticipated.

Written by: DRI Europe

The industry is represented at the EU level by: Association of Coal Producers of the European Community (CEPCEO). Address: Avenue de Tervuren 168, Bte. 11, B-1150 Brussels; tel: (32 2) 771 9974; fax: (32 2) 771 4104.

# Exploration and production of crude oil and natural gas

## NACE 13

*In 1993, 280 million tonnes of oil and natural gas were produced in the EU, 6.7 % higher than in 1992. The United Kingdom is the leading oil and gas producer within the EU, producing 54 % of total EU output in 1993. The Netherlands accounted for slightly over half of the remainder of EU oil and gas production.*

---

### INDUSTRY PROFILE

---

#### Description of the sector

NACE 13 comprises three main activities:

- exploration for crude oil and natural gas;
- production of liquid hydrocarbons (i.e. crude oil), condensates and other liquids resulting from gas processing operations; and
- production of natural gas.

#### Recent trends

Production of hydrocarbons in the EU increased steadily up until the middle of the 1980s, stimulated by rising oil prices. The 1986 oil price collapse reduced the attractiveness of upstream investment and set output on a downward trend. By 1989, hydrocarbon production had fallen to pre-1983 levels at 238.5 million toe (tonnes of oil equivalent). Since then, hydrocarbon output has increased to 280 million toe in 1993, principally due to growth in natural gas production.

Crude oil production contracted by 22 % between 1986 and 1989 due to lower prices. Since then, output has grown slowly such that in 1993, crude oil output was 9.2 % higher than in 1989 at 123.6 million tonnes. The increase was largely due to a 10.3 % increase in UK crude oil production which took UK oil production to 99.5 million tonnes in 1993. Other increases in output within the EU came from Denmark, Italy and Greece. Production remained constant in the Netherlands and fell in the other oil producing Member States.

The UK has maintained its position as the most important hydrocarbon producer in the EU over recent years. Its share of total EU hydrocarbon output increased from 53 % in 1992 to 55 % in 1993 as new gas fields came on stream. Meanwhile, the Netherlands (the second largest hydrocarbon producer in the EU) saw its share of EU production fall from 25 % to 24 %.

Natural gas output in the EU boomed in 1993 to stand at 156.4 million toe, up 8.2 % compared to 1992. The rise was principally a result of the "dash for gas" which took place in the United Kingdom. In 1993, natural gas production in the UK (which accounts for 35 % of EU total), rose by 20.1 %, as a number of combined cycle plants were brought into line. The EU's second largest gas producer, the Netherlands experienced only a 1.7 % increase in production while the third ranking Italy increased its output by 11 %.

Employment in the hydrocarbon industry has also followed movements in the price of oil. The 1986 price collapse led to cutbacks which saw employment in the sector contract by 30-35 %. In 1989, overall employment within the sector was estimated at 95 000 people. Employment did rise during 1990

and the beginning of 1991, but has since fallen back under the weight of economic slowdowns.

#### International comparison

##### Crude oil

Total world production of crude oil was 3.2 billion tonnes, in 1993, down 0.1 % from 1992. Increases in production from the Middle East (+5 %) and from Western Europe outside the EU (+4.7 %), were just sufficient to compensate for a 11.9 % fall in production in the former USSR and Eastern Europe. Other than the former USSR and Eastern Europe, production fell slightly in North America and in the New Zealand & Australia region.

Proven world oil reserves rose to 136.7 billion tonnes at the end of 1993, little changed from a year earlier but only 100 million tonnes short of the all-time high of 1989. The EU's share of total proven world reserves at the start of 1993, was 872.3 million tonnes or 0.6 % of the world total, up from 847.1 million tonnes at the start of 1992. The EU reserves to production ratio currently stands at seven years.

##### Natural gas

Total proven world gas reserves climbed by 2.6 % to 142 trillion cubic metres (134.9 billion toe) at the start of 1993. EU gas reserves account for around 2.7 % of the world total.

#### Foreign trade

##### Crude oil

The EU produces only about 22 % of the oil that it consumes compared to the OECD average of 43 %. Thus, the EU is relatively dependent upon crude imports to meet demand and, since the oil price collapse in 1986, crude oil imports have risen steadily.

Intra-EU trade is quite limited, and takes the form of crude oil originating in the United Kingdom North Sea exported to the rest of the EU.

Extra-EU imports of crude oil stood at 464.8 million tonnes in 1993, 1.5 % higher than in 1992. Growth in EU imports was lower than the previous year due to higher EU production and sluggish demand. The Middle East is by far the most important supplier of crude oil. Its share had been falling since the Gulf war, so that in 1992 the share of Middle East crude in total crude imports had fallen to 37 %. In 1993, however, the share had returned to the pre-Gulf war level of 40 % of total imports. Norway has steadily increased its market share between 1990 and 1993 as the proximity of the EU market provided an obvious destination for rising Norwegian exports. After marginally increasing its share in the EU import slate in 1991 to 33 %, imports from Africa have fallen to 25 % in 1993.

##### Natural gas

The share of natural gas demand met by indigenous production fell steadily over the 1980s to a low point of 60 % in 1989. As larger quantities of gas, mainly from the UK, have been brought on stream, this figure has risen to 61 % in 1993. Natural gas imports to the EU totalled 4.2 million TJ (terajoule) (89.8 million toe) in 1993, 1 % up on 1992. The greatest proportion of imports, 45 %, came from the former Soviet Union, followed by Algeria and Norway with 30 % and 24 %, respectively. Germany accounted for the greatest proportion of gas imports into the EU in 1993, taking 31.5 % of the total; Italy and France were placed second and third, accounting for 25.6 % and 24.5 %, respectively.

Intra-EU trade, in the form of gas exports from the Netherlands to the rest of the EU, fell slightly to 1.47 million TJ in 1993. A steep fall in exports to France was partially compensated by an increase to Belgium, Italy and Luxembourg. Around 60 % of Dutch exports are to Germany, the volume of which

remained stable in 1993 at around 872 million TJ. Germany chose to take additional quantities of natural gas from Denmark in 1993, to meet growing domestic demand. As a consequence, trade in natural gas between Denmark and Germany rose by 31.3 % in 1993 compared to 1992. Exports to Denmark's other trading partners remained steady.

## MARKET FORCES

### Demand

Crude oil and natural gas are key energy sources, used to generate power and/or heat. They are used widely in everyday life throughout the power generating, industrial, commercial, domestic and transport sectors. Demand for crude oil and natural gas is characterised by low price and income elasticities because of the lack of competitive alternatives for many applications, particularly in the transport sector. In recent years, natural gas has tended to replace petroleum products in power generation, industry and domestic heating applications, due to its cost competitiveness and its relatively favourable impact on the environment.

### Supply and competition

80 % of EU crude oil production originates from fields on the UK continental shelf. The Netherlands provides 40 % of total EU natural gas production, 79 % of which is from on-

shore fields (principally from the Groningen gas giant). Since natural gas consumer prices are linked to oil prices, however, the economics makes off-shore natural gas production favourable. Despite relatively high production costs, EU hydrocarbon exploration and production benefits from lower costs of transportation. This transportation cost advantage, along with OPEC's policy of maintaining artificially high prices, enable EU crude producers to compete with other crude producers which profit from lower production costs.

The number of wells drilled in the EU peaked in 1985 (just before the oil price collapse) before falling to a low in 1989 at 590 wells. A more favourable fiscal regime in the UK attracted exploration at the beginning of the 1990s, but since 1992 the number of wells drilled in the EU has been declining to reach 444 wells in 1993, well below the 1989 level. This represents 0.7 % of the total number of wells drilled in the world, compared to a share of 1.3 % in 1989.

In the USA, drilling was similarly sensitive to oil prices. The number of wells drilled have been on the decline since 1985. However, in 1993 their number, in the USA, increased for the first time since then to stand at 26 078 wells. The number of wells drilled in the world in 1993 increased by 9.8 % at 61 758 wells.

### Production process

Exploration and production of oil and gas requires a highly skilled and experienced work force. The fact that exploration in the EU takes place offshore only heightens these requirements. By the same token, the EU is in a position to export highly trained and skilled labour in this sector.

R&D activity in the industry has traditionally been high. The nature of R&D programmes reflect the significant proportion of offshore operations undertaken in the upstream oil and gas sector. The high price of crude oil during the first half of the 1980s encouraged research into enhanced recovery methods. To reduce costs, improvements were made in the tools and operating efficiencies of exploration and production. Most of these programmes produced excellent results and generated significant growth in terms of services and equipment installation within the EU. However, the 1986 fall in crude prices put a damper on much of this research as many players in the industry divested much of their upstream interests and became more integrated with their downstream businesses. Even so, the depth and the sometimes harsh operational environment of the North Sea has assisted EU companies involved in oil exploration and production to acquire unparalleled offshore operational experience.

Since the late 1980s, the increased emphasis on the development of smaller and deeper fields has led to further technological developments, many of which streamline or increase

the efficiency of production. Some of the important technological advances made in the North Sea include: improved and streamlined platform designs; development of sophisticated floating production systems; improved platform safety systems such as interlocking fireproofing panels, multimedia on-platform safety monitoring systems and offshore escape systems; more efficient sub-sea completion systems such as highly flexible and durable flowline swivel joints; the development of dynamically positioned drilling vessels capable of operating at depths of 2 000 metres; the completion of the first commercial horizontal drilling operation; the development of deep-diving techniques and submarine vessels for underwater activities; improved measurement of static and dynamic statistics; the development of sophisticated pigs such as high friction reversible safety pigs; improved pigging techniques; and better geophysical data acquisition systems such as real-time processing of short offset 3D data.

## INDUSTRY STRUCTURE

### Companies

Since the early 1980s, the participation of governments in the upstream oil and gas sector has steadily decreased. In June 1992, the French state sold 12.4 % of Total's shares which left it with a direct holding of 12.6 % and an indirect holding of 2.3 %. The government also sold its 6.7 % share of the company's capital in the form of petroleum certificates. The French state is expected to sell a further 3 % in late 1994 or early 1995. In February 1994, Elf Aquitaine was privatised, raising 5.4 billion ECU for the French state. The government retained a "golden share" to protect it from hostile take-over bids.

In Spain too, the oil industry has been completely restructured over the past decade. It has developed from a state monopoly, with all sides of the business tightly controlled, to a liberalised and disaggregated system. In June 1992, the Spanish government announced that it would give up its majority stake in Repsol through two share sales. The first took place in autumn 1992 and was worth some 604 million ECU. The second phase of the sell-off took place in 1993 and reduced the government's stake in Repsol to about 41 %. In the long run the government has indicated that it intends to reduce its stake to 33 %.

In Italy, ENI, which includes oil and gas groups AGIP and SNAM, is due to be privatised at some stage over the next couple of years. The structure and timing of the privatisation has not yet been finalised. Selected non-strategic assets have been, or are in the process of, being sold off.

Competition to obtain exploration licences grew during the 1980s, with increasingly smaller areas being allocated to a growing number of companies, many of which included small independent operators. Nonetheless, the major companies did not relinquish their dominant position in exploration and production. Though this was not entirely due to their own efforts but was also, in part, due to the damage wrought on many small players by the 1986 price collapse. That led to a concentration of exploration and operating licences, particularly in the North Sea. The majors in the EU include Shell, Exxon and BP, all three of which are very active in the United Kingdom North Sea (with Shell and Esso splitting many joint ventures 50/50), NAM in the Netherlands (50 % state controlled with the remained split evenly between Shell and Exxon), and BEB in Germany.

### Impact of the Single Market

The main impact of the Internal Market programme on the exploration and production of crude oil and natural gas to date has been an indirect effect on demand. The impact on the sector as a whole is mixed, however, as increased economic activity within the EU has provided a positive stimulus to energy demand and consumption, while measures taken in the environmental field have changed the energy mix and provided new incentives for energy conservation.

### REGIONAL DISTRIBUTION

The production of crude oil and natural gas in the EU is extremely polarised. The United Kingdom dominates EU crude oil output, accounting for 80 % of total EU oil production in 1993. As for natural gas, the Netherlands accounts for 40 % of EU production, while the United Kingdom accounts for 35 %. Italy, Germany and Denmark also contribute in a more limited way to EU oil and gas output.

### ENVIRONMENT

Stringent regulations are applied to all offshore operations in the EU. These include regulations concerning oil spills and discharges of cuttings and oil mud. Work is also being undertaken to define rules and standards for the abandonment of disused offshore installations and structures. Safety regulations are also very strict, having been tightened in the wake of several accidents that occurred in the North Sea at the end of the 1980s.

### REGULATIONS

Progress towards implementation of the Single European Market brought to light several significant obstacles to the free movement of goods and services in the EU. Most of the barriers to trade that were addressed by the Commission were regulations that favoured state-owned companies (i.e. compulsory government participation, reserved areas, local landing obligation) and requirements to procure goods and services locally. On 30 May 1994 the Council adopted Directive 94/22/EC of the European Parliament and of the Council on the conditions for granting and using authorisations for the prospection, exploration and production of hydrocarbons (the Hydrocarbons Licensing Directive 'HLD'). This Directive entered into force on 30 June 1994. It sets up common rules for ensuring that the procedures for granting authorisations for the prospection, exploration and production of hydrocarbons must be open to all entities possessing the necessary capabilities. Authorisations must be granted on the basis of objective and published criteria. The conditions under which authorisations are granted must likewise be known in advance by all entities taking part in the procedure.

### OUTLOOK

EU crude oil production is expected to reflect developments in the United Kingdom sector of the North Sea. Output is expected to peak towards the middle of the 1990s at some 127 million toe as enhanced recovery techniques are applied and small fields are brought on line in the North Sea. Later in the decade and into the next century, crude oil production in the EU is forecast to decline steadily with falling United Kingdom production. By the end of the century, total EU crude oil output should slip to 100 million toe. Moving through the early years of the next century, EU output is expected to drop off even more steeply, falling to just 68 million toe in 2005. Although modestly higher prices should lead to an upturn in exploration activity over the next few years, new finds are considered most unlikely to arrest the long term declining trend in United Kingdom oil output.

The outlook for natural gas production is more optimistic. EU production should rise by 9 % by 2000 compared to 1993, but decline by 4 % over the following decade. By the year 2000, Dutch output is expected to have risen 14 % from 1993 to 68.4 million toe, while United Kingdom output is forecast to climb by 6 % to 59 million toe. During the decade after 2000, Dutch output is expected to rise a further 15 %, while production in the United Kingdom is expected to fall by 18 %.

# Nuclear fuels

## NACE 15

*The slowdown in the development of nuclear power that has been experienced in the EU since the late 1980s has continued to have an impact on the nuclear fuels industry, and output has remained relatively flat in the front end, while capacities are expanding in the back end. The main developments in the sector in recent years were an increased use of imported uranium, and a further concentration in the production and reprocessing of fuel elements for light water reactors (LWR).*

---

### INDUSTRY PROFILE

---

#### Description of the sector

NACE 15 covers all activities relating to the nuclear fuel cycle. Specifically, NACE 151 covers the extraction of ore containing fissionable and fertile materials, and NACE 152 covers the production and processing of fissionable and fertile materials.

The key activities involved in the industry are:

- the mining of uranium and shipment to processing facilities;
- the conversion of natural uranium to uranium hexafluoride;
- the enrichment to increase the concentration of uranium 235;
- the production of nuclear fuel elements for use in power stations (all previous four activities form the front end);
- the re-processing of spent fuel elements and other nuclear waste (the so-called back end).

Companies active in the field of nuclear fuel cycle involve both dedicated nuclear companies and those providing a wide range of engineering services. The most important nuclear fuel companies in the EU are BNFL (UK), which is state-owned, and COGEMA (F), which is owned by the French State and the private oil company Total.

#### Recent trends

Capacity in the nuclear fuel supply industry has grown modestly, reflecting the rapid slowdown in the construction of nuclear power plants from the mid-1980s.

The main impact of the slowdown in the fuel supply industry has been felt by producers of uranium ore and service companies. In real terms, uranium prices for short term contracts have fallen from a peak of 52 ECU/kg in 1975 to 25 ECU/kg in 1990. During the 1980s, real prices fell steadily due to over-optimistic forecasts of demand for electricity from nuclear sources which resulted in a build-up of uranium stocks. The mining industry continues to find itself in a situation of over-capacity, with the likelihood of continuing low prices.

In the back end, after the opening of new facilities in France and the UK, reprocessing is rapidly reaching its nominal capacity.

#### International comparison

The EU accounted for 14 % of OECD production of natural uranium in 1993 with 1 994 tU (tonnes of uranium). Canada is the largest uranium producer with 9 150 tU, and remains the world's largest exporter. The EU produces 12 % of its annual uranium requirements, and production is concentrated in France which accounts for 80 % of the EU total.

France also has the largest conversion capacity of the OECD countries, with EU countries accounting for over 50 % of

the OECD total. Two-thirds of this is in France and the rest in the United Kingdom.

The EU had a total enrichment capacity in 1993 of 13 600 tonnes of separative work units (tSWU per year, which is a measure of a plant's enrichment capacity), 80 % of which was by the diffusion process (in France) and the remainder by gas centrifuge (the UK, The Netherlands and Germany). The USA, with the world's largest enrichment capacity at 19 300 tSWU/yr in 1993, produces enriched uranium solely by the diffusion process. The EU, therefore, has a slight technological edge over the USA in the enrichment process when it comes to higher electricity prices.

The EU has a number of world class companies providing a complete range of fuel fabrication capabilities. These include fuel elements for gas cooled reactors, and fast breeder reactors, as well as a growing mixed oxide fuel (MOX) capability.

#### Foreign trade

In the EU, Euratom, pursuant to the Euratom treaty has to ensure the principle of equal access to sources of supply and in this frame, is involved in both imports and exports of nuclear material.

The EU imports a considerable amount of its natural uranium requirements, nearly 88 % in 1993. However, the EU has a strong commercial position in the conversion and enrichment business, where it is a net exporter with significant market share in the Far East. Spent fuel from nuclear reactors bound for reprocessing is also traded. France and the United Kingdom being the world leaders in the reprocessing trade.

---

### MARKET FORCES

---

#### Demand

The demand for nuclear fuel services is totally driven by the use of nuclear power in the production of electricity. With the exception of France, and the UK (Sizewell B) on a smaller scale, there has been no expansion in nuclear power plants in the EU since the mid-1980s. Furthermore, during this period Italy has banned the use of nuclear power, resulting in the cancellation of a number of nuclear power plants, mostly at the construction stage. There has therefore been little growth in the demand for nuclear fuel within the EU.

Demand from other regions of the world has also been restricted. There has been little growth in the installed capacity of nuclear plants in North America since the mid 1980s. Japan, South Korea and Taiwan are the major export markets where the capacity of nuclear plants continues to rise.

The demand for different types of fuel elements stems from the different types of nuclear reactors. The main reactor designs currently in large scale use in Europe are:

- PWR (Pressurised Water Reactor), the most common reactor type which uses enriched uranium or MOX fuel;
- BWR (Boiling Water Reactor), which uses enriched uranium fuel or MOX fuel;
- AGR (Advanced Gas cooled Reactor), in use in the UK only and requires enriched uranium fuel;
- GCR/MAGNOX (Gas Cooled Reactor) now only used in the UK (MAGNOX), and uses natural uranium fuel;
- FR (Fast Reactor), not yet commercially available, but one large scale plant is in operation in France (another large FR is operating in Japan). FRs use plutonium fuel, which is separated from spent fuel from other reactor types.

## Supply and competition

### Uranium production

The EU itself has an annual uranium production of about 2 000 tU, with the remainder of its requirements being imported. Electricity producing companies have tended to diversify their sources of supply in order to guard against unexpected interruptions. They have also built-up stockpiles which can vary from two to four years' worth of consumption.

Within the EU, uranium is produced by few Member States, with 80 % coming from France. The EU now accounts for 14 % of OECD uranium production and around 12 % of world production outside of CPEs (centrally planned economies) and former CPEs. This contribution has declined steadily as economic resources of uranium in the EU have been depleted.

France is by far the leading EU producer, with annual production of 1 600 tU in 1993. However, production has been declining rapidly, and the only producer COGEMA is increasingly looking elsewhere for uranium resources in the higher ore grades.

Spain is the second most important producer in the EU, and production is owned and managed by the government organisation, Empresa Nacional de Uranio SA (ENUSA). Almost all the uranium produced in Spain comes from the Sealices el Chico mine works at Ciudad Rodrigo from ore extracted from the uranium deposits at Fe. The remainder was produced by the small Haba experimental mine situated at Don Benito (which has an annual output capacity of around 30 tU).

About 116 tU were produced in Germany in 1993 from the underground mine at Ellweiler and from Menzenschwand and Grobschlophen, which are both open cast. Production capacity is about 150 tU per annum, but limited ore supplies means that capacity is under-utilised. There are no plans to increase uranium production in Germany.

In the eastern Laender of Germany, there are an estimated 100-500 tU reserves. Production was centred on the Erzgebirge, which straddles the border with the former Czechoslovakia in the south-eastern part of Germany. Production was undertaken by SDAG Wismut Uranium Combine, which was reportedly once the third largest uranium producer in the world. All output went to the former Soviet Union under an agreement dating back to the immediate post-war period, where the uranium was enriched and made into fuel. Since the beginning of 1991, SDAG has practically stopped mining, with the company's only output coming from slag.

Also production in Portugal and Belgium has been stopped during the 1992-93 period.

The lack of growth in demand for nuclear fuel and the release of military stocks has led to a considerable excess offer on the uranium supply market, which has depressed prices for uranium. Widespread use of plutonium in mixed oxide fuel (MOX) for Light Water Reactors will also reduce the net requirements in that stage of the fuel cycle.

### Conversion of uranium

The EU's requirement for conversion is about 15 000 tU/yr. This figure is anticipated to increase by around 2 000 tU by 1995 with the membership of Sweden and Finland. However, at the European level demand will be stagnant.

At present, two companies carry out conversion operations in the EU, BNFL in the United Kingdom and Comurhex, a wholly-owned subsidiary of COGEMA in France. The EU conversion capacity is currently around 21 300 tU/yr, and therefore has a utilisation rate of around 75 %. The only other OECD region with significant conversion capacity is North America, where there is approximately the same capacity as in the EU.

The main importing region is north-east Asia, where between Japan and Korea there is a demand for nearly 10 000 tU/yr, and no significant conversion capacity.

Despite strong competition, BNFL (UK) and Comurhex (F) have been able to obtain a significant proportion of non-EU European markets and have thus been able to ensure adequate utilisation of their facilities.

### Uranium enrichment

Uranium enrichment accounts for about 25 % of the cost of the nuclear fuel cycle. The process increases the content of U<sub>235</sub> (fissile uranium) in the fuel from about 0.5 % to 3.0 %. Most modern reactors (PWRs, BWRs and AGRs) require enriched uranium fuel. A standard pressurised water reactor (PWR) with a capacity of 1 GW, has a requirement of about 25 t/yr of enriched uranium, which in turn requires about 150 tonnes of natural uranium.

Currently there are two commercial processes used for uranium enrichment, firstly gas diffusion and secondly centrifugal separation. Of the two, gas diffusion is the more widely used technology, but is more energy intensive.

Production in the EU is in the hands of two multinational groups, Eurodif (F) and Urenco (UK, NL, D). The Eurodif consortium has a large diffusion plant at Tricastin in France, with a nominal capacity of 10 800 SWU.

Urenco Ltd (UK) was formed on the basis of an equal equity split between Uranit GmbH (D), British Nuclear Fuels Plc (UK) and Ultracentrifuge Nederland (NL). The company was established to develop and apply, on an industrial scale, the centrifugal enrichment technique.

The present output of the Urenco group of plants is around 2 750 tSWU/yr, although a number of projects are currently being undertaken to increase this output to 4 500 tSWU/yr by the end of the decade.

### Fabrication

Within the EU, most countries are self-sufficient in fuel element fabrication. Only the Netherlands has no fabrication facilities of its own. For the EU as a whole, fuel requirements in 1993 were just over 3 000 tonnes, compared with a capacity of over 4 500 tonnes.

The largest producer of fuel elements for light water reactors (LWR) within the EU is FBFC, a subsidiary of the French companies Framatome and COGEMA, with plants in Belgium (Dessel) and France (Romans and Pierrelatte). Other producers include, Siemens (D), ENUSA (E), and BNFL (UK). BNFL produces fuel assemblies for both LWR and GCR (MAGNOX and AGR).

The production capacity of fuel elements has been relatively stable, and is expected to remain so. However, there is at present a changing mix in the assembly capacity. This is due to the reduction in demand for fuel elements for GCR and an increase in demand of mixed oxide fuel (MOX), mostly fabricated by Belgonucleaire and COGEMA. A new plant called MELOX was opened in France in 1994.

#### *Storage and reprocessing of discharged fuels*

The majority of EU countries (France, the United Kingdom, Germany, Belgium, Italy and The Netherlands) reprocess spent fuel elements in order to recover unburnt uranium and plutonium and minimise the volumes to be stored. Reprocessing usually takes place after an interim period of storing the fuel on the power station site, either in special dry storage facilities or in under-water storage tanks. COGEMA (F) and BNFL (UK) operate reprocessing facilities in the EU, and have both recently opened new ones: UP2 800 at La Hague and Thorp in Sellafield.

Fuel reprocessing and waste management represent a considerable proportion of the fuel cost, almost 20 % if account is taken of the credit of the recovered uranium and plutonium, and 30 % if this is not taken into account.

#### **Production process**

Uranium is mined from both open-cast and underground mines, and the natural ore is then refined by milling and using a leaching processes.

The conversion process converts natural uranium into uranium-hexafluoride, which lends itself to subsequent processing (enrichment and fabrication) and which possesses the required chemical purity. Conversion represents only about 3 % of the total cost of the fuel.

Enrichment is the process in the fuel cycle where the fissile isotope content of the uranium is increased. This stage is necessary in the case of fuel destined for light water reactors (either PWR or BWR) and for advanced gas cooled reactors (AGR). Three processes used for uranium enrichment exist. Two are currently commercially used. The technology based on gas diffusion is the sole process used in France. In the United Kingdom, Germany and The Netherlands, centrifuge technology is used. Since this technology uses far less power, it is the cheapest based on marginal costs. However, since centrifugal shops have a small capacity, this technology does not benefit of the scale effect of the much larger diffusion plants.

A new process now exists, known as atomic vapour laser isotope separation (AVLIS) which could cut costs even further, although this is not yet available commercially. This technology is being developed in France and in the USA, where the diffusion methods are also used.

Fabrication of the fuel elements comprises the operations during which uranium fluoride, enriched or otherwise, is used to produce the final fuel elements to be placed into the reactors. This stage represents about 11 % of the total fuel cost.

Reprocessing is a complex chemical operation performed on spent fuel discharged from nuclear power stations. This fuel is a mixture of reusable products (unspent uranium and plutonium created during the fuel irradiation in the power station's reactor) and fission products which are highly radioactive and are akin to the ashes from using fissile material.

The reprocessing operation enables the various products to be separated. Recycling uranium and plutonium recovered from thermal nuclear power stations in the reprocessing process reduces the amount of natural uranium needed by a nuclear power station. Plutonium may be recycled in LWR as MOX, or in fast breeder reactors.

The only OECD countries with reprocessing capabilities are France, the UK and Japan. Reprocessing is also practised for industrial purposes by Russia.

#### **Impact of the Single Market**

The nuclear fuels industry is regulated by a series of international agreements and organisations such as the Euratom Treaty, the International Atomic Energy Agency and the Nuclear Non-Proliferation Treaty, which are perceived as having a much greater impact on the structure and activities of the industry than the measures introduced to support the European Single Market. Issues of direct relevance to competition and trade in nuclear fuels tend to be governed by these wider international forums.

Compared to other industrial sectors, the nuclear fuels industry has relatively few suppliers and customers, and operates in only a limited number of countries, both within the EU and in the broader international context. Additionally, the industry is currently in a phase of very low growth, with the slowdown in growth of electricity demand and the limited number of new nuclear power plants being planned or built. The scope for increasing competition and reducing costs via current or proposed measures related to the Single Market is thus perceived as very limited.

The principal issues on which the industry would wish to promote international agreement are related to the definition of standards for the treatment and disposal of low-level radioactive material, the harmonisation of operating standards for nuclear power plants and the updating of international treaty obligations to promote a long-term stable framework for the development of the industry.

---

## **ENVIRONMENT**

---

Environmental considerations of the nuclear fuel cycle mainly stem from radioactive waste from nuclear installations. At this stage, it should be noted that the volumes generated by the nuclear energy are negligible compared to both the volume of ashes from fossil fuels combustion, or to the volume of industrial waste

In the attempt to limit the volumes of waste material is concentrated into solid and solidified forms. Solid waste materials arising from the nuclear fuel cycle are then stored on land. There are three main categories of waste: low level, intermediate and highly active wastes.

Low-level waste (LLW) forms the vast bulk of waste material. The material is either held in surface or near surface installations where the composition of the waste is controlled over a maximum period of 300 years. Prior to 1982, some of the low-level waste was dumped in special containers at sea. However, following the adoption of the Convention on the Prevention of Marine Pollution from the Dumping of Waste and Other Matters, the practice was curtailed in the OECD.

Intermediate level waste (ILW) can be divided into: a) material that has been contaminated by radionuclides which have a long half-life (the period of time taken for the level of radioactivity to fall to half of its initial level) but produce little heat because of their moderate concentration of radioactive elements, and b) material containing and emitters only, but containing intermediate levels of radioactivity that produce no significant amount of heat.

High-level waste (HLW) consists of irradiated fuel discharged from a nuclear reactor (when it is not intended to reprocess

and recycle them), and vitrified waste produced after the re-processing of spent fuel. This waste has a very high radioactive toxicity which can persist over thousands of years. At present this waste is kept in either storage ponds or dry storage facilities located at nuclear plants. It is likely that this kind of storage facility will be used for a period of 15 to 20 years, while permanent repositories can be developed.

However, given the length of time that containment of such material will require, final disposal systems have to be passive, with the long-term safety not dependent on human control or surveillance. Currently, investigations are being concentrated on the burial of high level waste in deep stable geological formations, which offer adequate isolation capabilities. On-land sites are the only ones currently under investigation, although research has also been carried out into the possibility of burial in sub-seabed formations or other geologically stable formations.

---

## REGULATIONS

---

The nuclear fuel industry operates under an extremely tight system of safety regulations. These have largely been developed on a national basis, but with a considerable amount of international co-operation through a number of institutions including the International Atomic Energy Agency, the Nuclear Energy Agency (OECD), and the EU. Regulations cover all aspects of the industry including such factors as the emissions of nuclear particles to the environment (air, land and water), the exposure of the public and employees to radiation and the control of plant construction and operation through licensing procedures.

Apart from regulations covering the civil use of radioactive materials the nuclear fuel industry is also subject to measures to control the spread of nuclear materials for military applications. Of particular concern is the illegal trade of nuclear materials.

Within Europe, Euratom was established in 1957, with its general objective being inter alia to ensure that nuclear materials do not get diverted to purposes other than those for which they were intended. The Euratom safeguards system is founded in European law, with strong sanctions for infringements. It applies to all nuclear materials from the moment they are mined on EU territory or are imported into the EU. Aside from ensuring that the material is not being diverted from the declared uses, Euratom also checks to see that declarations of specific use are correct and that the suppliers obligations are being respected.

It can be noted that since its foundation, no diversion of material, or no illegal trade has taken place.

---

## OUTLOOK

---

The long term future of the nuclear fuel industry is linked to that of the use of nuclear power in electricity generation, and to the energy markets as a whole. Since no new capacity of electricity has been required, there has been no strong incentive for new nuclear plants in recent times.

Since 1983, two thirds of the electricity capacity increase of the major OECD countries (USA, Japan, Germany and France) is due to nuclear energy. Today France and the UK are continuing to build new nuclear power plants. The only other countries where additional nuclear power plants may be built in the period up to 2010 are Germany and Belgium. However the prospects for nuclear power in the UK will depend on the outcome of the governments nuclear review. In Germany, whilst there is no moratorium, power companies have found it impossible to gain the necessary consents to build and operate new plants due to environmental objections. With the breakdown of the cross-party talks aimed at achieving a consensus

on the future of nuclear power, it seems increasingly unlikely that new plants will be built in Germany in the foreseeable future.

Without new construction, the number of operating plants will begin to fall increasingly after 2010 when existing plants reach the end of the operating life. This will have a direct impact on the demand for nuclear fuel services.

In the shorter term, the EU's annual nuclear fuel requirement is expected to edge slightly higher from its current level of 3 000 tHM (tonnes of heavy metal) before falling back over the balance of the decade. Uranium production is forecast to fall to around 1 905 tU by the turn of the century, a decline of 45 % from the 1992 level.

An increase in total output of MOX fuel will gradually increase during the 1990s. MOX annual production is expected to reach 255 tonnes from capacity increases in Belgium, France and the United Kingdom in order to satisfy the requirements of the plutonium thermal recycling programmes. Total fuel requirements are forecast to peak in the mid-1990s, falling to around 2 500 tonnes by the year 2000.

Current expansion plans for reprocessing facilities are set to raise capacity to over 2 225 tonnes in the EU by the turn of the century. This should ensure sufficient capacity to reduce the backlog of material that has been in storage. Taking account of quantities to be reprocessed from countries outside the EU, it is estimated that interim storage requirements could be about 20 000 tU from 1995 to 2000. The necessary storage capacity to cover these requirements is already in place.

It is anticipated that rationalisation of the fuel production industry will increase utilisation rates. Better use of fuel elements by the nuclear power industry will also have an impact on the demand for nuclear fuel services.

It is therefore likely that the demand for natural uranium will decrease more sharply than that for nuclear fuel services in general.

The industry is represented at the EU level by: European Atomic Forum (FORATOM). Address: Rue d'Egmont 15, Bte 4, B-1050 Brussels; tel: (32 2) 502 4595; fax: (32 2) 502 3902.

# Refining and distribution of oil products

## NACE 14

EU demand for petroleum products dropped back slightly in 1993 in the wake of the economic downturn, but is expected to resume slow growth as economies move into a recovery phase from 1994 onwards. Structural changes in demand will continue, however, acting as a brake on future demand growth, as natural gas continues to substitute for petroleum products in the heating, industrial and power generation sectors. Future trends in demand show an increasing proportion of middle distillate, as dieselisation of the transport fleet, and increasing air travel, boost consumption of diesel fuel and jet fuel. EU refineries will have to continue to invest to meet these changing market requirements.

The other major challenge for the refining and distribution sector in the mid-1990s comes from requirements for investment to meet changing environmental standards, both in the quality of fuels produced, and emissions from the refineries. Standards may be subject to significant change over the next few years, and refiners will have to carefully position themselves to optimise investment and maintain viability of their operations.

EU refinery capacity is currently roughly in balance with demand, in overall terms, although specific products are traded with other regions. The EU is open to this trade, ensuring a truly competitive environment for refined petroleum products.

### INDUSTRY PROFILE

#### Description of the sector

NACE 14 includes the activities of petroleum refining and the processing of petroleum derivatives, with the exception of petrochemicals. Inputs to this process are crude oil and semi-finished petroleum feedstocks. The main final products of this activity which are widely marketed are liquefied petroleum gases (LPG), naphtha, motor gasoline, aviation fuels, kerosene, gasoil (diesel fuel and heating oil), residual fuel oils and lubricants. The classification also includes distribution of refined petroleum products to consumers, including the operation of storage facilities, transport and retail outlets.

The refining and distribution sector is not a major source of employment in the EU. Over recent years, increased automation of refinery and distribution operations, and the widespread trend towards self-service in gasoline retailing at service-stations, has limited the potential of the sector to increase employment possibilities.

#### Recent trends

Total EU petroleum product demand in 1993 was 522 million tonnes (excluding refineries own consumption). This total represented a 1.2 % decline versus 1992. Of total deliveries, 35 million tonnes was consumed in the marine bunker market, and the remainder inland, in industry, transport, power generation and residential and commercial uses.

The share of oil in total primary energy demand in the EU was just under 45 % in 1993, unchanged from 1992, after falling to about 42 % in 1989, as other fuels were substituted for oil, and energy conservation and efficiency investments reduced the scope for oil demand. The only sector where petroleum products do not face widespread substitution is the transport sector, where demand has shown steady growth over the last ten years.

Figure 1: Refining and distribution of oil products  
Extra-EU exports of refined oil products, 1993

Source: Eurostat

These long term trends in energy and oil use have significantly modified the structure of oil demand, with lighter products taking a larger share, and heavy residual products a declining share of demand since the early 1980s. The share of residual fuel oil in total EU oil demand has declined from 25 % in 1984, to 18 % in 1993. This trend is similar when considering just inland demand. Over the same period, residual fuel oil's share of inland demand declined from 23 % to 14 %. The share of light products (refinery gases, LPG, naphtha and gasoline) in total petroleum products demand in the EU has increased from 31 % in 1984 to almost 34 % in 1993.

Consumption of middle distillates (jet fuel, kerosene and gasoil) declined in the second half of the 1970s, but then remained virtually stable through the 1980s. The share of middle distillates in inland oil demand seems now to be on a rising trend with dieselisation of the motor vehicle fleet and continuing growth in jet fuel demand. As a share of total petroleum product demand, the proportion of middle distillates has risen from 38 % in 1984 to 42 % in 1993. Excluding marine bunker demand, the middle distillate share has risen from 38 % in 1984 to 43 % in 1993.

Trends in production from EU refineries have generally followed the pattern of demand, with output volume and output structure adapting to the changing needs of the market. Since the early 1980s, the EU refining industry has shown considerable flexibility and ability to position its activities to respond to the needs of the market and the changing regulatory environment through a dual process of bringing total production capacity into line with demand, and investing in new production processes to ensure the mix of products corresponds to the structure of consumption.

Refinery production, net of feedstocks destined for further processing, has actually increased over the period 1984 to 1993, as refineries have been able to structure their output closer to market needs and thus increase capacity utilisation. In 1984, EU refinery output was 485 million tonnes (including Greece, Spain and Portugal); by 1993 this had increased to 518 million tonnes, an increase of 0.6 % per year. The proportion of residual fuel oil in EU refinery output declined from 24 % in 1984 to 19 % in 1993, leaving a small surplus of residual fuel oil for export.

#### International comparison

Demand for refined products in the EU, currently standing at about 560 million tonnes in total, remains significantly lower than in the USA. With demand for refined products

Source: Eurostat

currently standing at about 900 million tonnes, the USA is the largest single market for petroleum products in the world. The USA has also a demand configuration which favours lighter products than in Europe. The strong development of the gasoline market has led to this fuel representing about 45 % of demand, compared to about 25 % in the EU (where the middle cuts of the refined barrel (i.e. gasoil, kerosene) have been favoured by the development of diesel fuel for transport to a greater extent than the USA). Thus, typical US refineries have a much greater product upgrade capacity than those of Europe.

Although refining capacity in the USA like in the EU, is broadly in line with demand, seasonal and local imbalances, together with a very open trading environment, have encouraged an active trade in refined products across the Atlantic in both directions.

US refineries also face the challenge of meeting new regulations affecting fuel quality and the fuel demand pattern, which have potentially further-reaching implications for refiners than the measures enacted or proposed within the EU. The US Clean Air Act Amendments of 1990 sets deadlines for the use of clean fuels in cities or regions designated as ozone or carbon monoxide non-attainment areas (essentially gasoline containing 2.0 % oxygenate). The use of reformulated gasoline will be phased in from 1995 onwards, and is widely forecast to increase US refining and distribution costs by about \$0.1 per US gallon, and put strain on the storage and transport facilities. Another measure, the Energy Policy Act of 1992, contains provisions for the introduction of alternatively fuelled vehicles into the national vehicle park, in order to replace 10 % of motor fuel consumption by 2000 and 30 % by 2010. If implemented, this could have a severe impact on US refining activity, which is heavily geared to the production of transport fuels. It is forecast that a new series of refinery closures, primarily affecting the remaining smaller, less sophisticated refineries, could follow full implementation of these measures.

In Japan, the market for refined petroleum products is smaller than that of the EU, currently totalling about 230 million tonnes. The country is normally a net importer of petroleum products, as demand growth has outstripped local refining capacity. These are generally supplied from Singapore or the Middle East. The structure of the demand barrel is quite similar to that of the EU.

### Foreign trade

The EU is an open market for petroleum products, with Member States both importing and exporting products to match supply and demand. Refineries are also able to tailor production to more global trends in product demand, for example exporting products across the Atlantic to the USA when demand is high and prices are favourable.

In 1993, EU countries imported a total of 172 million tonnes of petroleum products, of which 80 million tonnes was supplied by non-EU countries. The principal non-EU suppliers were OPEC countries, representing 28 % of the total, and the former USSR, representing 18 % of the total. The USA accounted for 7 % of EU imports from outside the Union.

Extra-EU exports of refined products from EU countries totalled 77 million tonnes in 1993. The region as a whole was thus in the position of being a net importer, although this varied by product, with net imports of LPG, gasoil and naphtha offset by net exports of gasoline, jet fuel and residual fuel oil.

Intra-EU trade totalled 91 million tonnes in 1993. Germany, Ireland, Luxembourg and Portugal were net importers, with the other Member States in the position of net exporters.

## MARKET FORCES

### Demand

EU demand for refined petroleum products is subject to both volumetric and structural change. Total demand for petroleum products responds to general economic conditions, as well as the relative price of petroleum products versus competing fuels in applications where fuel substitution is feasible. Changes in the structure of demand, with evolving shares of light products, middle distillates, residues and special products, are driven by the differences in the potential for substitution between refined products. In general, gasolines and diesel fuel destined for the transport sector are resistant to substitution, while heating oil, and residual fuel oil, destined for the heating, steam-raising, industrial process or power generation market are susceptible to losing markets to competing fuels such as electricity, natural gas or coal, when expectations of differences in fuel prices, together with switching costs move consumer preference away from petroleum products.

These factors combined have contributed to a small decline in EU petroleum product demand, including marine bunker fuel, from 530 million tonnes in 1984 (including Greece, Portugal and Spain) to 522 million tonnes in 1993, an annual average decline of 0.2 %. Year-on-year variation in demand can deviate from this progression in line with economic activity, as seen, for example, in 1993 consumption figures, which registered a decline of 1.2 % compared to 1992. Over the same ten-year period, the share of residual fuel oil in total demand for petroleum products (including demand for marine bunker fuels) has declined from 25 % to 17 %, as industry and power generation have switched to competing fuels, including natural gas, coal and electricity in industry, and nuclear power and natural gas in the power generation sector.

### Supply and competition

#### Supply

Although the EU remains an open market for petroleum products, as described in the section on foreign trade above, EU-based refiners supply the vast majority of the region's petroleum product demand. This is due to the historical development of the EU refining industry over the last 30 years, during which most Member States developed domestic refining capacity to cover their own needs and to serve export markets. Such development was partly due to the economics of transporting and refining oil, since it is generally less costly to ship crude oil and refine it close to consuming markets than to refine it close to the source of production and ship the refined products. Prior to the availability of North Sea crude oil, which began to come on stream in the mid-1970s, Middle East crude oil formed the bulk of Europe's supplies, and was shipped to Europe to feed the local refining sector. Despite the rationalisation of refining capacity that took place in the 1980s after the slowdown in EU demand growth, EU refineries still cover practically all of the region's needs, with trade serving to balance supply and demand for specific products. Indeed, the reduction in capacity has meant an improvement in capacity utilisation rates from below 70 % in the early 1980s to over 90 % today, thus increasing the viability of those refineries which remain in operation.

The following paragraphs describe some of the more important changes in industry capacity over the recent past, with regard both to manufacturing (in refineries), and distribution (via retail outlets).

#### Refining

The decade of the 1980s saw the EU refining industry undergo profound restructuring. Capacity which had been constructed or planned in the 1970s, before the oil price shocks put a brake on regular demand expansion, was progressively taken

out of service in order to bring overall capacity back in line with demand. At the same time, refiners made large investments in upgrading facilities designed to produce more lighter products and less residual fuel oil, in line with the evolution of market demand. This process saw total primary distillation capacity in the EU decline to 569 million tonnes/year in 1990. At the beginning of 1994, EU primary distillation capacity stood at over 600 million tonnes/year (now including the refineries of the new Laender in Germany), and upgrade capacity for the whole of the EU stood at about 35 %.

The only major project entailing additional refining capacity in the EU is the planned construction of a new refinery at Leuna in Germany, where the existing 5 million tonne/year refinery is planned to be decommissioned and replaced by a new refinery of about 9 million tonne/year capacity. This refinery will be built and operated by a consortium led by Elf (F).

The period from the early 1990s up to the end of this century poses different challenges for the refining industry, of which the greatest is the need to adapt to the requirements of environmental legislation. Various new regulations covering emissions from refinery and distribution operations and potentially more stringent fuel specifications will add to refinery costs, and could also dampen demand for refined petroleum products if their competitiveness versus other fuels is reduced.

#### *Fuel retailing*

The drive to cut costs and increase productivity in petroleum product distribution over the last 15 years has had its most visible effect in the reduction in the number of service-station retail outlets across the EU. During the 1980s, the number of service-stations decreased by 26 %, as oil companies closed low-volume and rural outlets, to concentrate on higher volume service-stations. Rationalisation of the retail network did not occur uniformly across the EU, the most reductions in the number of outlets took place in the Netherlands (-36 %), France (-35 %) and Germany (-29 %), whereas the networks grew in Greece (+16 %) and Spain (+17 %). The rationalisation process, which is still continuing, has increased the competitiveness of those outlets that remain, in part because of increased throughputs. There is still considerable variation in average monthly throughputs from country to country: the highest are to be found in Spain where there is a small number of outlets per car. In contrast, average throughputs are approximately a fifth of Spanish levels in Italy, Ireland and Greece, where the rationalisation process has been slower. The number of outlets in Greece and Spain has been rising as a growing proportion of the population has had access to cars and as the average car size increased. In addition, regulatory restrictions limiting the development of new service-stations in Spain have gradually been lifted over the last five years, allowing new market participants to establish and expand their retail networks.

#### *Competition*

The petroleum product refining and distribution sector in the EU is generally recognised as being truly competitive. Several factors serve to safeguard this state of affairs. Firstly, each member state now has a number of major and independent oil companies operating within its market, competing for market share and profits. Secondly, there are no or few restrictions on trade, either between Member States, or between the EU and other suppliers, thus enabling product to be readily moved between markets in response to changes in the demand or price environment, and enabling new suppliers to take market share. Thirdly, there is a high degree of price transparency, with daily published quotations for all principal products in the Mediterranean and North West Europe, allowing refiners, distributors and consumers knowledge of movements in market prices.

Competition in the distribution chain is also reinforced by the presence of non-traditional fuel marketers such as hyper-

market and supermarket chains, which have gained significant market shares in France, Germany, the United Kingdom and the Benelux countries. Their low-cost operations and access to international supplies serve to maintain serious price competition right down to the final consumer.

#### **Production process**

The evolution in EU refining processes over the last ten years has focused around the increase in upgrading capacity, designed to produce more lighter products and less heavy products, and the installation of new production processes to manufacture unleaded gasoline in conformity with national and EU octane specifications. Although some Member States' refining industries moved earlier and faster on these developments, notably Germany, the United Kingdom, Denmark, the Netherlands and France, there is now a notable tendency to convergence, as southern European refining systems, in Spain, Portugal, Greece and Italy have invested, and are continuing to invest in these trends.

The major challenges for production processes in the EU refining industry over the next ten years are the increased proportion of middle distillates in the demand barrel, which will require different upgrading techniques than those used in the past to maximise light product yields, and the trend towards more stringent product specifications, notably the reduction in the sulphur content of gasoil, both for transport and heating use. These requirements will likely imply the need for further heavy investment by the refining industry in hydrotreatment and hydrodesulphurisation over the next few years. Although the costs of this investment will ultimately be reflected in prices paid by consumers, such price increases could dampen demand growth over the long term.

---

## **INDUSTRY STRUCTURE**

---

### **Companies**

#### *Refining*

Following the period of refinery capacity rationalisation in the 1980s, which not only saw the closure of capacity, but also sales of refineries to new operators, and the establishment of some joint-venture refining operations, the current environment for the role of companies in oil refining seems to be more stable. Broadly speaking the same companies that were involved in refining over the last two or three years have maintained their operations, and there are few plans for changes in the ownership structure of the network which remains.

The most recent addition to the EU refining network occurred in autumn 1991, when the 7.8 million tonne/year former Mobil refinery at Wilhelmshaven, in Germany, was brought back into operation. The refinery was acquired by Beta Refining & Marketing, a company jointly owned by the trading company Bulk Oil and the trading firm, Dreyfus.

During the second half of 1993, Elf and Thyssen announced plans to invest in a new refinery as a joint project in Leuna, in eastern Germany. This new refinery, that will replace the existing one in Leuna and another in Zeitz, will now have a planned capacity of 8.5-9 million tonnes/year. Following delays and renegotiations on the scope of this project, the initial planned capacity has been reduced, and the share of Elf reduced, as Russian crude supplier Rosneft will enter the consortium. Thyssen are also likely to divest their share of the venture to Buna, a chemical supplier which is one of the refinery's principal customers.

The role of refining companies owned by the state continues to recede with the wave of privatisation and liberalisation in the EU.

In Portugal, Petrogal, which owns and operates the country's three refineries was sold into the private sector in 1992 to a

Source: Eurostat, 1993 - Oil and Gas Journal, DRI Europe

consortium including several Portuguese financial institutions, and French oil company Total. Although initially, the consortium took only a 25 % stake, commitments were made to increase this to 51 %. However, progress on this objective has been delayed by disagreements over responsibility for Petrogal's pre-privatisation debt, and the investments needed to modernise its refining and distribution assets. Plans are proceeding, however, to upgrade the refineries. The oldest refinery at Cabo Ruivo, in the suburbs of Lisbon, no longer distils crude, but operates as a distribution centre and batch blending plant using feedstock from Petrogal's other two refineries. This facility is shortly to be completely closed down, as the site is needed for redevelopment to stage Lisbon's Expo 98. The other refineries, at Porto and Sines have been subject to extensive upgrading programmes.

In Greece, previous plans to privatise state-owned energy activities, including DEP, the holding company for Greece's two state-owned refineries, were put on ice following elections and a change in government at the end of 1993. However, since mid-1994, the new government has again been considering selling off a stake in DEP to the private sector, in order to raise revenue for the government.

In Ireland, the country's only refinery, Whitegate, operated by state-owned INPC, requires a major upgrading programme to be competitive, and the Irish government is actively seeking a private-sector partner or acquirer to ensure its future.

In Italy, where the domestic refining and distribution sector is dominated by state-owned Agip Petroli and Italiana Petroli, each part of the ENI group, privatisation has been on the political agenda for the past two or three years. Several proposals and timetables have been put forward for privatising the group. The latest plans call for privatisation in 1995, of an integrated upstream and downstream oil and gas company, including Agip (upstream oil), Agip Petroli and IP (downstream oil) and SNAM (natural gas transmission and distribution).

#### Fuel retailing

In petroleum product distribution and retailing, the major companies with refining assets continue to have a dominant position, even during years of recession, as they have invested large amounts to protect their market share. They now account for nearly 30 % of the EU retail outlets. Shell (NL/UK) has the dominant market share, closely followed by BP (UK). Some of the traditionally national oil companies have now spread their presence throughout Europe: Total is present in eight countries for a market share of 4.4 % (1992). A relative newcomer to the European refining and marketing business is Kuwait Oil, which introduced the Q8 brand in 1986 and now owns 4.5 % (1992) of the EU retail outlets. Kuwait Oil

is now the largest retailer in Denmark and has a major presence in Italy, the United Kingdom, Belgium and the Netherlands.

Overall, in the countries where regulations permit, hypermarket and supermarket chains have an important market share, but nowhere is it as large as in France where a third of automotive fuel is sold by supermarkets (their market share is over 40 % for gasoline alone). In the United Kingdom, their market share is nearing 15 % and is expected to increase to 20 % by 1995. The other two countries where hypermarkets have a substantial market share are Belgium and Germany, where it is 10 %, though this share is not expected to increase much more in the near future.

Liberalisation is also affecting the structure of the petroleum product retailing sector. In Spain, the refinery and product distribution sectors have been liberalised. The structure of its industry has changed in that Repsol (part state owned), Cepsa (part owned by Elf) and Petromed (owned by BP) inherited the former Campsa retail outlets and jointly own Compania Logistica de Hidrocarburos (CLH), which inherited the Campsa distribution network of storage depots and pipelines. The share of ex-Campsa retail outlets is roughly 60 % Repsol, 25 % Cepsa and 10 % Petromed. In 1993, Shell Espana also entered the shareholding structure of CLH upon acquiring 5 % of the capital equity formerly held by Repsol in the logistics company. In addition to this a number of other oil companies have entered the Spanish retail market, most notably Shell and Petrogal, with smaller networks being established by Agip, Conoco (USA), Esso (USA), Mobil (USA), Total (F), Texaco (USA) and Petrofina (B). This has been facilitated by the gradual removal of restrictions on expanding the overall service-station network, by reducing, and finally removing, minimum distance requirements between service-stations.

#### Strategies

While each company involved in the refining and marketing sector pursues its own strategy in terms of its geographical positioning, the markets it chooses to serve, its investments in research and development, production processes and technology, its control of operating costs, and the diversification of its business mix, the issues which face the sector in the mid 1990s are requiring an increasingly co-operative approach in order to preserve the industry's future.

Environmental compliance will require potentially heavy investments by refiners and distributors of petroleum products. The industry is already co-operating through its industry association, Europia, to review the impact of proposed environmental legislation. It is highly likely that this co-operation will extend to new agreements or joint-ventures between refineries to ensure that investment is optimised.

### Impact of the Single Market

The introduction of the European Single Market has had some impact on the downstream oil industry, without radically changing the level of activity or the competitive environment. The field of environmental legislation has provided one of the main areas where harmonisation and change in standards has been implemented on a EU-wide basis. Specifications for petroleum products, emissions standards for large industrial plants, labelling of dangerous substances, and measures to reduce harmful emissions during the storage and distribution of petroleum products have all been defined at EU level, allowing companies to operate under the same set of rules throughout the EU. Currently, the oil industry is working closely with the Commission and the automotive industry to define cost-effective measures to improve air quality by reducing emissions from vehicles.

Harmonisation of the excise taxes on petroleum products only had a limited impact on oil markets, since only minimum levels were set. Excise tax convergence has not followed from this measure, leading to final consumer prices for oil products which can vary considerably from one country to another.

Most remaining barriers to investment or establishment of oil refining and distribution operations in EU countries have been lifted in the period since the introduction of the Single Market. In Spain, foreign oil companies have been able to set up new distribution networks or take significant shareholdings in existing Spanish companies; and in France, the refining and product import licensing system has been abolished, making it easier for new operators to enter the market.

### REGIONAL DISTRIBUTION

Activities of refining and distribution of petroleum products are fairly well distributed around the EU Member States, with infrastructure having been developed to serve each national market. More broadly, the EU market is generally perceived as being divided into two major zones. These are north-west Europe and the Mediterranean. The north-west Europe zone covers the Benelux countries, the United Kingdom, Germany, Denmark and France's northern half and Atlantic seaboard, while the Mediterranean zone includes Italy, Spain, Greece, Portugal and southern France. Separate price quotations are generated for each of these zones, based around trade from the principal refineries in each zone. In north-west Europe, these are the refineries of Rotterdam, Antwerp and the Thames, while in the Mediterranean they are the refineries located in southern Italy, including Sicily.

The unification of Germany in 1990 also increased the importance of supply linkages and price formation involving Russia and the Baltic region, which do not always follow patterns established for the other regions.

### ENVIRONMENT

Environmental considerations remain high on the EU's policy agenda, and the energy sector has a particularly important role to play in meeting environmental targets.

As a response strategy to the threat of global climate change, the EU committed itself to stabilising CO<sub>2</sub> emissions at the 1990 level by the year 2000 and signed the Climatic Convention at the Rio de Janeiro conference. Although specific plans to achieve this target have been relatively slow to be developed at the national level, the implications of succeeding in meeting the target are both a substitution of low carbon content fuels for high carbon content fuels and a reduction in the growth rate of overall energy demand. Both of these will result in a relative decline in demand for petroleum products, and hence the activity of the EU refining industry.

The move to reduce emissions of other toxic substances, such as SO<sub>2</sub>, NO<sub>x</sub>, CH<sub>4</sub>, particulates and VOCs (Volatile Organic Compounds) also have a direct impact on the refining and distribution sector.

The sulphur content of gasoil is already scheduled to be reduced, the maximum sulphur content of diesel fuel will be 0.2 % wt. (by weight) from October 1994, and 0.05 % wt. from October 1996. The sulphur content of heating gasoil is also to be reduced to be 0.2 % wt. from October 1994. The regulation mandating closed systems with vapour recovery to minimise VOC emissions during storage and transport (Stage I) was approved by the Council in December 1994. The means for vapour recovery during refuelling of cars (Stage II or large carbon canister) are still under discussion in the Commission services.

In early 1994 a proposal was tabled by the European Commission for a new directive regarding sulphur levels in liquid fuels. This proposes phased reduction of sulphur content in residual fuel oil, for both inland and bunker use, heating gasoil, jet fuel and diesel. Maximum levels could vary by region according to the air quality of the region. The oil industry association, Europia, believes this directive to be unnecessary in light of the Second UN-ECE SO<sub>2</sub> Protocol which leaves it to Member States to apply cost-effective measures for achieving scientifically justified SO<sub>2</sub> reduction tar-

gets. Moreover, the proposal is unfairly targeted on petroleum products, when particularly coal is the dominant source of SO<sub>2</sub> emissions in the EU. Europia also points out that changes in the specifications for marine bunker fuels and jet fuel require widespread international consensus to be effective. The debate on further restrictions in petroleum product sulphur content is continuing.

Further regulations on fuel quality and VOCs are likely over the rest of the decade, but are pending a detailed review by a tripartite group representing the European Commission, the oil industry and the auto industry. This group will analyse whether additional reductions of transport emissions will be necessary beyond 2000 to achieve an acceptable air quality in the EU prior to the development of draft legislation. Measures under study to further curb emissions include vehicle inspection and maintenance, traffic management, vehicle technology and fuel composition. Fuel quality changes which could have an impact on emissions reduction, which are under study by the Tripartite initiative, include: for gasoline, reduction in volatility (RVP), elimination of residual lead, reduction in sulphur, reduction in benzene, reduction in aromatics, and an increase in oxygenates; for diesel, further reduction in sulphur content after October 1996, increase in cetane number, reduction in density and final boiling point in the distillation range, and a reduction in poly-aromatics; and, for other fuels, reduction in sulphur content, as referred to above.

Over the past decade, the most visible change to petroleum product specifications in response to environmental concerns has been the introduction of unleaded gasoline, following reduction in the lead content in the early 1980s. An EU directive adopted in 1985 required that unleaded gasoline be marketed in all Member States from 1 October 1989. This date coincided with the date when all large cars produced (above 2 litres) were to be equipped with catalytic converters. Unleaded gasoline is now widely available in all European countries. Moreover, all cars produced after 1 October 1990, whether they are equipped with catalytic converters or not, must be able to run on unleaded gasoline (Eurograde 95 research octane number [RON]). Although there have been some derogation for old-type engines, 90 % of cars produced can run on Eurograde.

The directive encouraged Member States to introduce tax incentives in favour of unleaded gasoline in order to accelerate its penetration, which all countries have done. In addition, in order to allow a larger proportion of the existing car population to run on unleaded gasoline, most oil companies introduced an unleaded fuel with a higher octane level, Super-premium unleaded (98 RON). Super-premium is marketed in most EU countries

From the beginning of 1993, all new gasoline-powered cars registered in the EU had to be fitted with three-way catalytic converters to meet exhaust emissions standards. This presages the universal use of unleaded gasoline. However, the speed

with which unleaded gasoline gains 100 % market share depends on the rate at which owners of pre-1993 cars opt for unleaded fuel and the rate at which old cars, able to use only leaded fuel, are scrapped. The effect will be relatively small in Germany, Denmark and the Netherlands, where the purchase of catalyst-equipped cars has been favoured for some time by tax incentives. However, in other countries, the new emission rules will give a significant push to sales of unleaded gasoline.

## REGULATIONS

### Petroleum product quality

EU legislation relating to fuel quality addresses the content of lead, benzene and oxygenates of gasoline and the sulphur content of diesel and other gasoil (national standards specify other fuel properties). The European Standard Organisation (CEN) adopted European specifications for unleaded gasoline (EN228), for automotive diesel (EN590) and LPG (EN 589).

The maximum authorised lead level in leaded gasoline is 0.4g/litre, but EU countries are encouraged to use a maximum limit of 0.15 g/litre. All EU countries, except Portugal, have now adopted this lower limit. The maximum benzene content of gasoline is set at 5 % for both leaded and unleaded grades.

CEN EN228 specifies the octane quality of Eurograde unleaded (95 RON/85 MON [motor octane number]), the benzene content (5 % vol. max.) and the lead content (0.013g/litre). The sulphur content is currently set at 0.1 % wt. maximum, but will be reduced to 0.05 % by 1995. Volatility and density specifications have also been agreed upon.

A directive requires that Member States permit fuel blends containing oxygenates and specifies the maximum content. If this maximum is exceeded, then the pumps must be clearly labelled. Most countries restrict limits below the maximum, with only four countries (Belgium, Denmark, Ireland and Luxembourg) permitting levels equal to, or exceeding, this level.

A 1987 directive specifies a maximum level of sulphur in gasoil of 0.3 % wt., except for gasoil used in shipping or further processing; the directive allows Member States to reduce the sulphur content to 0.2 % if necessary for environment or health reasons. Five EU countries have already reduced the sulphur content to 0.2 %. A directive, adopted in March 1993, calls for a reduction in the sulphur content of all gasoil to 0.2 % by 1 October 1994. A further reduction is to be implemented by 1 October 1996 for the sulphur content of automotive diesel (to 0.05 % by weight), as this is required to meet the exhaust emissions limits for diesel engines. The Council asked the Commission to propose a further reduction of the sulphur content of gasoil for industry, space heating and shipping, and sulphur limits for aircraft kerosene. This

directive also requires that the distributed automotive diesel of 0.05 % sulphur be gradually available by 1 October 1995.

### Emissions

As part of the EU policy to limit the emissions of harmful substances to the atmosphere, in 1988 the EU passed the Large Combustion Plant Directive (LCPD) and on 14 June 1994 the 2nd Sulphur Protocol was signed in Oslo. The LCPD applies to all industrial plants above 50 MW capacity, and applies to all existing refineries. Its objective is for plants to achieve a phased reduction of SO<sub>2</sub> emissions from 1990 levels totalling 60 % by 2003, by limiting the amount of SO<sub>2</sub> present in flue gas emissions. To meet these targets, refineries and other industrial plants and power generation facilities have been obliged to choose between burning lower sulphur fuels in their boilers, generally at higher cost than the high sulphur coal or residual fuel oil traditionally used, or to invest in flue-gas clean-up technology, such as FGD (flue-gas desulphurisation). Refineries have largely chosen to reduce the sulphur content of their own-use fuel. The LCPD will soon be due for review and revision. If tighter standards are introduced, conversion to natural gas firing for refinery boilers could be the only way to meet new standards.

### Reserve or strategic stocks

Reserve or strategic stocks consist of quantities of crude oil or refined products which can be called upon at any time by a country to bridge a temporary oil shortage situation. This withdrawal would have to be made according to the provisions of existing EU emergency legislation and IEA Rules. Directive 68/414 required the creation and maintenance of reserve stocks at the EU level initially representing 65 days' consumption;

this was then increased on 1 January 1975 to 90 days' consumption for three categories of product: petrol, middle distillates and heavy fuel oils. Since the directive merely imposed the obligation to achieve an end result, the EU Member States have established over the years systems quite different from one another and which can be divided into two categories depending on whether a centralised stockholding authority has been established.

#### EU countries with a central reserves administration

Five countries have a central reserves administration: Denmark, Germany, France, the Netherlands and Spain.

Denmark has had legislation governing reserve stocks for over 30 years; the reserves are administered by the Foreningen Danske Olieberedskabslager (FDO), a non-profit making foundation established in 1959 with voluntary membership. The FDO is financed by contributions from its members. The 1959 legislation related chiefly to fuels and was amended when Denmark joined the EU by the law of the 24 May 1972 which widened the stockpiling commitment to the three product categories specified in the EU directive. As of 1 January 1993, Denmark reduced its total reserve requirement from 125 days to a 90 day reserve of stocks.

In Germany, the lion's share of the stockpiling requirement of 80 days' consumption is administered by the Erdölbevorzugungsverband (EBV), a national body with public corporation status financed by means of a special tax. At least 90 % of the reserves stocked by the EBV are its own property. The refineries themselves ensure a mandatory 15 days supply. In addition, the federal government has amassed stocks of crude oil equivalent to a 30 day supply.

France long ago established legislation requiring the stockpiling of oil reserves (the commitments to create and maintain safety reserves can be traced back to the law of the 10 January 1925). In 1988, France established a central reserve administration, the Société Anonyme de Gestion des Stocks de Sécurité (SAGESS), which was responsible for half the total legal stockpiling requirements. As of January 1993, SAGESS has been replaced by a new organisation, the Comité Professionnel des Stocks Stratégiques Pétroliers (CPSSP). Under the new law, registered operators establish stockholding obligations of up to 50 % of their commitments, but this progressively decreases to 20 % by 1 January 1996. The balance of the stockholding obligation is met by the payment of fees to CPSSP. CPSSP uses these fees to build and maintain strategic stocks equivalent to 90 days imports. Unregistered operators are obliged to pay fees for their total commitments. As of 1 January 1994, France held emergency oil reserves equal to 95 days of net imports.

In the Netherlands the collective administration of stocks is entrusted since 1986 to the Central Organ Voorraadvorming Aardolie-produkten (COVA), a public body which maintains 70 days of reserves of the light and medium distillation fractions. COVA is financed out of a levy on oil products additional to excise tax. The refineries are required to maintain a 50 day stockpile and sixteen and two-thirds days are maintained by the independents. The stockpiling of heavy fuel oils has been administered since 1 January 1987 by the Union of electricity generators (SEP).

Spain is attempting to adapt to EEC regulations with regard to stockpiling. Since 1988 numerous legislation has been enacted in order to facilitate the transition from a state monopoly to a free market. The latest Royal Decree on 22 December 1992 provides for the creation of a new entity to build-up, maintain and manage strategic stocks under the authority of the Ministry of Industry, Commerce and Tourism. Under the new law, oil distributing companies and consumers are required to maintain emergency stocks of up to 120 days of yearly sales or consumption. On January 1, 1994, Spain's emergency oil stocks were equal to 75 days of net imports, well below the 90 day IEA commitment level.

#### *EU countries with no central reserves administration*

In Belgium, compulsory stockpiling represents one quarter of domestic supplies made during the previous calendar year; the responsibility is assumed by refineries and importers who are both required to maintain 90 days of reserve stocks.

In Greece, the distributors are principally required to maintain 90 day reserve stocks, however this obligation may be assumed by the local refineries which supply the distributors. Distributors only commit themselves to the products which they actually import.

In Ireland, stockpiling is ensured by importers by means of coverage contracts signed with the state refinery company located at Whitegate.

In Italy, the compulsory 90 day reserves are administered by various bodies: the refiners, importers, ENEL, the national electricity generating company, as well as the government itself whose strategic stocks are handled by ENI.

For Portugal, Law Decree 77/91 of 16 February 1991 obliges all importers of crude oil products to maintain emergency reserves corresponding to one-quarter (for jet fuel) and one-third (for gasoline, diesel oil and fuel oil) of their previous 12 months net imports. In addition, stock utilisation depends on government authorisation, although a certain operational flexibility exists. The early use of stocks at the beginning of an oil crisis, or their utilisation in a sub-crisis situation, will be considered by the authorities when it appears necessary.

A maximum of 15 % can be deducted by the EU Member States from the stockholding obligations to take account of indigenous production used to satisfy inland demand. The maximum of 15 % is, for the time being, only attained by the UK and Denmark.

## **OUTLOOK**

Whereas the 1980s was the decade of capacity restructuring in the refining industry, the 1990s and the early years of the next century look to be the years of meeting the challenge of environmental compliance in a low growth market.

Overall growth in inland petroleum product consumption in the EU 12 is expected to average just under 1 % per year up to the year 2000, and only 0.3 % per year between 2000 and 2010. This growth is likely to be heavily concentrated in the middle distillate segment of the barrel (specifically diesel and jet fuel), with its share of total petroleum product demand in the EU reaching 45 % by 2000, and 48 % by 2010. This change in demand structure alone will place constraints on refiners who will need to invest heavily in hydro-treatment to increase production of these products. Parallel to this, oil's share of total primary energy demand will decline gradually over the next 15 years, reaching 40 % by 2010, as

natural gas makes further inroads into the power generation, industrial and domestic heating markets.

In addition, refiners will have to face the investment needs and higher operating costs associated with reducing emissions and producing fuels with new and tighter specifications.

Under such an environment, it is plausible that further rationalisation of EU refining capacity will be required over the next decade, as higher-cost refiners see their margins and profitability eroded by additional costs and stagnant demand. However, unlike what has happened in the USA, the EU refining industry is involved in the consultative process which will lead to changes requiring investment, and thus has the opportunity of being better prepared for whatever changes will be implemented.

The petroleum product refining and distribution industry in Europe is well accustomed to adapt to changing circumstances, as it has had to do continually over the last 20 years, and should be able to demonstrate its continuing viability and vitality over the coming years.

# Electricity generation and distribution

## NACE 161

*Electricity consumption in EU countries has grown only very slowly since 1990. This has primarily been due to the slowdown in economic growth in 1992 and 1993.*

*However the slow growth in peak demand has not prevented considerable construction of new generating plants. The United Kingdom, France and Germany have all seen, and will continue to see over the next few years, a large amount of replacement plant. This is being driven by both economic and environmental forces, and has resulted in the substitution of new, cleaner fossil-fuelled plants (i.e. gas-fired plants or plants fitted with flue gas cleaning equipment) and nuclear plants for older solid fuel-fired plants.*

*However, despite continued construction of nuclear plants in France and the United Kingdom, the share of nuclear power is likely to start to decline after 1995. Electricity production from renewable sources remains limited by high investment costs and increasing concerns over siting. Limitations on these primary electricity sources will mean that an increasing share of electricity production is likely to be met by increases in fossil-fuel fired capacity, and in particular gas-fired capacity. This will have important environmental consequences, in particular the ability to meet CO<sub>2</sub> reduction targets.*

---

### INDUSTRY PROFILE

---

#### Description of the sector

This chapter covers the activities of electricity generation, transmission, and distribution of electricity. NACE 161.1 to 161.3 cover generation of electric power by public suppliers from conventional thermal plants, hydro plants and nuclear plants respectively. NACE 161.4 covers the operation of public electricity transmission and distribution systems. NACE 161.5 to 161.7 include the production by non-public suppliers of electricity for their own consumption.

The supply of electricity involves numerous commercial and industrial activities, including: fuel purchasing; power station construction and electricity generation; expansion, maintenance and operation of transmission and distribution networks; trading bulk electricity (both nationally and internationally); and operation of customer billing and accounting systems.

#### Recent trends

Average growth in electricity demand in Europe during the first few years of this decade was 3.1 %, slightly higher than that seen towards the end of the 1980s. However, much of the growth occurred in 1991 as a result of the re-unification of Germany and colder weather. Growth since 1991 has been slow, although, despite the recession and a return to more normal weather conditions, electricity demand has not fallen.

Growth in production in 1993 varied between EU countries, largely reflecting variations in economic cycles. Most countries, however, fell within the range -2 % to +3 %.

There has been little change in the concentration of electricity production over the past decade. The largest four countries in the European Union have consistently accounted for around 78 % of production. There has, however, been a continuing increase in the share of EU electricity generated in France. This has risen from around 18 % in 1980 to over 24 % in 1993. This reflects both an increase in exports as well as an above average growth in domestic demand.

Despite the slow growth in demand in recent years, together with the excess generating capacity available in many countries, the first half of the 1990s has seen considerable investment in new generation facilities by public suppliers. Much of this new capacity has been replacement capacity, particularly to allow early retirement of ageing coal- and oil-fired power plants on environmental grounds.

In the United Kingdom, the liberalising of electricity generation, along with economic investment decisions by UK electricity companies, has led to a rapid expansion in gas fired power plants. The concurrent removal of protection to the indigenous coal industry has resulted in a rapid fall in coal consumption, and hence a fall in sulphur dioxide emissions. In France, investment in nuclear power plants has continued, in line with an energy policy aimed at reducing dependence on imported oil and replacing closing coal- and oil-fired capacity to reduce sulphur dioxide emissions. In eastern Germany, several large lignite-fired plants are to be closed on environmental grounds and replaced with either new lignite plants fitted with flue gas cleaning equipment, or gas-fired plants.

In other countries in the EU, investment has been hampered by planning constraints, and changes to national energy plans. This is particularly true of Italy and Greece, where there is a need for new generating plants.

The electricity intensity of GDP increased between 1970 and 1985, but has since stabilised in more recent years, although across countries the trend has varied widely.

Several factors explain why electricity intensity in the EU stabilised after 1986:

- the continuation of low oil prices, and hence low fossil fuel prices in general, while electricity prices remained much more stable, which resulted in electricity becoming less competitive;
- the saturation effects in some applications and some countries. This is most evident in the northern EU Member States, while there is scope left for increased penetration of electrical appliances in the Mediterranean area;
- the development of more efficient appliances and processes in general.

Electricity has increased its penetration of total energy consumption, rising from less than 15 % in the early 1980s it reached 18 % in 1989, and has since remained roughly constant. The share of electricity in final energy consumption varies substantially across countries, reflecting the structure of industry, the level of automation in industry, the use of electricity for space heating and the level of appliance ownership in the domestic sector.

With the exception of the United Kingdom, there has been little change in employment levels in the electricity industry in the EU. This reflects the relatively mature nature of the industry, with small increases in output being met by increases in productivity. In the United Kingdom, the recent privatisation and deregulation of the electricity industry has given rise to a significant fall in employment. However, this has not had a large impact on the overall level of unemployment for a number of reasons. Firstly, most redundancies have been made voluntarily, particularly in conjunction with early retirement packages. Secondly, direct employment in the industry has fallen as a result of a greater degree of contracting-out for services as companies have sought to control costs and concentrate on core activities.

#### International comparison

The structure of electricity production in the EU is similar to that of North America. The key differences are a lower contribution of electricity generation coming from coal, and a correspondingly higher nuclear component. In comparison

to Japan, the EU has higher coal, nuclear and hydro components and lower oil and gas. Clearly, the mix of fuels varies considerably within the EU, the most extreme cases being France with a share of nuclear generated electricity of over 80 %, and Italy which still has a large oil component.

In general, prices for both industrial and domestic consumers in the EU are higher than those in the USA, but lower than Japan.

#### Foreign trade

The flow of electricity between Member States has significantly increased over the past 15 years. However, differences in marginal generation costs, particularly in off-peak periods, together with the level of interconnection between EU countries, indicate the potential for still far greater levels of trade.

The main barriers to higher trade are technical constraints to ensure the safe and stable operation of the transmission systems; difficulty for commissioning new lines; and market restrictions due to monopolistic industry structures or restrictive contractual arrangements. Losses on the transmission system also provide a disincentive to trade.

International exchanges are coordinated, without executive powers, by two co-operative organisations of the electricity authorities. These are UCPT (Austria, Belgium, France, Germany, Italy, Luxembourg, Netherlands, Switzerland, Greece, Portugal, Spain and former Yugoslavia), and NORDEL (Denmark, Norway, Sweden, Finland and Iceland).

The electric utilities enter into a range of commercial arrangements for the exchange of electrical energy; these fall into three main categories: hour-by-hour exchanges on a cost

basis, including back-up in the event of grid difficulties; contracts (usually short-term) for net transfers; longer term contracts, including permanent arrangements for the transfer of energy from joint-owned production plants in a neighbouring country. It should be noted that all the elements of the international connection system are owned by companies which can be other than those involved in the electricity exchange, and transfer arrangements are made on a co-operative and not a mandatory basis.

Ireland and Greece are still not directly interconnected with any other Member State. In the case of Greece, it was disconnected from the UCPT grid because of the war in the former Yugoslavia. The EU has recently approved funding of the interconnection to Italy as a means of providing both countries with transfer power benefits. In Ireland, links between Northern Ireland and Eire have been cut as a result of past terrorist activity, although these will soon be re-established. Funding has been approved for a link between Northern Ireland and Scotland, but plans are being delayed by public enquiries. Proposals for a direct link between Ireland and the United Kingdom have been postponed due to the cost of the link.

In 1993, exports by EU countries were 112.8 TWh (terawatt hour), and imports 130.2 TWh. This represents a small increase compared with the previous year. However, throughout the past decade the amount of electricity traded has risen faster than consumption, such that in 1993 imports accounted for around 6 % of gross inland consumption, up from 1 % in the mid-1980s. Nearly 15 % of intra-EU trade is accounted for by the 2,000 MW DC link between France and the United

Kingdom, and through which France exports around 16 TWh per year.

Trade with countries outside the EU is still very limited due to the lack of interconnections between countries. Currently only Austria, Switzerland and Norway exchange significant amounts with the EU. Switzerland has for many years traded electricity with other European countries on both a daily and seasonal basis. Norway, with its excess of hydro-capacity, has historically exported power to Denmark. However, this trade has fluctuated considerably in recent years both as a result of reduced precipitation and changes in the electricity market in Norway which have reduced the incentive for generators to export power.

Clearly, with the expected joining of the Scandinavian countries and Austria to the EU in 1995, the amount of trade outside of the EU will fall considerably. Further interconnections with other countries, particularly Eastern Europe, are unlikely to be capable of offsetting this fall until towards the end of the century.

France is the major net exporter of electricity within the EU. Its most important markets are Italy, Germany, Switzerland and the United Kingdom. The Netherlands is the third largest net importer in the EU, its main supplier is Germany. Net exports from France amounted to over 14 % of the country's production in 1993.

## MARKET FORCES

### Demand

The key drivers for electricity demand are the weather and the level of economic activity. Demand patterns therefore show important seasonal trends, and reflect growth in the economy. Response to price is typically quite low for domestic consumers, but can be significant with larger industrial and commercial users.

Over the longer term, societal trends towards higher living standards and technical developments in industrial processes have resulted in higher electricity consumption. Higher appliance ownership, higher heating standards and greater use of air-conditioning have been responsible for demand increases in the domestic and commercial sectors. At the same time a move towards electricity specific processes in the industrial sector, either due to technical necessity or overall process economics, has raised the electricity intensity of industrial production.

### Supply and competition

In most countries the regulated and monopolistic structure of the electricity industry prevents the operation of normal competitive pressures. Instead prices and service standards are set by either national or local governments, or are agreed between the utility and government following some form of consultative procedure. In some cases price controls can take the form of an explicit formula, and customer service standards may be subject to some form of objective measurement. Where utilities are state-owned, government finance targets play an important role in setting consumer prices.

Therefore, despite the lack of direct competitive pressures, most European electricity industries operate in a manner designed to achieve least cost supplies. This objective is pursued through government supervision and/or industry co-operation. For their part electric utilities seek to control costs by basing the utilisation of plant on short run marginal costs, and are usually required to demonstrate that new investment provides a least cost option for meeting future needs.

The main exception to this pattern is the United Kingdom, where, since privatisation in 1991, a competitive market now exists for all consumers taking over 100 kW (kilo Watt). This market covers over 50 000 customers, and about half the total electricity supplied in the UK. Price controls are only applied to residual monopoly businesses. The privatisation process in the United Kingdom was accompanied by a formalisation

of price controls and other performance objectives for electricity supply to domestic consumers. Prices to this market segment are set according to an explicit formula, and each of the regional electricity suppliers is monitored against a set of customer service standards.

It is now becoming more widely accepted that whilst transmission and distribution may remain natural monopolies, electricity generation, and particularly the construction of new plants, need not be. Several countries are now in the process of opening their electricity generation industries to competition. Furthermore, it has also been demonstrated that transmission and distribution systems can be opened to competitive suppliers, by the use of Third Party Access (TPA) regulations. The new structure of the industry in the United Kingdom provides one example of TPA in practice.

However, irrespective of whether or not electricity supply is operated competitively, larger customers in most countries have the option, or are required, to buy their electricity on a contractual basis. Prices (usually discounted against published tariffs), indexation clauses and payment terms are negotiated on an individual basis. For some customers with the capability to shed load at short notice, special terms may be agreed whereby the consumer can avoid paying capacity related costs in return for reducing demand, or operating their own generating plant, during peak periods. Industrial customers can also exert considerable buying power when choosing the location of new plants.

### Production process

The key steps along the electricity supply chain are fuel procurement and storage, electricity generation and delivery to the high voltage transmission network, transmission to substations near demand centres, distribution to final consumers on lower voltage lines and cables.

A variety of technologies are available for electricity production. The most common type of power plant is the traditional fossil fuel fired power plant using a conventional steam power cycle. Other common options include nuclear powered plants, open cycle gas turbines, and hydro electric plants. More recently gas turbines used in a combined steam and gas power cycle, and renewable generating capacity, such as wind, have become more important. Diesel plants, or small gas turbines, are frequently used to provide power to isolated systems.

The mix of generation in each country varies considerably, and reflects access to the various primary energy sources. However, it is possible to determine some key trends that will shape the future supply picture for the EU as a whole.

Hydro-electric power, having maintained a relatively stable share of the total energy input over the 1970s and first half of the 1980s, has seen its share edge lower as growth has returned in electricity consumption. Should electricity pro-

duction increase further over the next decade, it is expected that hydro-electric's share of the total will fall further. The scope for additional hydro-electric development is limited for a variety of political, economic, and environmental reasons, with the result that the remaining exploitable hydro resources will see limited development throughout most of the EU. Significant developments are only expected to occur in the Mediterranean area.

Electricity production from renewable sources remains small, although there are considerable efforts at the EU and national government level to promote and subsidise their development. Excluding hydro-electricity, only geothermal and wind power have made real inroads into the public supply sector, although across the EU there are wide variations in the use of renewable sources. Of these two energy forms, Denmark has the highest share of wind power, 1 % of total generation, while Italy has the highest EU level of geothermal power, 1.5 % of total generation. The principal limitations to the development of renewable sources are high investment costs, and concern over siting in a number of countries. However, more recently, considerable interest has been shown in the use of biomass and waste as a source of fuel for electric power plants. It is anticipated that these sources will become more important and widespread in the future.

The development of nuclear power during the past decade has been mixed. With the exception of France, no new orders for construction of nuclear power plants (which have not subsequently been cancelled or indefinitely postponed) have been placed in Europe since the early 1980s. Indeed in two countries, Italy and Denmark, nuclear power is banned, and in two others, Spain and the Netherlands, there is a moratorium on new construction. New construction of nuclear facilities in Germany is effectively prevented by the difficulty in obtaining the necessary consents and licences to build and operate nuclear plants. The question of continuing the use of nuclear power in the United Kingdom is currently subject to a government review.

In 1993, conventional thermal generation accounted for 53 % of supply, down slightly from the previous year. Indeed, the share has declined substantially over the past two decades, down from 83 % in 1973, largely due to the increase in nuclear power generation. The share of nuclear power share has risen from 5.4 % in 1973 to 36.2 % for the EU as a whole in 1993. However, fossil fuel use in conventional thermal power plants continues to dominate the energy input mix within the power generating sector.

In general, the use of a power station is determined by its marginal cost, and plant will be scheduled in order to minimise costs. However, the nature of electricity requires that any increase in demand must be met with an instantaneous increase in production from within the confines of the transmission system. This imposes technical requirements for the opera-

**Table 9: Electricity generation and distribution

tional management of the system and the scheduling of power stations. Other factors, such as power losses, will also provide a second order input into the economic scheduling of power plant. Thus more expensive plant capable of fast response is sometimes used in order to maintain grid stability.

## INDUSTRY STRUCTURE

### Companies

The structure of the electricity supply industries in the EU countries varies considerably, reflecting a number of factors, including the historical development of the industry, and government policy in such areas as security of supply and competition. Some countries of the EU have industries dominated by a single, often state-owned, vertically integrated utility. Others have far more decentralised industries with a separation between generation and distribution, and others have a mixture of small municipal distribution companies and much larger vertically integrated companies. France and Italy have highly vertically and horizontally integrated utilities, while, at the other extreme, the United Kingdom and the Netherlands have decentralised structures.

In Belgium, the three private generators (Ebes, Intercom, Unerg) were grouped together in July 1990 to create a new entity, Electrabel. The municipalities are responsible for the distribution of electricity destined for public lighting and domestic use, as well as to industrial users who consume less than 1 000 kW in the Flemish region and less than 10 000 kW in the Walloon region.

In Denmark, electricity generation is in the hands of twelve companies, most of which are directly or indirectly owned by municipalities. The public electricity generation companies are grouped into two associations, Elsam and Elkraft, which are responsible for co-ordination and planning of generation and transmission capacities, as well as the daily operational co-ordination of fuel purchases for power stations. Electricity distribution is provided by 105 companies, 53 are municipal companies and 52 are co-operatives or foundations.

In France, the monopoly for electricity generation, transport and distribution was given to *Electricité de France* (EdF) in 1946. EdF operates 88 % of installed capacity and 96 % of electricity distribution. The remainder is accounted for by auto-producers and a few municipal distributors.

In Germany, the electricity supply industry is highly decentralised, with some 960 individual public electricity companies. The electricity companies operate on a commercial basis, subject to state supervision in accordance with energy and cartel legislation. Nine large public companies own and operate the majority of generation capacity, including all the nuclear power stations and almost the entire national high-voltage grid. In

the former East Germany, the main generator and transmission system operator, VEAG, has now been privatised, and the grid is scheduled to be connected to UCPTÉ.

In Greece, the Public Power Corporation holds the monopoly for generation, transmission and distribution. Electricity generation by autoproducers, or small independent producers exploiting renewable energy sources or co-generation potential, is also permitted.

The Irish electricity industry has been substantially reorganised in order to give it greater flexibility and cost transparency, and to accommodate potential developments in regulation at the European level. The Electricity Supply Board (ESB) now has a horizontal structure, with the main activities of generation, transmission and supply, separated into different divisions. The new structure specifically allows for the development of independent power generation. The company is still state-owned.

In Italy, the electricity industry largely consists of a single state-owned company, ENEL, responsible for electricity generation, imports, exports, transmission and distribution throughout the country. The only exceptions to this are: municipal companies in existence before 1962; generating organisations which consume more than 70 % of their own production; production by combined heat and power plants of less than 15 MW; generation from renewable resources. In July 1992, ENEL was incorporated as a joint company following a decision by the Italian government to privatise its industrial and commercial activities. The timing of the privatisation of ENEL S.p.A. will depend on government decisions on the structure of the industry, the creation of a new regulatory authority, and the signature of the concession act. It is presently anticipated that it will take place in 1995.

In the Netherlands, electricity generation, transmission and distribution is in the hands of municipal and provincial companies. Since the coming into force of the Electricity Act of 1989, there are four generating companies which co-operate within a pooling system operated by SEP, the electricity producers' co-operative. Forty five municipal companies distribute electricity and are grouped within VEEN.

In Portugal, *Electricidade de Portugal* (EdP) previously held the quasi-monopoly for generation and transmission, except in areas not covered by its system. However, EdP has now been substantially reorganised, and the grid company REN has been recently created. The most important aspects of this are that distribution is now in the hands of four regional distributors and the generation of electricity is open to competition, and that the private sector has an increased role.

In Spain, the electricity industry has seen a number of mergers and asset swaps in recent years. This has resulted from the need to consolidate the financial position of some companies

following the nuclear moratorium and insufficient return on equity during the 1980s. The industry currently consists of a number of companies, some privately owned and some public, but is dominated by just four, which own or have effective control over virtually all generating plant. These are Iberdrola (controls 40 % of capacity), Endesa (75 % state-owned, 40 % of capacity), Union Fenosa (15 % of capacity), and Hidroeléctrica del Cantabro. The capacity controlled by Endesa includes the plant of two other important companies, Sevillana de Electricidad and Fuerzas Eléctricas de Cataluña, in which it has large minority interests. The national transmission system is owned and operated by Red Eléctrica de España, in which the state has a 51 % interest. New legislation approved by the council of ministers in June 1994 (it is expected to come into force as a law in January 1995), which allows for independent electricity traders and requires the separation of generation and distribution business accounts. It also provides for the introduction of a bulk electricity market, and a new national regulatory authority.

The United Kingdom undertook a privatisation and re-structuring programme in 1990 and 1991. This created 15 public electricity suppliers, which have a monopoly until 1998 on distribution, sales to smaller customers and an obligation to supply. In England and Wales transmission is carried out by the National Grid Company (currently jointly owned by the 12 public suppliers in the region, but likely to be sold during 1995), whilst in Northern Ireland and Scotland transmission and distribution are both controlled directly by the public suppliers. Electricity generation is largely open to competition, although some measures have been introduced to ensure that nuclear power and renewable energy power have a guaranteed market share.

### Strategies

During the 1970s and early 1980s, most countries saw a decline in the amount of electricity produced by non-public suppliers. This reduction was largely due to the widespread use of oil-fired capacity which had become uneconomic. At the same time utilities typically had policies of purchasing excess generation from such plants at prices reflecting their own short-run marginal cost, thus making investment in non-utility generation unattractive.

However, since the mid-1980s there has been a gradual reversal of this trend. Firstly, governments are increasingly requiring utilities to base purchase prices on full avoided costs. Secondly, the widespread availability of gas and technical developments in power plant have increased the attractiveness of self-gen-

eration, and in particular co-generation of heat and power. Finally, partly in response to national legislation (and anticipation of future EU requirements), and partly due to their own financial constraints, many utilities are themselves turning to independent generators to meet capacity needs.

### Impact of the Single Market

Although some specific elements of the Single Market measures have had a direct impact on the electricity sector, the future shape of the industry will depend on the outcome of ongoing discussions to define the measures which will be implemented to form the Internal Energy Market. The type of Third Party Access (TPA) mechanisms introduced will have a critical influence on the structure of competition in the electricity sector in Europe, as will the generalisation of the right to establish power generation facilities in other EU Member States. The initial measures contributing towards the Internal Energy Market, the electricity transit directive, and the price transparency directive, have not had a significant impact on business activities of the existing electricity utilities.

Measures which have had a direct impact on the electricity companies include the liberalisation of service industries, which has facilitated direct investment by electricity utilities into the telecommunications industry; the Large Combustion Plant Directive, which has caused many utilities to invest in emission abatement equipment, or to modify their fuel mix; and the Utilities Directive which, together with the Government Purchasing Agreement, is perceived to have increased the administrative burden of tendering for equipment supply.

The main priority for the industry is to resolve the outstanding issues surrounding the Internal Energy Market, thus allowing a clear framework for long-term planning of the development of the electricity sector in Europe.

### ENVIRONMENT

The electricity industry is responsible for a number of important environmental impacts, including emissions of sulphur dioxide (SO<sub>2</sub>), nitrogen oxides (NO<sub>x</sub>) and CO<sub>2</sub>. Furthermore, whilst nuclear power generally results in very low environmental impacts, the associated fuel cycle does have important environmental consequences. There are also considerable emissions of particulates and visual intrusion.

All countries have their own national regulations and strategies for controlling environmental impacts. The main piece of EU legislation in this area is the Large Combustion Plant Directive

(no. 88/609). This controls emissions of SO<sub>2</sub> and NO<sub>x</sub> from boilers with thermal capacity above 50 MW, as well as imposing national emission targets. Under the directive, all new large combustion plants are subject to a licensing procedure to ensure that the plant meets specified emission standards for SO<sub>2</sub>, NO<sub>x</sub> and particulates. The second part applies to existing stationary combustion sources (those for which authorisation was given prior to 1st July 1987), and specifies target values for reduction of emissions based on the 1980 level. Reductions in emissions are targeted at different levels by country; compared to 1980, overall EU SO<sub>2</sub> emissions must be reduced by 60 % by the year 2003, and NO<sub>x</sub> emissions by 30 % by 1998, the former in three stages, the latter in two phases. Plants authorised prior to 1987 and built before 1990 must either conform to the new plant standards or be taken into account in the global ceiling value.

However, a new international agreement has now been reached under the auspices of the UNECE (United Nations Economic Commission for Europe), which involves tighter emission targets. The targets have yet to be incorporated into legislation at the EU level, but it is likely that most countries will be able to comply as a result of current strategies and national policies.

The strategies used to meet these emission targets vary from country to country, once again reflecting the resource base. In Germany, compliance has been achieved by the widespread use of flue gas treatment plant (both for SO<sub>2</sub> and NO<sub>x</sub>). In other countries, fuel switching is the main abatement option. In France the expansion of nuclear power has ensured that emission targets for the power generation sector have been met. In Italy switching from high sulphur fuel oil to low sulphur fuel oil has been the main route, whilst in the United Kingdom there is currently a switch to gas from coal.

In order to reduce CO<sub>2</sub> emissions some countries are introducing higher energy taxation and in some cases specific CO<sub>2</sub> taxes. In addition, many have active energy conservation programmes as well as support for renewable energy schemes.

At the EU level there has been proposed a carbon/energy tax as a way to give an incentive to the industry to achieve CO<sub>2</sub> reduction targets and limit other environmental degradation caused by energy consumption. The proposals have yet to gain support from all Members of the Union due to concerns that it may affect industrial competitiveness. The carbon/energy tax was proposed as part of a package of measures which included initiatives on energy conservation (SAVE) and the development of renewable energy (Altener).

## REGULATIONS

The supply of electricity is subject to a number of technical and safety regulations. These are mostly established at a national level, although interconnections and international co-operation has insured that there is a level of uniformity across countries. At the EU level the key regulatory developments have been in the implementation of the Single Market and the Internal Energy Market. To this end, the Council has adopted a number of directives which constitute the first stage of a planned three stage approach towards the completion of the internal market in electricity. The EU is also pursuing a number of test cases on the application of existing EU trade legislation on the energy sector.

The transit directive (no. 90/313/30), approved by the Council on 30th October 1990, provides that "each high voltage transmission utility shall facilitate power exchanges between other utilities through its grid, provided that transmission reliability is not affected." Meanwhile, the price transparency directive (no. 90/185/16), approved by the Council in June 1990, provides that "electricity and gas utilities shall supply to the Statistical Office the rates they charge to all categories of

customers on the understanding that published aggregate figures will respect confidentiality."

The Commission has also presented plans for the further development of an internal energy market within the EU, involving two further stages in addition to the two directives cited above. The second stage is three-fold. Firstly it is based on the creation of a transparent and non-discriminatory system of licensing or tendering for the production of electricity and the building of electricity lines. The aim of this proposal is to "open up investment in production and transport to independent operators, and in particular to large industrial users". Secondly it is based on the creation of transparency of operations by the separation of accounting of production, transmission and distribution operations in vertically integrated undertakings (commonly called "unbundling"). Thirdly it is based on the introduction, on a limited basis, of third party access (TPA). The transmission and distribution companies will be negotiated to "offer access to their network to certain eligible entities at reasonable rates, within the limits of available transmission and distribution capacity". Those eligible will include large industrial users and distribution companies.

The Commission also wishes to see subsidiarity play a substantial role during the second phase. This involves Member States retaining their regulatory powers for all end-users not eligible for TPA, as well as determining the extent and nature of distribution companies' rights and their public service obligations. Member States will also be free to establish the criteria used for granting licences to build power stations and transmission and distribution lines. The Commission initially wanted to see the second stage enter into force on 1 January 1993. However this did not happen; discussions are still continuing and no firm timetable has yet been announced. The third stage will be defined in detail in the light of the experience acquired during the second stage.

## OUTLOOK

The outlook for growth in the demand for electricity is slow, on average 1.7 % per year between 1993 and 2010. The main development within the industry will therefore be changes in fuel mix, rather than growth in capacity. Developments in the structure and regulation of the industries will have an increasingly important bearing on this issue.

Increases in the standard of living will continue to put upwards pressure on the demand for power but this will be limited by saturation effects and will be offset by efficiency gains. In addition, over this time frame, the electricity intensity of industry will be limited by the relative low price of fossil fuels. Furthermore, the use of explicit demand side management is likely to become more widespread as governments seek to take advantage of economic energy conservation as a means to meet emission targets.

On the supply side, development of hydro power, renewable sources, and nuclear power is expected to be limited over the next decade. The reasons for this are that most economically exploitable hydro resources have been developed. The development of nuclear power will be limited by planning constraints, or moratorium on construction. The completion of capacity currently under construction, and firmly committed capacity, will lead to a peak in nuclear generation production in Western Europe in the late 1990s. Unless further nuclear plant is ordered within the 1990s the share of nuclear power will begin to decline in the early 21st century, due to increasing electricity demand and plant retirement. New construction in France, and possibly the United Kingdom, after the year 2000 will not be sufficient to offset the steady decline in nuclear generation capacity (though life-extension programmes are expected to draw out operating spans to as much as 40 years for most reactors).

The slowly declining shares of nuclear and hydro/geothermal power over the next decade will be offset by expansion of the share of conventional thermal power. Consequently, the major capacity development questions facing the Western European electricity supply industry surround the refurbishing, replacement, and expansion of conventional thermal power generation capacity.

Within this context, there is considerable scope for natural gas use for power generation in Europe. It is, however, only in a few EU countries where the use of gas in power generation will increase substantially. Italy, Belgium, Denmark and the United Kingdom are all in the process of changing the fuel mix in favour of gas. Such a move is also planned in Spain and Portugal, but in these countries the future of gas depends upon the development of supply infrastructure. In Greece, electricity production from gas will be introduced by the Public Utility for the first time in the fuel mix before 1998. Natural gas fired power generation could almost double its share of the power generation fuel mix in the EU by the year 2010, from its 1990 level, almost tripling the volume of gas consumed in this use.

It is expected that the development of environmental legislation and competition regulations will have a large impact on the future of this sector. Environmental legislation, aimed at internalising the significant external environmental costs associated with electricity generation, could have an impact on the economics of plant choice. The introduction of competition in generation is likely to encourage the development of smaller lower capital cost plants. The move towards privatisation and de-regulation of electricity industries is expected to gather pace. The next major privatisation is likely to be in Italy, with the sale of ENEL. It can also be expected that current moves within the EU to liberalise the sector will result in greater trade, even if full TPA is not implemented. The number of countries with TPA regulations in the EU will increase with the membership of Finland and Sweden.

These factors, together with the removal of protection for domestic coal industries, are likely to favour gas fired plants and auto-production (particularly co-generation). The reasons for this are that gas offers both environmental and financial benefits. It is less polluting than other fossil fuels, thus avoiding the need for expensive flue-gas treatment plant; combined steam and gas cycle plants, and particularly co-generation, offer higher efficiency and therefore reduce specific fuel consumption; plant costs are lower and present therefore lower risk than more capital intensive options.

However, despite the cost of emission abatement equipment, coal will remain an important source of fuel, reflecting the importance the power generating utilities place on flexibility, and the expectation that coal will retain a relatively low and stable price profile. In the longer term, the prospects for coal will be improved with the development of high efficiency Integrated Gasification Combined Cycle (IGCC) generation.

In the longer term, after the year 2000, it is unlikely that emissions of CO<sub>2</sub> can be stabilised without recourse to greater use of non-fossil generating capacity. This may lead to new orders for nuclear power stations early in the next century.

# Transmission and distribution of natural gas

## NACE 162

*Natural gas is growing in importance in the EU energy demand mix, with its market share in 1993 exceeding 20 % for the first time. Its growth is being encouraged by environmental concerns, but also by the abundant supplies of natural gas and its continuing cost-competitiveness versus other fuels. New gas markets are being developed, or will be developed over the next few years, in Spain, Portugal and Greece. There are also growth opportunities for gas in the more mature markets where natural gas is already firmly established such as the United Kingdom, Germany and France.*

*Gas demand growth is likely to be accompanied by changes to the competitive and regulatory structure, as the EU promotes measures to open up markets to more competition. Some progress has been made on these issues, but there is likely to be a continuing debate over the most appropriate solutions to promote competition while preserving security of supply.*

### INDUSTRY PROFILE

#### Description of the sector

NACE 162 is defined as the production of manufactured gas in gasworks and the distribution of gaseous fuels via mains (pipeline systems). In the EU, this sector is now dominated by the distribution of natural gas, which has come to play a significant role in the energy mix over the past 20 years.

Natural gas is a hydrocarbon fuel composed mainly of methane, which is produced from natural deposits, sometimes containing just gas, and sometimes containing both oil and gas. This chapter concerns solely the transmission and distribution of natural gas to final consumers. Exploration and production of natural gas is dealt elsewhere in the book. It should be noted, however, that, in many instances, companies involved in exploration and production activities are also involved in transmission and distribution.

There is also an important distinction to be made between transmission and distribution of natural gas.

Transmission activities typically involve:

- the bulk purchase of natural gas supplies, normally under long-term contracts with gas producers;
- the transport of gas via high-pressure, high-capacity pipeline systems from the point of purchase to the principal zones of demand;
- the storage of natural gas for strategic or load-balancing purposes; and,

- the bulk sales of natural gas to distribution companies, other transmission companies or large-volume industrial or power generation customers.

Distribution activities involve the movement of gas through local low-pressure, low-capacity pipelines to final consumers in the residential, commercial and small industrial sectors, together with associated meter-reading, invoicing and account administration services.

Natural gas is used in a variety of ways to meet a number of energy needs in various demand sectors. It is burned as a fuel for space heating and hot water production, especially in the residential and commercial sectors; it is used in power stations to generate electricity; it provides a feedstock for the petrochemical industry to produce ethylene and propylene; and it is used in industry for steam raising, firing furnaces, and in drying processes.

#### Recent trends

Table 1 shows that 1993 natural gas consumption increased significantly over 1992, by 6.5 %, as natural gas increased its share of total primary energy demand, as it is rapidly gaining favour as the fuel of choice in the power generation sector.

Although over a third of EU natural gas consumption is supplied by imports (primarily from Algeria, Norway and the former USSR), higher gas output from the United Kingdom sector of the North Sea was sufficient to meet most of the 1993 increase in demand.

Since 1985, natural gas consumption in the EU has increased at an average rate of 3.5 % per year, roughly double the rate of increase of inland energy consumption as a whole. Natural gas has increased its share of EU primary energy consumption from under 18 % in 1985 to 20.5 % in 1993. Natural gas has thus become a major competitor for oil in all sectors except transport, for electricity in all sectors except lighting, appliances and electricity-specific applications, and for coal in all uses.

#### International comparison

The West European natural gas market is the third largest in the world, currently accounting for nearly 14 % of total world natural gas demand. Natural gas represents 20.5 % of primary energy demand in the EU, a proportion which has been growing and is expected to continue to grow over the remainder of the decade. This level of penetration is slightly less than that observed in the USA, where a mature natural gas supply and transmission system has resulted in a share of natural gas in primary energy demand currently standing at about 25 %. This has been favoured by deregulation of the natural gas transmission and distribution industry in the USA, which has promoted competition, price transparency, and end-user natural gas prices which are very competitive with other fuels. In Japan, which has no indigenous resources of natural gas, natural gas only represents about 10 % of primary energy demand, mainly into the power generation sector and into local distribution grids in some of Japan's major cities. Japan currently imports all of its natural gas requirements in the form of

Liquefied natural gas (LNG). The region of the world where natural gas has the largest place in the primary energy mix is the former USSR, where natural gas accounts for over 40 % of primary energy demand. Abundant low-cost resources and the use of natural gas as a base-load fuel in industry, power generation and municipal heating have resulted in natural gas being the dominant fuel in this region.

### Foreign trade

Since production of natural gas in the EU is primarily focused in the United Kingdom and the Netherlands (with smaller contributions from Denmark, France, Germany and Italy), and EU production satisfies only 63 % of demand, foreign trade is an important component of the natural gas supply mix in the EU. The importance of the investments required to develop gas transport and transmission infrastructure, either by long-distance pipeline or by LNG (Liquefied Natural Gas), have favoured the existence of long-term relationships between suppliers and transmission and distribution companies in EU Member States. Imports continue, therefore, to be primarily sourced from three major suppliers: Algeria, Norway and the former USSR. Imports from outside the EU rose by 0.5 % in 1993 versus 1992 to 4198 TJ (Terajoules), representing 37 % of gross EU consumption. Since 1985, total extra-EU imports of natural gas have risen by 4.9 % per year, on average, as rising demand has outpaced increases in EU indigenous production.

Natural gas transmission links between the EU and its suppliers are continuing to be developed in anticipation of future growth in EU natural gas demand. For example, from Norway, two new pipelines, Zeepipe (commissioned in 1993) and Europepipe (to be ready in 1995), are in the process of adding 25 bcm/year (billion cubic metres) of export capacity to the continent. These are part of the Troll contracts which were signed in 1986 and saw first deliveries at the end of 1993. By the year 2000, Troll contract deliveries should reach a plateau of 55 bcm/year while exports based on older, depletion contracts will have decreased to around 10 bcm/year. Most of this gas will be heading into the current EU countries.

Algerian gas is either transported by pipeline via Tunisia and into the Italian grid, or is imported as LNG from liquefaction plants at Arzew and Skikda to reception and regasification terminals in Belgium, France and Spain. Within a few years Greece will also receive Algerian natural gas in this manner. An extension of the Trans-Med pipeline from Algeria to Italy is currently under way and will see its capacity double to 25 bcm/year by 1996. The liquefaction plants, including the oldest in the world, are, in parallel, being refurbished and should reach a capacity of 30 bcm/year in 1996. Finally, work on the EuroMaghreb pipeline started in 1994. This 9 bcm/year pipeline will run through Morocco and supply Spain after crossing the Straits of Gibraltar as of next year. In 1997, an off shoot will provide 2.5 bcm/year to Portugal.

Russian gas is currently supplied through major gas pipelines from the Western Siberia gas-producing fields, crossing Ukraine and former Czechoslovakia to the German border. A number of projects are being developed for new pipeline routes including a line through Belarus and Poland, and a pipeline from the major gas fields in the Yamal Peninsula. In addition, Russia is scheduled to supply Greece with natural gas by pipeline over the next few years. These developments are expected to reinforce the position of the former USSR as a major supplier to the EU over the next 10 to 15 years.

## MARKET FORCES

### Demand

EU natural gas demand has increased at over 3.5 % per year, on average, since 1985 and is expected to continue to expand over the rest of the decade and in the early years of the next century.

In the EU, almost 50 % of natural gas is used in the residential and commercial sector, predominantly for space heating, while small amounts are used for water heating or cooking. The big users are the Netherlands, the UK, Germany, Italy and France. Only in the latter country is gas encountering serious competition (from electricity) in new dwellings. Rates of penetration, with an EU average of 37 %, should keep progressing except in the Netherlands, where this segment of the market is virtually saturated at a share of over 70 %.

Industry, the next biggest sector for natural gas demand, corresponds to a third of total gas consumption. Use for boilers accounts for over 80 % of natural gas demand, where it competes quite successfully with heavy fuel oil and coal, because of its price and environmental advantages.

In 1993, power generation represented 17 % of total natural gas use. This relatively small market is the most promising for natural gas which has seen its share grow from 6.7 % in 1992 to 8.4 % in 1993. Several recent developments have increased the attractiveness of gas as a power station fuel. Firstly, increasing environmental concerns have in particular led to tighter emission norms: emissions of SO<sub>2</sub> and CO<sub>2</sub> are lower for natural gas than for other fossil fuels. In addition, the European Community repealed in 1991 a 1975 Directive that limited the use of natural gas in power plants. Thirdly, technological developments have increased the efficiency of gas plants to over 50 % for a combined cycle system, compared to an efficiency of only 35 %-40 % for oil or coal plants. And lastly, structural and institutional changes in the electricity industry have contributed to the growth of natural gas demand, with privatisation in some countries and the widespread development of independent power generation: this evolution favours the use of gas, because of the lower capital cost and shorter construction lead time for gas plants.

### Supply and competition

As befits a sector in a phase of expansion, the natural gas transmission and distribution industry in the EU is subject to diversity in the existing arrangements, and pressure for change, as competition, privatisation and deregulation make their impact on market structures. The effects of these developments on specific companies is highlighted in the following section on Industry Structure, but more broadly speaking, there is a dichotomy between countries which wish to keep faith in traditional market organisations, dominated by central or local/regional government-owned entities with a monopoly over their service area, and countries which are introducing competition on a large scale. The United Kingdom is the country which has gone the furthest in the latter route with the break-up of British Gas and the appearance of a number of new competitors with firm access to gas supplies. Germany has also become open to competition, with the appearance on the market of WinGas, a joint-venture between Wintershall and Russian gas supplier Gazprom, which is aggressively seeking new business in areas served by the traditional gas transmission and distribution companies.

The European Commission has been promoting the introduction of a Third Party Access (TPA) regime in the EU, in order to accelerate the introduction of competition by allowing major consumers or distribution companies a greater choice of suppliers. These proposals are still subject to debate, and are being resisted by many of the existing gas companies. If implemented, a TPA regime could have a major impact on the competitive structure of the industry, leading to greater competition, and downward pressure on margins right along the gas supply chain.

The natural gas supply profile will also favour the development of a more competitive structure for natural gas transmission and distribution in the EU. The EU's traditional suppliers have an abundance of gas reserves which can be brought to the market at relatively low cost, thus contributing to mod-

Source: Eurostat

eration in price increase trends compared to other fuels. However, according to Eurogas, future supplies of gas will be dependent on huge investments from more distant sources which will be technically and economically more difficult to exploit.

The price of gas to final consumers is normally linked to that of competing oil products, heating oil for residential and commercial sector applications and residual fuel oil for industrial and power generation applications. This principle has seen some exceptions in recent years, particularly in the power generation sector, where natural gas price escalation linked to coal prices or inflation has been introduced into some sales contracts. If this trend spreads, it will also act as a moderating factor on natural gas price increases and contribute to increasing competitiveness of natural gas versus other fuels.

## INDUSTRY STRUCTURE

### Companies

The structure of gas markets in Western Europe is still dominated by central or local/regional government-owned entities, which purchase or import gas, store and transport it and deliver it to the end user. The major exceptions to this state of affairs are Germany and the United Kingdom. In both countries private capital now controls most of the major gas companies (although final distribution to small and medium sized customers is usually controlled by municipalities in Germany), and competition is becoming more a feature of the market place.

In the United Kingdom, evolution of the market structure has been overseen by the government regulatory office put in place after the privatisation of British Gas (BG) in 1986, which has seen BG required to unbundle its gas supply and transmission business from its gas marketing business, and allow competitors to take increasing shares of gas end-user markets, securing their own gas supplies and having access to the BG pipeline network at a regulated tariff.

In Germany the major gas companies until recently enjoyed virtual regional monopolies. However, the advent of the new market entrant WinGas, a subsidiary of Wintershall in joint-venture with Russian gas supplier, Gazprom, has introduced a new element of competition into the market. WinGas is competing directly with the gas companies already in existence to supply industrial users and municipalities as their current contracts come up for renegotiation. WinGas also has ambitions to significantly expand its activities, not only in Germany,

but also as a supplier of Russian gas to other West European countries.

Although the markets retain the dominance of monopolistic and/or state-owned structures, the trend to liberalisation has clearly begun. The wave of privatisation and liberalisation that started with the sell-off and subsequent restructuring of the United Kingdom's British Gas in the years following 1986 is liable to continue. Countries where further developments in privatisation are expected during the life of the forecast are Belgium, Portugal, Greece, Spain, and Italy.

In Belgium, the state's 50 % participation in the gas import and transmission company Distrigaz is in the process of being sold off to the existing minority shareholder Tractebel, the private holding company controlling most of the Belgian electric power generating sector.

In Portugal, the consortium of state-owned banks, insurance and energy companies which comprise the ownership of Transgas, the company charged with importing and transporting gas purchased from Algeria, will be opened up progressively to private capital over the next five years. A number of European gas companies are interested in taking a strategic stake in order to participate in one of Europe's last remaining new markets for natural gas.

In Greece, arrangements for the import of Russian gas supplies by pipeline, including new pipeline developments, have been changed several times. State gas company DEPA was initial signatory to the contract, prior to losing and then regaining monopoly transport and marketing rights to the gas. The situation is likely to evolve further over the next few years as the Greek government seeks to privatise energy sector assets.

In Spain, the gas sector recently underwent significant consolidation when, in 1993, state-owned Enagas, which previously held the import and transmission monopoly, was merged into Gas Natural, a subsidiary of partially privatised hydrocarbons giant Repsol and La Caixa Bank. Gas Natural was originally formed in 1990/91 by a merger between Catalana de Gas, Gas de Madrid, and some of Repsol's gas distribution holdings. The new company is thus in a position to dominate all parts of the gas chain in Spain. Privatisation of further tranches of Repsol capital will reinforce the independence of the new company vis-à-vis the state.

In Italy, privatisation of state energy holding company ENI, which includes gas importer and transporter SNAM, has been the objective of successive Italian governments for the past three years. Political changes, together with the need to achieve consensus on the structure and role of the privatised companies,

have delayed the process, but it is expected that ENI will enter the private sector before the year 2000.

### Impact of the Single Market

The natural gas supply and distribution sector draws a generally favourable overall picture of the Single Market measures implemented so far. The benefits are, however, seen to be indirect, in that liberalisation of financial and other services have improved the overall business environment in Europe. The direct activities of natural gas supply, transmission and distribution have not changed as a result of the Single Market. Natural gas production takes place in only a minority of EU Member States, and the EU as a whole is a net importer of natural gas. There has thus always been an incentive for EU states to develop open trade in natural gas, and there have been no significant barriers to trade, either within the EU or between the EU and other countries. The gas transit directive, and price transparency, have not altered the structure of activity or prices to consumers in any meaningful way.

Where changes in the structure of the gas industry have taken place, such as the introduction of regulated competition in the UK, the appearance of new competitors in Germany, and the forthcoming creation of a new gas industry in Portugal, these have been primarily due to particular national circumstances rather than EU-sponsored measures.

Further development of the Internal Energy Market could have more profound consequences for the industry, but the impact is difficult to foresee prior to agreement on the type of liberalisation or Third Party Access (TPA) regimes which would be implemented. In most cases, the current gas transmission and distribution companies have been opposed to the full-scale TPA arrangements proposed by the Commission, arguing that they would impede their ability to invest in supply infrastructure and to enter into long-term gas supply contracts. The gas industry sees the main priority for the EU and national governments to ensure a stable political and regulatory framework within which a diversity of long-term gas supply contracts can be negotiated on a commercial basis.

## REGIONAL DISTRIBUTION

The development of natural gas markets in the different European countries has been extremely uneven, because of differences in indigenous resources and in pipeline access. The most developed, and mature, market is the Netherlands, where the share of gas in primary energy consumption is nearly 50 %. The other countries where the discovery of the Dutch Gröningen field favoured the penetration of gas are Belgium, France, Italy and Germany. However, the development of nuclear power in France and Belgium has limited the role of gas, whereas abundant indigenous coal resources in Germany were a constraint on the penetration of gas. In Italy, which has substantial gas reserves but little other energy resources, the gas market expanded rapidly and gas accounts for 28 % of primary energy demand. The other gas market that developed rapidly thanks to indigenous reserves is the United Kingdom, where the share of gas is 27 %. The three most mature markets (the Netherlands, United Kingdom and Italy) account together for 52 % of Western European gas demand. Germany is the largest market with consumption of 65 bcm, but the share of gas in German energy demand is only 18 %, and there is considerable scope for higher penetration, because of the currently low level of use in the power generating sector.

Some countries are just introducing natural gas, or will introduce it soon, such as Greece and Portugal, and offer considerable scope for gas consumption, if the required infrastructure can be developed. Finally there is a middle tier of underdeveloped markets, with the share of gas ranging from 6 % in Spain to 13 %-20 % in some of the more mature markets listed earlier (France, Germany and Belgium). The share of gas in Spain is low because gas was only recently introduced but the market should now expand rapidly, with the development of the appropriate infrastructure.

The scope for further developments of these markets vary considerably depending on their energy resource endowment (other than gas), their energy policy and the development of the required infrastructure (for transmission and distribution within the country but also pipelines and LNG facilities to import gas). In particular, infrastructure developments will be essential to the development of middle tier, and especially new or "yet-to-be-created", markets. However greater integration of the European Union energy infrastructure (especially regarding electricity

and gas markets) has been given high level of priority in the completion of the Internal Energy Market. In 1992, a Communication on electricity and natural gas transmission infrastructure noted that infrastructure integration was essential to completion of the Internal Energy Market, while ensuring flexibility and security of energy supplies.

More recently, the Delors White Paper on growth, competitiveness and employment (COM(93) 700 final) stressed the role of trans-European networks in strengthening the competitiveness of European industry. The White Paper identified eight priority projects to which the Union funds can contribute 13 billion ECU. The list of projects for gas is given in Table 7, and concerns both interconnection of existing networks or development of national networks and the development of new supply pipelines. In addition to this, the projects to connect peripheral parts of the Union can also be financed by structural funds under the REGEN initiative.

## ENVIRONMENT

The environmental advantages of natural gas compared to other fuels has been one of the major factors in its success in increasing its market share in the EU. Natural gas contains very little sulphur and it emits less NO<sub>x</sub> per unit of energy than other fossil fuels. It also contributes to less emissions of CO<sub>2</sub> and other greenhouse gases than oil or coal, and is thus perceived as a lesser contributor to the threat of global climate change.

Initiatives taken within the EU, such as the Large Combustion Plant Directive (LCPD), and internationally, such as the Framework Convention on Climate Change, under which the EU has set targets to limit its CO<sub>2</sub> emissions to 1990 levels by the year 2000, have contributed to a favourable climate for increased penetration of natural gas. The economics of burning natural gas versus the cost of installing emissions clean-up equipment and burning other fuels, has favoured gas in many industrial and power generation sector applications.

## REGULATIONS

The regulatory environment in the EU embracing the natural gas transmission and distribution industry is gradually moving towards one designed to support a more competitive envi-

ronment. Although the evolution towards TPA is currently moving quite slowly, and the final shape of TPA is difficult to forecast at the time of writing this article, other measures are moving ahead. One such supporting measure already enacted was the gas transit directive, adopted by the EU in 1991. This directive is aimed at facilitating the transit of gas between high pressure transmission grids. Companies owning or controlling high pressure gas pipelines in one EU Member State are obliged to allow a counterpart company in another State to carry gas across its transmission system if capacity is available and subject to price and quantity negotiations. Article 3 of the Directive requires all transit requests and the outcome of negotiations to be notified to the Commission. With gas able to be moved across a third country, this process is seen as forming the first step towards liberalisation of West European gas markets.

---

## OUTLOOK

---

Natural gas is expected to continue its growth over the next 10 to 15 years, rising to over 25 % of primary energy demand by 2010 and over 26 % by 2015, primarily at the expense of oil and nuclear electricity. This trend is due to its abundant supply, its continuing price competitiveness versus other fuels, and its environmental advantages. In addition, over this period new natural gas markets will develop, in Greece and Portugal, and there should be a significant expansion in gas demand in Spain, which is currently a relatively immature market.

Written by: *DRI Europe*

The industry is represented at the EU level by: European Union of the Natural Gas Industry (Eurogas). Address: Ave. Palmerston 4, B-1040 Brussels; tel: (32 2) 237 1111; fax: (32 2) 230 6291.

# Renewable energy

*In 1992, primary electricity generation from renewable energy sources grew by 3 % compared to the previous year while total primary energy demand fell by 1 %. Thus the share of primary electricity from renewable energy sources grew slightly as a percentage of EU primary energy demand from its 1991 share of 9.7 %. In 1991, total energy production from renewable energy sources contributed around 4 % to total primary energy demand in the EU. Of this percentage, the majority of the share came from large scale hydro-electricity production (31 %) and from the combustion of biomass (60 %). The remaining 9 % was accounted for by other renewable technologies in varying stages of development. Hydro-electricity production dominated electricity production from renewable energy sources with a 92 % share and biomass accounted for 98 % of EU heat production. Expansion of the role of renewable energy is an important part of EU energy and environmental policy, and a number of programmes are in place to promote its development.*

---

## INDUSTRY PROFILE

---

### Description of the sector

The renewable energy industry is very broad in definition and is not classified as a single industry under NACE.

Fuels from renewable sources, that is those that are not depleted due to their exploitation, may be in the form of electricity or as gases, liquids or solids. Some renewable energy sources are limited to one form of energy transformation, e.g. hydro-electric power generation to produce electricity. Others are more flexible: biomass may be converted to liquid fuels, burnt as a low calorific solid fuel or gasified. The major renewable energy technologies are listed together by the form of energy they most commonly produce.

#### Electricity

Tidal power extracts energy from the tides using the same principles as hydropower facilities but captures the tidal ebbs and flows rather than the flow of a river to generate electricity.

Small hydro-electricity generation uses the same principles as large scale hydro-electricity, but plants use different types and sizes of turbines.

Wind power generation uses the wind turbine to generate electricity by the same principles as the old fashioned windmill but using a higher level of technology.

Photovoltaic systems use semiconductor materials to convert solar radiation into DC (direct current) electricity without moving parts.

#### Heat and/or electricity

Geothermal energy use takes heat from the earth directly for heating purposes, or uses it for electricity generation. The temperature determines the application.

Biomass is considered all matter that can be derived directly or indirectly from plant photosynthesis. "Indirectly" refers to the products available via animal husbandry and the food industry. Feedstocks for the technologies include wood resources, agricultural wastes, industrial and municipal solid waste (MSW) residues and surpluses and energy crops.

#### Heat

Active solar generation produces heat by capturing solar radiation. It usually consists of one or more collectors, an energy transport system to move the heat to the point of use, an electronic control system and an energy storage system.

In addition, a number of industries are associated to the renewable energy sector. They fall into two types:

- Industries that provide feedstock, e.g. the agricultural products industries (NACE 011, 014, 020) who provide feedstocks such as straw, slurry and wood residues for biomass derived renewable energies; the pulp and paper and wood processing industries (NACE 471/2, 461/2) who produce waste products and residues which can be used as feedstocks; and the waste and recycling industries (NACE 62, part of 921) who provide low cost feedstock.
- Manufacturing industries that provide components for use by renewable energy technologies: e.g., the mechanical engineering industry (NACE 32) that is involved in the manufacture of renewable energy equipment, the most important being turbines (water turbines for hydroelectric plants, aeroturbines for wind farms and steam turbines for geothermal power stations); agricultural equipment used for biomass collection and processing; and the electrical engineering industry (NACE 34) which, in addition to manufacturing electrical components for control equipment, provides semiconductor material for photovoltaic cells.

### Recent trends

Mature renewable energy technologies such as biomass combustion and hydroelectric power have been a significant part of EU energy supply for some time. Since around the 1970's, the energy supplied by these sources has seen significant growth. The energy supplied from other renewable sources has grown very quickly, though it is still a very small fraction of total energy supply.

Around 10 % of electricity demand is met by renewable energy sources. Hydro-electric power generation accounts for 86 % of the renewable electricity supply. Biomass and hydro, together, make up nearly 98 %. Biomass sources provide almost all of the renewable heat supply and 3 % of total EU heat demand.

Greece has the largest installed capacity of solar collectors. But the penetration in France and Portugal is also significant. The Danish have by far the largest amount of wind power installed, generating roughly 77 % of electricity from wind power in the EU. Italy, France and Spain generate the majority of electricity from small hydro sources in the EU. Italy has the largest geothermal energy industry, a large proportion of which (520 MW (megawatts)) is used for electricity generation. France, Germany and Italy have the largest biomass consumption due to much direct wood combustion. Denmark, however, uses a high proportion of agricultural waste, mainly crop residues, in biomass consumption. Spain generates the most electricity from biomass in the EU.

---

## MARKET FORCES

---

### Supply and competition

#### Tidal power

The development of large scale tidal power stations in the EU has been inhibited by the huge investment cost, the very long construction time and concern over the environmental impact of tidal barrages. The largest tidal power station in the world was built in 1968 at La Rance, in France with an installed capacity of 240 MW. However, no further sites have been developed in the EU, despite their considerable potential.

In the EU, the best sites are to be found along the west coast of Portugal, France, Ireland and the United Kingdom. In the United Kingdom, where the tidal potential is approximately 54 TWh/year (terawatt/hours per year) - over half of the total European tidal resource - the government has heavily invested on tidal energy research and feasibility studies since 1979. A barrage across the Severn Estuary could generate around 17 TWh, equivalent to about 2.5 large power stations (1 000

MW). Another project is on the Mersey which could generate 0.5 TWh.

#### Small hydro-electricity generation

In the EU, the total installed hydroelectric capacity is about 80 GW (gigawatt). Small hydroelectric plants (less than 1 MW) contributed 1.3 GW to this or just over 1.7 % in 1991. There is a marked trend towards small scale applications of hydropower which have a smaller impact on the environment than their larger counterparts. The shift has mainly been due to the limited availability of new large scale sites. The percentage of sites economically exploitable and already in use is 95 % for large hydro but only 20 % for small hydro-electricity. The total additional EU exploitable potential for small hydro-electricity is between 4-5 GW. France, Italy and Spain have by far the largest small hydro potential. In Spain, the electric utility, Union Fenosa, has 28 small hydro plants with a total generating capacity of 55 MW in operation, and plans to bring a further 52 plants on-line before 1998.

#### Wind power

Denmark is the largest generator of electricity from wind energy in the EU. The industry has expanded considerably so that in 1991, the total installed capacity in the EU was 509 MW of which Denmark accounted for 70 %, the Netherlands and Germany both for 11 %. The USA has an installed capacity of 1 500 MW, consisting of around 15 000 turbines. Denmark has one of the smallest wind power potentials, and yet has by far the largest installed capacity. Sizeable subsidies were given by the Danish government during the late 1970s and early 1980s which boosted the industry and enabled it to enter the large Californian, USA export market ahead of competitors. The United Kingdom, in contrast, has the largest potential but relatively few turbines installed. However, under the national programme to promote non-fossil fuels, the wind power industry is currently enjoying rapid growth.

Germany is witnessing a huge boom in wind farm construction: in the first six months of 1994, 100 MW of wind power generating capacity came on line. In Spain, a 30 MW plant has been commissioned, built largely by Endesa, the state electricity company, and Ecotecnica, a Spanish turbine manu-

facturer. In Greece, 13 new wind farms have begun operation in the last two years, with a total generating capacity of 22 MW. Two new farms of 5 MW each are planned for Crete in 1995. In Ireland, an EU Thermie grant is being used in the construction of a 5 MW wind farm in county Kerry.

Technical difficulties have meant that off shore farms are less commercially developed. In Denmark, however, the electric utility Elkraft brought on-line the world's first off-shore wind farm consisting of eleven 450 kW (kilowatt) turbines. A second 5 MW farm is planned by the other electric utility, Elsam consisting of ten 500 kW turbines. In the UK sector of the North Sea, a total of four wind turbines of a capacity of 5 kW are to be installed on two unmanned oil installations.

#### Photovoltaic systems

The decrease in cost accompanied by the increase in efficiency of photovoltaic (PV) cells has enabled a rapid growth in the market for photovoltaic systems. Since 1978, when a mere 1 MW was installed worldwide, it has increased to reach around 56 MW in 1991, primarily for remote sites. However, it is now becoming feasible to use PV for power generation in a centralised manner. In 1992, in Switzerland, a 500 kW PV power station came on-line. In Greece, a 600 kW plant has been completed. In Spain, Union Electric Fenosa are to build a huge 1 MW PV power station for water pumping. The Spanish government also plans two other large projects of 100 kW capacity. In Italy, a PV power station over three

times this size is under construction. Currently, the demand in Europe exceeds the production capacity. In 1991, the two largest PV manufacturers in Europe were BP Solar (UK) and TST with a market share of around 15 % each. Other large PV manufacturers are Helios (GR), Italsolar (I) and Photowatt. Together this group of companies accounts for about two-thirds of the PV market. Europe has increased its share in the world market since 1985 at the expense of the Japanese and US industries.

#### Geothermal energy

In the EU, the greatest amount of geothermal electricity generating capacity by far lies in Italy where over 50 geothermal units are in operation. Other countries include France, Portugal and Greece. Further developments are centred in Italy where the largest geothermal power plant in the world, a 60 MW plant, opened in Tuscany in 1991. Plans for three more plants of this size are being considered in line with governments policy to increase the share of geothermal-derived electricity to 3 % of total national energy production. Other plans include a 5-10 MW plant which is planned for 2000 in one of three sites in France, Germany and UK, funded by the EU JOULE programme.

From a world perspective, the production of electricity from geothermal sources has accelerated over the past decade. Between 1980 and 1990, production increased by 50 % from 3 900 MWh (megawatt/hour) to 5 850 MWh.

In addition to energy for electricity production, hot ground water may be used for space heating on a smaller scale. In the EU, it is estimated that in terms of primary energy, geothermal heat provided 370 000 toe of energy in 1990. The regional distribution is the same as that for geothermal electricity production, and is used predominantly in urban areas. In 1990, the equivalent energy saving from using this source of energy was 170 000 toe in France and 200 000 toe in Italy. Other countries with geothermal potential for heating include Spain, Portugal, Greece and Germany. In former East Germany, much use was made of geothermal energy for district heating. A 12 MW plant will come on-line in 1994 in Mecklenburg-Vorpommern. In the west, a 20 MW project in Bavaria will be Germany's largest geothermal plant, and is due for completion in 1994. Worldwide, the consumption of geothermal energy for heating was around 2 million toe (tonnes of oil equivalent), the majority being used in Japan, China, Iceland and Hungary.

#### Biomass

The theoretical potential for biomass in the EU is very large, at around 100-120 million toe. Within the EU, wood, straw and municipal solid waste are the most commonly used biomass fuels. The primary energy derived from these sources amounted to almost 22 million toe in 1989.

The great proportion of this total is given by wood. The EU currently consumes around 20 million toe of wood energy. France is by far the largest consumer of wood taking 45 % of the EU total due to the large proportion of wood burning stoves used in rural areas.

The biggest consumer of straw for energy in the EU is Denmark, where there are over 12 000 straw-burning stoves on farms and over 30 district heating schemes using straw. The combustion of straw currently provides 1.5 % of Denmark's primary energy needs. As a means to reduce coal imports, achieve environmental objectives and indirectly subsidise farmers, the Danish government has obliged electricity utilities to purchase 1.2 mt/year (million tonnes per year) of straw. Biomass as a whole provides 5.8 % of Denmark's total primary energy requirements and the government intends to increase this to 9 % by the year 2000.

The most widely used method of recovering energy from MSW is by incineration; another rapidly expanding major source

**Table 5: Renewable energy

is landfill gas. In the EU, around 550 schemes were operating in 1988, including 174 with heat recovery of which more than 80 % are in France, Germany and Denmark. Disposal of MSW in landfill is widely practised in many Member States. In the United Kingdom, 90 % of MSW is disposed of in landfills. Typical schemes generate between 1 to 5 MW and may be used to generate electricity or used directly as fuel in industry.

Biogas is a fuel consisting mostly of methane, produced from the anaerobic digestion of organic material. Agricultural waste, sewage and a variety of liquid industrial effluents can be treated anaerobically. The technology is widespread at sewage works and it is expected to be used increasingly in treating food industry waste and slurry from intensive livestock farming. Member States currently using biogas to any extent are Italy, United Kingdom, Denmark and the Netherlands, due to their livestock farming industries.

The development of energy crops is closely tied to the Common Agricultural Policy (CAP). Set-aside land, which farmers must put to a use other than food production, will total around 15 % of EU agricultural land. Energy crops are therefore an attractive option to farmers. Wood could be sustainably harvested or coppiced (where only the outer branches of a tree are stripped away). If 15 million hectares of farmland is in surplus by the end of the century, and if it was all turned over to fuel wood crops then it is estimated that 120-150 million tonnes of wood with an energy content of 55 to 65 million toe might be produced per year.

Biofuels may also be produced from energy crops. For example, the Netherlands is investigating using feedstocks such as elephant grass, poplar wood or straw for gasification to a fuel for use in electricity generation plants. An Italian biofuel refinery, run by Distilleria F. Palma is operating with a capacity of 70 000 tonnes/year. The largest biofuel producer is Novamont which operates refineries in Italy and France with a capacity of 240 000 tonnes/year, including the world's largest plant at Livorno (80 000 tonnes/year).

#### Active solar collectors

By far the largest user of active solar collectors is Greece. In 1989, the total installed solar collector surface area was around 1.3 million square metres that contributed around 67 thousand toe to primary energy production. In Greece, hot

water from active solar collectors contributes 4.5 % to the total hot water needs. In the other Member States, this fraction is considerably less, due to less favourable climatic conditions and a smaller area of collectors installed.

Today, solar collector sales in Greece represent over half the total sales in the EU. Solar collector production in Greece, however, is solely for the home market, which is very large. At EU level, imports from outside Europe are decreasing: they amount to about 2 500 solar water heaters and about 1 000 additional collectors each year.

#### Production process

##### Tidal power

The simplest systems generate power by capturing water at high tide and running the head of water through turbines (ebb generation). More complicated systems impede the flow of water in both directions. The turbine best suited for the low head characteristics is the bulb-type turbine, and units are manufactured with runner diameters of 7.5 metres and capacities of 60 MW.

##### Small hydro-electricity generation

Countries and institutions define "small" differently. An upper limit for small hydro is 10 MW, while capacities may be as low as a few hundred kilowatts. The technology differs compared to large scale hydro-electricity generation in that turbines are specifically designed for low head conditions and control equipment differs in its complexity.

##### Wind power

Wind power in Europe, in its present form, can be said to have begun in the mid 1970s in the wake of the oil crisis. The industry went through a slump in the mid 1980's with lower energy prices, which prompted intensified efforts to reduce costs and improve operating efficiency. Costs have come down dramatically and the percentage of capacity used on average has increased steadily.

Modern wind turbines operate on either a horizontal or a vertical axis, though horizontal axis machines are the most common units manufactured. Turbine designs have improved considerably such that the efficiency, measured in energy generated per swept area per year, doubled between the beginning and the end of the 1980s. The average size of wind turbines installed in the EU has increased steadily since the 1970's though there is no consensus as to the optimum size. R,D&D work is currently centring on 300 kW machines with rotor diameters of 25 metres. Along with improved technology comes increased reliability and lower costs. A study of the top performing wind farms in California showed an increase in the availability of electricity generated from 60 % to around 95 % over the 1980's. Based on Danish experience, turbines in the range 100-300 kW have an average total cost per swept area of 280 ECU/square metre. The costs vary from country to country and from site to site, depending on the terrain and other factors.

In addition to onshore wind sites, a great potential exists for turbines situated off-shore. There are particular problems associated with this, however, such as difficulties of operation

in a saline environment, achieving designs rigorous enough to stand up to storms and the difficulties of access for maintenance. Off-shore sited turbines tend to be larger than their land based counterparts and environmental constraints hindering turbines on land are more relaxed for off-shore sites.

#### Photovoltaic systems

The basic element is the PV or solar cell. This is comprised of semiconductor materials which have both negative and positive charge carriers. When photons fall on the cell, electrons in the semiconductor are freed, and an electric current is generated. Cells are built into modules of around 1 square metre in size and may generate in the region of 100 W<sub>p</sub> (peak watts). Efficiency has increased by about 50 % over the past decade.

Three methods of production exist. First, single crystal silicon is a well established technology, with cells that tend to be stable and relatively efficient. The cost of manufacturing, though decreasing, is still relatively high. Second, polycrystalline silicon ingots with grain sizes of several millimetres can be produced by a casting process less expensive than single crystalline process. Larger areas are needed for the same power and module efficiency is slightly lower. Polycrystalline silicon ribbons may be manufactured using edge defined film-fed growth and dendritic web processes. The manufacturing process is complex though it has high potential for high speed production. Third, thin film technology is an area of intense research effort. Films are deposited directly onto substrates by technologies such as glow discharge, chemical vapour and electro-chemical deposition. Semiconductor materials being investigated include amorphous silicon, copper indium diselenide, gallium arsenide and cadmium telluride.

#### Geothermal energy

At temperatures below 150° C the most common application of geothermal energy is for direct heat. This has advantages in terms of its simplicity, efficiency and adaptability and is relatively cheap. The hot water cannot economically be transported at distances greater than about 1 km, so the site location is limited by the end use location. Electricity generation at high geothermal steam temperatures is the most attractive application due to the low distribution costs.

The basic technology involves drilling geological formations to obtain hot water or steam, which is then used in the direct application or to power turbines to produce electricity. Other methods such as magma, geopressed and hot dry rock technologies have been investigated though none are near to commercial viability.

#### Biomass

On a global scale, the majority of the population relies on biomass as its primary source of fuel. In the industrialised world, where energy production is more centralised, biomass energy conversion is perhaps the most technically, economically and socially complex renewable energy option. Old, well developed technologies co-exist with completely new, advanced techniques for converting biomass to useful energy.

Over recent years, considerable investment has been made in developing techniques to produce transport fuels, or components thereof, from biomass as an alternative to fuels refined from petroleum. These fuels may be produced by various methods, three of which are mentioned here.

The first is the production of biodiesel, consisting of complex natural esters from the esterification of oils extracted from plants such as rapeseed, linseed and the sunflower. A second method involves the hydrolysis and subsequent fermentation of plants with a high energy value to produce methanol or ethanol. Thirdly, a diesel or gasoline fuel may be produced by liquefaction, a variant of the pyrolysis technique. An indirect method gasifies the biomass and is followed by the catalytic conversion of the product to a liquid fuel. Direct liquefaction skips the gasification step using lower temperatures to produce partially dcoxygenated, complex oils which are then upgraded.

Electricity generation and heating requirements can be met by direct combustion or gasification of wood, straw or other dry biomass. Household waste may be incinerated, or the landfill gas used to provide heat and/or electricity. Agricultural waste such as slurries from animal husbandry may be used in the anaerobic digestion process to produce biogas. In addition, any organic material may be gasified (or liquefied) by pyrolysis (thermal decomposition in the absence of oxygen).

#### Active solar collectors

Active solar technology can supply heat at moderate temperatures for industrial processes, and heat at ranges that satisfy building energy needs. The essential component is the collector and designs include flat plate collectors (glazed or unglazed), evacuated tube collectors and air collectors.

Unglazed solar water heaters are used in outdoor applications, predominantly for heating swimming pools. Glazed solar water heaters form the bulk of the market, representing approximately 90 % of total installed collector surface area in the EU. Evacuated tube collectors form a small but growing part of the market, particularly in northern Europe. In value terms, they account for approximately 10 % of total EU sales. Air collectors are generally built into the building structure to produce warm air directly or in connection with a heat pump for space heating. The most important and widely used application is for drying hay, particularly used in Sweden, where an estimated 200 000 square metres have been installed.

## INDUSTRY STRUCTURE

The renewable energy industry is a heterogeneous mixture of companies in terms of size, specialisation and geographical scope of operations. Small companies, which tend to rely on business generated through EU and national programmes, generally concentrate in niche markets where their core expertise lies. Large multinational companies have historically tended to view renewable energy investments as part of a long term strategy of diversification, and these activities generally form a very small part of their overall business portfolio.

Research into renewable energy technologies is conducted predominantly in universities and government research institutes. However the research budget for renewable energy in large companies has been on the increase. Government incentives have made renewable energy technologies more at-

tractive and companies involved in the market have stepped up investment in order to retain a competitive edge in the field.

### Impact of the Single Market

There is no umbrella association representing the renewable energy industry in Europe, which is composed of several quite different activities and technologies. While the European Commission has sought to increase the role of renewable energy in the EU energy mix, the latter's contribution remains small, and varies from country to country, depending upon the overall financing and incentive packages available for R & D, pilot projects, information campaigns etc., through EU funding programmes such as ALTENER, JOULE and THERMIE, and from national sources.

### REGIONAL DISTRIBUTION

The factors currently governing the regional distribution of renewable energy technologies are the relative size of national financial incentives promoting renewable energy, the technical and commercial maturity of the technology and the size of the resource base.

For more mature technologies, such as biomass combustion and hydro-electricity generation, the size of the resource is the most important. For other technologies, financial incentives are more significant drivers. For example, although the wind resource in the region around Denmark is relatively small, a government commitment to wind energy has produced the largest wind energy industry in Europe. In the United Kingdom, which has the biggest wind energy resource in Europe, the wind energy industry is less well established.

In the long term, as renewable energy technologies mature, the size of the resource base should become the main factor controlling the size of the industry. PV, active solar energy and biomass all rely on sunlight, hence the southern regions have the most potential. The mountainous regions of the Union have the largest potential for small hydro power. The largest tidal potential exists along the western coasts of the United Kingdom and France. Wind energy has the largest potential in the north west region of Europe. Geothermal power will remain essentially confined to Italy.

### ENVIRONMENT

In the mid 1970s, interest in renewable energy was born as a result of high crude oil prices. Recent interest has been largely due the relatively benign effects on the environment of fuels from renewable energy sources (particularly with respect to their contribution to reducing carbon dioxide emissions).

With the exception of biomass, renewable energies are almost free of pollution. This clearly differentiates them from conventional methods of energy production, where increasing concerns over pollution from the energy sector is forcing very large investments in emission control equipment. This is not to say that renewable energy has a negligible environmental impact. Ironically, the growth of the renewable energy industry is driven by two antagonist factors: on the one hand by world scale environmental factors such as the threat of global warming, while on the other hand, being constrained by environmental factors on a local or regional level such as the visual impact of wind turbines and the environmental impacts of tidal and hydro-electric schemes.

There are two main environmental factors promoting the industry. The first is that renewable energy technologies produce zero or negative net CO<sub>2</sub> emissions. Biomass releases carbon dioxide when burnt to produce energy. However, during biomass growth, carbon dioxide is sequestered from the atmosphere. If biomass use is accompanied by afforestation then the net carbon dioxide emissions for biomass could theoretically be zero or even negative in the long run. The second factor is that, with the exception of biomass, energy produced from renewable sources does not produce sulphur dioxide, sulphur trioxide or nitrous oxide, the principal components of acid rain.

The environmental impacts of renewable energy technologies are generally lower than that of conventional energy sources but are significant since, along side costs, they determine the feasibility of implementation. For example, tidal power systems have a very large impact on the environment due to changes in water levels, flow patterns and velocities, sediment movement, and the physical presence of the barrage. In addition water quality will be affected and the impact on wildlife, mainly birds and fish, is particularly acute. The most serious effects are felt in navigation and for port facilities.

The environmental impact of wind power is essentially on the human rather than the natural environment. There is significant visual intrusion, especially since the best sites are often on a skyline. Other environmental impacts are noise and interference with telecommunications.

Active solar collectors and photovoltaics have a visual impact since their use is predominantly in a widely dispersed fashion and because they must, for maximum efficiency, be placed in prominent positions.

---

## REGULATIONS

---

Over the last decade, many Member States have successfully encouraged the development of domestic renewable energy industries through policies discussed below.

In Denmark, subsidies for installing wind turbines were phased out in 1989 and replaced by tax credits: shareholders obtain income from the electricity sold tax-free below a set limit. State aid also encourages the use of straw as fuel, biogas plants and certain solar projects. The Energy 2000 action plan calls for 1 500 MW of installed wind power capacity by 2005, and is setting up demonstration projects for new renewable energy technologies.

In France, the government sees the greatest potential for an increase in renewable energy production coming from the combustion of wood. Also, special grants have been used to cover the exploration risks of geothermal development. In the area of biofuels the French government gives grants derived from a tax on petroleum products and a newly created biofuels agency co-ordinates R,D&D. Biofuels are exempt from excise taxes. Special grants are given to develop pilot programmes.

In Germany, a law (Einspeiseverguetungsgesetz, 1991) has helped renewable energy technologies producing electricity by forcing the utilities to pay for electricity generated by these methods at a premium rate. Subsidies encouraging the installation of wind power are also available. A proposed change in the law to facilitate planning permission for wind turbines is currently under discussion.

In Greece, the government has made particular commitments to the promotion of wind and geothermal installations. Financial incentives take the form of subsidies in the region of 40-55 % of the total investment. Tax breaks and low interest loans are also available. Wind power has enjoyed a boom over recent years, mainly on isolated islands.

In Spain, the national energy plan gives a clear objective for the contribution of renewable energy in the year 2000 and provides for government support. A number of large scale solar and wind power demonstration projects have come on line, though the majority of renewable energy use comes from biomass.

In Portugal, the EU Valoren project and a national programme to promote renewable energy (STURE) have benefited many projects in small hydro-electric generation, active solar collectors, photovoltaics, geothermal energy, wind power, the use of wood residues and the production of biogas. The relaxation of the authorisation procedure for the production of electricity from small installations has benefited renewable energy production. Also, fiscal incentives to promote the penetration of renewable energy technologies exist in the form of reduced VAT on renewable energy equipment.

In Italy, funding is available covering a portion of the capital costs for renewable energy projects. Efforts to remove barriers to the incorporation of electricity from small generators has resulted in very favourable tariffs for wind, photovoltaics, geothermal and biomass energy in particular. Biofuels are exempt from excise taxes and production has increased rapidly over recent years.

In the Netherlands, wind power installation is subsidised on the basis of the swept area and in the area of R,D&D, funding for 50 % of the costs are made available. A second phase of an integrated programme on wind energy provides government funding for research, development and market introduction of wind power technology. Other government programmes exist to promote biofuels and photovoltaics. General subsidies go to solar, biomass and geothermal projects.

In the United Kingdom's privatised electricity sector, regional electricity companies (REC's) are obliged to purchase a portion of their electricity from non-fossil sources under the Non-fossil Fuel Obligation (NFFO). This obligation also forces the REC's to purchase the electricity at premium prices organised in bands. Different renewable technologies are associated to different price bands according to their commercial status. Most projects receiving support are for the production of energy from waste, but a number of wind and small hydro-electric generation projects have also been undertaken.

The European Commission has several programmes running which support renewable energy.

The Altener programme was launched by the Commission to promote greater penetration of renewable energy. It will run until 1997 on a current budget of 40 million ECU. The plan contains the political EU objectives which are to increase the penetration of renewable energy's contribution to total primary demand from the current 4 % to 8 % by 2005, to triple the production of electricity from renewable energy sources (excluding larger hydro-electricity power stations) and to secure for biofuels a market share of 5 % of total fuel consumption by motor vehicles.

In 1994, the Fourth Framework for R, D & D was agreed by the European Parliament, incorporating funding for existing programmes set up under the Joule programme for research and technological development, and the Thermie programme for energy demonstration projects. Both these programmes originally included support for renewable energy research and pilot projects, covering such areas as wind energy, photovoltaics, biomass and geothermal energy. Continued funding will be provided under the umbrella of the non-nuclear energy component of the Fourth Framework, which has a funding of around 1 billion ECU.

---

## OUTLOOK

---

Strong growth in the renewable energy industry is predicted into the next century. Some technologies will see faster growth than others and this will depend more on the type and effectiveness of policies promoting market penetration than technological development, though this will also take place.

Strongest growth could occur in the area of biomass and other renewable energy technologies, notably wind and geothermal energy. The share of large hydro-electric generation, though remaining large, will see relatively slow growth due to the lack of suitable sites remaining.

For electricity generation, biomass, predominantly wood, agricultural residues like straw, and waste will be increasingly used. Direct combustion will be the main method, though gasification should see larger growth. Electricity generation from wind energy is expected to grow rapidly though it is dependent on political factors to enable its widespread development. In the generation of electricity from geothermal sources, only Italy and Greece have high temperature geothermal resources. Italy is likely to see the largest growth in this area in the short term. Small hydro-electricity generation will experience higher growth than its larger counterpart. Photovoltaics, though a small component, will see growth in applications for remote locations. In the long term, PV will see higher growth through grid connection from either centralised or decentralised generation sites.

Geothermal energy for heating will experience growth in all Member States where resources are available, principally in Italy. However, biomass should remain the major fuel for heat production from renewable energy sources, with gasification technology showing the largest growth.

The outlook for biofuels, formed from energy crops such as rapeseed or sunflowers, depends very much on future agricultural policy in the EU. Energy crops could supply farmers with a valuable source of revenue from set-a-side land. Tax breaks, as seen in Italy and France and continued Member States support will ensure that the use of biofuels increases.

The prospects for the active solar collectors market depends to a large extent on the effectiveness of national and EU energy plans. Denmark and the Netherlands will see large growth due to government commitments to reducing carbon dioxide emissions; similar conditions should favour the industry in Germany. Italy has recently included the development of active solar energy into its national energy plan, ambitious targets have been made and these should promote strong growth. Spain has considerable potential; a government commitment combined with public education campaigns could result in active solar being widely implemented. In Greece, the market, though large, is not near to saturation and is likely to continue increasing steadily.

# Water supply and distribution

## NACE 170

*The sector of drinking water supply is organised very differently in the various Member States.*

*Water is essential to life and health. Water suppliers, therefore, have to comply with technical and health standards and regulations that are becoming ever stricter and which, in consequence, have an increasing impact on the price of water.*

### INDUSTRY PROFILE

#### Description of the sector

The service of supplying drinking water covers abstraction, treatment, quality control, storage, transport and distribution, including maintenance of the infrastructure, metering (in Member States where metering is generally applied), invoicing and customer information and advice services, both for domestic and industrial users.

Research and development efforts, for the most part carried out by the water suppliers themselves, whether they are public or private, are constantly increasing to ensure compliance with the quality requirements imposed by European legislation (cf. section on Regulations) because of the increasing pollution of raw water sources.

The water supply may be provided by private companies, by public companies or by municipalities.

The water suppliers are represented by national associations, which are themselves members of a European association, EUREAU.

A few representative figures on the economic and social importance of the sector and its evolution are illustrated by the tables. The text does not provide a qualitative analysis of any particular management structure.

#### Recent trends

Water supply services are facing developments in connection with their rationalisation, the requirement to comply with European legislation, and the economic aspects of their function.

The main options for change currently being considered by some Member States are whether to:

- take into account the complete water cycle by integrating water supply and sewerage into one entity;
- reinforce co-operation between small isolated operations under the care of a limited number of large regional companies;
- separate the accounting of services or reorganise the services into individual entities;
- encourage the formation of water supply companies for the smallest communities.

In general water supply services are under pressure to comply with both national and European legislation, that is becoming more and more stringent in terms of quality, and is leading to increased investment costs, on one hand, and to improve the infrastructure (i.e. the distribution networks), on the other hand.

Some Member States therefore currently decide to delegate the management of the total or part of their water supply and wastewater treatment services to private or public organisations under their responsibility on a contractual basis and using methods agreed by both parties, for all or part of the infrastructure and the service(s) (see Table 1).

In some Member States water prices tend to evolve so as to incorporate not only the costs of the service, including the

protection of resources, but also various taxes (such as taxes on water abstraction) and charges for waste water treatment.

In certain Member States, however, the water prices do not cover all of the costs of the service provided. The investment requirements imposed on water services regularly lead to price increases.

There is a clear tendency in some of the Member States to give preference to abstraction from surface water sources because groundwater sources are insufficient and their protection is becoming more and more difficult with less certain results. In others, groundwater abstraction is increasing to ensure sufficient supply.

In general, significant efforts will be necessary in the future to prevent both surface and groundwater pollution when these waters are intended for human consumption.

### International comparison and foreign trade

Generally speaking, water is not an exportable "product" and its distribution therefore essentially has a national, regional or even local character. Certain water suppliers nevertheless export their know-how in the framework of international co-operation agreements (technical assistance, training, etc.). They also delegate some of their activities to foreign partners and sometimes purchase foreign materials or products to carry out their services.

Major private European players, namely French, British and Spanish companies, share their knowledge in consortia with large cities in other parts of the world, such as Buenos Aires, Mexico, Caracas, Sydney....

Some public or private entities have engaged in the development of operations, service provisions, co-operation and

training programmes with other countries (for example, the Netherlands in Indonesia and Germany in Eastern Europe).

Recently, American involvement in the European water supply sector has grown.

## MARKET FORCES

### Demand

Factors influencing drinking water demand are demographic evolution, consumer habits (varying in the Member States), climate, price structures, the number/types of sanitary installations and industrial development.

In all Member States, raw water abstraction for the production of drinking water is a key priority and it must be carried out in accordance with conditions which ensure the adequate protection of the environment and economic use of water resources. In all Member States, measures are taken to encourage water conservation (including leakage control).

General emphasis is put on quality improvement (European Directives) and on the rational use of drinking water.

The availability of sufficient drinking water quantities to satisfy customers' needs (drinking, hygiene, leisure....) nevertheless remains an important issue for water suppliers.

### Distribution and competition

The function of water supply is carried out either by public, private or mixed entities operating within the framework of geographical monopolies.

The direct management system excludes, except in certain cases, competition within the water distribution sector, while the delegated management system allows a renewal of the service provider's contract at the sovereign discretion of the local community.

Work and supply contracts relevant to the water service and its execution are open to full competition in compliance with the specifications of the European Directives on procurement procedures for public utilities.

Although there are differences between Member States, the general trend is to increase the price of water services, par-

ticularly in the wastewater treatment segment, due to constant increases related to:

- general investments for modernisation of installations and for improvement of processes (involving significant research and development-work) to meet the ever increasing quality requirements,
- investments for aquifer protection, water treatment, maintenance of networks and modernisation of distribution (automation, remote metering where applied; leakage detection),
- payments to farmers in some of the Member States to compensate for their efforts to ensure better protection of water resources,
- water abstraction and treatment taxes in some of the Member States (incorporated in the price of drinking water).

As is the case for environment related industries in general, the water supply sector will make use of more and more refined and diversified skills.

Wages and service operating costs differ from one Member State to the other because of varying requirements due to differences in local conditions: therefore, no reliable estimate is available.

In general, water supply conditions must reflect the regional and local conditions of the raw water resources and the nature of the local customer base.

## INDUSTRY STRUCTURE

As indicated in the EUREAU 1992 report on EU Management Systems, the structures of drinking water production and distribution services are extremely diverse even within each member state.

This diversity is due to historical circumstances which governed the creation of these services and to specific institutional and legal practices.

The main characteristics may nevertheless be described as follows:

- in general, the provision of drinking water is ultimately the responsibility of a public body (except in England and

**Table 4: Water supply and distribution

Source: IWSA

Wales) whether it is a municipality, another territorial community, a province, a region or the central State;

- management of the service is guaranteed either by the responsible entity and by its own resources, or by a body distinct from the appointed entity (e.g. delegated management contracts);
- the organisation of the service varies according to whether or not a distinct legal status is or is not granted to the management entity, the nature of the law that is applicable to its function (administrative law or company law), the structure of the share capital and especially the option to use private capital, exclusively or in association with public capital (mixed companies), the nature, composition and method of appointment of the management bodies, the degree of budgetary independence granted to a management entity compared to the general budget of the responsible entity (German Regiebetriebe);
- when management is delegated, there can be significant differences in the relationship between the responsible entity and the management body (participation of the responsible entity in the management entity: operating, regulatory, statutory or contractual rules);
- delegated contractual management is the formula that gives the management entity the most freedom in negotiation and operation;
- investments are financed either through the overall budget of the responsible entity (which, in this case, generally finances other public services apart from drinking water supply with this budget), or by the management entity;
- it is frequently the case that the responsible entity and the management entity - when they are distinct - each finance part of the investments for infrastructure or operation;
- when responsibility and management are grouped under a single entity, this entity is the owner of the installations and equipment;
- when they are distinct, one or the other can own the installations and equipment, dependent on the particular case;
- clearly, it is not necessarily the case that one entity provides the financing and owns the system;

- as to price-setting, a distinction is made between management systems. Some are based on prices set "at the risk of the management body" (found mainly in contractual forms of management), others have prices set with the aim of balancing income and costs (Cost Recovery), while others have a system in which unreasonable costs will not be refunded. In the first case, once the tariff is set (it is usually accompanied by an adjustment formula or a revision procedure) the management body bears all the consequences of any gap between the costs of service provision and income (except if there is a change in circumstances). In the second case, the price is set so as to equalise income and reasonable costs;
- the activities of the bodies responsible for monitoring the proper execution of public services (generally sanitary authorities and the local community) mainly include control of the tariffs, of the nature and areas or investment, of the management of service and of compliance with health standards.

### Impact of the Single Market

When taking into account the impact of the Single Market program in the drinking water and supply sector, one must consider the different effects that this may cause to the companies operating in the sector. On the whole, the industry feels that the impact has been negative for government controlled companies as crumbling national barriers will force them to restructure and adapt to enhanced market conditions; instead, private companies will be hit positively by internal market completion because the monopolistic aspect of markets will be gradually eliminated. Further, the industry is aware that the implementation of the Single Market will force companies to spur certain un-procrastinable changes, especially in the field of rationalisation, compliance to European legislation and general economic aspects of their activity. Finally, completion of EU legislation in the domain of liberalisation of concessions deems of the utmost necessity.

### PUBLIC HEALTH AND ENVIRONMENT

European drinking water suppliers all share one daily objective: to ensure that the quality of the drinking water supplied by their networks meets the public health standards and the

requirements laid down in European legislation (see section on Regulations).

The public service of water distribution requires ever increasing efforts in the field of R&D, investment and quality assurance, especially in the light of the political and economic climate which tends to limit public financing and availability of private financing.

However, the socio-economic and political impact of the price paid by the consumers which increasingly covers, as previously mentioned, both drinking water supply and wastewater treatment and disposal, cannot be neglected and must remain within socially acceptable limits.

In this context, the European water suppliers are combining their efforts with those of other professional sectors in this field and with the national public authorities and European institutions in order to define a legal framework and a series of development actions which both match the needs of public health and environmental protection and also anticipate future developments.

The task is made even harder by the diversity of the interests involved (agriculture, industry, public health) which are often in conflict. This calls for a clear and consistent legal framework with a realistic timetable and availability of sustainable and sufficient public and private funds.

## REGULATIONS

European legislation governing the field of drinking water quality, protection of surface and groundwater resources and the activity of the sectors having a direct or indirect impact on the quality of these resources is at present being revised with a view to easing its implementation and improving its coherency to produce an integrated approach for the entire water cycle.

More specifically, Directive 80/778/EC of 15 July 1980 on the quality of water intended for human consumption was based on scientific knowledge available in the 1970s and needs to be updated, though there is no doubt that this Directive made a useful contribution to the recognition of the importance of drinking water quality and led to constant improvements in this field.

Since it was adopted, substantial improvements in technical and scientific knowledge of the factors influencing water quality and in the methods of measuring this quality were made. Moreover, the knowledge of the harm to drinking water quality caused by various sources of pollution is constantly increasing.

The Commission proposal for the revision of the Directive 80/778/EEC was adopted on 4 January 1995: there is likely to be extensive discussion in Council and Parliament before its final adoption. The revision of Directive 80/778/EEC aims not only at adapting its content to scientific and technical progress, but also at resolving the implementation problems which occurred with this Directive, and at taking into account commitments on subsidiarity made at the Edinburgh European Council.

The current initiative to revise and update the Directive is one of a number of measures which will have a significant impact on the quality of drinking water and on the harmonisation of technical standards for products having a significant impact on the quality of drinking water and on the cost of its distribution.

This European process of legislation/standardisation takes account of the evolution of international legislation and builds on the work of ISO and the recommendations of the World Health Organisation (WHO).

## OUTLOOK

The legitimate expectations of consumers and of health authorities can only be fulfilled if the following conditions are met:

- the raw water resources are protected and the relevant European legislation is revised on the basis of an integrated approach;
- research & development efforts and costs for improvement of infrastructure (especially networks) are sustainable and the necessary funds are easier to reach.

The water supply organisations will continue their efforts to reach these goals together with the relevant public authorities.

They will also continue their efforts to share their acquired technological skills with developing countries and will continue to improve such skills in the European context.

Written by: EUREAU

The industry is represented at the EU level by: European Union of National Associations of Water Suppliers (EUREAU). Address: Chaussée de Waterloo 255, Bte 6, B-1060 Brussels; tel: (32 2) 537 4302; fax: (32 2) 539 2142.

## Overview

### NACE 21, 23

Mining and quarrying activities in the EU cover a wide range of minerals and include a number of world-class operations. The EU is a significant producer of copper, lead, zinc and chemical industrial minerals and a major centre for both construction raw materials and physical industrial minerals production. Mined products, although relatively low in value terms, provide the raw materials for a number of major added value industries. The sector continued to face adverse conditions in 1993 which were manifest in weak demand and low prices, but the leading operations demonstrated resilience which is expected to be translated into generally improved performance in the short term.

### INDUSTRY PROFILE

#### Description of the sector

The non-energy mining and quarrying sector comprises the extraction and physical processing of all solid minerals with the exception of coal and uranium. The minerals are extracted by open-pit or underground methods and are normally subjected to mineral dressing techniques to provide ores and concentrates for further upgrading or use in their own right.

The sector is subdivided into metallic and industrial minerals. Metallic minerals are discussed under the chapters on ferrous and non-ferrous ores and industrial minerals are reviewed under the chapters of stone, construction raw materials, chemical industrial minerals, crystallised salt and physical industrial minerals. In the case of metals, the ores and concentrates produced form the raw materials for metals production which is covered in chapters 3 and 4. Industrial minerals may also be classed as intermediates, which proceed for further processing, but are normally considered as finished products.

The scale of mining operations within the EU varies, although there are over two thousand operations and over three hundred companies involved which extract around fifty commodities, most of them are small scale, producing for local consumption. The major metallic ores mined in the EU are copper, lead and zinc. The major industrial minerals include: bentonite, dolomite, kaolin, limestone, sand and gravel, silica and stone. The total value of the non-energy mining and quarrying sector is around 18 billion ECU. Although small in comparison with other industrial sectors, mining provides key raw materials for value added industries such as metals production, chemicals and construction. The metals production industry also provides value added materials for industries such as engineering, transportation and power generation and transmission.

All EU member countries enjoy some mining activities, although Germany, France and the UK together account for around two-thirds of output. Spain, Italy, Greece, Belgium and Ireland are also significant producers of certain minerals.

#### Recent trends

Overall volume production in the sector remained relatively unchanged to that of 1992, although the individual mineral groups fared differently. The tonnage of iron ore produced declined, in value terms, by 47 % in 1993 with low prices continuing. Output levels for non-ferrous metal ores recorded a marginal increase of 7 %, but experienced an average price reduction of 15 % compared with 1992.

Figure 1: Non-energy mining and quarrying Production in comparison with related industries, 1993

Source: B.M.Coope & Partners, DEBA

The construction raw materials sector grew by over 30 % over 1992s production level, although there were variations between individual countries. In the chemical industrial minerals sector the decline experienced since 1985 continued with an 11.4 % decrease in production from 1992, primarily due to falling prices. Finally, the physical industrial minerals sector showed some growth (1.5 %) during 1993.

The prospects for all areas appear brighter for 1994, although fears exist for the long-term sustainability of the iron ore mining industry in the EU.

#### International comparison

Iron ore mining in the EU is insignificant in world terms, producing less than 1 % of the world's production while consuming around 13 %. EU operations are small and low grade

Production and employment compared to EU total manufacturing industry**

in world terms and may not survive in the medium term, despite more optimistic price and demand predictions. The situation in the EU compares with that of Japan, while the USA remains self-sufficient.

In non-ferrous metals the EU's position is a little better with over double the level of self-sufficiency of Japan. Here again, production and consumption in the USA are largely in balance. However, the EU does have a small number of world-class mines which compete effectively with international operations in this sector.

For the construction raw materials sector the EU is the largest world producer with an output twice that of the USA and three times that of Japan. The USA, however, is dominant in the production of chemical industrial minerals due to the fact that they are a leading producer of four minerals (salt, sulphur, phosphate rock and boron) and an important source of two others (potash and barite). These minerals combined exceed EU output three-fold. Japan has only two minerals of significance (sulphur and iodine). In physical industrial min-

erals the EU leads the USA by around 40 % in output, while Japan is only a minor producer.

Overall the EU is a major player in the international non-energy minerals mining sector; where, with the exception of iron ore mining, it shares a leading position with the USA.

**Foreign trade**

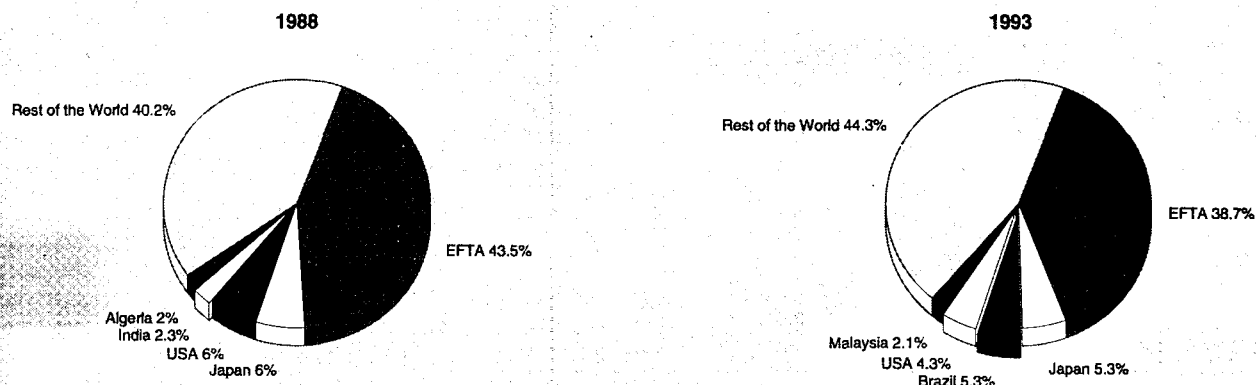

The trade features of each of the groups within the sector are somewhat different. In the case of iron ore the value of EU ores is relatively low precluding exports, while it is almost totally dependent on imports. Despite a dependency rate of 77 % on imports for non-ferrous metals ores, approximately 45 % of EU output was exported in 1993, demonstrating the international nature of the markets.

Foreign trade accounts for very little with respect to construction raw materials, but the EU has a substantial import and export trade of chemical industrial minerals, importing in particular phosphate rock, potash, borates and sulphur and exporting potash, salt and sulphur. The position of physical industrial minerals lies somewhere in between the previously

**Figure 4: Non-energy mining and quarrying  
International comparison of main indicators in current prices**

**Figure 5: Non-energy mining and quarrying  
Destination of EU exports**

Source: Eurostat

mentioned industrial mineral groups, with imports exceeding exports but at a decreasing rate.

Trade partners for all commodities in this sector are widely distributed with nearby EFTA countries receiving 38.7 % of EU exports and the rest of the world receiving 44.3 %. Data on imports reveals that Brazil (15.5 %), EFTA countries (14.7 %) and Canada (10.6 %) supply the EU with 40 % of its imports.

## MARKET FORCES

### Demand

The minerals in this sector have a very wide range of applications which provides a dampening effect with regard to demand. However, consumption levels and prices generally follow international economic trends. For the period 1992-1993 overall EU demand was different from country to country but total consumption declined by 11.53 %. Prices levels were also depressed due to high stock positions built up during the recession.

This position was broadly held by each of the groups in the sector in 1993, with demand reflecting the generally modest

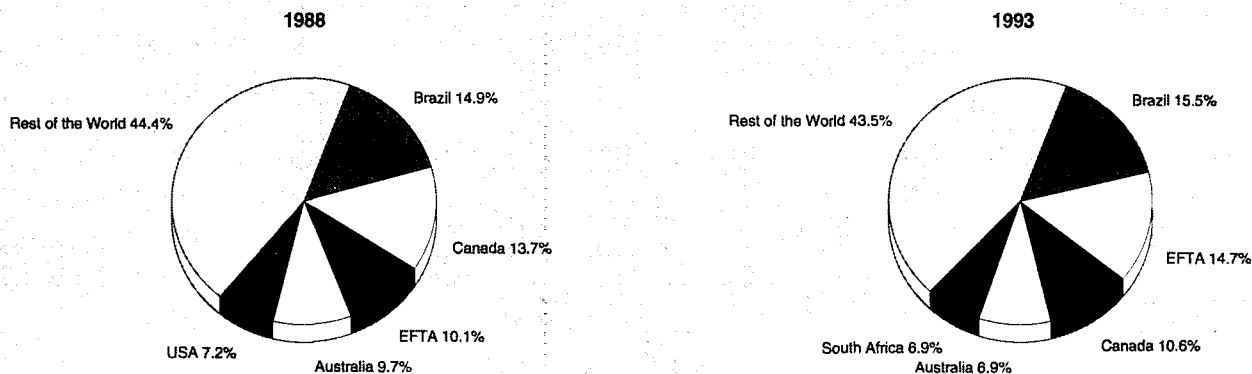

industrial demand in the major internal and EFTA markets, compensated to a small degree by better conditions in the USA and, particularly, South East Asia.

### Supply and competition

In iron ore mining, the EU has a very limited supply capability and cannot compete with the large, high grade deposits exploited overseas, despite having a large and continuing demand for steel making raw materials. In contrast, EU non-ferrous metals mining operations provide between 2-7 % of the world's minerals for metals manufacture and the leading operations are competitive in cost and quality. However, the number of potentially economically-exploitable ore deposits in the EU limits the expansion of supply.

In the industrial minerals field, with its relatively lower unit prices, transportation costs are a major factor restricting foreign competition, except where absolutely necessary. Fortunately, the EU is virtually self-sufficient in construction raw materials and for the bulk of its needs for physical industry minerals. Thus, for the EU the only practical competition is in selected chemical industrial minerals and where specific grades of materials cannot be matched by internal supply.

**Figure 6: Non-energy mining and quarrying  
Origin of EU Imports**

Source: Eurostat

**Figure 7: Non-energy mining and quarrying Trade Intensities**

Source: B.M.Coope & Partners, DEBA

### Production process

The fundamental processes of mining and mineral processing have changed very little over the years, however they have adapted to the response to international competition and the need to reduce operating costs. The main features of these changes have been, and continue to be, energy reduction, scale-up and increased utilisation of process control and automation. The combination of these effects has resulted in a steady increase in productivity in the sector with a corresponding lowering of employment.

## INDUSTRY STRUCTURE

### Companies

In the EU only two significant producers of iron ore remain in operation, CAM in Spain and ARBED in France, less than 1 % of the number of companies active in the 1960s. The number of operations in the non-ferrous area has also declined, but no-where near as dramatically, although small operations were forced to shut-down or suspend activities in 1993. The major producing companies are Somincor (Portugal, copper), Tara (Ireland, zinc) and Asturiana de zinc (Spain, zinc) and two new zinc mines are planned to open in Ireland in the coming years. A number of major international mining companies have their headquarters in the EU, but their mining operations are almost exclusively overseas.

The largest companies in the construction raw materials sector are the major cement and aggregates groups including Lafarge of France, RMC, Redland, Tarmac, Tilcon, Blue Circle, Hanson

and Bardon of the UK, Heidelberger Zement, Dyckerhoff and Basalt AG of Germany, Italcementi of Italy, CBR of Belgium and CRH of Ireland. Chemical industrial minerals production is dominated by a group of large companies including AKZO (Netherlands, salt), Solvay (Belgium, salt), BASF and SKW (Germany, salt), Kali und Salz (Germany, potash), MDPA (France, potash), INI (Spain, potash), Cleveland Potash (UK, potash), Elf-Aquitaine (France, sulphur), BEB (Germany, sulphur), Pechiney (France, fluorspar), Laporte (UK, fluorspar), Nuova Mineraria Silius (Italy, fluorspar), Minersa (Spain, fluorspar), Sachtleben (Germany, fluorspar and barite), M-I (UK and Ireland, barite) and Barytine de Chaillac (France, barite). Most of the leading companies in the physical industrial minerals area are industrial minerals specialists, although some companies from construction, petroleum and metals are involved. The major companies in kaolin and ceramic clays are ECC and Watts Blake and Bearne (UK), Amberger Kaolinwerke (Germany), AGS and Imetal (France). The main enterprises in the bentonite and special clays area are Sud Chemie (Germany), Laporte and Redland (UK), Tolsa (Spain), Eliopoulos (Greece), and Laviosa (Italy). The major companies in other areas are CECA (France, diatomite), Grecian Magnesite (Greece for magnesia and natural magnesite), Sardamag (Italy), NedMag Industries (Netherlands, magnesia) and Talc de Luzenac (France, talc).

### Strategies

The strategies of the various groups within this sector are varied. In the case of iron ore, survival is the major factor, and for non-ferrous metal ores the development of world-class orebodies is the main criteria. In the construction raw materials area strategies are interlinked with the downstream activities of the major companies and continue to feature a number of acquisitions aimed at strengthening raw material supply.

For the chemical industrial minerals sector rationalisation, mergers and acquisitions are ongoing strategies. The largest restructuring has occurred in the German potash industry with the combination of Kali und Salz Beteiligung AG. A similar trend is being followed in physical industrial minerals with the strategies being world-wide and not just confined to the EU.

## REGIONAL DISTRIBUTION

Iron ore mining is concentrated in the Lorraine and the Pyrenees, while virtually all the non-ferrous metal ores mining activity is in Iberia, Ireland and Greece. New gold operations are projected with the re-opening of the Salsigne mine in France and the deposit at Omagh in the UK.

Industrial minerals mining activities are undertaken in every EU member state, with sand, gravel and clays particularly well distributed. Commodities with particular areas include dimension stone (Italy, Spain), gypsum (Germany, France, Spain, UK), potash and salt (Northern Europe), salt evaporites (Mediterranean coast), kaolin (south-west of England), bentonite (Bavaria, Milos and Sardinia) and sepiolite (Madrid).

### Impact of the Single Market

The creation of the Single Market is perceived to have had an important and primarily positive impact on the non-energy mining and quarrying sector -- not least because the mining industry is accustomed to thinking long-term and in an international context.

The whole industry sees free movement of goods, services, and capital as highly beneficial but the importance of other issues varies according to the sub-sector.

For instance, technical harmonisation and intellectual property issues are more important to the physical industrial minerals sector (where product differentiation is important) than to the

metallic ores and chemical industrial minerals sectors (where international product standardisation is the order of the day).

Meanwhile, public procurement is highly relevant to the construction minerals sub-sector but is regarded as almost irrelevant by the metallic ores sector.

Remaining obstacles or areas where future progress is deemed necessary include monetary union, energy transit and price transparency, and competitiveness issues (e.g. "hidden" subsidies in southern Europe and dumping by non-EU suppliers).

## ENVIRONMENT

Environmental features for the mining industry include dust and noise suppression, minimisation of disturbance to the natural habitats, as well as, mine after-life restoration. Non-ferrous metals mining has to contend with acid mine and rock drainage caused by water leaching of sulphide ores. Great care must be taken to avoid discharging acidic waters into local water courses.

Industrial minerals mining faces objections to proposed superquarries but, in general, it has a good record of pollution abatement and also produces a number of materials used in environmental processes, such as lime for flue gas desulphurisation. Environmental restrictions continue to be especially strict with respect to chemical industrial minerals, most notably, avoidance of potash waste discharge into waterways, prevention of emissions from sulphur recovery units and constraints on the fluorspar industry by regulations on the production of chlorofluorocarbons.

## REGULATIONS

In general EU regulations for mines and quarries are similar to those of the major industrialised nations and are well understood and complied with by operating companies. Recent regulations on free competition have been blamed for the demise of some small operations, most notably the base metal mines in Sardinia. Leading companies are starting to gain registration for EU standards and codes in quality and environmental areas.

## OUTLOOK

The current outlook for iron ore mining is not optimistic with low quality, high cost and strong international competition threatening the future of the industry in the EU. The non-ferrous area is more robust, and new projects in the planning stage should boost output of zinc and gold. In both metals mining areas improved prices are being experienced as 1994 progresses, and improvements to output and profitability in the non-ferrous metals ore mining sector are likely for 1994 and immediately beyond.

The EU will continue to be a major player in construction raw materials, the fortunes of which are linked to the level of building activity, particularly in Europe. The short-term future is thus seen as one of modest improvement. Unfortunately, the prospects for the chemical industrial minerals sector appear less bright in the short term as the recession has provided large stocks of products which are bound to restrain prices and new material demand. The outlook for physical industrial minerals is reasonable, and the international influence of EU companies is likely to extend.

The entire non-energy mining and quarrying sector will be significantly impacted by the addition of three new EU members. Iron ore dependency will improve 19 % by virtue of Sweden joining and non-ferrous metal ores will improve by about 10 % with lead, zinc and copper from Sweden and Finland, nickel and chromite from Finland. All three countries will contribute to industrial minerals operations, in particular, in the construction raw materials and physical industrial minerals areas. At present these countries provide around 10 % of EU imports in the sector and receive around 20 % of exports.

Generally speaking, the EU Council conclusions of 18 November 1993 on a "Community approach to the development of the non-energy mining industry", which is aimed at reinforcing the competitiveness of this sector, have confirmed the fact that this sector is increasingly been considered as important by the EU; in the framework of these Council conclusions, the Commission has been invited to focus particularly on four different aspects: access to information (transparency); environmental considerations commensurate with economic requirements; adaptation of training to the industrial needs; and deepening of the co-operation with non-EU countries.

# Iron ore

## NACE 211

The EU is a major consumer of iron ore, requiring in 1993 around 125 million tonnes as raw material for its world class iron and steel making industries. Restrictions on the reserves, quality and cost of production and distribution of EU iron ore mines limit their production to only around 5 % of this figure, a level which is expected to further decline. The entry of Sweden into the EU will reduce import dependency to 80 % and increase to three the number of EU countries with active iron ore operations.

### INDUSTRY PROFILE

#### Description of the sector

NACE 211 covers the mining and physical processing of iron ore and the primary feedstock for iron and steel making. Mining may be from open pits or underground and mineral processing techniques are employed to concentrate the ore. Agglomeration and sintering are not performed by iron ore producers in France and Spain, the only countries in the EU which mine iron ore. The products are mainly iron oxide ores of relatively low grade.

#### Recent trends

Production within the EU continues to fall, with tonnages being at 70 % of 1992 levels. In France, Usinor's last operation, the Moyeuve mine in the Lorraine closed leaving the Montrouge mine at Tressange, owned by ARBED (L) the last mine in operation. In Spain work was suspended at Aznalcollar. World production was around 932 million tonnes in 1993, of which 5.7 million tonnes were produced in the EU.

International growth was good in 1993 but prices were at the second lowest levels in ten years. Consumption of iron ore in the EU remained virtually unchanged from 1992 (136.7 million tonnes against 133.5 million tonnes) with declines in France and Germany being offset by increases in the United Kingdom, the Netherlands, Italy and Spain. Short-term prospects for iron ore are good with recoveries expected in several countries as they come out of recession and continuing high demand from China. Prices for good quality ferrous scrap are also high which would favour the use of iron ore in steel making.

#### International comparison

In Japan, despite the softening of the economy and weak domestic demand, iron ore imports and steel production remained similar to 1992 levels and the country is now the largest single importer of iron ore at around 114 million tonnes, about 4 million tonnes lower than the EU total in 1993. Consumption in Japan is similarly at 94 % of the EU level which in turn is 58 % higher than that in the USA. In global terms the EU produces less than 1 % and consumes around 13 % of world output.

#### Foreign trade

The negative trade balance improved slightly as the value of consumption was lower in 1993, mainly due to weaker prices. EU imports continue to originate most significantly from Brazil, Australia and Canada. Extra-EU exports of iron ores are nominal only. No significant change is expected in this pattern.

Figure 1: Iron ore Production In comparison with related industries, 1993

Source: B.M.Coope & Partners

### MARKET FORCES

#### Demand

Iron ore demand in the EU is dominated by the fortunes of the EU steel makers who are subject to a number of mergers and are experiencing significant restructuring with consequent capacity cutbacks. Despite this the net consumption remained very close to that of 1992, and although there were widespread job losses in the steel sector, stocks were reduced and the supply/demand situation came more into balance.

#### Supply and competition

In spite of the massive demand in the EU for iron ore, there appears little prospect of iron ore production in the EU arresting its decline. A combination of the relatively low quality of EU ores and the economies of scale achieved in production and transport of high grade ores to Europe from America and Australia in particular is leaving little scope for continued economic production in the EU.

**Production process**

There has been little investment activity among EU iron ore producers in recent years, and although there have been no significant changes in the technology employed internationally, overseas mines employ newer equipment on a much larger scale.

**INDUSTRY STRUCTURE**

**Companies**

Only 5 companies now remain of the nearly 200 which were in operation thirty years ago. Apart from the low quality of EU iron ores, the cost of delivery of ores from intercontinental origins is lower than that within the EU, and with the largest

PRESUR	E	2	100

Source: B.M.Coope & Partners

company (CVRD, Brazil) operating at a throughput over 30 times higher than any EU mine, the competition from overseas is overwhelming. Only 2 significant producers remain in the EU, CAM in Spain and ARBED in Luxembourg, although the entry of Sweden into the EU would increase iron ore extraction four-fold.

### Impact of the Single Market

The iron ore industry in the EU is small and the only significant operations are captively owned by iron and steel companies.

The Single Market is highly relevant to the EU's iron and steel industry, of course, and in comparison the impact on existing EU iron ore operations is insignificant to the point of irrelevance. On the other hand, the entry of Sweden into the EU means that Single Market issues will assume greater importance to Swedish iron ore producers, which are substantial in size and international by nature.

### REGIONAL DISTRIBUTION

Apart from the two areas currently exploited, the Lorraine in France and Andalucia in Spain, no economic iron ore deposits are believed to exist within the EU.

### ENVIRONMENT

Virtually all iron ore mining is at established sites and from oxide ores which pose minimal environmental threat. Sulphide mining, with the potential for acid mine drainage is almost extinct. Environmental impacts addressed by the operations include dust and noise and the ingress of particulate solids into local waterways. Energy consumption in the extraction of EU iron ores is high because of the low grades.

### REGULATIONS

Although mining and environmental legislation is less stringent and applied to a lower degree in some countries producing iron ore, EU regulations are similar to those in force in the USA, Canada and Australia and allow responsible mining developments.

## OUTLOOK

There appears little change in prospect from previous forecasts which point to a continuing and possibly terminal decline in iron ore mining in the existing EU, excepted the good prospects for the Swedish mining industry. This outlook is not based on EU demand, which is strong and exceeds production more than twenty fold, but on the inherently weak competitive position of EU mines with limited, low grade reserves and comparatively high distribution costs. In the short term closure of further operations cannot be precluded.

# Non-ferrous metal ores

## NACE 212

The non-ferrous metals mining sector in the EU has suffered, along with the metals industry internationally, a year of abundant supply and muted demand, resulting in low prices and profitability. The major copper, lead and zinc operations which dominate the sector have shown good resilience to the adverse conditions, however, and provided 23 % of the EU's primary raw material requirements for metals production. No significant changes in the behaviour of this mature sector are predicted in terms of tonnage output, although increased revenues from higher metal prices should be forthcoming as the tide of recession turns.

### INDUSTRY PROFILE

#### Description of the sector

NACE 212 covers the mining and physical processing of all non-ferrous metal ores. In the EU significant mining operations exist for lead/zinc, copper, bauxite, nickel and tin. Gold and silver are recovered as credits with lead/zinc concentrates, and there remains a small output of tungsten ore. The EU has world class deposits of lead/zinc and copper which account for 5.2 %/16.5 % and 2.0 % of world production respectively. Other operations are small in world terms, and the EU is 100 % dependent on imports for all other non-ferrous metals.

Products from the sector provide the raw materials for the production of non-ferrous metals (NACE 224). In 1993 the total value of non-ferrous metal ores and concentrates produced in the EU was just under 600 million ECU. The main production is from Portugal, Spain, Greece and Ireland in descending order, these four countries accounting for 91 % of EU output. Lead/zinc production is projected to increase in Ireland where two major developments are at the planning stage. Output of lead, zinc and copper will also increase when Sweden and Finland enter the EU. Finland is also a nickel ores and chromite producer.

#### Recent trends

1993 was a poor year for the metal mining industry in general, with falls from 1992 average price levels being registered by copper (16 %), lead (28 %), zinc (21 %), nickel (25 %) and tin (16 %). Only silver and gold registered increases of 9 % and 5 % respectively. In addition stocks were generally high as were exports of certain metals from China and the CIS. Notwithstanding, the turn from recession in some important world economies has provided encouragement to the mining sector and 1994 price levels are expected to be higher across the board. The major EU mining operations maintained production levels during 1993 and proved resilient to price falls, although further damage was suffered by fringe operations.

#### International comparison

South-East Asia and South America have established themselves as the growth areas in non-ferrous metals mining, with the advent of free market economics also beginning to encourage development in Africa and Eastern Europe. In each of these areas, together with traditional mining countries such as Australia, USA and Canada, geological factors favour the finding and exploitation of economic orebodies which are scarce within the boundaries of the EU. Nevertheless the EU produced 23 % of the non-ferrous metallic minerals required by its metals industries in 1993, compared to 10 % in Japan, while the USA remains largely self sufficient.

Figure 1: Non-ferrous metal ores  
Production in comparison with related industries, 1993

Source: B.M.Coope & Partners

#### Foreign trade

Despite producing less non-ferrous metal ores than are needed in the EU, over 45 % of production was exported in 1993, demonstrating the international nature of concentrate markets. This is in part due to overseas involvement of EU operations and the sending of concentrates to group smelters, as is the case with Irish lead/zinc to Finland. But in the main, this reflects the fact that concentrates are sold on the basis of grade and price irrespective of source location, shipping costs not being a major factor, a point further borne out by the wide range of locations from which ores are imported.

### MARKET FORCES

#### Demand

Non-ferrous metal ores are consumed in the manufacture of metals which in turn provide the raw materials for industries such as construction, machinery, transportation and electrical engineering. Demand for the ores is thus directly related to

world economy which was muted in 1993 due to continuing recession in Europe and Japan and only modest growth in the USA, although growth was exceptional in south-east Asia. World overcapacity for the production of many ores, together with large sales of mostly metals from the former Soviet Union have combined with weak demand to create substantial stocks of several metals. The emergence of more countries from recession, some plant closures and trade reductions give an expectation that a stronger performance from the sector can be expected in 1994 and immediately beyond.

**Supply and competition**

As indicated there is no shortage of supply from overseas and the advantages to be gained by virtue of location have to be assessed in purely economic terms. Thus for an EU mining operation to be successful it must compete in terms of quality and cost, features which exist at the leading large-scale EU mines, but hinder development of smaller operations unless some local niche opportunity exists. The expectation of expanding the number of operations in the present EU is

good in the short term in terms of lead and zinc, but the level of exploration expenditure across the region is minimal compared to that overseas, and it is thus unlikely that the EU non-ferrous metals mining sector supply position will change significantly.

**Production process**

Productivity gains are significant, not so much as an outcome of major changes in the techniques used in mining or minerals processing, but out of continuous improvements in diverse stages of the mining and processing technologies. In this regard, the leading EU operations compare favourably with overseas mines in the application of technology and in production efficiency.

**INDUSTRY STRUCTURE**

**Companies**

Whereas the leading EU mining companies are weathering the recessionary period, a number of casualties have been

**Figure 4: Non-ferrous metal ores  
International comparison of main indicators in current prices (1)**

(1) In previous years the USA figures were quoted from the USBM; this year they are based on tonnages and metal contents, which have been factored to provide more consistent and accurate values.

Source: Eurostat

experienced amongst smaller operators. In Portugal the Panasqueira tungsten mine remains on a care and maintenance basis and the zinc operation at Aljustrel has closed, although there are plans to re-open in 1995. The last zinc mine at Noailhac St Salvay in France has also shut, as has the gold and silver operation at Rouez. In Spain the lead/zinc production at Reocin has been limited and the Troya mine closed. Copper production at Sotiel has also been suspended. Italy has been forced to shut its Sardinian lead and zinc operations, and no new mine has come on stream within the EU, although the Salsigne precious metal mine in France is scheduled to re-open in 1994. As indicated, new lead/zinc mines are under development at Lisheen and Galmoy in Ireland, and a new gold mine at Omagh (UK) is also possible.

It should not be forgotten that although mining operations within the EU are at a modest level, the community is the home of a number of international mining companies who between them are responsible for over 10 % of world non-ferrous metals ore production. One of these companies, Billiton of the Netherlands, has sold its assets to Gencor, a South African mining group. Metallgesellschaft of Germany is also undergoing major restructuring, but the other majors continue to play a strong role in the sector internationally, with RTZ (UK) and Minorco (L) in particular expanding their operations.

On a smaller scale, the privatisation of the downstream operations of BRGM is worth to mention: it created a new international company, based in Europe, with BRGM retaining a 40 % share, together with Normandy Poseidon of Australia which controls the remaining 60 %.

**Strategies**

The strategies pursued by all mining companies in the sector are similar, that is the location, development and operation of profitable orebodies irrespective of location, as long as political and financial stability exists in the region. Their policies reflect the international nature of the industry and are unlikely to deviate in the future. For the industry in the EU, this means that new developments must fulfil international criteria of profitability and enjoy no favoured status because of location.

**Impact of the Single Market**

The impact of the Single Market on the non-ferrous metal ores industry has been significant and positive. This sector has always operated on an international scale and most of the companies involved are multinationals working to international standards. Thus the freedom of movement of goods,

services, and capital are seen to be of paramount importance to the successful operation of this industry.

Energy and environmental issues also loom large in the industry's consciousness and there is strong concern that European legislators take proper account of the international framework in which companies must operate.

With regard to future priorities it is felt that more progress can be made to liberalise capital, insurance, and energy markets. Further attention also needs to be paid to overseas payments, and investment guarantees. The political clout of the EU should be used to promote cooperation with and open up the markets of other nations.

**Figure 7: Non-ferrous metal ores  
Trade Intensities**

Source: B.M.Coope & Partners, DEBA

## REGIONAL DISTRIBUTION

As indicated, EU non-ferrous metals ore production is dominated by Portugal (copper), Spain (zinc), Greece (bauxite) and Ireland (zinc). The importance of the last mentioned is set to grow and may make Ireland the largest contributor by the end of the decade. There is little likelihood of the United Kingdom or Italy improving output, and whereas France's production should improve with the re-opening of Salsigne, any major new deposits which emerge will probably be in the currently dominant regions.

The entry of Sweden and Finland into the EU would expand the base of non-ferrous metals mining, and significant increases in the output of copper (61 %), lead (107 %) and zinc (43 %) would arise, as well as additions from silver, nickel, chromite, cadmium, cobalt, gold, mercury and selenium. Sweden accounts for between 60 % and 95 % of the potential extra production of lead, zinc and copper.

## ENVIRONMENT

The non-ferrous metals mining sector is under environmental pressure in two areas, namely the extraction of minerals and their subsequent use. In the first case, environmental pressure groups continue to oppose new ventures, most notably in 1993 at the gold prospect at Omagh. Environmental planning and husbandry at EU operations is, however, of a high standard, and compares well with international practice.

In the case of some uses, opposition exists in particular to the use of lead, cadmium and mercury. In these cases the proponents of change include official national organisations, and it is certain that much work will be necessary by the metals industries to resist material substitution.

---

## REGULATIONS

---

EU regulations pertaining to exploration, mining, processing and the environment are similar to those in other advanced mining regions and are well understood and complied with. As indicated, mining in Europe is in the forefront of environmental concern and, being a natural science activity with a long history, its experience can help in separating what is essential from what is superfluous in the increasing inflation of regulations. The major operations are little affected by single market regulations, although implementation of the EU's rules on free competition has been blamed for the closure of some operations, notably in Sardinia.

---

## OUTLOOK

---

The sector has survived some difficult times of late and the leading operations, which account for the vast majority of production, have shown good resilience. With improvements in international economic performance predicted, albeit cautiously, the industry is expected to continue to play a minor but significant part in years to come. The level of self-sufficiency in non-ferrous metals ore production should remain at around the same 20 % level, although this will increase to nearly 30 % when the three new proposed entrants join the EU. The levels of mining investment being attracted to regions worldwide with better geological conditions precludes the likelihood of significant change to the status quo.

The industry is represented at the EU level by: International Association of European Mining Industries (EUROMINES). Address: Avenue Broqueville 12, B-1150 Brussels; tel (32 2) 775 6311; fax: (32 2) 779 0523.

# Stone

## NACE 245

The European stone industry is still the world leader. The European industry produces, transforms, trades and consumes all kinds of stone materials including marble, granite, travertine and other similar stone. These products are destined for various uses although the largest consumer is the building industry, particularly the upper end of the industry, where there is strong competition from alternative materials such as ceramics and glass which have greater investment capacities for research, development and marketing.

### INDUSTRY PROFILE

#### Description of the sector

The ornamental stone industry is divided into two main sections, that is the excavation of raw materials and their subsequent transformation into the various finished products. In the 1980s, the industry experienced a real boom. From 1981 to 1992, world quarry production rates rose from around 20 to over 31 million metric tonnes and this was accompanied by an equally significant increase in the number of producing countries. At present, only ten countries exceed an annual production of one million metric tonnes and six of these belong to the European Union (see Table 1). Up until 1992, the EU ornamental stone industry accounted for over 50 % of world production and around the same percentage of global international exchange in terms of volume. The products exchanged within and outside the European Union include rough blocks and a wide variety of finished articles.

The processed materials are mainly calcareous (marble, travertine, etc.) or siliceous (granite, sandstone, porphyry, slate, etc.) and their relative uses differ to some extent. Granites are principally employed for exteriors or wherever greater resistance is required to stand wear and tear and atmospheric pollution; marbles are principally destined for interiors or where there is greater protection from external elements.

The development in processing technology has widened the field for the use of stones, especially in the building and furnishing industries, and this development has been accompanied by improvements in stone laying and maintenance techniques. The new uses have emerged mainly thanks to the techniques for obtaining minimal thickness units and for applying them, which have enabled stone products to penetrate the avant-garde markets such as the removable floorings for electronic processing centres and the light vertical claddings. Marbles and granites can therefore be used inside lifts, in ships, on skyscraper facades in areas subject to typhoons and in other situations which would otherwise be inconceivable for traditional methods.

Alongside these avant-garde uses, there are of course the more traditional, well-established areas of usage, such as funeral art, furnishings, monuments, decorative architecture, where production processes have also undergone a radical technological transformation.

For some of the traditional uses, the processing of stone is part of production in other industrial sectors. Particularly in the case of furniture production, marble and granite cutting and polishing workshops for vanity tops, kitchen table tops and bathroom furniture coverings are an integral part of the production line of finished furniture.

However, the most interesting market as regards the quantity of material sold and the value added absorbed is still the

traditional building industry including new buildings, restoration and maintenance work.

### Recent trends

Present production figures amount to an average of around 31-32 million metric tonnes per annum with a recent, constant upward trend mainly due to the entry of new producer countries into the world market. Since the early 1980s at least ten new producers of some significance have emerged and become self-sufficient. This phenomenon has also led to an increase in machine production for the quarrying, sawing and processing of stone. This stone industry sector has been flourishing and is mainly based in the EU, particularly Italy followed by Germany and France. The EU countries in the Mediterranean basin form the heart of the sector at both European and world level, even though other areas in the world are now also developing. In 1992, the greatest producer country of blocks for ornamental use was Italy which has always

held the leading position in the market, followed in the EU by Spain, Greece, Portugal and France.

### Foreign trade

Trade in volume mainly involves raw and semi-raw materials. The leading importer was Italy, closely followed by Japan (see Table 2 and 3) which has only recently attained this position. Both these countries import mainly blocks of raw granite, but in Japan this is mainly destined for funeral art whereas in Italy it is for all possible uses. Important exporters apart from Italy include Spain, Greece, China and South Korea. China and South Korea are the only countries to have recently (1988-89) penetrated the market as a producer, transformer and consumer.

EU exports mainly consist of finished products, which are principally destined for the building industry. They are intended for non-EU European countries and non-European countries, mainly North America and the Far East (see Table 4 and 5). Right up until 1982-83, there was also a strong demand from the Middle East. Subsequently, external factors led to an abrupt decline in demand to a mere 35 % of its most memorable peak. The effects of the international crisis in the Persian Gulf are mostly responsible for the most recent figures. Nevertheless, the most important export market is still within the EU, first and foremost in Italy and Germany, followed by Spain and France. This is true for semi-finished products, but Italy is a major net exporter of finished products.

### MARKET FORCES

#### Demand

The demand for stone materials is varied. It ranges from the large importers of blocks which amount to only a few dozen firms throughout the world, concentrated in Italy and Germany, to the large North American building firms and developers and the final consumers for all the other sections of the market.

The greatest problems for the sector arise from the extreme fragmentation of the consumer market together with the very limited average size of companies. Moreover, the lack of capital to invest in research, development, promotion and marketing makes it difficult to exploit this dispersed consumer market which is often regional. On the other hand, the factors which sustain the demand are above all the intrinsic factors regarding the products themselves such as their reputation.

response to technical problems, aesthetic variety and image rather than the few sporadic promotional campaigns effected by marble and granite companies.

Stone constitutes a natural resource which almost all European countries possess to varying degrees; also many developing countries have already begun or are beginning to exploit this natural resource by quarrying the raw material. Quarrying technology is relatively simple and problems can only arise

from the lack of infrastructures. Countries capable of offering technologically advanced finished articles at competitive prices are however very few. With the exception of Italy and Spain and to a lesser extent the other EU countries, all the other significant stone consumers are far from being self-sufficient even within their own home markets.

Japan is a good example. Since 1985, Japan has been a very significant importer mainly of granites which are primarily

Source: Various sources

destined for funeral art. It prefers to procure lower-range semi-processed or finished articles from Taiwan and South Korea, but imports stone for complex work which requires the expert use of sophisticated production techniques and a wide range of different products from Italy.

The same picture applies to the USA, even though it has high national production rates. However, since 1988 the USA witnessed a gradual reduction in demand for finished products, especially in granite, due to the slump in the market which most used them, that is non-residential building. The strong decline in this sector, which has been compensated to some extent by the increase in residential housing, has influenced international trade in terms of sales and volumes.

In South East Asia there is a tendency towards self-sufficiency which is likely to continue over the next few years. The great buying power of the Japanese market, the extensive building activities in some of the newly industrialised countries, the availability of low-cost labour, the proximity of areas with high raw material production rates such as India, South Africa and more recently China, all create a depletion of the outlets for products which excludes all small niches in the market, save a few privileged ones. The EU industry occupies a strong position as far as the latter are concerned.

The main market for the European stone industry is the EU itself. The traditional usage, the extensive and intensive production, the ability to transform raw materials, a building industry very much oriented towards maintenance and restoration, all favour the use of stone. It is often considered a material which adds prestige to buildings where it is used, be they residential or non-residential. The difficulties of a sector which is not in a position to invest sufficient capital in promotional and marketing activities may affect its development over the next few years. Sections of the market which are in a position to expand despite the recession which has been threatening certain countries are still confronted with the deep penetration of the market by their competitors such as glass and ceramics.

Indeed, the general increase in the competitiveness from substitute products has already adversely affected the price trends, which had to decrease in real value to retain a hold in the major markets.

## INDUSTRY STRUCTURE

### Companies

The average size of companies in the sector is generally very limited. In Italy, for example, the average company has no more than ten employees, although there are various groups of companies which have joined forces to develop a common strategy and pool resources. Recent and reliable statistics are not available for all the EU countries, but it is calculated that there are now at least 189 840 employees in the EU (including Sweden and Finland, but excluding countries for which data are not available, i.e. Denmark, Germany, Ireland, Luxembourg and the Netherlands), about half of whom working in the quarries. There have been great changes in the production methods, speed and costs in recent times due to the mass introduction of diamonds in the quarrying and processing of marble at the beginning of the 1980s. The greatest concentration of productive firms is in Italy, where stone materials are available in nearly all its regions: it is calculated that there are over 70 000 quarry workers, plus those working in industries connected to quarrying, transformation and commerce. The same situation as regards the structure of the sector can be seen in Spain, France, Greece and Portugal.

A problem which affects almost all EU countries, however, is the ageing labour force. The turnover of the generations of workers is very slow indeed and this is a problem which may become very serious in the future for a sector which often requires a long period of complete professional training. The biggest question mark in the sector remain the economic and commercial prospects. The sector is inevitably dependent on the building industry, and especially the upper end (residential, non-residential, urban landscape, restoration of old town centres, renovation). The tendency towards even partial self-sufficiency be it even partial, of certain extra-EU markets could reduce the overall market of the European stone industry and limit it more and more to the EU market itself. As far as stone companies are concerned, all this could lead to even more problems for smaller companies which would be forced to specialise still further or opt for subcontracting, leaving the larger companies to deal with the more complicated contracts and the more distant markets. The major companies and groups are already working as corner-stones on the international market. They are directly present on distant markets, have local associates and among other things coordinate complex projects.

### Impact of the Single Market

The creation of the Single Market has had limited direct impact on the stone industry, but is regarded in positive terms because of the overall effect on general economic activity. Few of the measures in the Internal Market package were of direct relevance to this sector - with the exception of environmental policy measures. The sector is not very trade intensive, due to the high cost of transport.

## ENVIRONMENT

Important environmental issues involve the stone industry in both its productive divisions, i.e. quarries and workshops. There are serious problems as regards the respect for and restoration of the structure of the mountains where quarrying activities are carried out. Various countries and regions do actually impose a programme of temporary management of the quarry dumps and at least partial reconstruction of the natural habitat to be included in the quarrying plans. This is not always feasible and sometimes leads to the interruption

of activities due to the impossibility to comply with regulations in force.

Respect for the environment must continue after the quarrying process. This requires compliance with the regulations regarding interior working environments (microclimates inside the workshops, noise levels, dust, mud, complete safety) and mutual respect between workers and inhabitants. Thus, the management of reflux slurry, the protection against noise, the protection of water courses from polluted waste, overloaded roadways, are problems which concern technical researchers, machine manufacturers and environmentalists alike. Technical researchers are in fact working towards finding the best solutions (for example, the re-utilisation of marble rubble) while manufacturers are trying to produce machines with lower noise levels and less dust production (sound-proof machines, purified plants at the design stage, etc.) and environmentalists are involved in imposing respect for the environment and the regulations in force.

The ecological issue goes hand in hand with the problems regarding safety in the quarries. Unfortunately, every year in spite of both the workers and the employers' awareness of safety measures, accidents continue to occur and are sometimes fatal.

## REGULATIONS

The EU industry is subject to the regulations which in general cover building material products and has resisted to the dumping accusations made by the North American firms at the end of the 1980s. Now, it has to face two major restraints:

- as regards production, the respect of the environmental and workers' safety regulations both inside and outside the quarry and the workshops;
- as regards usage, the respect of special safety regulations regarding anchorage systems for vertical cladding and the development of a joint set of regulations for the EU for certain production methods.

There are various technical committees within the EU, some of which began working in 1988 and 1989 and have an internal sub-commission which deals with processed stones. Among these, we can name:

- TC 125, which deals with masonry, and plans to set up a sub-commission for natural stone masonry;
- TC 128, which deals with building coverings, and has a work group for slates;
- TC 178, which deals with roadways and curbs, and has a sub-committee for natural stone;
- TC 246, which deals with floorings in natural stone, interiors, stairs, terraces, balconies, etc., and exterior facades. It is the most recent group (1990) and it shares its tasks with more established groups. It is however already organised into three subgroups, one for terminology and classification, one for test methods and one, the most important one, for the prerequisites and limits for specific products. During 1993 and 1994, much work has been done to give the stone products the necessary characteristics so as to be able to circulate freely within the EU and withstand competition from substitute materials.

## OUTLOOK

The present economic trends and the recession in some of the major markets trouble producers in the sector. The crisis was felt hard in 1992 and 1993. Now, however, there are some signs of recovery.

The world stone industry is in constant but modest overall expansion. However, the European sector's future is closely linked to the general tendencies of the European economies and their building activities. The unification of the European markets will not really affect the firms already operating outside their own region. At worst, these companies will have to conform to the standardised regulations and the consequent quality certification prerequisites. EU trade relations with extra-EU countries will prove to be more difficult as the latter are tending to form autonomous production systems. It is predicted that it will be more complicated for individual firms, especially smaller ones, to gain a place on foreign markets without having privileged partnerships with local firms and the necessary support in the form of assistance, services and credit facilities.

On the other hand, the opening of new quarrying activities in third world countries and the consequent increase in familiarity with using natural stones, is gradually creating much better prospects for new markets. Whether or not the European stone market will be able to continue to expand in the 1990s depends on how effectively it addresses these new realities.

# Construction raw materials

## NACE 231

The EU is one of the world's major regions for the production and consumption of construction raw materials. In the construction raw materials sector, the EU is theoretically self-sufficient for virtually all mainstream products, and external trade tends to be in material chosen on aesthetic grounds. The economic performance of this industry is tied directly to the level of building and construction activity in the EU, which appears to be on the rise again after a four-year dry spell. Some minerals which predominantly are used for construction - notably limestone, dolomite and silica sand - are also widely used in industrial sectors such as glass and ceramics, metallurgy, paper, paints, plastics, etc. The proportion of minerals used in industry is generally less than 10 %.

### INDUSTRY PROFILE

#### Description of the sector

The mainstream products comprising most of the categories under NACE 231 (apart from clays) include: crushed stone for construction and road aggregate; sand and gravel for construction and road aggregate; limestone and chalk for cement and lime; gypsum for plaster and cement; and dimension stone (including marble and granite).

Construction aggregates and cement are the bulk raw materials used in the building of roads, railways and buildings, and value added data tend to be in line with overall economic activity. Thus, Germany displays the largest value followed by France, the UK, Italy and Spain.

Many larger operations are owned by important construction and civil engineering groups. However, the abundance of deposits and the localised nature of their markets (most operations serve markets within a 50 km radius) also allow for the existence of many small enterprises.

Limestone, chalk silica and alumina are the main raw materials used in cement. Lime manufacture and quarries for these end-products are invariably captively-owned by the large cement (or lime) manufacturing groups featured in Chapter 5.

#### Recent trends

Production and consumption levels increased gradually throughout the 1980s, peaking in 1989 and declining thereafter in 1990. There was minimal growth between 1991 and 1993. The pattern during the 1990-1994 period has varied from country to country according to the level of construction activity in each, e.g. strong in Germany, weak in the UK. Nevertheless, the long-term trend is upward, and both production and consumption are expected to show renewed growth in 1994 and beyond.

#### International comparison

The EU is the world's leading producer of construction raw materials with an output 50 % higher than the US and three times that of Japan in 1993. Both the USA and Japan displayed a similar pattern of production and consumption over the past ten years with growth in 1983-89 period followed by decreases in the 1989-1993 period.

#### Foreign trade

Foreign trade represents only a small part of the total commercial activity in construction minerals - with imports accounting for about 6 % of total consumption and exports 3 %

Figure 1: Construction raw materials Production in comparison with related industries, 1993

Source: B.M.Coope & Partners

of total production. Nevertheless, the sheer size of the sector means that tonnage measured in tens of million of tonnes are involved.

Thus, the EU is highly active in both the importing and exporting of these materials but in recent years has become a net importer. This is primarily due to a surge in the imports of dimension stone granite from countries such as Norway, South Africa, Brazil and India. At the same, these imports have tended to be in raw form and have provided a boost in the value added activity of the EU's domestic stone processing industry (particularly in Italy).

Exports are dominated by shipments to EFTA countries, particularly of construction aggregates to Switzerland. Highlights in export trade to non-EFTA countries are the shipments of dimension stone marble and granite to Japan, the US and the Middle East.

As far as sources of 1993 imports are concerned, the EFTA countries accounted for about two-thirds of the total, with the main prominence on dimension stone granite and crushed

stone aggregate from Sweden and Finland. This traffic will become intra-EU trade in 1995. Presently, intra-EU trade is dominated by cross border movement of aggregates and industrial limestone/dolomite products between Germany, the Netherlands, Belgium and France, and by trade in dimension stone products in which Italy, Spain, Portugal and Greece are prominent.

## MARKET FORCES

### Demand

The construction industry is clearly significant to any discussion of markets for this group of raw materials. Demand for the major product lines is directly dependent on overall construction activity, as they are fundamental to the construction of roads and buildings. However, it should not be forgotten that the industrial grades of limestone, dolomite and sand are consumed primarily in the chemicals, metallurgical, glass and ceramics industries. These industries are also affected by recession, although to a lesser extent than the construction industry is.

No major technological changes have taken place recently in construction materials, although on aesthetic grounds the increasing use of natural stone (as represented by dimension stone granite and marble) for the exterior and interior surfaces of buildings already has been noted.

### Supply and competition

The EU is a major world producer and is theoretically self-sufficient for virtually all of the minerals and rocks in this group. Thus, prices tend to be based on contracts negotiated between producer and consumer at the intra-EU level. Indeed, because of the high degree of captive ownership in the construction minerals domain, many prices tend to be an intra-company affair.

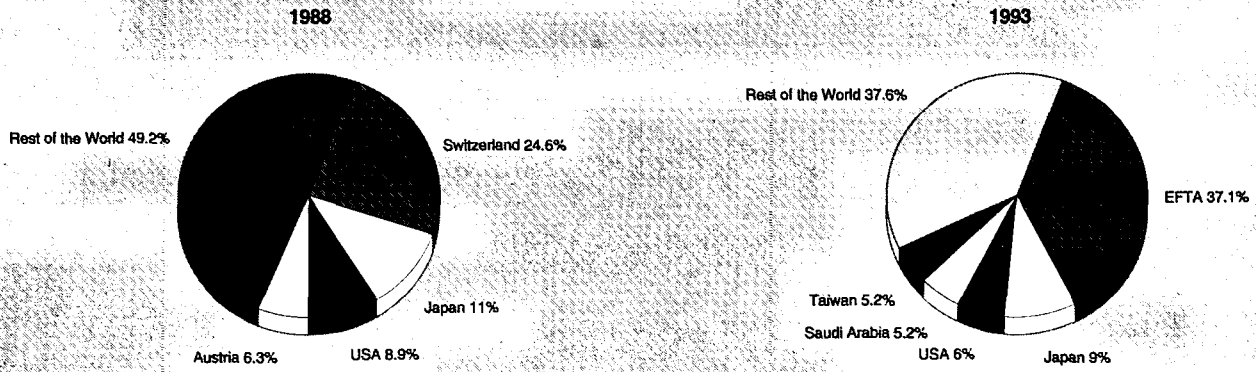

Transportation is a major consideration in bulk raw material markets and therefore, producers often operate their own trucks and sell on a delivery basis. In many cases, producers sell semi-finished or finished products such as ready-mixed concrete, coated roadstone and plasterboard. Sales of these value-added products plus the strong element of service offered to

**Figure 4: Construction raw materials  
International comparison of main indicators in current prices**

Source: B.M.Coope & Partners, DEBA

**Figure 5: Construction raw materials  
Destination of EU exports**

Source: Eurostat

the customer often combine to give attractive operative margins for companies operating in the sectors.

Transportation costs can rule out foreign competition in bulk construction raw materials. The exceptions to this rule cover situations where non-EU countries are neighbours (e.g. Norwegian and Swedish stone shipped to Denmark and Germany), where "superquarries" have been set up to export stone in low-cost bulk carriers (e.g. Glen Sand in Scotland, Wimpey in Ireland) and where high value items are preferred on aesthetic grounds (e.g. dimension stone granite from South Africa, Brazil and India).

**Production process**

Construction raw materials extraction is often in the hands of large construction groups whose activities may range from cement and plaster products manufacture to civil engineering. The quarrying divisions of such groups tend to be large-scale, highly mechanised operations with quality control systems to cover what is in essence a crushing and grading exercise. Much attention has been focused on improving the efficiency of the crushing process and new or improved technologies are being used to cut costs and maximise the output of high grade products.

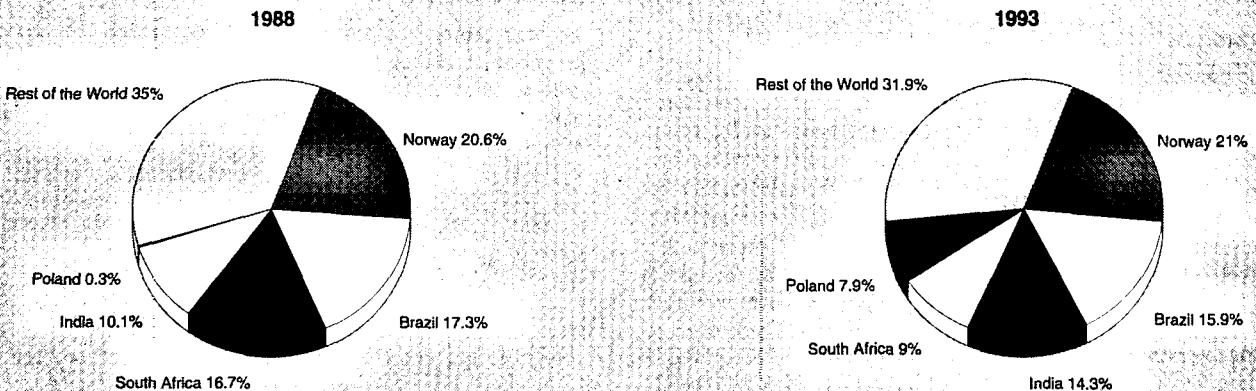

**INDUSTRY STRUCTURE**

**Companies**

The largest enterprises operating in the construction raw materials sector are the major cement and aggregates groups such as Lafarge Coppee of France; RMC, Redland, Tarmac, Tilcon (BTR), Blue Circle, Hanson, and Bardon of the UK; Heidelberger Zement, Dyckerhoff, and Basalt AG of Germany; Holderbank of Switzerland; Italcementi of Italy; CBR of Belgium; and CRH of Ireland. All of these companies have staffs numbering in the thousands or tens of thousands.

Other major enterprises extracting limestone include the lime specialists such as Lhoist (B), Carmeuse (B), Rheinische Kalkstein-Werke owned by Wulfrath (D) and Buxton Lime owned by Minorco (UK); and calcium carbonate specialists such as Pluess-Stauffer (CH), English China Clays (UK), Provençale (F), Faxe Kalk (DK) and Reverte (E). In the gypsum and plaster sector the major enterprises are BPB Industries (UK), Lafarge Coppee (F) and Gebr. Knauf (D). Major players in the industrial sands industry are Sibelco (B), Quarzwerke (D) and Hepworth (UK).

In each of the sub-sectors in which they operate, the above-named enterprises represent over 60 % of total EU turnover. All these companies are either European or international in character. Most of the large cement and aggregate groups maintain major international interests, particularly in North America.

### Strategies

In the construction raw materials sector, the market strategies of the larger enterprises are bound up in their downstream activities. Nevertheless, there has been a marked consolidation of the industry in the EU itself, as major groups have continued to increase reserves of raw material and influence downstream products by acquisition.

In the aggregates sector the acquisition of quarries (or sand gravel pits) is a chief aim - i.e. the best way to increase aggregate reserves (with planning permission) and to maximise involvement in major construction activity is to acquire existing operations and invest to expand or modernise as required. Important recent developments include the purchase by Basalt AG (D) of a 50 % share in a new aggregate plant in Sweden, which followed earlier acquisitions in the former East Germany, Hungary, Czechoslovakia and Poland. Two companies

pursuing the coastal superquarry concept are Tarmac (UK) at Jossingfjord in Norway and Redland (UK) at Harris in Scotland. Attention should also be called to a "de-merger" in which English China Clays (UK) spun off its aggregate-related activities in a new company, Camas plc, with operations in the UK and the US.

The restructuring of Europe's cement industry is a continuous process and although the primary objective of major groups is to acquire cement manufacturing capacity and associated markets, the secondary purpose is to concentrate limestone operations (and reserves) within the major groups. In the past five years, intra-European acquisition and merger activity has involved major companies such as Italcementi (I) acquiring a majority of Ciments Français plus ownership of Halyps Cement (GR) and three companies in Spain (SFM, Cementos Rezola and Cementos Molins); Holderbank (CH) taking over Cedest (F); Heidelberg Zement acquiring 42.4 % of Cimenteries CBR (B); Calcestruzzi (I) taking over the two Greek cement producers, Heracles and Halkis Cement; and Lafarge Coppee (F) taking control of Perlmooser Zement (A).

Lafarge also has been active in China, where it is setting up a cement manufacturing joint venture in Beijing and has made further cement acquisitions in Morocco, Brazil and Venezuela.

**Figure 7: Construction raw materials  
Trade intensities**

Source: B.M.Coope & Partners, Eurostat

It has also bought into the US plasterboard producer, National Gypsum. Meanwhile, Europe's largest gypsum and plasterboard producer, BPB Industries, announced plans to build a major new plant in Berlin.

In the calcium carbonates sector Pluess-Stauffer (CH) increased its share of European markets by acquiring Ernstrom Mineral of Sweden.

### Impact of the Single Market

The impact of the creation of the Single Market on Europe's construction minerals industries has been mixed but essentially positive. Many of the industry's products such as aggregates are high bulk, low-cost commodities which serve local markets and are generally unaffected by international trade -- either intra-EU or extra-EU. However, many of the companies involved in their production operate on an international scale and tend to view all measures which facilitate the movement of goods and services in a positive light.

Among the more important Single Market issues are technical harmonisation and mutual recognition of rules, public procurement policies, and administration in small and medium sized enterprises. Planning and environmental issues are also particularly relevant to this highly visible industry. A major priority for the future would involve EU recognition of the extractive industries to allow full consultation of Single Market legislation or fiscal initiatives.

### REGIONAL DISTRIBUTION

Aggregates and cement are produced throughout the EU with all Member States (including Austria, Sweden and Finland) reporting production. With regard to aggregates, sand and gravel are more prevalent in low-lying regions, and crushed stone is more common in highland areas. Dimension stone workings tend to be highly concentrated, for instance in the Carrara marble district of Italy and the Pontevedra/Badajoz granite district of Spain. Gypsum is not nearly so widespread as limestone, but large deposits exist in Germany, France, Spain and the UK. Mining (both open cast and underground) and processing (including plaster and plasterboard) tend to be carried out at single sites. Sand deposits are fairly widespread, although the better quality industrial grades are obtained from deposits located in Belgium and in northern Germany and France.

Source: B.M. Coope & Partners, DEBA

### ENVIRONMENT

Most of the minerals and rocks in this group are mined by open cast methods. Therefore, operations consist of a quarry (or sand and gravel pit) with an associated processing plant. Many such operations are thus highly visible and subject to the so-called NIMBY factor (Not In My Back Yard, a term coming from the USA).

The modern quarrying industry has an excellent record for dealing with potential problems such as dust emissions and noise pollution during an operation and for restoration of the land once the extractive process is finished. Nevertheless, the restrictions imposed on new workings in some Member States will result in some areas of the Community having to import materials at a high cost. Although the use of waste materials as aggregates is growing, it will remain modest because of the stringent performance requirements which specify only high-grade aggregate. Recycling of aggregates shows more promise and is becoming a common part of road maintenance.

This sector also supplies major products for use in environmental processes - most notably limestone and lime in water and air treatment, and silica sands for water filtration. Paradoxically, many limestone and lime-based processes to remove sulphur from gases or waste streams yield chemical gypsum as a by-product. The use of this by-product gypsum will reduce demand for natural gypsum; nevertheless, this variety is not well adapted to all uses as the natural type is.

### REGULATIONS

Producers of construction minerals are actively engaged in the broad initiative to increase harmonisation of building codes and standards in Europe through the EURONORMS programme of CEN (European Committee for Standardisation). The scheme involves not only the EU countries but also EFTA countries. The former COMECON members of Eastern Europe are also following events closely.

### OUTLOOK

The EU will continue to be a major centre for the production of construction raw materials and EU enterprises operating in this sector will continue to be major players on the world

scene. Future development of EU production and consumption will be closely tied to the overall level of building activity.

# Chemical industrial minerals

NACE 232, 233, 239

The EU is a major producer of salt, potash and sulphur (mainly from secondary sources) and is a significant producer of fluorspar and barite. However, it is a major importer of phosphate rock and borate (and their derivatives), since it is lacking in these minerals. Currently, the markets for several of these items are severely depressed, particularly those for sulphur, phosphates and potash, which are heavily influenced by fertiliser demand.

## INDUSTRY PROFILE

### Description of the sector

The chemical industrial minerals are major raw materials for the chemicals and fertiliser manufacturing industries covered in Chapter 6. The products are covered under the new NACE Rev 1 codes 1430 and 1440, but under the current system, they are listed as NACE 232, 233 and NACE 239. The principal bulk items are salt, potash, phosphates and sulphur. Other significant products include fluorspar, barite and borates.

The EU is a leading world producer of salt and potash and is a significant player in world markets for sulphur, fluorspar and barite. However, it has no phosphate or borate mineral production of its own.

Germany, France, the UK, Italy and Spain are the principal EU producers of chemical industrial minerals and are all active to some degree in potash, salt, sulphur, fluorspar and barite production. The Netherlands is also notable for its major contribution to EU salt production.

### Recent trends

The production and consumption values for this group of minerals show a major decline since 1985. This was due to a combination of falling tonnage and decreasing or stagnant prices. In particular, sulphur prices in 1993 were less than one-quarter of those prevailing in the mid-1980s.

The fall in consumption has been more marked in the fertiliser sector than in the industrial chemicals sector. The decline in fertiliser consumption in the EU has reduced the demand for all fertiliser minerals, but especially for phosphate rock. Further, it should be noted that much of EU phosphate imports now consist of phosphoric acid rather than phosphate rock and this has been one major factor in reducing the trade deficit apparent in the figures presented in Table A. A sharp reduction in sulphur imports has been another major factor. In fact, the EU's increasing output of by-product sulphur will turn it into a significant sulphur exporter in the later 1990s.

### International comparison

The US is the world's leading producer of salt, sulphur, phosphate rock and boron minerals, and is an important producer of potash and barite. Thus, its production of chemical industrial minerals exceeds that of the EU by a factor of three. Total production values have been maintained over the period of 1984-94, with declines in some commodities such as sulphur and barite balanced by increases in the production of potash, soda ash, bromine, etc. Meanwhile, Japan's only significant contribution as a producer is for sulphur (and the small volume, high value product, iodine), and it is a major importer of all the other commodities, including salt.

Consumption trends in Japan have been similar to the EU as reflected in overall value decline and falling tonnages in the

Figure 1: Chemical industrial minerals  
Production in comparison with related Industries, 1993

Source: B.M.Coope & Partners

fertiliser sector (seen most strongly in reduced phosphate consumption). In the US, demand for fertiliser minerals has held up better and thus overall consumption shows a somewhat smaller decline in value terms.

### Foreign trade

The EU is active in both import and export trade of the chemical industrial minerals. Major export items are potash, salt and sulphur and major import items are phosphate rock, potash, borates and sulphur. Although the EU continued to show a negative trade balance in 1992 the deficit is now quite small compared to that of the mid-1980s. This is due to both reduced imports - particularly of phosphate rock and sulphur - and increased exports of potash and salt. In the future, exports in sulphur are expected to increase as well.

The most important supply countries to the EU are Morocco (phosphates), the US (phosphates), Israel (phosphates and potash), the former Soviet Union (potash), Turkey (borates), South Africa (phosphates) and Canada (potash), Poland (sulphur), Egypt (salt) and China (fluorspar).

**MARKET FORCES**

**Demand**

The main consuming industries for these minerals are the bulk inorganic chemical and fertiliser industries. Salt is the main raw material of the chlor-alkali chemical sector, which includes chlorine, caustic soda and soda ash. Such products and their derivatives are used not only within the inorganic chemicals sector, but also in plastics (PVC), soaps and detergents, glass, paper manufacturing and in a wide range of general industrial processing.

Sulphur is the source of sulphuric acid, probably the most versatile chemical used in chemical and other industrial processes. Nevertheless, it should be pointed out that about 60 % of sulphuric acid is consumed by the fertiliser industry. Thus, EU fertiliser manufacturing, which in turn is highly dependent on demand from EU agriculture, is a major influence on the EU markets for sulphur, phosphates and potash. These three minerals have all been adversely affected by EU agricultural reforms and environmental legislation concerning fertiliser usage.

**Supply and competition**

It is probably fair to say that there is a major world oversupply in all the major products of this grouping, although perhaps less so for salt than for potash, phosphate rock and sulphur. The downward pressure on prices that this has created is certainly hurting some of the more vulnerable producers of these minerals, i.e. the smaller, relatively high-cost producers.

The sulphur supply situation is further complicated by the high proportion of co-product and by-product output in world production. The bulk of EU sulphur production is from secondary sources ranging from elemental sulphur recovered from sour natural gas and oil (particularly in Germany and France) to sulphur recovered as sulphuric acid from metal smelters. Production from primary resources is limited to the now modest output of sulphuric acid produced from natural pyrite in Spain, Portugal and Greece.

The EU potash industry has faced major challenges in recent years from low price competition from the former Soviet Union and the integration of the former East German potash industry into a unified German market. The EU imposed anti-dumping

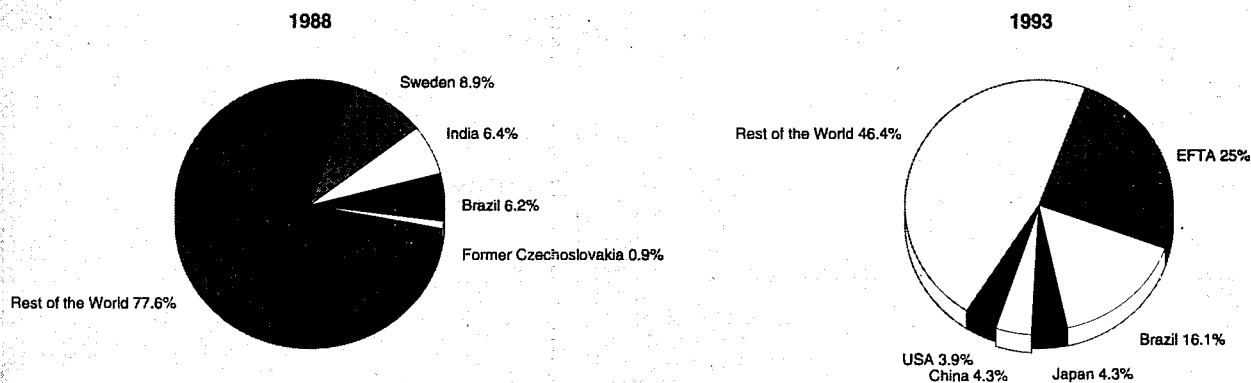

**Figure 4: Chemical industrial minerals  
International comparison of main indicators in current prices**

Sources: B.M.Coope & Partners, Eurostat

**Figure 5: Chemical industrial minerals  
Destination of EU exports**

Source: Eurostat

duties on potash from the former Soviet Union during 1992. The industry also has to compete with low-cost producers in Canada (with its economies of scale) and Israel (with its low-cost brine operations).

As a high volume, low value commodity, salt tends to be less vulnerable to foreign competition; most bulk grades of salt - i.e. for chemicals and road de-icing - are consumed close to the point of production. Much of this production is captive or subject to long-term contract agreements. However, salt consumption has been adversely affected by the move away from chlorine-based products - particularly paper pulp bleaching agents - for environmental reasons.

The EU's domestic fluorspar industry has been cut drastically in recent years as a result of exposure to low-priced competition from foreign countries (especially China) and because of the phasing out of chlorofluorocarbons (CFCs), as provided by the Montreal Protocol (1992). In fact, the main source of these imports, China, continued to be subject to anti-dumping duties by the EU in 1993 and 1994.

### Production process

No major technological developments have taken place in the processing of chemical industrial minerals. However, the

trend towards larger-sized equipment and the treatment of finer material has continued, together with efforts to save energy and improve environmental compliance.

## INDUSTRY STRUCTURE

### Companies

EU production of chemical industrial minerals is concentrated in a few large organisations. The salt industry involves major chemical groups such as AKZO (NL), Solvay (B), BASF (D) and SKW Trostberg (D), as well as salt specialists such as CSME-Salins du Midi (F), Salt Union (UK), British Salt (UK) and Union Salinera (Spain). The EU potash industry consists of five operating companies: the BASF subsidiary, Kali and Salz (D); the Entreprise Minière et Chimiques subsidiary, MDPA (F); the two INI subsidiaries, Suria K and Potasas de Subiza (E); and the Minorco subsidiary, Cleveland Potash (UK). The operations of the IRI subsidiary, Italkali (I), remained closed during 1993/94. Most potash producers are also significant producers of by-product salt, and Kali and Salz produces another important by-product, the magnesium sulphate mineral, kieserite. Meanwhile, sulphur is recovered from sour gas by two energy companies: Elf-Aquitaine (F) and BEB (D).

BHS	D	180	2.0
Sudwestsalze	D	91	0.6

Source: B.M. Coope & Partners

Major EU fluorspar producers include Sogerem of the Pechiney group (F); Laporte (UK); Nuova Mineraria Silius (I); Minersa (E); and Sachtleben of the Metallgesellschaft group (D). The most important barite producers are M-I (UK and IRL), Barytine de Chaillac (F) and Sachtleben (D).

With regard to borates, it should be noted that the world's largest producer, RTZ (UK), is a EU-based company and thus there exists a significant boron compounds capacity and technology in Europe. Furthermore, the second largest borate producer is based in Turkey, a neighbouring country with close associate status to the EU.

### Strategies

One of the most significant strategic developments in this sector has concerned the restructuring of the former West and East German potash industries under the single ownership of Kali und Salz Beteiligung AG. The last few years already have seen a number of mine closures. Further rationalisation will concentrate production on five main mine/plant units with

a total output of around 3 million tonnes per annum, which compares with a combined output of over 6 million tonnes per annum for the two Germanys in the 1980s. Meanwhile, the sales joint venture between MDPA of France and Kali und Salz has been at the centre of a dispute between the companies and the French government on one side and the European Commission on the other. This results from the EU requiring Kali und Salz to withdraw from the arrangement as a condition of the German merger.

It should be noted that the French industry is due to phase out producing operations over the next ten years (because of a lack of new reserves). The continuing role of EMCs in the potash business thus will depend increasingly on its commercial arrangements with Kali und Salz and its joint operating subsidiaries such as Potacan of Canada.

In the salt sector AKZO (NL) has been active in taking over Dansk Salt and Icelandic Salt, setting up joint venture operations in China and merging its combined salt/soda ash operations with Rhone-Poulenc (F). It should be noted that Rhone-Poulenc, which was privatised in December 1993, is active in other mineral-related fields such as rare earths, titanium dioxide pigments and phosphates. Meanwhile, the US company which took over ICI's salt operations in the UK - D George Harris Associates - has acquired the salt/soda ash operations at Duisburg, which were formerly operated by the Henkel subsidiary, Methes & Weber.

### Impact of the Single Market

The creation of the Single Market has had limited direct impact on the chemical industrial minerals sector but is regarded in positive terms because of the overall effect on general economic activity. Some companies operating in this sector are multinational chemical companies who would regard the Single Market as highly relevant to their principal activities but only of marginal significance to captive salt operations. The medium-sized potash and salt specialists, many of which are active in international trade, see the Single Market as important with regard to freedom of movement of goods and capital. Single market policies concerning competition, small and medium size enterprises, and most of all environmental protection are also highly relevant. Future priorities would include common environmental standards and dumping issues concerning minerals such as fluorspar.

## REGIONAL DISTRIBUTION

The underground potash and salt operations are associated with the Zechstein geological formation in northern Europe. Salt operations based on the solar evaporation of sea water are located in the more arid climates of the Mediterranean EU countries.

## ENVIRONMENT

Recently, the principal environmental issue facing the EU potash industry has concerned the disposal of waste salt from processing operations, particularly into water courses or rivers such as the Rhine and the Werra. Legislation has forced producers either to adopt alternative means of disposal, increase production of saleable salt, or close down offending operations.

The introduction of phosphates to water courses through fertiliser and detergent products also became a major issue in the 1980s and has been a contributing factor towards the reduced levels of fertiliser application in recent years.

The by-product nature of most of EU sulphur production has already been commented on, and it is worth noting that sulphur recovery units are required by legislation to prevent emissions. Some sulphur control processes yield gypsum rather than sulphuric acid as their by-product.

Environmental constraints have made a major impact on the EU fluorspar industry through drastic cuts in the production of chloro-fluorocarbons (CFCs) in response to the requirements of the Montreal Protocol. The ozone-depleting CFCs once provided the major market for fluorspar. While certain hydro-fluorocarbons (HFCs) are already providing ozone-friendly replacements in some applications, fluorspar purchases are unlikely to reach former levels.

The concern over chlorine has focused on the release of carcinogenic dioxins by chlorine-based bleaching processes, including paper pulping and water treatment.

## OUTLOOK

The outlook for the chemical industrial minerals does not look very bright in the short term. The existing lack of demand caused by industrial recession, combined with major over-supply for the major internationally traded products, is expected to prolong this period of low prices and trade disputes for some time to come. Further mergers, rationalisation and closures may be necessary before any major recovery occurs, perhaps in the late 1990s, in response to renewed demand in the former Eastern Bloc and in the agriculturally less mature areas of the world.

# Crystallised salt

## NACE 233

European salt manufacturers are far from seeing signs of recovery. Demand remains sluggish in most of the market outlets. The most significant features of EU enlargement are the integration of the Nordic countries, where there is no salt production, and the dismantling of the salt monopoly still existing in Austria. Food grade salt appears to be a very popular carrier of both iodine and fluorine used in the prevention of health disorders. This development meets the requirements of UNICEF and WHO. Generally speaking, overcapacity remains one of the main features of the industry.

### INDUSTRY PROFILE

#### Description of the sector

The activities of the sector are based on solar evaporation (sea salt), conventional mining operations (rock salt) and solution mining (vacuum salt, salt in brine). The description "crystallised salt" also includes salt that is recovered as a co-product in potash mining. In the monograph, salt in brine will be excluded unless otherwise specified. The crystallised salt types are interchangeable in most of the major end-use sectors.

#### Recent trends

Total production capacity for crystallised salt represents about 40 million tonnes. Based on the period 1991-93, production averaged 19.2 million tonnes. In 1993 there was a slight improvement (+6 %) in comparison with 1992 due to the increased demand in road de-icing. Weather conditions explain both market and output ups and downs. However, the negative trend prevailing in the former continues to affect the latter, with overcapacity being evident in various studies. Forecasting for the 1994-97 period remains difficult because climate dictates directly (sea salt) and indirectly (impact of winter maintenance on crystallised salt) output levels.

A breakdown by the main methods of production shows that in 1993 rock salt (including by-products) accounted for 39.3 % of the total crystallised salt production, sea salt (solar) for 17.8 % and vacuum salt for 42.9 %. The move from rock salt to vacuum salt for chloralkali use, which had been forecast,

**Figure 1: Crystallised salt**  
Production in volume compared to EU total manufacturing industry

Source: European Committee for the Study of Salt, Eurostat

will not be as pronounced as had been estimated for the period under review. And, the net effect on the production of vacuum salt is likely to be small, because its use as road salt will decline.

#### International comparison

For the United States, the results for 1993 are remarkable. Severe North American snowstorms in March 1993 resulted in heavy salt usage, a record 17.1 million tonnes. This represents 59 % of total sales of 28.9 million tonnes.

Production of salt in Central and Eastern Europe is estimated at 25 million tonnes. The main producing countries of Romania, Russia, Ukraine and Poland have aggressive export traditions. As a result of revamping and modernisation of salt facilities, increased competition is to be expected from these countries.

Demand for salt is declining in several end-use sectors in Europe and the United States. Meanwhile, strong regional growth in Asia and the Middle East is likely to boost salt

output in these areas. In China, Akzo Nobel is thinking of setting up a salt mine in Changzhou (Jiangsu) with a capacity of 1.5 million tonnes. In addition, a new salt works is to be set up in Thailand with the participation of Solvay, whose current capacity of 330 kt/year will be expanded to 550 kt/year in 1996. In Japan, salt sales amounted to 8.4 million tonnes in 1993, with the chloralkali sector accounting for 85 %. Local production in Japan only meets about 14 % of the total consumption.

### Foreign trade

Salt is a widely found, low value, bulk commodity. However, the cost of transport prevents expansion in trade just as much as the widespread abundance of the natural resource. The Nordic countries constitute an exception because of the absence of any salt deposits and facilities. However, EU salt imports by Finland, Norway and Sweden have shown a 28 % decline since 1988 because of the chlorine phase-out in the pulp and paper industry. Globally, extra EU exports reached 2.8 million tonnes in 1993 and intra EU trade represented 3.7 million tonnes. Imports originating in third countries amounted to 0.5 million tonnes.

## MARKET FORCES

### Demand

Consumption of crystallised salt within the EU amounted to 16.9 million tonnes in 1993. A breakdown of consumption by end-use sectors reveals: chloralkalis with 48 %; miscellaneous industries with 19 %; food grade salt with 13 %; and road salt with a 20 % share of the total consumption for the industry.

Salt has been a basic raw material for the chemical industry since its development at the end of the eighteenth century (salt-based patent by LEBLANC). The development of the chloralkali industry, which uses salt to produce chlorine and caustic soda, boosted the demand for this mineral and increased the multiplicity of its uses in non-food sectors. Chlorine is consumed today by many converters and manufacturers. However, increasing public concern about the use of chlorine has resulted in a marked reduction in certain uses. But, chlorine phase-out would not make sense. In the face of unfounded claims, which foster fear in the public opinion but bring no objective contribution to environmental debate, the industry develops its arguments on scientific grounds. Those consultants who foresee a high-growth scenario for chlorine, anticipate a resumption of demand; especially for PVC, although mainly outside Europe.

"Miscellaneous industries" include animal feeding and water softening. From a statistical point of view, however, both are subject to variations dependent on external factors. Due to the catch-all nature of this heading, it looks like a sector where the demand remains static.

The healthy organism is characterised by a great flexibility in its adaptation to a number of variables, including the dietary intake of sodium chloride. For the population at large, some attention must be paid to adequate salt intake, taking into consideration that Health Authorities have selected this mineral substance as a carrier of iodine and fluorine.

For snow and ice control, salt was first used in the 1930s. Today, salt is considered everywhere as an efficient de-icer because it is readily available, easy to store, handle and spread, and is less expensive when compared with alternatives like abrasives and chemicals. Salt also saves lives by reducing accidents and response time to medical emergencies. A study entitled, "Accident, Analysis of Ice Control Operations", performed in 1992 by Marquette University, found that costs related to accidents decrease by 88 % after the spreading of road salt.

### Supply and competition

Road salt sales were 3.4 million tonnes in 1993, but mean requirements exceeded 4.5 million tonnes. Requirements for this type of salt depend on the severity of winter. The severe winter conditions which prevailed last winter (1993-94) in the American snow belt reveal that, as a result of insufficient local stockpiling, supply can become difficult, even impossible. However, the extraction capability is more than sufficient to keep up with demand.

Salt is also used as a regenerator of resins in water softeners based on the ion exchange process. The effects of ion exchange water softening can impact on several factors for both the environment and households, such as: energy, detergency, maintenance, and comfort. More attention needs to be paid to the advantages of ion exchange in domestic water softening over alternative technologies for hardness modification. Although salt consumption is steady in this end-use subsector, markets differ in the various regions of the EU due to the impact of centralised water softening, physical treatment, and information made available to the consumer. Hence, supply widely depends on such peculiarities.

In certain Member States, food grade salt covers salt which is marketed for non-food uses. In other words, the demand for food grade salt is not equivalent to the requirements of households, caterers and food manufacturers.

**Figure 4: Crystallised salt  
Trade intensities**

Source: European Committee for the Study of Salt, Eurostat

Market conditions differ according to end use. In the chemical and food industries the supply chain is relatively short, making the development of competitive marketing strategies relatively simple. In contrast, the market for special grades of salt for water softening is not so straightforward. Here, the marketing process includes the identification of sales opportunities and after sales follow up of the suitability of the product for various types of equipment. The retail market for salt is still bedevilled by the notion that "salt is bad for blood pressure" and its intake should be reduced. Although scientific thought has moved on from this simplistic statement, medical opinion is still divided as to the precise relationship between salt intake and blood pressure; unfortunately the legacy of the simplistic statement lives on, with harmful effects on public opinion. At the same time, it has been realised that salt is ideal as a carrier for fluorine (to prevent dental decay) and iodine (to eliminate iodine deficiency disorders). However, some countries have been slower to adopt this concept; although it is undoubtedly true that salt can in this way fulfil a vital role in promoting public health.

## INDUSTRY STRUCTURE

### Companies

Producers involved in the salt business can be split into three categories: large multinational chemical groups and/or their subsidiaries; companies specialising in salt (and potash producers who are also producing salt); and low sized firms.

Unfortunately, information on manpower is scarce, and the number of workers is not comparable from one region to another.

### Strategies

Companies involved in the crystallised salt industry are pursuing strategies ranging from privatisation and expansion to mergers and acquisitions. The dismantling of the Austrian salt monopoly as of January 1, 1995, is a preliminary step towards the normalisation of their market; however, since state ownership is fixed by the Austrian constitution, an amendment has to be adopted before there is any further consideration. Recently, the Hellenic Salt Works S.A. in Greece has also been opened to private share holding. In Italy, as of January 1, 1994 a new company started to put salt on the market which was produced by the Amministrazione dei Mo-

nopoli di Stato, which is the company replacing Azienda Italiana Sali S.p.A.

Dansk Salt has been organised as a joint venture in which Akzo Chemicals B.V. participated with a 50 % share of ownership. After agreement between the interested partners, it was decided in 1993 that Dansk Salt's activities would be continued in a limited company owned 100 % by Akzo Chemicals B.V. The European Commission has given an unconditional approval for the acquisition of the bulk of Nobel Industries by Akzo, and Akzo shareholders have given their stamp of approval as well. After this decision, the company's name was changed to Akzo Nobel.

Further to the approval of the European Commission, the planned merger of the rock salt and potash activities of Kali und Salz AG and Mitteldeutsche Kali AG is expected to be implemented in 1994-95.

Finally, Frima B.V. has confirmed it will build a 1.2 million tonnes/year salt plant; although salt demand is feared to fall by a further 3 to 4 million tonnes by the end of the century. The company has applied for various subsidies and incentives.

### Impact of the Single Market

The creation of the Single Market has had limited direct impact on the crystallised salt industry, but is regarded in positive terms because of the overall effect on general economic activity. Few of the measures in the Internal Market package were of direct relevance to this sector.

## ENVIRONMENT

Dietary salt is used in a number of countries as a suitable carrier for micro-nutrients. The supplementation of discretionary salt with iodine and/or fluorine has proved to be an appropriate response to reduce iodine deficiency disorders (IDD), dental decay and to curtail the social costs which have to be paid for the management of such deficiencies. Universal salt iodisation is one of UNICEF's mid-decade goals and, in order to reach it, various steps have been taken to promote consumption and to raise consumer awareness on its benefits.

In December 1993, UNICEF experts met on iodine deficiency disorders (IDD) and universal salt iodisation for European countries and determined priorities for the immediate future. As a follow-up, UNICEF collaborated with the European Salt Producers' Association to organise a forum with the partici-

**Figure 5: Crystallised salt  
Consumption by sector, 1993**

Source: European Committee for the Study of Salt

pation of the World Health Organisation (WHO) and ICCIDD representatives, which took place in July 1994. The main objective was to explore the ways and means of involving salt producers in the IDD elimination campaign and individual households the general prevention of such disorders. American health agencies also indicate that IDD can be eradicated by salt iodisation. This is supported by the recent Quito Declaration which calls for the inclusion of this type of salt in food uses and animal feeding. As far as Europe is concerned, the primary objective is to advocate the harmonisation of existing pieces of law on iodisation in various countries. The supplementation of salt with fluorine (salt is more secure and less expensive than water) is another issue of a similar nature; although the public is already aware of the role played by this micro-nutrient in the prevention of dental decay. However, it is not enough to adopt and to bring into operation the laws requiring iodisation and fluoridation of salt, effective prevention requires a positive process of education and implementation.

Several companies have obtained a certification based on the ISO 9002 standard after auditing their mines and/or surface installations and other facilities.

---

## REGULATIONS

---

The Codex Alimentarius' aim is to protect consumer health and to ensure fair trading methods. Whether the standards adopted by the Codex Alimentarius Commission are integrated or not into the national law systems, they are gaining in importance due to the new status attributed to them by the GATT negotiations. As a result, national or regional measures are only acceptable if they comply with international standards, or if countries can justify the measures they are contemplating. Food grade salt is covered by the Codex Alimentarius standard (STAN 150/1985). But, generally speaking, this type of salt meets the general provisions valid for foodstuffs (additives, labelling, etc.).

---

## OUTLOOK

---

Overcapacity remains a problem for the industry. In addition, it is very difficult to forecast the future for the salt industry because the severity of coming winters is unpredictable. Obviously, future sales of road salt are dependent on weather conditions. However, history suggests that sales are generally between 2 and 6 million tonnes. As far as the chloralkali industry is concerned, how the drive to reduce mercury emissions and cell room conversions (membrane technology) will affect salt consumption is unclear at this time. Decreased environmental pressure and technological developments will have to be positively combined with economic recovery in order to reactivate the demand for crystallised salt. Various consultants predict a bleak future for crystallised salt in Europe, which is far from being a buoyant market.

Written by: ESPA

The industry is represented at the EU level by: European Salt Producers' Association (ESPA). Address: 17 rue Daru; F-75008 Paris; tel. (33 1) 47 66 52 90; fax (33 1) 47 66 52 66.

# Physical industrial minerals

NACE 231, 239

The EU is the world's major consuming region for physical industrial minerals and currently produces around 85 % of its own requirements. Major EU producers of these minerals are recognised as world leaders in their fields and are actively involved in operating in other countries. This leadership has been gained through technical expertise and a close understanding of its consuming industries' requirements.

## INDUSTRY PROFILE

### Description of the sector

Physical industrial minerals are defined as those industrial minerals used predominantly for their physical characteristics rather than for their chemistry. They correspond with the minerals covered by the existing NACE codes 231.7 and non-chemical items in NACE 239 (and the more coherent grouping under the new NACE Rev 1 codes 1422 and 1450).

These minerals are used in such fields as ceramics, refractories, and abrasives; as filler/extender pigments for incorporation into paper, paints, and plastics; and, as filters, absorbents, and insulating materials. The range of products includes clays such as kaolin, kaolinitic clays, bentonite, and sepiolite, as well as, a variety of minerals such as diatomite, feldspar, magnesite & magnesia, perlite, pumice, and talc. The EU is a leading producer and exporter of these products.

### Recent trends

EU production and consumption in physical industrial minerals displayed excellent growth during the 1980s followed by declines in 1990, 1991, and 1992. For 1993, the sector displayed modest growth which is expected to be followed by stronger growth in 1994 and beyond. Extra-EU exports increased in 1993, although the trade balance has remained consistently negative.

### International comparison

EU production of physical industrial minerals in 1993 was over 21 % higher than that in the USA and consumption was twice that of the USA. However, the USA is a larger exporter of these minerals than the EU. Japan is only a minor producer of physical minerals and thus its consumption (which was less than 30 % of that for the EU in 1993) is heavily based on imported raw materials. Over the period 1984-93 the EU displayed stronger growth in consumption than either the USA or Japan. Indeed the USA appears to show a value decline between 1984 and 1993, although this has more to do with exchange rate movements than any decline in volume terms.

### Foreign trade

The EU is a net importer of physical industrial minerals. Nevertheless, during the period 1984-93 exports grew by 83 % compared to a growth in imports of 35 %, thus lowering import dependence. The major EU export items are the industrial clays - kaolin, ball clay, bentonite, etc. - which, in 1993, made up over 60 % of total exports of these minerals. Ironically, industrial clays are also the major imported items in this group. In fact, the value of imports almost exactly balances exports in most years. It should be noted, however, that for a number of other important EU export items such as magnesia and talc, imports actually exceed exports by a considerable margin.

Figure 1: Physical industrial minerals  
Production in comparison with related industries, 1993

Source: B.M.Coope & Partners

Major sources of EU imports of physical industrial minerals are the USA (kaolin, other clays, diatomite, talc and bentonite), Brazil (kaolin), China (magnesia and graphite), Canada (asbestos), Austria (magnesia and talc), Finland (talc), Norway (feldspathic minerals and quartz(ite)), Turkey (bentonite, perlite, pumice), Cyprus (bentonite) and Switzerland (quartz(ite)). The major destinations for EU exports in 1993 were the EFTA countries, an important element of which is the supply of kaolin to the paper industries of these countries.

## MARKET FORCES

### Demand

Physical industrial minerals are consumed by a very wide range of industries. Prominent among the industries using them are ceramics, refractories, glass, and abrasives; paper, paints, and polymers (plastics, rubber, sealants/adhesives, etc.); and, filters, absorbents, and insulating products. Since the ceramics industry also includes building products such

as bricks, tiles and pipes based on common clays, the construction industry looms large as both a direct and indirect consumer of these other products.

The technical requirements of the manufacturers of many of these products have become more stringent with time. As a result, raw material producers have tended to upgrade their products accordingly. Many producers of physical industrial minerals maintain close technical relationships with major consuming companies in order to meet future requirements. Thus, many products are "speciality" rather than "commodity" minerals and long-term contracts between producer and consumer are common.

**Supply and competition**

The EU is theoretically self-sufficient for the bulk of its mineral needs in this group. In general, EU producers compare with foreign competition as a result of either the quality of deposits or the processing expertise or a combination of both. However, the high technical input into many of these products is reflected in the USA, Canada, and the EFTA countries, where they are

the major outside suppliers. It should also be noted that certain products such as graphite, mica, and clays are bought in raw form for further processing in the EU before reaching the eventual consumer.

The EU is clearly deficient in certain minerals such as asbestos, vermiculite, and graphite and has to import the bulk of its requirements. Asbestos is no longer quite as vital as it used to be and a range of replacements have been developed (many of them based on indigenous EU raw materials) to overcome the health hazards associated with this mineral.

One area where the EU industry is suffering from foreign competition is in magnesite and magnesia. The EU produces a wide range of grades of magnesia from natural magnesite or from sea water or brines for applications in refractories, construction, general chemicals, and agriculture. But, for most of the past decade, EU magnesia producers have faced strong competition in the lower grade sections of the market due to low-priced products from China. More recently, further competition has become evident in the higher grade sectors of the market from new low-cost production in Australia. In

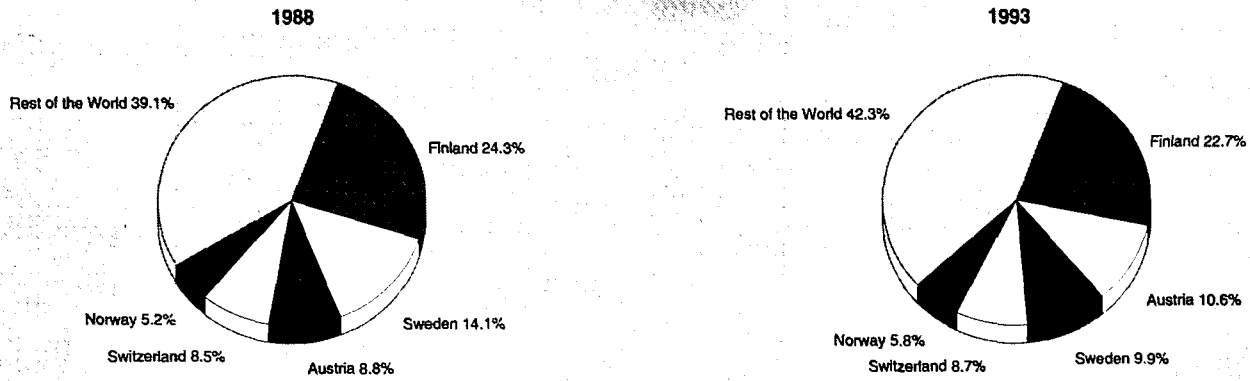

**Figure 4: Physical industrial minerals  
International comparison of main indicators in current prices**

Source: B.M.Coope & Partners, Eurostat

**Figure 5: Physical industrial minerals  
Destination of EU exports**

Source: Eurostat

addition. China has been improving the quality of certain grades as well. During 1992 anti-dumping action was taken against China and a duty was imposed on certain products. Even so, the EU magnesia industry is undergoing a process of rationalisation with producers tending to focus on more specialised grades and value-added products.

**Production process**

Many of the minerals in this group are enhanced by highly sophisticated processing techniques. Kaolin, bentonite, talc, magnesia, and diatomite are all subjected to a wide range of treatments involving such processes as high intensity magnetic separation, acid or alkali treatment, high temperature processing, laser sorting, jet milling, attrition grinding, classification at micron sizes, and surface modification. Such techniques have not only improved product quality in traditional uses but have introduced new grades to new markets and have expanded viable reserves.

**INDUSTRY STRUCTURE**

**Companies**

Most of the companies operating in this sector tend to be industrial minerals specialists although some companies from

the construction (Redland and CRH), petroleum (Elf-Aquitaine), and metals (RTZ) sectors are involved. In the kaolin and ceramic clays sector major enterprises include English China Clays and Watts Blake Bearne (UK), Amberger Kaolinwerke (D), AGS and Imetal (F), and Group Minerale Harwanne (CH).

Major enterprises in the bentonite and special clays sector are Süd Chemie (D), Laporte and Redland (UK), Tolsa (E), Eliopoulos (GR), and Laviosa (I). Leading companies in other minerals are CECA (F) for diatomite; Grecian Magnesite (GR) for magnesia from natural magnesite; Redland (UK), Sardamag (I), NedMag Industries (formerly Billiton Refractories - NL), and Premier Periclase (part of CRH - IRL) for magnesia from sea water and brines; and the RTZ subsidiary, Talc de Luzenac (F).

**Strategies**

Several of the companies mentioned in the previous section operate on an international level and are justly recognised as world leaders in their own particular fields. English China Clays (ECC), Watts Blake Bearne (WBB), RTZ/Luzenac, Laporte, Sud Chemie, and Imetal all have important operations in North America and other parts of the world including the Far East and Africa.

The world's largest kaolin producer, ECC of the UK, recently sold off its Construction Materials Division (as Camas plc) in order to concentrate on white minerals (kaolin and carbonates) and a developing interest in speciality chemicals (typified by its acquisition of Calgon chemicals in the USA).

Germany's main kaolin producer, Amberger Kaolinwerke (AKW), has been active on the acquisition trail. They have bought some of the more important kaolin operations in former East Germany (Kemmlitz and Caminau) and, more recently, a near neighbour in Bavaria, Eduard Kick GmbH. Meanwhile, WBB successfully avoided a take-over by Sibelco (B), which was, until recently, only a minority shareholder.

Other companies growing by acquisition include Talc de Luzenac (F), which increased its share of the North American talc market by taking over Montana Talc in 1994; Harwanne (CH) which added Kaolin due Finisterre to its existing kaolin, feldspar, quartz, and mica operations in France and Portugal; and Imetal (F), which added the synthetic graphite operations of Lonza in Switzerland to its growing portfolio of assets in

the fields of andalusite, refractory and ceramic clays, and natural graphite in Europe, North America, and South Africa.

### Impact of the Single Market

The Single Market has had a positive impact on the physical industrial minerals sector due to the overall economic activity it has induced. The free movement of goods, personnel, and capital are all highly relevant, and in an area of the minerals industry concerned with speciality products (i.e. with strong product differentiation) rather than commodities the aspect of intellectual property is also important.

Regarding barriers, although paperwork concerning intra-EU exports has been simplified there is still room for improvement. For extra-EU exports the administrative and customs procedures remain cumbersome. The question of EU external barriers causes considerable concern since it is felt that the implementation of the Single Market has not been accompanied by sufficient control regarding the entry into the Union of products from third countries. As a result, a low price policy

Source: B.M.Coope & Partners, DEBA

is developed by such countries where social and environmental regulations are limited or even non-existent. As far as the Single Market is concerned it seems necessary to impose European standards regarding the production of goods entering the Union.

---

## REGIONAL DISTRIBUTION

---

Clays which are suitable for the production of bricks and tiles are to be found in many regions of the EU, although the more specialised industrial clays are much rarer and more localised. The Cornwall and Devon regions of England account for about two-thirds of total EU kaolin output, while other important regions include Bavaria in Germany and Brittany in France. The main ball and ceramic clay producing districts in the EU are Westerwald in Germany, Charente in France, and Devon in the UK. For bentonite the main centres are Bavaria in Germany, Milos Island in Greece, Sardinia in Italy, and south-east England, while the region around Madrid is the sepiolite capital of the world. In addition, the volcanic regions of Greece and Italy are well-known for their deposits of perlite, pumice, and pozzolana.

---

## ENVIRONMENT

---

The main environmental issues concerned with quarrying physical industrial minerals are shared with those of the construction raw materials sector (NACE 231), and indeed most of the EU mining industry. The modern quarrying industry has an excellent record in overcoming potential problems of dust, noise, waste disposal, and land reclamation.

---

## OUTLOOK

---

The EU will continue to be a major producing and consuming area for physical industrial minerals. Likewise, the influence of major EU producers will continue to spread well beyond Europe. Technical expertise and innovation will continue to play a major role in the development of the industry. Consequently, projects in other countries - notably in Eastern Europe and the Far East - will benefit from the involvement of EU-based expertise. Within the EU itself most new developments are likely to be extensions to existing producing areas rather than new greenfield projects.

## Overview

### NACE 221, 222, 223

Despite rationalisation and continuous labour and production cutbacks during the 1980s, the EU ferrous metals industry suffers from world-wide overcapacity. After upswings in 1988 and 1989, EU production of ferrous metals continuously declined. Weak demand and increased competition contributed to this decrease. In the near future, however, increases in EU apparent consumption and production are expected as demand in downstream markets and extra-EU exports has started to rise again. New EU investments will increasingly be directed towards improvements in quality and productivity, which will be accompanied by a further drop in employment.

### INDUSTRY PROFILE

#### Description of the sector

The ferrous metals industry is divided into three sectors: the iron and steel industry (NACE 221); the manufacture of steel tubes (NACE 222); and, first processing of steel (NACE 223).

This monograph covers the activities of the iron and steel industry, as defined in the European Coal and Steel Community (ECSC) Treaty, the manufacture of steel tubes, cold drawing, cold rolling and cold folding of steel, steel-wire drawing and manufacture of steel-wire products. The share of iron and steel production in the total industry of ferrous metals is approximately 70 %, leaving 14 % for the manufacture of steel tubes and about 16 % for first processing of steel.

EU production of ferrous metals is mainly concentrated in Germany, Italy, France and the United Kingdom. These four countries account for about 84 % of total value added. With a 38 % share of total value added, Germany is the largest ferrous metals producing country within the EU, followed by Italy with a 16 % share. Employment in the EU ferrous metals industry has been declining over the years. In 1993, 524 000 people were employed in this sector against 847 000 people in 1984.

#### Recent trends

In the early 1990s, EU production and consumption decreased as a result of the economic recession. From 1989 to 1993 consumption dropped by 31 %, while production declined somewhat less (28.5 %) as EU manufacturers were able to increase their extra-EU exports.

In 1993 the world steel market remained extremely depressed, due to weak demand in the industrialised countries. Steel export prices slid more than 35 USD/metric tonne since the Chinese stopped buying in June 1993. The shortfall of orders from China is a result of growing self-sufficiency for ferrous metals in the Chinese economy. Since demand of the Western countries for mill products totalled about 430 million tonnes last year, the 35 million tonne reduction in Chinese buying created serious oversupply.

In the course of 1994, EU demand and production started to recover, resulting in more favourable prospects for the coming years. In the near future, growing demand is expected from the Far East, Oceania and North America.

#### International comparison

In 1993 Japan was the largest manufacturing country of ferrous metals with a production value of over 109 billion ECU. The

Figure 1: Ferrous metals  
Value added in comparison with related industries, 1993

Source: DEBA

EU and the USA followed at a distance with production values reaching 74 and 65 billion ECU, respectively. The latter two countries have recorded production declines since 1984, while Japan increased its production level by 27 % since 1984. The Japanese production increase, however, is positively influenced by the appreciation of the Japanese yen against the ECU.

The Japanese workforce (259 000) in this industry is less than half of the EU workforce (523 000), while the US counted 356 000 people. As a result, the countries' labour productivity rates differ significantly. In 1993, Japanese production per employee equalled 421 243 ECU, while the corresponding European value only reached 140 759 ECU.

Other major manufacturing countries include: China, the CIS and other East European countries. While the EU and the US have suffered setbacks in their shares of world ferrous metals

production since the 1980s, newly industrialised countries (NICs) and developing countries (DCs) gained market share. Often supported by heavy state aid, some of these countries, such as Turkey, Mexico, Venezuela, Brazil, Argentina, Taiwan, Korea and Thailand, have continued to expand production capacity.

In the production of steel tubes, the EU is ahead of Japan and the US. In this subsector, however, the CIS is the largest producing country. With respect to first processing of steel, value added figures in the EU, Japan and the US are of equal size.

**Foreign trade**

The EU is a net exporter of ferrous metals products. During 1984-92, however, the trade surplus declined as extra-EU imports grew faster than extra-EU exports. Recently, due to weak domestic markets, EU manufacturers of ferrous metals have increased their efforts to sell their products in non-EU markets.

As a consequence, extra-EU exports grew, while extra-EU imports suffered from weak EU demand. Both developments resulted in an increase of 65 % in the trade surplus in 1993.

Major suppliers of ferrous metals products for the EU market are the EFTA countries; especially Sweden and Austria. However, the importance of East European countries such as Russia, the Czech Republic, Poland and Slovakia is growing. Furthermore, the growing importance of Libya should be noted. All of these countries are expected to increase their shares in total extra-EU imports.

Major export destinations for EU ferrous metals products are the USA, the Far East and EFTA countries. The importance of the CIS as an export destination declined as a result of the lack of hard currency.

**MARKET FORCES**

**Demand**

Important ferrous metals consuming sectors are: machinery manufacturing; oil and gas industry; nuclear and other steam generation industries; mechanical engineering; automotive industry; and the building industry.

After increases in apparent consumption in 1988 and 1989, EU consumption declined due to increasing use of substitutes for ferrous metals (other materials) and lower investment activity in downstream markets. In addition to these general factors, the EU ferrous metals industry faced a reduction in demand because of the emergence of new competitors, particularly from NICs, DCs and East European countries. These countries not only succeeded in covering their own needs, but they also competed successfully on the world market.

Despite weak demand from the CIS and other East European countries, caused by their lack of purchasing power, the EU industry has been able to increase foreign sales. In the near future, further increases in extra-EU exports are expected. Following the recovery which started in 1994, EU consumption is also expected to record growth in the short and medium term.

### Supply and competition

Reduced demand for steel, induced by structural and cyclical factors, gave rise to a massive restructuring programme. Market controls regulated by Article 58 of the ECSC Treaty and the Steel Aid Code, formed the basis of the restructuring process which took place between 1980 and 1986. The market control measures expired mid-1988. Along with small increases in output in the 1980s, a considerable reduction in production capacity and the labour force of the EU steel industry was attained. Despite capacity reductions, however, the restructuring was not completed. Envisaged capacity reductions, which were even subsidised, were not carried out. However, the sudden improvement of the market in 1988, together with subsidies, enabled less competitive plants to survive.

In the early 1990s, the EU ferrous metals industry suffered from world-wide overcapacity, despite continuous labour and production cutbacks. Other structural problems of the industry were high costs, strong international competition and competition from substitutes.

In order to solve the structural problems, the European Commission came up with a new rescue plan for the EU steel industry in 1992. According to this plan, total EU steel production should be cut by 19 to 26 million tonnes in three

years time. At the end of 1994, however, the Commission's rescue plan collapsed, leaving the industry with excess capacity of 30 million tonnes.

### Production process

EU investment in research and development ensures high quality products and processes. In most EU production facilities, the quality assurance system is certified according to ISO 9001/9002. Continuous rationalisation efforts in production and labour have kept costs at competitive levels.

Looking at trade figures, the competitiveness of the EU industry seems to have improved. The penetration rate of extra-EU imports demonstrates a slightly increasing figure in 1991 and 1992 and has stabilised in 1993. In contrast, extra-EU exports grew by 19 % in 1993.

Improved production techniques, together with reduction of production capacity, have enabled the EU industry to reduce costs and increase efficiency and competitiveness. Over the last ten years, EU labour productivity increased by 30 %, while total unit costs remained stable.

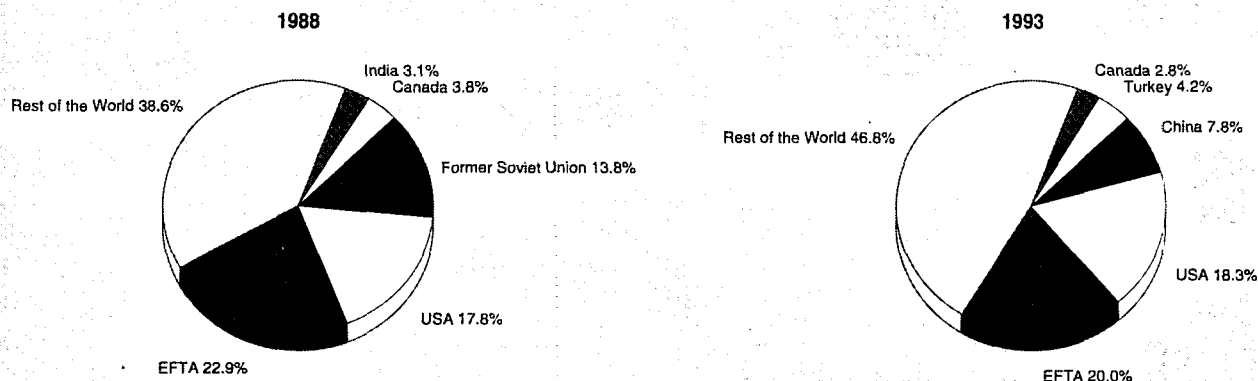

## INDUSTRY STRUCTURE

### Companies

The ferrous metals industry is highly concentrated. In the iron and steel industry, for instance, the ten major European steel producing companies account for about 80 % of total production. Usinor Sacilor (F) is the largest company in crude steel production, followed by British Steel (UK) with 12.3 million tonnes and Thyssen (D). The importance of Germany in this sector is further emphasised by the appearance of three other German companies in the top ten: Krupp Hoesch, Preussag and HKM. Two firms, ILVA (I) and Riva (I) represent Italy in the top ten and the remaining two firms originate from Belgium (Cockerill Sambre) and the Netherlands (Hoo-govens).

In the steel tubes industry Germany, Italy, France, the United Kingdom and Spain account for about 90 % of total production. In some countries a single producer sometimes accounts for 50 % or more of the national output. In 1992, three European companies were among the five largest steel tubes manufacturers in the world: TI Group (UK), Vallourec (F) and Dalmine (I). Some steel tube manufacturers, often small and medium-sized, operate in niche, high value-added markets. At the end of 1993 some 285 production units, owned by an estimated 245 enterprises, were involved in the EU steel tube industry.

### Strategies

Due to capacity reductions, induced by the difficulties in the market since 1985, investments are directed towards improvements in productivity and quality rather than expanding capacity. The need to be flexible if demand fluctuates is a vital lesson most companies learned during the recession. Other lessons include: paying more attention to customer service and commercial investment; diversifying into other areas; take-overs and mergers; specialising in high-quality products; and more integrated production techniques. EU ferrous metals manufacturers will continue to merge or cooperate during the course of modernisation and restructuring of the industry. Examples in the iron and steel industry are the merger between Usinor and Sacilor in France, the creation of ILVA in Italy, the rationalisation agreement between Krupp and Mannesmann in Germany and the take-over of Hoesch by Krupp. In addition, the Belgium steel producing company, Cockerill-Sambre, recently bought a 60 % stake in Eko Stahl, the largest steel mill of former East Germany.

### Impact of the Single Market

The overall impact of the creation of the Single Market on the ferrous metals industry has been very limited so far. This is mostly due to two factors. Firstly, most impact on the industry was due to ECSC measures instead of Single Market measures. The ECSC Treaty has affected the industry since 1951. Secondly, the persistence of a number of internal barriers which hamper the achievement of a true free internal market for the ferrous metals industry, hinders any impact. These mainly reflect various types of state aid. However, the opening-up of the public procurement market is expected to affect the sector positively. Amongst the next priorities should be the harmonisation of environmental protection legislation in Europe which result in cost and competition distortions, and the liberalisation of upstream industries (energy, transport) which should lead to greater price convergence.

### ENVIRONMENT

The ferrous metals industry intensively developed and generated techniques to reduce environmental pollution long before protection of the environment had been placed on the political agenda. Examples are: low-pollution manufacture of steel products, steel recycling and the utilisation of waste material.

Together with restructuring of the EU ferrous metals industry in the 1980s, attention has been given to the reduction of environmental pollution. Production processes were innovated in such a way that no toxic gases could develop during the production process of steel and steel tube manufacturing and that waste material would be recycled immediately and completely.

In the iron and steel industry, recycling of scrap represents about 45 % of total steel production. This is one of the highest rates for any industry. Furthermore, the steel industry's emissions have been lowered considerably by an overall reduction in energy inputs.

Harmonisation of environmental protection legislation in Europe is essential for avoiding distortion of competition as environmental protection measures increase costs considerably. European steel producers continue to work in the framework of the Environmental Protection Research Programme. The EU Council Directive of 1st February 1993 on the movement of waste (ferrous scrap is on the Green list) within and

outside the EU, follows the conclusions of the Basle Convention, as well as other similar conclusions at the OECD level. The steel industry fears that this Directive will include scrap on the waste list rather than consider it as a raw material. The subsequent cost increase (because of penalties) may be

detrimental to further innovation of production processes and may jeopardise further reductions of environmental pollution.

## REGULATIONS

The European Coal and Steel Community (ECSC) was founded in 1952 together with the ECSC Treaty. During 1980-88 (the steel crisis) steel prices were fixed and investments were directed by the EU. At the same time, ECSC institutions set quotas for EU production and imports into the EU from non-ECSC countries.

The ECSC Treaty strictly forbids government subsidies (Article 4c), although this rule was not being enforced until 1986. Since 1986, subsidies may only be geared to the encouragement of research and development, to safeguard the environment and to meet social costs incurred by total plant closure. However, the 'hard' line of the European Commission concerning restructuring of the EU steel industry collapsed at the end of 1994.

Harmonisation of EU standards is well advanced; internal barriers have practically disappeared and do not impede the free circulation of goods within the EU. The EU ferrous metals market remains open for imports from third countries provided they enter under fair trade conditions. Unfair trade practises will be countered by antidumping and countervailing procedures. Future regulations for the steel market and steel policy of the EU are expected to be increasingly geared to liberalisation.

## OUTLOOK

---

It is expected that apparent consumption of ferrous metals will increase slightly in the short and medium term. Recovery of demand from major downstream markets, such as the automotive industry and mechanical engineering, will stimulate overall consumption of ferrous metals.

EU production is also expected to increase in the short and medium term, although increases will differ among the three subsectors. Production increases in iron and steel will be modest compared to increases in steel tubes and first processing of steel. Despite production increases, excess capacity in EU steel production is expected to persist.

Production increases will be partly induced by growing extra-EU exports, especially iron and steel products. Despite the collapse of the Commission's steel restructuring plan, further rationalisation of production in the iron and steel industry is expected, leading to a decline in employment. However, necessary capacity cuts will probably be postponed until the industry enters its next downturn. Moreover, the steel industry has started to invest in new, modern capacity.

Written by : Netherlands Economic Institute

# Iron and steel

## NACE 221

The year 1994 was marked by an upswing of demand and the withdrawal of the restructuring plan of the European Commission. The result is a postponement of necessary capacity cuts. Together with developments in the regulatory environment, the major challenge for steel producers will be to strengthen up during the period of favourable market conditions. Survival, sometimes accompanied by painful measures to further increase production efficiency, will increase competitiveness in the future.

### INDUSTRY PROFILE

#### Description of the sector

Steel and coal were the subjects of the ECSC Treaty in 1952, one of the first European industry agreements. Special provisions governing these two products remained in force after the two administrative bodies of the Community were merged.

The steel industry encompasses steel production from raw material processing to the production of finished and final steel products. These products include ordinary, special and alloy steels. The steel industry covers the following operations:

- coke manufacture (except if coke is purchased from the coal industry or from independent coking plants);
- ore preparation, especially for the production of sinter and pellets;
- manufacture of pig-iron in blast furnaces;
- manufacture of steel from pig iron in converters and from scrap in electric furnaces;
- continuous casting and/or hot rolling of semi-finished products;
- hot rolling of long products and flat products;
- cold rolling of flat products; and
- metallic and organic coatings.

The finished products of the steel industry, including ordinary, special and alloy steels, can be further divided into hot-rolled (flat and long) and cold-rolled (flat) products.

#### Hot-rolled

- Flat products: sheet strip obtained directly from the hot mill or by slitting of sheet in coils; heavy or medium wall plate obtained directly from the hot mill or by cutting of sheet; and
- Long products: heavy sections, light sections, including concrete reinforcing bars, and wire rods.

#### Cold-rolled

- Thin wall sheet in coils uncoated or coated with zinc, tin, lead, aluminium, plastic, paint, etc.

EU production of steel is mainly concentrated in Germany, France, Italy and the United Kingdom. These four countries together account for nearly 74 % of total production. With about 38 million tonnes, Germany is the largest steel producing country within the EU, followed by Italy (26 million tonnes).

Compared with other industries in terms of value added, the iron and steel industry is similar in size to the consumer electronics industry, but much smaller than the motor vehicle industry. With a total labour force of 335 300 people, however,

Figure 1: Iron and steel  
Value added in comparison with related industries, 1993 (1)

(1) Including non-ECSC steel products.

Source: DEBA

the steel industry is still a major employer. As such, it is not surprising that some Member States attach a high importance to the performance of their domestic industry.

#### Recent trends

Over the period 1984-1989 steel production in current prices increased by an annual average growth rate of 3.1 %, while apparent consumption recorded a somewhat higher average of 4.4 %. Extra-EU exports, in contrast, recorded a declining trend, which only started to turn in 1991.

In the early 1990s, the economic recession negatively affected consumption and production of iron and steel. From 1991 to 1993 consumption dropped by 12 %. Consequently, EU manufacturers started to look for other non-EU markets and thus raised exports. As a result, the production decline was limited to a drop of 4 % in the same time span. In 1994, demand recovered, resulting in more favourable prospects for the coming years.

Recently, the European Commission intensified its action in the sector. At the beginning of 1994, it seemed likely that important capacity cuts would be negotiated. As time went on, however, it became clear that the Commission would have great difficulty in delivering a package of cuts and measures acceptable to all parties. At the end of 1994, the Commission's steel restructuring plan was withdrawn.

**International comparison**

In 1993, the EU was the leading manufacturer of iron and steel products. With production totalling 132.2 million tonnes, the EU was far ahead of Japan and the USA with production figures of 99.6 and 89.2 million tonnes, respectively.

If compared to 1984, the EU has recorded a production decline of 1.6 % against a decline in Japanese steel production of 5.7 % and, remarkably, an increase in US production of 6.3 %. For US producers, continued growth in their own domestic market is likely as the country is still a net importer of steel products. While 39 % of EU production and 26 % of Japanese production is exported, US exports only account for 5.7 % of total domestic production.

Other major steel manufacturing countries are the former USSR and China with output in 1993 totalling 95.7 and 88.7 million tonnes, respectively. Total steel production in Central and Eastern Europe amounted to 125.4 million tonnes in the same year.

### Foreign trade

The EU is a net exporter of iron and steel products. During 1984-92, however, the trade surplus went from 14.3 million tonnes to 7.8 million tonnes as extra-EU imports grew faster than extra-EU exports. This also caused the exports/imports ratio to drop from 2.77 in 1984 to 1.63 in 1992. Until 1991, intra-EU trade grew even faster than extra-EU imports, increasing its share of total imports from 75.3 % to 78.9 %. Over the 1984-93 period, extra-EU imports recorded a higher average annual growth rate (2.6 %) than apparent EU consumption (0.9 %), demonstrating the growing importance of foreign suppliers on the EU market. Consequently, the penetration rate increased from 9.07 % in 1984 to 10.81 % in 1992. In 1993, however, this rate demonstrated a slight decline.

In search of other markets, EU manufacturers were able to increase their foreign sales by more than 10 million tonnes in 1993, a growth of 50 % against 1992. At the same time, extra-EU imports declined due to weak EU demand. Consequently, the trade surplus recorded an increase of 12.5 million

tonnes and the export/import-ratio increased from 1.63 in 1992 to 3.0 in 1993.

Major export destinations for EU steel products are the USA, the Far East and the EFTA countries. Asian countries such as China, Taiwan, Hong Kong, South Korea and Thailand have become increasingly important as export markets. The Asian share in total extra-EU exports increased from 20.4 % in 1988 to 40 % in 1993.

EFTA countries are major suppliers of steel and iron products for the EU market. In 1993 these countries together accounted for 53.6 % of total EU imports against 43.3 % in 1988. Sweden and Austria are large suppliers to the single market. Eastern Europe also increased its share in total extra-EU imports from 26.1 % in 1988 to 31.6 % in 1993. Major steel producers in this region are Russia, the Czech Republic, Poland and Slovakia.

## MARKET FORCES

### Demand

Primary processing industries account for over one-third of ECSC steel used in the EU; most of it is used for the production of steel tubes, wire and bright drawing, and cold-rolling and cold-forming, which allow for 6 % to 14 % of steel requirements. In terms of final internal demand, principal consumers are building and civil engineering and manufacturers of transport equipment and metal goods. Their shares vary from 10 % to 15 %. With shares of 6 % to 7 % mechanical engineering and structural steel work are also important customers.

Since the mid-1970s steel consumption in the EU (and in industrial countries in general) has decreased. Various factors have contributed to this development, such as: recent cuts in the production of a number of steel-consuming industries; technological development, entailing a decrease in the quantity of steel needed for the production of a given product; improvement in quality, i.e. the durability of the steel products themselves; and substitution of steel by other materials (plastics, aluminium etc.). In addition to these general factors, the EU steel industry faced a reduction in demand because of the emergence of new competitors, particularly from newly industrialised countries and more recently Eastern Europe.

### Supply and competition

Reduced demand for steel, induced by structural and cyclical factors, gave rise to a massive restructuring programme in

**Figure 6: Iron and steel**  
Destination of EU exports

(1) Excluding Japan.  
Source: Eurostat

**Figure 7: Iron and steel  
Origin of EU imports**

Source: Eurostat

the 1980s. Market controls were regulated by Article 58 of the ECSC Treaty and the Steel Aid Code, which fixes conditions where subsidies can be authorised: research, social and environmental protection. These controls formed the basis of the restructuring process which took place between 1980 and 1986. The market control measures expired mid-1988. The restructuring process brought about a reduction in the EU's production capacity for crude steel of 40 million tonnes (19 %). Moreover, by the end of 1988, hot rolling capacity had been reduced by 34 million tonnes (18 %).

At the same time, however, newly industrialised countries increased their production capacity significantly. Low production costs (cheap labour, energy, and indigenous raw materials) and technological development in steel production (mini-mills) enabled them, apart from satisfying their own needs, to compete successfully with traditional exporters on the world market.

Along with small increases in output in the 1980s a considerable reduction in production capacity and the labour force of the EU steel industry was attained. Despite capacity reductions, however, the restructuring was not completed. However, the sudden improvement of the market in 1988, together with subsidies, enabled the less competitive plants to survive.

Deteriorating market conditions in the early 1990s forced an additional drop in the industry's employment. Since 1991, total employment has dropped by more than 53 200 or 13.7 %. These developments revealed the specific structural problems of the EU steel industry: overcapacity, strong international competition on the world steel market and competition from steel substitutes. Even some of the best-known steelmakers, such as Krupp and Thyssen (D) and Ilva (I) were in deep financial trouble.

In order to solve the overcapacity problem, the European Commission came up with a new plan in 1992 to help restore the beleaguered industry to health during the recession. According to this plan, total EU production would be cut by 19 to 26 million tonnes in three years time. The steel industry should solve the problem itself, i.e. steel producers would have to indicate which enterprises should reduce their capacity and to what extent. The aim of the exercise was to allow no unprofitable plants to remain in production artificially and to take painful restructuring measures. The only solution to solve this problem was strict control over State subsidies (Art. 4c of the ECSC Treaty): State subsidies should only be authorised by the Commission if they are aimed at achieving substantial reductions in inefficient production capacity. To create a sound EU steel industry, fair competition and market stability, the plants concerned should be identified and dismantled, even in case of a sudden recovery of the market.

At the end of 1994, the Commission's plan was withdrawn. The plan resulted in pledged and implemented cuts in production capacity amounting to 17 million tonnes. In 1993, a significant blow to the plan occurred when a powerful local campaign prevented the closure of the loss-making Klockner works in Germany. Closing this factory would have given an early push toward the 19 million tonne target. On the other hand, a plan for assistance in closures in the Italian region of Brescia was recently approved and is now being enacted.

At the end of 1994, total capacity still equalled 170 million tonnes, involving an estimated excess capacity of 30 million

tonnes. Moreover, new modern capacities are going to be built in the European market: Eko Stahl (1.8 million tonnes), Sestao (1.8 million tonnes), Freital (200 000 tonnes), and Siderurgia Nacional (900 000 tonnes), all with state subsidies.

### Production process

Improved production techniques, together with the reduction of production capacity, have enabled the EU steel industry to reduce its costs and increase efficiency. An example is the proliferation of continuous-casting plants, in which one step in the production process is eliminated with a subsequent drop in crude steel requirements.

Technical criteria are not the only decisive factors in international competition though, products must also be competitive from a cost angle. Developments in labour productivity, unit labour costs and total labour costs indicate that efficiency in production increased over the period 1984-1989. Labour productivity in current prices increased while unit labour costs declined. Weak downstream markets, accompanied by lower capacity utilisation, caused a stabilisation of labour productivity in the early 1990s, which could only partly be compensated for by German reunification. This stabilisation has also been accompanied by a reduction in unit costs. Competitiveness of the industry can only be maintained and further improved if production costs are controlled and production is efficient.

## INDUSTRY STRUCTURE

### Companies

The iron and steel industry is a sector with a high degree of concentration. The 10 major European steel producing companies account for about 80 % of total production. Usinor Sacilor (F) is the largest company in crude steel production with output of 17.6 million tonnes, followed by British Steel (UK) with 12.3 million tonnes and Thyssen (D) with 9.6 million tonnes. The importance of Germany in steel production is further emphasised by the appearance of three other German companies in the top ten: Krupp Hoesch, Preussag and HKM. Italy is represented by two companies; ILVA and Riva, and the Netherlands and Belgium are each represented by one.

Two major categories of producers can be distinguished: integrated companies and mini-mills. Integrated mills generally have large production capacities, ranging from 2 to 10 million tonnes of finished products. Although these large production units allow economies of scale, they allow little production flexibility. Mini-mills owe their success to flexibility and the capacity to adapt production to market demand. In certain Member States (Italy and Spain) mini-mills account for a substantial share in total steel production.

### Strategies

Despite political commotion about the withdrawal of the Commission's plan, most steel companies have understood the need to be flexible if demand fluctuates. As a result, steel companies are trying original market solutions. Innovative transnational alliances, reciprocal equity stakes and investments are examples of a trend towards a less nationally-based industry. Other lessons include: paying more attention to customer service and commercial investment; diversifying into areas other than steel; take-overs and mergers; specialising in high-quality products; and more integrated production techniques.

A number of mergers and acquisitions occurred during the course of modernisation and restructuring of the EU steel industry. Examples are the merger between Usinor and Sacilor in France, the creation of Ilva in Italy, the rationalisation agreement between Krupp and Mannesmann in Germany, and the take-over of Hoesch by Krupp. Recently, the Belgian steel producing company, Cockerill-Sambre, bought a 60 % stake in Eko Stahl, the largest steel mill of former East Germany. Together with Treuhand, the German privatisation agency, the Belgians have come up with a plan to modernise Eko Stahl's existing blast furnace and to build a new hot-rolling mill.

### Impact of the Single Market

Whether the impact of the creation of the Single Market has been positive or negative on the industry is not yet clear. The impact of the Single Market could have been positive by providing companies with a greater access to other EU markets for public procurement. A positive impact may also have resulted from reduced administrative costs and increased efficiency of cross-border transactions/ shipments. No true internal market has come into effect yet, however. Existing distortions include the variety of national environmental policies, the continuation of state subsidies and differences in energy prices across Member States - energy being a main input for this sector. In this respect, the liberalisation of energy markets is important. More price convergence in upstream industries (electricity, transport) should be a priority for future. The elimination of unfair competition and the removal of all, internal and external, barriers to free trade are also essential.

## REGIONAL DISTRIBUTION

Steel plants are located throughout the EU with varying levels of production capacity. Originally, steel plants were built inland, usually near coal or iron-ore fields from where they drew supplies, or near steel consumers. More recently, they are built on the coast, where they have easy access to imported raw materials without the cost of land transport. They are also better placed to capture international markets.

**Table 6: Iron and steel**

Oxygen (%)	66.5	62.2	68.8
EAP (%)	33	37.8	31.2

Source: IISI, Eurostat

Whereas Germany is the largest EU producer of steel, the importance of the steel industry for the economy is greater in Luxembourg, where the share of steel production in total industry exceeds 40 %. By contrast, the contribution of steel to total manufacturing production only accounts for about 1 % in Denmark, Ireland and Portugal. With regard to mini-mills, the highest concentrations can be found in Northern Italy and Spain.

## ENVIRONMENT

Long before environmental protection had been placed on the political agenda, the steel industry intensively developed and generated techniques to reduce environmental pollution. These measures include: low-pollution manufacture of steel products; steel recycling; and, the utilisation of waste material. Restructuring of the industry in the 1980s encouraged innovation of the production process; older installations were replaced by modern plants, fully equipped with a whole range of pollution-control equipment. The increasing use of electric arc furnaces (EAF) across Europe is a leading example of such new processes.

The steel industry's dust emissions have been lowered considerably. Emissions of carbon dioxide (CO<sub>2</sub>) have also been strongly reduced by optimisation of process technology and an overall reduction in energy inputs. For example, in mini-mills the average required input of electricity per tonne of steel declined from 510 kWh in 1980 to 380 kWh in 1990.

In recent years, the EU steel sector consumed about 60 million tonnes of steel scrap, the bulk of which was collected from discarded steel-containing products. Recycling of scrap, which represents about 45 % of total steel production, is one of the highest rates for any industry.

Environmental protection places considerable financial burdens on iron and steel companies. In light of the high costs and the fact that requirements and enforcement of environmental protection are not equally strict in all Member States, a harmonisation of environmental protection legislation in Europe is essential for avoiding distortion of competition. European steel producers continue to work with the European Commission in the framework of the Environmental Protection Research Programme established under Article 55 of the Treaty of Paris.

## REGULATIONS

For more than forty years, the European steel industry has been regulated by the European Coal and Steel Community (ECSC). The ECSC was originally established in 1952 to ensure an orderly supply of coal and steel to the common market for coal; to ensure equal access to sources of production; to ensure the establishment of the lowest prices; to encourage undertakings to expand their production potential; to promote improved working conditions; to promote growth of international trade; and to promote the expansion and modernisation of production.

As to recent legislation, particularly in the field of the environment, it is worth noting the EU Council Directive of 1st February 1993 on the movement of waste (ferrous scrap is on the Green list) within and outside the EU. This Directive follows the conclusions of the Basle Convention, as well as other similar conclusions at the OECD level. The industry fears that this Directive will include scrap on the waste list rather than consider it as a raw material. The subsequent cost increase may be detrimental to further innovation of the production process and may jeopardise further reductions of environmental pollution.

The possible introduction of a new tax on CO<sub>2</sub> emissions will have a negative impact on the steel sector. Steel industry efforts to reduce energy consumption are being pursued. For example, in the course of 1994, a large number of new electric arc furnaces started producing, replacing blast furnaces. This could mean a considerable decrease of global CO<sub>2</sub> emissions coming from the steel industry.

## OUTLOOK

The year 1994 was marked by an upswing of demand and the withdrawal of the restructuring plan of the European Commission. Both developments will have an impact on the industry in the short and medium term. Recovery of demand is expected to continue and no further agreements on capacity reductions are expected in the short run.

Despite the withdrawal of the Commission plan, a package of social subsidies, designed to ease the impact of steel plant closures, will continue to apply until the end of 1995.

Together with developments in the regulatory environment, the major challenge for steel producers will be to strengthen up during the present positive market conditions. Survival, sometimes accompanied by painful measures to further increase production efficiency, will increase competitiveness in the future. Nevertheless, moderate increases in demand for and production of steel are forecast for the short and medium term.

# Steel tubes

## NACE 222

The steel tube industry has faced a severe volume and financial downturn since the mid-1980s due to world-wide low demand and over capacity. Seamless tubes and welded tubes with an outside diameter of over 406.4 millimetres, in particular, were deeply influenced by import quotas imposed by the USA until March 1992 and later by the harassing threat of trade cases, and the low international value of the dollar. Furthermore, the collapse of the former Soviet Union and other East European markets and reduction of orders from China are of great concern to EU manufacturers. As from 1994, US dumping allegations against several Latin American, EU and other producers have fundamentally altered export flows in the world market of steel tubes.

The EU has maintained its leading position in the world market, ahead of the USA and Japan, due to continuous productivity gains achieved through industry restructuring. Nevertheless, foreign trade has been steadily deteriorating. Despite improved competitiveness, the EU steel tube industry is under the strongest pressure from low priced imports from Central and Eastern Europe which have forced significant reductions of output, capacities and workforce.

### INDUSTRY PROFILE

#### Description of the sector

Activity of NACE 222 encompasses the manufacture of steel tubes, as well as, steel tube fittings and compressed gas cylinders. This monograph, however, only covers the manufacture of steel tubes. Data is based on production figures compiled from surveys conducted by the national organisations of the producers located in EU Member States. Export and import figures are provided by Eurostat sources.

Steel tubes cover three product categories which differ considerably in their manufacturing processes, raw materials, and investment requirements. These categories are classified as: seamless steel tubes, welded steel tubes of circular cross-section over 406.4 millimetres in outside diameter, welded steel

**Figure 1: Steel tubes**  
Value added in comparison with related industries, 1993

Source: DEBA

tubes of circular cross-section up to and including 406.4 millimetres in outside diameter and welded steel tubes of non-circular cross-section of any perimeter.

The main consumers are the energy markets (e.g. oil, gas, nuclear, steam generating industries), petrochemical, automotive, mechanical engineering, mechanical services, and construction industries. Economic development in each of the product areas of the steel tube sector varies according to their different end markets. Calculated using a crude steel equivalent, EU steel tube production consumes 16-19 % of ECSC steel output. Steel tubes are manufactured at varying levels in each EU country.

#### Recent trends

After a peak in 1990, a steep downturn in 1993 and a slight recovery in 1994, the long term trend of consumption can

International comparison of main indicators in volume

Source: ESTA, Eurostat

be seen as developing slowly. However, since 1992, production has been reduced dramatically in some countries as a consequence of lower export possibilities and heavy imports. For 1994, production figures show some upturn. For the medium term, no noticeable growth can be expected.

During 1993, apparent consumption of steel tubes in the EU decreased by 9.4 %, but is expected to rise by 6 % in 1994. Production, reduced in 1992 by 10 %, saw an additional reduction of 10 % in 1993. However, a recovery of 7 % is expected for 1994. Extra-EU exports, after a dramatic decrease of 27.4 % in 1992, experienced a 15 % decrease in 1993, but were expected to increase by 9.5 % in 1994. Extra-EU imports declined in 1993 by 18 % due to weaker consumption, but were estimated to rise by 7 % in 1994.

Data for steel tubes employment shows a 4 000 person decrease in 1993. In total, between 1984 to 1993 employment has experienced a 42 % reduction. Although apparent consumption has increased steadily, or at least remained level, over the past decade, it has mostly been to the advantage of third country competitors. The share of imports from third countries of EU consumption, measured in tonnes, has increased strongly from 9.1 % in 1984 to 13.7 % in 1993. Consequently, trends for employment can only be assessed with pessimism. In 1994 a further 2 700 jobs were to be lost.

Growth in the steel tube sector has clearly lagged behind developments in general manufacturing as a whole. Since 1987, general manufacturing has been characterised by strong growth in production and consumption and a stagnation in extra-EU exports and employment. In contrast, all indicators for the steel tube sector, with the exception of consumption, have shown sharp declines with a temporary recovery in 1994.

#### International comparison

EU production of steel tubes in 1993 accounted for 18.6 % of world production compared to a 1984 production share of 20.6 %. In world ranking, the EU is ahead of Japan and the USA. The former Soviet Union had been at the top of the list for the past several years. In Japan and the EU, steel tube production greatly exceeds domestic consumption which is reflected in their roles as the most significant steel tube exporters.

While the EU, the USA and Japan have suffered setbacks in their shares of world production since the 1980s, the newly industrialised countries (NICs) and developing countries (DCs) have been winners. Consequently, some of these countries, such as Turkey, Mexico, Venezuela, Brazil, Argentina,

Taiwan, The Republic of Korea and Thailand have continued to expand their production capacity, often supported by heavy state aid. Other winners since 1992 are steel tube producers in the East European countries where, in most cases, raw materials, energy and labour costs are subsidised.

#### Foreign trade

The EU's share of estimated world exports of steel tubes amounts to about 38 %, intra-EU trade included, or roughly 25 %, intra-EU trade excluded. Extra-EU exports of steel tubes have fluctuated since 1985, while extra-EU imports have generally increased in volume, leading to a declining trade balance. However, 1993 was an exception as weak consumption of steel tubes led to a 17 % decline in extra-EU imports.

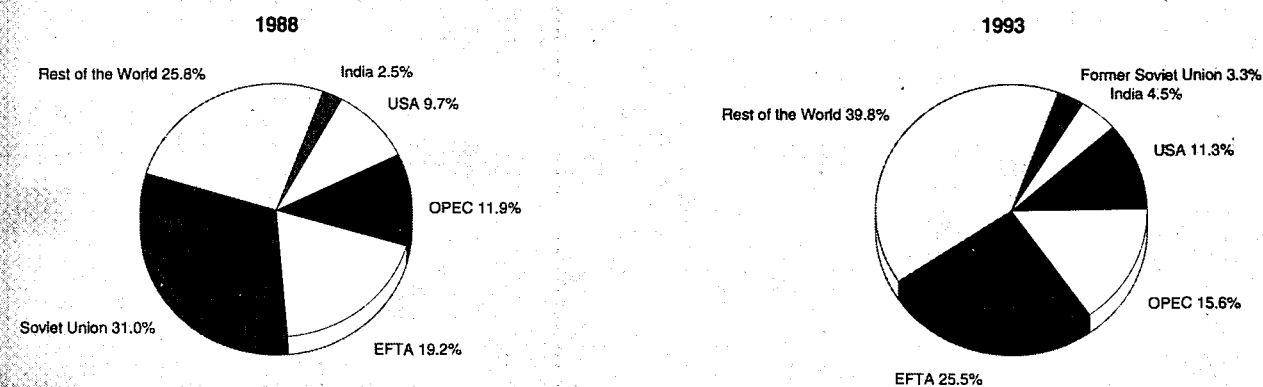

The list of countries receiving EU exports has changed considerably between 1988 and 1993. Exports to EFTA and OPEC countries rose 25 % during this period, while the former Soviet Union, which was a major export market, has reduced its share of EU exports from 31 % to only 3.3 %. EFTA countries remain the dominant suppliers to the EU steel tube market. However, over the last five years, there has been an 8 %

**Figure 4: Steel tubes**  
International comparison of production in volume

Source: ESTA

**Figure 5: Steel tubes  
Destination of EU exports**

Source: Eurostat

decrease in the share of EU imports coming from EFTA countries, while Central and East European countries have more than doubled their exports to the EU. Intra-EU trade is significant, but has shown a decline in 1992 and 1993. In value terms, it amounted to 68 % of total EU imports in 1993.

## MARKET FORCES

### Demand

The most important steel tube consuming sectors are: oil and gas exploration and extraction, transport of oil and gas by pipelines, nuclear and other steam generation industries, mechanical engineering, the automotive industry, structural steel work, the building industry and other metal processing industries. Due to economic developments in these sectors, apparent consumption of steel tubes in the EU rose by 30 % from 1984 to 1990, reaching 10.6 million tonnes. In the following years, however, consumption shrank due to lower investment activity in almost every steel tube consuming sector.

As from 1994, the automotive and mechanical engineering industries have registered growing order volumes, which have led to the expectation of higher consumption figures for steel tubes in 1994 and 1995.

At the same time though, export markets for EU mills have decreased. In 1984, 48.3 % of EU steel tube production was exported to third countries, while in 1993 this share was down to only 25 %. This decrease shows a serious fall in sales opportunities for the EU. The main reason for the reduction in extra-EU exports is the dramatic fall in orders from the former Soviet Union and other East European countries, caused by their lack of purchasing power. Another reason is the short-fall of orders from China as a consequence of their growing self-sufficiency for ordinary steel tubes.

### Supply and competition

Despite continuous labour and production cutbacks, the EU steel tube industry still suffers from world-wide over capacity. The effects on profit margins for commodity steel tubes are

**Table 6: Steel tubes

Origin of EU Imports**

Source: Eurostat

considerable; especially in export markets. Given the range of purchase possibilities world-wide and rising imports, customers are in a strong position to dictate price.

Internal competition within the EU is high. In 1993, intra-EU trade amounted to more than 2.6 million tonnes (with some figures still missing) or roughly 30 % of the consumption of steel tubes. In value terms, intra-EU imports for 1993 totalled 1 859 million ECU, about 31 % of consumption. This is an indication of the fact that there are very few trade barriers in the steel tube sector. Thus, further impacts of the EU single market are expected to be low.

EU competitiveness with respect to third countries, however, is threatened when imported steel tubes are subsidised in their production and/or are produced under non-market economy conditions.

### Production process

Technically, the EU steel tube industry is at the leading edge. Continued investment in research and development ensures high quality steel production and rolling processes. In most

**Figure 7: Steel tubes  
Trade intensities in volume**

Source: ESTA, Eurostat

EU steel tube production facilities, the quality assurance system is certified according to ISO 9001/9002. On-going rationalisation efforts, both in production and labour, have kept costs at a competitive level. In the period from 1984 to 1993, the number of employees in the steel tube industry dropped by 42 %. However, productivity increased by 23 % over the same period.

It should be noted that in many sectors of seamless and welded tubes different product categories are manufactured in the same mill, i.e. tubes of commercial grade, as well as, tubes of highly sophisticated quality. This means that installations need to be filled with a substantial base load of commodity products along with high added value grades to obtain a cost level which is competitive on the world market.

## INDUSTRY STRUCTURE

### Companies

The steel tube industry is a primary steel processing industry with a highly concentrated structure. Five countries, Germany, Italy, France, the United Kingdom and Spain, account for roughly 90 % of total production. In some countries, a single company can account for 50 % or more of national output. In addition to the major integrated steel tube manufacturers (mainly welded tubes), there are a relatively large number of small and medium-sized firms that are independent. Some manufacturers, often small in tonnage terms, operating in niche, high value-added markets, concentrate on the manufacture of special dimensions and grades of tubes according to particular customer specifications. At the end of 1993 there were 285 production units in the EU belonging to an estimated 245 enterprises. Of these, 67 specialise in cold drawing of seamless or welded tubes.

### Strategies

No significant investment has taken place in recent years due to reductions in capacity imposed by the difficulties in the market since 1985. Contrary to the early 1980s, when some investment was directed towards expanding capacity, current investments relate to improvements in productivity and quality.

In the past, companies and countries tended to either manufacture a full range of products or to specialise in niche markets. To strengthen the competitiveness of the industry, consideration is now being given to cross-border mergers and cooperation followed by capacity reductions.

### Impact of the Single Market

As for many sectors, the customs duties for steel tubes were reduced to zero on July 1st 1968. Starting slowly in the sixties, then accelerating, the interpenetration between the EC countries grew from year to year. Exports and imports within the Community reached a share of 40-50% of the market consumption. The free movement of goods within the EU was thus realised at least twenty years before the installation of the "Single market" on January 1st 1993.

The free movement of goods has by far been the most important aspect of European market integration. The other aspects have had less incidence on the situation of the sector. Some non-

tariff barriers have been abolished. Beside some other positive effects, there was also a negative effect in that the system for gathering data on trade between Member States from businesses (Intrastat) has created a situation of incomplete and late statistics. This makes it difficult to monitor developments in the industry.

### ENVIRONMENT

Costs arising from environmental protection legislation are considerable. To a large extent, costs of classical end-of-the-pipe measures, such as the treatment of emissions from raw material production units, reheating furnaces, noise control,

**Figure 8: Steel tubes**

Source: ESTA

and the treatment of waste water, can amount to as much as 50 ECU per tonne and average at least 1 % of turnover for EU firms. Waste reduction strategy is implemented more often in refurbishments or modifications of current production processes, procedures and feed stock than it is in the input/output balance. Heat usage and water saving measures, treatment of process liquids, recycling of materials and maximising yields are just a few of the measures used that follow the needs of "best available technology" (BAT). Additional costs, which at present cannot be estimated, arise from the installation of measures to maintain and boost confidence in an environmentally friendly industry. This also prevents site closures for environmental reasons. These measures are in line with the Community Eco Audit Regulation and the Regulation of Free Access to Environmental Information requirements. Steel and steel tube manufacturing enjoy the advantage that during the production process no toxic gases develop and waste material is immediately and completely recycled. Another environmentally sound characteristic of steel is that it can be entirely recycled without polluting the environment.

## REGULATIONS

Trade regulations are a key source of concern for EU steel tube producers. Trade barriers in several countries of the world hamper the penetration of EU exports. The reduction of non-tariff barriers was an important item in the framework of the GATT negotiations.

Harmonisation of EU standards in the sector is well-developed. Internal barriers have practically disappeared and thus do not impede the free circulation of goods among Member States. The EU steel tube market remains open for imports from third countries, provided they enter under fair trade conditions, however, they face strong competition from domestic suppliers and suppliers in other Member States. And, unfair trade practices will be countered by Antidumping and Countervailing procedures.

## OUTLOOK

After a decrease of 9.4 % in EU consumption of steel tubes in 1993, a 6 % recovery is expected in 1994. Production, after the 1992 and 1993 downturns of 10 % each, is estimated to pick up about 7 % in 1994. EU countries which are affected by heavy imports and lack of export opportunities suffer most from production cutbacks, which amounted to as much as to 25 % in 1993. Full recovery of the steel tube industry cannot be expected before mid-1995, brought about by stronger overall economic growth. Exports, however, will continue to decrease.

In the medium term, the development of the EU steel tube industry will be characterised by a number of risks and opportunities. The main risks are a continued increase of imports from Central and East European countries which could lead to further plant closures in the EU. Continued weak demand in the US market and an increase in the export activities of subsidised producers in third countries will also dampen export demand for EU steel tube manufacturers. A new development, however, is the change of export flows into the US market, which are now prevented by actual or threatened trade cases. These tonnages now are diverted to other markets in the world including the EU.

There are promising opportunities for the future, however. Economic recovery in the former Soviet Union and Central and East Europe could emerge more quickly, bringing larger export markets. An improvement in the world economic situation with related growth in demand from the energy industry will increase the order books of the steel tube mills. Finally, fair trade enforcement under confirmed GATT regulations will also support the industry's activity.

# First processing of steel

## NACE 223

After a period of growth from 1988 up to 1990, the production of the first processing of steel sector decreased. It was of 14 millions tonnes in 1993 against 15.5 million tonnes in 1990, the highest level of the period, but should have reached 14.6 million tonnes in 1994. Extra-EU exports have been increasing from 1988 to 1993 as well as extra-EU imports (except for 1993).

The exports/imports ratio in value has been decreasing from 1988 to 1992, and improved in 1993. The steady increase of imports from Eastern Europe is one of the major factors behind the deterioration of the export/import ratio. As a consequence of these trends and of intensified rationalisation measures, there has been a drop in employment of 10 000 workers during the period 1988 to 1994.

### INDUSTRY PROFILE

#### Description of the sector

Sector 223 of NACE is in fact just a part of first processing of steel. The manufacture of steel tubes (sector 222 of NACE) is also a first processing of steel activity but is considered separately in this publication.

Sector 223 includes the following subsectors:

- NACE 223.1: Cold drawing of steel bars
- NACE 223.2: Cold rolling of steel strip
- NACE 223.3: Cold forming of steel flat products
- NACE 223.4: Cold drawing of steel wire and manufacture of wire products.

The manufacture of cold drawn wire and wire products is the largest activity of the sector with a share of 58.5 % of production volume and 45 % of extra-EU exports in 1993.

#### Manufacturing process

Cold processing of hot rolled raw material is a common feature of the four subsectors: this processing method leads to more accuracy in size and mechanical properties, as well as improvement of the surface condition (except for cold forming) compared to products obtained in the hot mill. The products are mostly manufactured according to the requirements of each individual customer, something which is obviously not possible for the primary steel industry.

#### Classification in the Combined Nomenclature (C.N.)

Products covered here are classified in chapters 72 and 73 of the "C.N.". Except for cold rolled strip and cold formed wide sections, external trade statistics can be used for the calculation of apparent consumption. The problem for cold rolled strip is that strip produced by the cold rolling industry cannot be classified apart of the cold rolled products obtained by slitting of cold rolled sheet manufactured by the primary steel industry. Concerning cold formed sections, as production figures for wide sections are not available, consumption can only be calculated for long sections. Consequently, apparent consumption is not available for sector 223 as a whole.

#### Period covered

In order to have homogenous figures for external trade statistics, the period selected for the tables and figures begins in 1988, the year of enforcement of the C.N. based on the Harmonized System, which has replaced the previous Common

**Figure 1: First processing of steel**  
Value added in comparison with related industries, 1993

Source: DEBA

Custom's Tariff and Nimexe nomenclatures. Accordingly, the period 1988 to 1994 has been selected for all other statistical information.

#### Recent trends

In 1993, production in value was 14.7 % lower than in 1989 and 1990. In 1994, the production has increased by 9.8 % (see Table 3).

Production in volume decreased by 2.8 % in 1991, 1.2 % in 1992 and 6.2 % in 1993. For 1994, a 4.5 % growth was estimated. The trade balance has dropped by 20.7 % in 1991, 5.9 % in 1992. In 1993, there has been an increase of 31.5 % due to higher exports and lower imports (see Table 1).

Similarly to the primary steel and steel tube sectors, since 1990 production and employment in the first processing of steel sector have clearly lagged behind the growth in the manufacturing industry as a whole (see Figure 3). Labour productivity has been improving since 1988 except for 1993, while unit labour costs have increased year after year since 1988.

### International comparison

The available statistics of production in current prices (see Figure 4) show a slight difference between 1988 and 1993 for the EU while there were increases of 7.2 % for the USA and of 17.8 % for Japan. In 1994, there were increases of 9.8 % for the EU and 7.5 % for the USA, while for Japan there has been a decrease of 3.5 %.

EU production was 39.7 % that in the USA in 1988, against 33.2 % in 1994. As for Japan, EU production was by 12.6 % lower in 1988, against 15.4 % in 1994.

### Foreign trade

Extra-EU exports have been decreasing from 1989 up to 1992, while they increased by 9.7 % in 1993. Extra-EU imports have been increasing from 1988 up to 1992 (except in 1991). In 1993 they fell by 6.2 % against 1992. The trade balance has been decreasing from 1989 up to 1992 and increased by

12 % in 1993 (see Table 1). Accordingly, the exports/imports ratio has been decreasing until 1992 and has improved in 1993 (see Table 3).

Figure 6 shows slight changes in the destination of extra-EU exports except for the share of the former Soviet Union which has shrunk by 3.5 times over the 1988-93 period. As for extra-EU imports (see Figure 7), the share of Eastern Europe has almost doubled over the period under consideration.

## MARKET FORCES

### Demand

A wide variety of sectors are customers of the first processing of steel industries which are described below. In 1993, most users had to cope with recession. In 1994, there have been signs of recovery in users sectors.

### Supply and competition

In order to improve its competitiveness, during recent years the first processing of steel sector has been forced to cut its workforce. There has been a loss in employment of around 10 000 workers between 1988 and 1994.

With the slowdown of production, labour productivity has declined in 1993, but it increased by 5.8 % in 1994. The situation of overcapacity is still persistent in most producing countries. Capacity is estimated around 20 million tonnes.

Competition within the EU remained keen in recent years, but intra-EU imports which were of 4.8 million tonnes in 1992, dropped to 4.1 million tonnes in 1993.

Imports from third countries have been increasing since 1988, growing from 1 million tonnes up to 1.3 million tonnes in 1992 corresponding to 0.9 million ECU and 1.1 million ECU respectively. However, extra-EU imports dropped by 2.9 % in volume and 6.2 % in value in 1993. The three new Member States accounted in 1993 for the following quantities of EU-12 imports: 237 thousand tonnes for Austria, 169 thousand tonnes for Sweden, 55 thousand tonnes for Finland.

Imports from East Europe were in 1993 86 % higher than in 1988. The quantities have been of 202 thousand tonnes in 1988, against 376 thousand tonnes in 1993. They corresponded to 19.4 % of total extra-EU imports in 1988, 28.7 % in 1992,

**Figure 4: First processing of steel  
International comparison of production in current prices**

Source: DEBA

**Figure 5: First processing of steel**  
International comparison of production in constant prices

Source: DEBA

15.2 % in 1993. The average prices of this group of countries have been very low compared to the average prices of intra-EU imports and of third countries other than East European. In 1993, the Czech Republic was the most important competitor with 180 thousand tonnes, followed by Slovakia with 87 thousand tonnes, Poland with 70 thousand tonnes, Hungary with 22 thousand tonnes. The other main competitors in 1993 were South Africa with 39 thousand tonnes, Japan with 38 thousand tonnes, Russia with 37 thousand tonnes, Slovenia with 26 thousand tonnes, the USA with 25 thousand tonnes, China with 18 thousand tonnes, India with 14 thousand tonnes, South Korea with 13 thousand tonnes.

## INDUSTRY STRUCTURE

### Companies

The number of companies declined from 990 in 1988 to 910 in 1994 due to the closing of redundant installations. The situation at the end of 1994 was the following: Germany 301, Italy 222, France 125 Spain 116, the UK 90, Benelux 45, Denmark 7, Portugal 2, Greece 2. Among the biggest com-

panies, some are integrated to the steel industry, the others are independent and mostly small-size specialised companies.

### Strategies

In contrast to the major firms in the primary steel industry and the steel tube industry, mergers, acquisitions, alliances and cooperation are a less suitable strategy for the medium and small size companies of the first processing of steel sector.

The emphasis will continue to be placed on investments to achieve productivity gains. In addition, the trend towards specialisation will intensify. This applies also with regard to the completion of the Single Market. The introduction of the Single Market has had only relatively minor effects on the sector, given that trade among the various Member States was hardly hindered in the years previously to 1993.

As said above, products exchanged within the EU amounted to 4.1 million tonnes in 1993 which is considerable compared to the total deliveries on the EU market which amounted to 11.7 million tonnes. Due to comparable production techniques in all Member States and harmonisation of Standards published by the National Standardization Organizations, the quality of these products is consistent.

### Impact of the Single Market

As far as circulation of goods is concerned, the Single Market was born on July 1st 1968 with the abolition of custom's duties on trade between the Six Member States which founded the EEC. Since then, internal trade has been growing year after year. The date of January 1st 1993 marked the beginning of a new stage in the development of the Single Market, particularly with the free circulation of goods, services and capital.

Improved circulation of products across the EU and possibly reductions in costs could be achieved through the adoption of European Standards harmonising the technical specifications, or through changes in the organisation of the common commercial policy. In particular, several branches of the Sector consider that the commercial defence instruments may be strengthened. As the internal market becomes reality, there will be a further increase in the number of cross-border ventures in this sector.

One area in which the Internal Market programme may not have had a positive effect is the availability of valuable and up to date statistics making it possible to monitor developments in the sector.

(1) European Committee estimates.

Source: Eurostat, European Committee

The elimination of controls at internal frontiers has axed the Single Administrative Document and made compulsory a new system for gathering data on the Trade between Member States (Intrastat) based on direct monthly return from businesses. The new system is, however, not yet satisfactory. For different reasons, figures published are not complete nor timely. The revision of NACE and the introduction of Prodcod will, however, substantially improve the knowledge on the production and activity of the First Processing of Steel Industries, for the two systems are to cover at least 90% of each sector in the Member States.

### REGIONAL DISTRIBUTION

The majority of the mills is concentrated in the highly industrialised regions: Ruhr district, Northern part of Italy, East and North of France, North East of Spain, West and South Midlands in the United Kingdom.

### ENVIRONMENT

Costs arising from environmental protection are significant in the first processing of steel sector. They are, to a large extent, due to costs incurred in the treatment of smoke emissions from reheating furnaces, treatment of waste water from the pickling installations where they still exist and noise control in the production units.

### REGULATIONS

Trade regulations are a key concern for the EU producers of steel and articles of steel. Up to the end of March 1992, the Voluntary Restraint Agreements (VRA) provided for quotas by group of products for exports to the USA. Since then, trade barriers have hampered the penetration of EU exports into the USA.

Different versions of a draft of "Multilateral Agreement on Steel Liberalization" have been subjected to negotiations between steel producing members of the former GATT, particularly the USA, EU Member States and other partners who were subject to a VRA. A number of meetings have been

held on the matter in Geneva on a multilateral basis or in Washington on a bilateral basis but it has still not been possible to solve the dispute.

### OUTLOOK

Economical recovery in the CIS and East Europe will progressively give the possibility of a development of foreign trade with these countries. In the meantime, imports from East Europe will certainly continue to increase.

As long as there are no clear rules to regulate the exports to the USA, the EU Members States will have all kind of difficulties to sell their products in this country.

Since January 1st 1995, the GATT has been replaced by the World Trade Organisation. This new body will have to implement the final agreement of the Uruguay Round. This should lead to intensification of foreign trade in the world and to higher industrial activity.

On January 1st, 1995 as well, Sweden, Finland and Austria have joined the EU. If the imports into the EU of these three countries were added to intra-EU imports for 1993, the results would have been 4.6 million tonnes corresponding to 3.8 million of ECU against 4.1 million tonnes and 3.3 million ECU for the twelve Member States.

## Cold drawing of steel bars NACE 223.1

### INDUSTRY PROFILE

#### Manufacturing process

Cold drawing concerns the manufacture of steel bars or sections by cold drawing, grinding or peeling of hot rolled steel bars into so-called Bright steel bars, having the form and characteristics required by the users. The finished product has tight tolerances, accurate mechanical properties and a high quality surface. Improved quality surface conditions and closer tolerances can be achieved by additional grinding and pol-

ishing. Cold finishing during drawing operations hardens and increases the tensile strength of the steel, while at the same time reducing the ductility, which may require an annealing treatment of the product after drawing. Bright steel bars are mainly of circular, square rectangular or hexagonal section, but all kinds of sections can be produced according to demand. They are delivered in fixed length.

### Products manufactured

The subsector manufactures the following products: non alloy steel bars of free cutting steel and carbon steel bars; stainless steel bars; alloy steel bars of different grades including high speed steel and other tool steel and shapes and sections of different grades of steel. All these products meet the specifications of each individual user.

### Recent trends

Production has decreased by 10.2 % in 1993. Comparing 1993 with 1989, the decrease has been of 24.8 %. An increase of 10.6. % was estimated for 1994. Apparent consumption has decreased similarly to production from 1991 to 1993. Extra-EU exports have decreased since 1989, but increased by 23.9 % in 1993, due to growing demand from the USA, leading to a trade balance increase of 57.4 %.

### International comparison

The statistical yearbook published by the International Iron and Steel Institute (IISI) gives figure showing that besides the EU, the major producing countries of cold finished bars are the USA and Japan. The evolution since 1988 is shown in Table 6.

### Foreign trade

There have been some changes in the destination of extra-EU exports in value. The share of Eastern Europe decreased from 5.7 % to 3.9 %. For the USA, the share in 1993 was of 32.4 % against 26.7 % in 1988.

Extra-EU exports to the USA have been of 86 thousand tonnes in 1988, against 107 thousand tonnes in 1993.

There have also been changes in the origin of extra-EU imports. The share of East Europe has almost doubled with 11.7 % in 1993 against 6 % in 1988.

### MARKET FORCES

#### Demand

Bright steel bars are used by industries such as manufacture of motor vehicles, machinery, electrical goods and other industries, where a high quality basic material is compulsory.

#### Supply and competition

The loss in employment was of around 800 workers from 1988 to 1994. Labour productivity has decreased since 1990 by 22.3 %. It should have increased by 10.6. % in 1994. Production capacity was around 4 million tonnes in 1993 compared to a production of around 2 million tonnes.

Intra-EU imports amounted to 490 thousand tonnes against 596 thousand tonnes in 1988. After strong increases in 1989 and 1990, extra-EU imports have decreased, albeit at a slow pace.

(1) European Committee estimates.  
Source: Eurostat, European Committee

### Technological progress

There has been steady progress in processes used to manufacture bright steel bars, mainly with the introduction of computers in the production lines, in order to meet the demand of users for even higher quality finished products. The methods used keep gauge, mechanical properties and surface condition under much stricter control.

### INDUSTRY STRUCTURE

#### Companies

The number of companies declined from 162 in 1988 to 141 in 1992. The situation at the end of 1994 was the following: 51 in Germany, 20 in France, 25 in Italy, 26 in Spain, 16 in the United Kingdom, 1 in Denmark, 1 in Portugal, 1 in Belgium.

### ENVIRONMENT

An innovation in this field has been the substitution of pickling by shotblasting in the de-scaling of raw material. This has eliminated problems of discharging acid pickling tank contents into local waterways. This industry has no major problems of acoustic pollution.

## Cold rolling of steel strip NACE 223.2

### INDUSTRY PROFILE

#### Manufacturing process

Cold rolling of steel strip is a process in which pickled flat hot rolled steel products are rolled between polished cylinders. The dimensions of the finished product are of less than 600 mm in width and 0.025 mm up to 12.5 mm in wall thickness.

In the wall thickness range of 0.3 mm up to 3 mm, other flat cold rolled steel products can be obtained by slitting coils of large cold rolled sheet manufactured by the primary steel industry. This operation is done either by the primary steel industry itself or by distributors of steel products.

Rerolling gives a high quality product with consistent dimensional and internal characteristics. The equipment used to roll, anneal, slit, edge and heat treat cold rolled steel strip is highly capable of producing an unique product when compared to large cold rolled sheet mills found in all integrated steel plants throughout the world.

The specialised rolling mills and processing equipment used allow to meet all the different requirements of each individual customer; mainly close tolerances, special forming capabilities

and special finishes (surface edges, coating, for instance) which are not possible for the primary steel industry.

#### Products manufactured

The subsector manufactures the following products: steel strip of a carbon content up to 1.25 %, including rolled or blue strip for packaging; steel strip coated with zinc, tin, lead, copper, nickel or with paint, varnish or plastic, printed on request; clad steel strip; quenchable or quenched steel strip; stainless steel and other alloy steel strip.

#### Recent trends

Production has decreased by 11.6 % in 1993. Comparing 1993 and 1988, there has been a decrease of 20.3 %. An increase of 5.1 % was estimated for 1994. Extra-EU exports have been decreasing from 1988 until 1991. In 1992, there was an increase of 8.8 %, in 1993 of 2.6 %. Nevertheless, the level of 1993 was 7.8 % under 1988. For extra-EU imports, there has been a continuous increase from 1989 up to 1992 while they stagnated at a similar level in 1993.

#### Foreign trade

There have been some changes in the destination of extra-EU exports in value between 1988 and 1993. The share of East Europe grew from 4.5 % to 6 %, while the share of the former Soviet Union fell to 1.3 % from 9.1 %. There was an increase for the USA, 14.7 % against 12.2 % in 1988. China, which was at 6 %, fell to 1.4 %, while Hong Kong which was at 1.8 % reached 4.4 %.

For extra-EU imports, the share of Eastern Europe increased from 2 % to 5.5 %, while the USA grew from 6.8 % to 10.2 %.

### MARKET FORCES

#### Demand

Cold rolled steel strip is used for the manufacturing of automotive parts, hardware, office equipment, fasteners, bearings, chains, tubes and many other products, whenever a high quality basic material is compulsory.

The most important consuming sectors are the manufacture of motor vehicles and other transport equipment including bicycles, which account for more than half of the demand.

#### Supply and competition

The loss in employment was of around 1 200 workers between 1988 and 1994; nevertheless, labour productivity has decreased by 16.2 % between 1988 and 1993. It was expected to increase by 5.8 % in 1994. Capacity was around 4.3 million tonnes compared to a production of 2.6 million tonnes in 1993.

Intra EU imports amounted to 1 535 thousand tonnes in 1988, against 1 501 thousand tonnes in 1993.

Total extra-EU imports increased year after year between 1989 and 1992 but decreased slightly in 1993. Imports from Austria

**Table 9: Cold drawing of steel and manufacture of wire products of steel****Main indicators**

(thousand tonnes)	1988	1989	1990	1991	1992	1993	1994 (1)

*(1) European Committee estimates.**Source: Eurostat, European Committee*

were of 114 thousand tonnes, imports from Sweden 91 thousand tonnes. Imports from the Czech Republic were of 18 thousand tonnes in 1993, 35 thousand tonnes from Slovakia. Other imports in 1993 mainly came from Japan with 18 thousand tonnes and the USA with 17 thousand tonnes.

**Technological progress**

In the 1960s, an important technological innovation was brought on by the multi-cylinder rolling mills and particularly the so-called Sendzimir mill, which allowed rolling of wall thicknesses under 0.20 mm and as low as 0.025 mm. Since then numerous technological innovations have been made, e.g. the introduction of computers in the processing lines which keep gauge, mechanical properties and rolling speed under much stricter control.

**INDUSTRY STRUCTURE****Companies**

The number of companies declined from 164 in 1989 to 155 in 1994: the situation at the end of 1992 was of 64 in Germany, 32 in Italy, 18 in the United Kingdom, 15 in Belgium/Luxembourg, 13 in France, 11 in Spain, 1 in Portugal, 1 in The Netherlands.

**ENVIRONMENT**

Pickling installations have disappeared from the factories in many cases because coils ordered from the steel industry are delivered pickled and protected. In the coating installations, it is necessary to aspirate smokes especially when strip receives a metallic coating. Today, smoke aspiration is also necessary for annealing processes. As for acoustic pollution problems, cold rolling mills are not noisy except when charging the coil in the rolling mill.

**Cold forming of steel flat products NACE 223.3****INDUSTRY PROFILE****Manufacturing process**

Cold forming concerns the manufacture of open sections of steel by progressive forming on a roll mill or folding on a press of hot rolled de-scaled flat products of steel or cold rolled coated flat products of steel. Cold forming is a continuous process which allows the manufacture of big quantities of simple or complex forms. Cold folding is generally used to obtain sections of simple forms in small quantities. Compared to the simple form sections produced on the hot mill, cold formed sections are more accurate in size.

**Products manufactured**

The subsector covers two production areas:

- Long sections: standard sections such as L, C, U, Omega and Z and products for specific uses of complex form according to the requirements of each individual customer;
- Wide sections for building purposes coated with zinc, paint, varnish or plastic, such as sandwich panels, corrugated sheet, profiled sheet and safety barriers.

All these products are mainly of non alloy steel with a content of carbon up to 0.25 % but can also be of stainless or of other alloy steel.

**Recent trends**

Production of long sections decreased by 8.6 % in 1993, and it was estimated to have increased by 7.5 % in 1994. Apparent consumption followed a similar pattern of production. For extra-EU exports, there has been an increase of 12.9 % in 1993, due mainly to increased supply to China. Imports are generally higher than exports in this sector. Imports increased until 1992, while there has been a drop of 22.7 % in 1993 due mainly to lower demand from Eastern Europe.

**Foreign trade**

Extra-EU exports and imports are less important for this subsector than for the other subsectors of first processing of steel. As for exports, the share of Eastern Europe grew from 2.7 % to 7 %. In 1993, the share of China was suddenly of 5.9 %.

As for imports, the share of Eastern Europe, which was of 0.6 % in 1984, reached 13.3 % in 1993.

**MARKET FORCES****Demand**

Cold formed sections are used by sectors such as building, civil engineering and transport equipment, mainly for safety barriers for the highways, sheet piling and manufacture of trucks, railway rolling stock and furniture.

A fact of increasing importance is backward integration by certain users, who at present produce themselves the sections they need. A significant example of this kind of development is provided by the sector specialised in storage equipment.

**Supply and competition**

The loss of employment was of around 1 600 workers from 1988 to 1993. An increase of 300 people may have occurred in 1994. Labour productivity has been improving during the years 1988 to 1992. There has been a decrease of 3.1 % in 1993 but a 4.3 % increase was estimated for 1994.

Intra-EU imports have been of around 200 thousand tonnes for the years 1988 to 1990, but fell to 147 in 1993. Extra-EU imports have been very volatile during recent years: for Eastern Europe they were of 11 thousand tonnes in 1988. They more or less doubled in 1989 and 1990 and were five times higher in 1991 and 1992 with 47 thousand tonnes and 51 thousand tonnes, but fell to 29 thousand tonnes in 1993. Imports from South Africa were of 15 thousand tonnes in 1988 and 1989, they decreased progressively the years after to fall to less than 1 thousand tonnes in 1993.

### Technological progress

One of the main technological innovations has been the automatic machining of forming rolls. The automatic conditioning of products before shipment is also to be mentioned.

---

## INDUSTRY STRUCTURE

---

### Companies

The number of companies was of 136 at the end of 1994: 28 in Spain, 26 in the United Kingdom, 25 in Germany, 25 in Italy, 20 in France, 5 in The Netherlands, 4 in Denmark, 3 in Belgium/Luxembourg.

---

## ENVIRONMENT

---

Pickling installations have disappeared from the factories because coils ordered to the steel industry are delivered pickled and protected. Previously used acid waters were rejected from the pickling tanks in the rivers or the lakes. This industry does not produce acoustic pollution, except when charging the coils in the forming mill.

## Cold drawing of steel wire and manufacture of wire products NACE 223.4

---

## INDUSTRY PROFILE

---

### Manufacturing process

Wire drawing is an operation which consists in cold stretching hot rolled wire rod, through a die, with a form corresponding to the cross-section of the finished product. The mechanical properties of the hot raw material must be appropriate in order to have sufficient ductility to pull it through the die. After this operation, the hardness and tensile strength of the wire becomes higher and may require an annealing after drawing. In some cases a parentage heat treatment is required. The finished products have tight tolerances, accurate mechanical properties and a smooth surface. Their cross-section may be circular, flat with rounded edges, rectangular, hexagonal, triangular, oval, semi-circular etc.

### Products manufactured

The subsector covers two fields of activity:

- Drawn wire: mild steel wire with a carbon content up to 0,25 % and hard steel with a carbon content of over 0,25 % stainless and other alloy steel wire. Non alloy steel wire is delivered uncoated or coated with zinc, copper, tin, nickel, chrome, plastic, varnish or other materials.
- Wire products: strand and ropes, heavy welded mesh, plaited bands; barbed wire, wire fencing, grill, netting; welded link chains, hooks, springs, nails, etc.

### Recent trends

Apparent consumption has been increasing steadily year after year from 1988 up to 1992, but decreased by 4.6 % in 1993. The growth of production was similar until 1992 but the drop

for 1993 was of 2.9 %. An increase of 2.4 % was estimated for 1994.

Extra-EU exports have decreased from 1989 up to 1992. In 1993, they increased by 11.8 % due to shipments to the USA and to Far East countries. Extra-EU imports increased year after year from 1988 up to 1992, while they dropped by 3 % in 1993. As a consequence, the trade balance improved by 39.2 % in 1993 while it had been decreasing since 1988.

### Foreign trade

The main changes in the destination of extra-EU exports in value have been for the USA (21 % in 1993 against 25.3 % in 1988), and for the Far East (10.3 % against 5.1 %).

The main changes in the origin of the extra-EU imports in value have been an increase for Eastern Europe (18.8 % in 1993 against 13 % in 1988), and for Japan (8 % against 4.9 %).

---

## MARKET FORCES

---

### Demand

Drawn wire and wire products are used by the construction of buildings and civil engineering sectors, the manufacture of motor vehicles, of machinery, of fasteners, screw machine products, chains and springs and furniture sectors, agriculture and telecommunications.

### Supply and competition

The loss in employment was of 5 700 workers from 1988 to 1994. Labour productivity has been improving year after year. It was 12 % higher in 1993 than in 1988. A new increase of 4.5 % was estimated in 1994.

Intra-EU imports dropped to 1 820 thousand tonnes in 1993, against 2 170 in 1992 and 1 864 in 1988.

The main competitors in 1993 were the Czech Republic with 128 thousand tonnes, Slovakia with 52 thousand tonnes, Poland with 48 thousand tonnes, South Africa with 35 thousand tonnes, Switzerland with 29 thousand tonnes.

### Technological progress

What is said about cold drawing (223.1) on the introduction of computer-aided manufacturing techniques in the production lines can be applied to wire drawing.

---

## INDUSTRY STRUCTURE

---

### Companies

The number of companies declined from 529 in 1988 to 480 in 1994. The situation at the end of 1994 was in Germany 161, in Italy 140, in France 72, in Spain 51, in the United Kingdom 30, in The Netherlands 7, in Belgium/Luxembourg 13, in Greece 2, in Denmark 2, in Portugal 2.

### Strategies

A number of mergers and restructurings have taken place since 1988, especially in and among major steel producing group subsidiaries. Besides these efforts to improve productivity, a tendency to rationalise and specialise production has been spreading among the main European wire-drawing and wire products companies concerned.

---

## ENVIRONMENT

---

Pickling installations have disappeared from most factories because the hot rolled wire ordered to the steel industry is delivered pickled and protected. In the coating installation, it is necessary to use fume extractors especially when applying metallic coatings.

## Overview NACE 224

The EU non-ferrous metals industry employed just under 300 000 people at some 3 000 industrial units in 1993. Having very few mining resources at its disposal, the EU is responsible for less than 3 % of the mining production of the market economy countries for aluminium, copper, zinc and lead. Nevertheless, in refined metal production the EU is a leader among the market economy countries with 21 % of refined metal output of the four major non-ferrous metals (Al, Cu, Zn and Pb). EU consumption of these same metals is even higher, representing nearly 30 % of market economy countries' demand.

The EU non-ferrous metals industry is a net importer of raw materials: ores, concentrates and other raw materials for refining, and unwrought metals for processing. It also highly dependent on secondary materials (scrap and residue), which constitute the only "domestic" resource of major size in the EU. In purchasing the raw materials which are necessary for its supplies, and, to a lesser extent, in selling its products outside the EU borders, the EU non-ferrous metals industry is very much present on the international market, and is subject to its price fluctuations.

### INDUSTRY PROFILE

#### Description of the sector

The EU non-ferrous metals industry is widely diversified in terms of metals which are produced or processed. These include the major non-ferrous metals aluminium (Al), copper (Cu), zinc (Zn) and lead (Pb) - but also the precious metals gold (Au), silver (Ag), platinum (Pt), palladium (Pd) and rhodium (Rh); and the alloying metals and other minor non-ferrous metals molybdenum, vanadium, tungsten, manganese, cobalt, germanium, cadmium, etc. In view of the fact that the EU is relatively poor in mining resources, its industry is largely dependent on primary raw materials imports, and also finds a significant proportion of its supplies in secondary materials (scrap and residue). It is consequently geared to primary and secondary smelting, and refining metallurgy, and to processing.

The most important consumer markets for the EU non-ferrous metals industry are within the EU itself, but outlets have also been found beyond EU borders. The industry is therefore involved in the international non-ferrous metals market, not only as a purchaser of raw materials, but also as a supplier of metals and processed or speciality products. In both these respects, it is extremely sensitive to the world balance of markets and to their cyclic developments, which are often irregular. The EU non-ferrous metals industry operates in a highly competitive environment and is supported by long years of technological expertise making it the world leader in various segments of its activities.

### MARKET FORCES

#### Supply and demand

In terms of volume produced, aluminium, copper, zinc and lead are the dominant metals of the EU non-ferrous metals industry.

In the aluminium sector, EU production hovers between 3.5 and 4 million tonnes of metal per year, which is equivalent

**Figure 1: Refined metals  
Production and consumption, 1993**

(1) Consumption estimated.  
Source: EAA and OEA (aluminium), World Bureau of Metal Statistics (copper), International Lead and Zinc Study Group (zinc and lead)

to about 65 % of EU demand. This represents only 16 % of world production, however.

The aluminium industry is facing two serious problems: the recent massive increase in exports of metal from the CIS and the ongoing tendency to move production units to geographic zones where energy (an important cost component) is both abundant and inexpensive.

The EU zinc industry produces about 1.8 million tonnes of metal per year. Such an output represents 26 % of world production and slightly exceeds EU market demand. The industry's major problem is unquestionably how to manage the long cycles which affect its market, with a certain degree of inertia in the adjustment of supply to demand.

## INDUSTRY STRUCTURE

### Companies

The EU non-ferrous metals industry comprises about 3 000 companies, most of which are active in the processing sector. The upstream sectors of primary and secondary smelting and refining metallurgy are more concentrated.

Of the four basic non-ferrous metals - aluminium, zinc, copper and lead - the activities of the primary aluminium industry are most strongly integrated.

In 1993, Germany accounted for 29 % of the total EU refinery output of the four major non-ferrous metals, compared with 16 % accounted for by France. Italy, Spain and the United Kingdom follow closely with 13 % each, while Belgium and the Netherlands trail behind. The breakdown of semis production by country confirms the leading position of Germany with about 33 % of the total EU copper and aluminium semis output, followed by Italy and France.

### Strategies

Recycling is an important feature of the EU non-ferrous metals industry. "Secondary" materials, i.e. recyclable scrap and residue constitute an essential input for many of its metallurgical and processing concerns. Some of the latter's supplies depend entirely on access to secondary materials, although, for most of the producers, recourse to secondary materials goes together with primary raw materials supplies for both economic and technical reasons.

As a result of the scarcity of European mining reserves, the EU non-ferrous metals industry has naturally developed much expertise in the processing of secondary materials. Recycling has therefore traditionally enabled the industry to reduce its dependence on raw materials imports by making use of the "surface" resources generated by the consumption of goods (old scrap) and by the industry itself (new scrap and metallurgical residue). Considerable investments are devoted to recycling, in terms of research, equipment and human resources, to such an extent that recycling is at the root of more than 50 % of total EU production of the four major non-ferrous metals (aluminium, copper, zinc and lead), and accounts for more than 35 % of their consumption in the EU.

### Impact of the Single Market

The legislative measures taken as part of the Internal Market programme had a globally positive impact the non-ferrous metals sector. Most relevant to this sector were the measures related to the harmonisation of business conditions across the EU. Differences across Member States in energy prices, taxation and environmental and safety regulations indeed distort competition between producers in different countries, not only in the non-ferrous metals industry but also in most other sectors. These distortions have been reduced, but not yet entirely removed, by convergent EU legislation.

Particularly relevant to the non-ferrous metals industry in view of the completion of the Internal Market are measures aimed at liberalising electricity markets, the harmonisation of VAT rates and the harmonisation of regulations concerning transborder movement of waste. In contrast, the removal of technical barriers to intra-EU trade is not particularly relevant to this sector. The output of the non-ferrous metals sector is largely composed of standardised products, for which there are no non-tariff barriers to trade.

## ENVIRONMENT

More than ever, environmental concerns are impelling the EU non-ferrous metals industry to keep abreast of innovation in the recycling sector. The upgrading and processing of scrap and metallurgical residue are contributing to the protection of the environment, reducing the need for disposal capacities

**Figure 3: Copper semis  
Breakdown of production by Member State, 1993**

Source: IWCC

In the copper sector, the EU produces about 1.3 million tonnes of metal each year. As the EU is the largest consumer market in the world, this production volume barely reaches about 45 % of its requirements. To lessen its dependence on imported copper raw materials, the EU industry has considerably developed recycling technologies, and is therefore able to secure a significant amount of its supplies from scrap and residue within the EU itself.

Producing about 1.4 million tonnes of metal per year (one quarter of world production), the EU lead industry is able, for the most part, to satisfy the requirements of its domestic market. The industry is experiencing problems due to inherent properties of the metal, the use of which, particularly in "diffuse" applications, is tending to decrease due to constraints connected with the environment. With this in view, the car battery sector is the only consumer industry capable of offsetting the losses of consumption in the other sectors, and increased recycling will further boost the share of secondary lead in the industry's supplies (more than 50 %).

**Figure 4: Refined metals (aluminium, copper, lead, zinc)  
Breakdown of production by Member State, 1993**

Source: World Bureau of Metal Statistics (copper), ILZSG (lead, zinc), EAA and OEA (aluminium)

and dependence on non-renewable natural resources, and allowing considerable energy savings in the extraction and processing of metals (from 60 % for copper to 90 % for aluminium).

EU environmental policy emphasises integrated pollution control. Many of the issues related to the protection of the environment are of direct relevance to the non-ferrous metals industry.

Several draft legislations currently being drawn up by the EU in the field of industrial pollution are based on the concept of "Best Available Techniques". This approach increases the need to analyse in an integrated way the impact of an activity on the whole environment taking into account the whole life-cycle of a product and managing the specific risks accordingly at each individual stage. Legislation on hazardous products is developing in such a way as to take into account the conditions of exposure over and above the intrinsic properties of products, which is a positive trend when it comes to assessing the real impact of heavy metals.

Waste management also raises difficult questions of direct relevance to the non-ferrous metals industry. A clear definition of what is to be understood by waste, as opposed to product or by-product, and a legislation on the management and the control of movements of wastes are critical for the non-ferrous metals sector as non-ferrous scrap and residue are used as feed materials by the sector and are traded extensively on the international market. A competitive recycling industry and considerable energy-saving potential could be affected by limits on this trade.

Additional measures are under discussion concerning waste incineration and landfills. This is another area which could entail a large number of adjustments for the industry. Finally, the new directive on packaging waste will also have implications for the non-ferrous metals industry.

---

## OUTLOOK

---

During the 1990s, the industry will have to face two major problems. The first is the opening-up of the economies of Central and Eastern Europe and the CIS, which have greatly increased their exports of raw materials; consequently, the full weight of these changes is being borne first and foremost by the EU non-ferrous metals industry, which is closest to the CIS.

The sudden, massive development of exports from former COMECON countries on the international market, particularly on the EU market, is throwing the cyclic adjustments between supply and demand structurally off balance and jeopardising the very survival of companies.

In the case of aluminium for instance, the export level of the CIS has dramatically increased from some 300 000 tonnes per year in 1990 to nearly 2 million tonnes in 1993. In the case of zinc the CIS has become a net exporter whilst it was previously an importer.

These radical changes in trade flows have resulted in an unprecedented piling of stocks on the London Metal Exchange, both for aluminium and zinc, thereby pushing the metal quotations down to historically very low levels.

In the case of non-ferrous metals semis, the countries of Central and Eastern Europe are exporting increasing tonnage at lower than prevailing market prices, fostering a severe downward pressure on the industry's revenues.

In view of these developments, it is vital to make every effort to ensure that the liberalisation of trade develops on a more harmonious basis, which does not disrupt the international markets; this is to be done, among other things, by a greater control of the trade flows, by adapting product quality to international standards, by diversifying outlets and by taking into account the free-market mechanisms in which this trade will henceforth be conducted.

The second major challenge of the non-ferrous metal industry for the 1990s is the mushrooming legislation relating directly or indirectly to environment protection, the development and effects of which ought to be managed not only with a view to maintaining the access to a whole range of raw materials (secondary materials) but also to maintaining future development of the non-ferrous metals uses.

The industry is represented at the EU level by: **Association Européenne des Métaux (Eurométaux)**. Address: Avenue de Broqueville 12, B-1150 Brussels; tel: (32 2) 775 6311; fax (32 2) 779 0523.

# Aluminium

## NACE 224

The aluminium market is currently facing the emergence of the CIS industry onto the international scene; this is taking the form of massive exports from the former Soviet Union, throwing the cyclic adjustments between supply and demand off balance and causing an unprecedented accumulation of stocks. The European Union has been particularly affected by this phenomenon, being the closest market outlet for CIS producers. However, the industry can count on sound fundamentals to overcome the current difficulties: there is room for structural growth of demand from the major consumer industries (transportation, packaging, construction), and the producers are continuously improving and rationalising their installations with a view to higher productivity and environmentally-sound production process.

### INDUSTRY PROFILE

#### Description of the sector

The aluminium industry is the largest of the non-ferrous metal industries, and is the youngest as well in that aluminium smelting only began about a century ago. Lightness, longevity, resistance to corrosion, electrical and thermal conductivity and reflectivity make aluminium a popular choice in many sectors of the economy. Its aesthetic qualities, alloy possibilities and easy recyclability all add to this appeal.

The aluminium industry encompasses several activity segments, from bauxite mining and alumina production to primary and secondary smelting and metal processing into semi-finished products (bars, profiles, wires, sheets, foils, tubes, pipes,...) or specialty products (powders, special alloys,...).

As far as the major EU metal producers are concerned, those activities are to a large extent integrated, but a number of EU manufacturers are focusing their activity on one particular segment only, such as recycling and secondary smelting or semis fabrication.

#### Recent trends

The EU aluminium industry directly represents a workforce of about 200 000 people and its annual turnover is in the order of 20 billion ECU. Total production of unwrought metal amounted to 3.6 million tonnes in 1993, a 5 % decrease from the 1992 figure. About 42 % of this output is accounted for by secondary production, i.e. the recycling of scrap, which has been constantly growing.

The EU consumer market for aluminium exceeds domestic supply. Posting 5.7 million tonnes in 1992, demand has dropped by about 6 % in 1993 due to the poor economic climate. The market enjoys a rising trend of approximately 2.5 % per year in the long term; there are, however, ups and downs in relation with the business cycle fluctuations.

#### International comparison

In terms of primary metal production, the EU accounted for 14 % of the market economy countries' total production in 1993, ranking third to the USA and Canada. On the other hand, secondary production in the EU is the highest in the world. Hovering at about 1.5 million tonnes in 1993, it represented 42 % of the market economy countries' total.

Regarding the production of semis in 1993, the EU was responsible for approximately one-third of the market economies' output of rolled and drawn products, wires, cables and castings, with a 5.2 million tonnes production.

Figure 1: Refined metals  
Production and consumption, 1993 (1)

(1) Consumption estimated.

Source: EAA and OEA (aluminium), World Bureau of Metal Statistics (copper), International Lead and Zinc Study Group (zinc and lead)

Supply requirements of the EU primary and secondary metal producers are largely met by domestic alumina production and scrap recycling, but the total metal output falls short of the processing industry needs: it meets only 55 % of the EU demand, which is rising, while there has been hardly any net growth of metal production capacity during the past years.

#### Foreign trade

As a result of the deficit in metal production capacity versus semis production capacity, the EU is a regular importer of unwrought aluminium. The EFTA countries traditionally accounted for about 45 to 50 % of EU imports, with Brazil, Africa and Canada making up another 25 % at least. Imports from the CIS, however, have made sharp inroads since 1991, increasing from about 60 000 tonnes per year in the late 1980s to 576 000 tonnes in 1993 and pushing back the share of the traditional major suppliers to 63 % of total imports, or 1.88 million tonnes.

This phenomenon not only affected the import picture regarding the sourcing of the metal, but it also had a major impact on the overall market balance. The sudden and massive aluminium export flow originating from the CIS created a huge surplus which resulted in soaring inventories on the London Metal Exchange (LME) and unprecedented price collapse.

Regarding trade of semi-finished aluminium products, the EU used to be a net exporter for a long time. This trade, however, is highly contingent on currency developments and during the last few years it has been adversely affected by the development of the USD/ECU exchange rate.

### MARKET FORCES

#### Demand

Aluminium is a material with a large range of applications, in the transportation, construction and packaging industries, the electricity sector, household appliances, and the mechanical and agricultural sectors.

Researchers and engineers have been constantly improving the qualities of the material; they have developed new alloys and production processes to open up new areas of application.

**Table 1: Aluminium**  
**Main indicators in volume - semi products**

(thousand tonnes)	1984	1985	1986	1987	1988	1989	1990	1991	1992

Trade balance	328	311	213	220	160	106	-85	-33	-30

Source: European Aluminium Association

The transport sector is by far the largest client sector, accounting for approximately 29 % of total EU aluminium consumption. It is the market segment with the best growth potential, as the strength and stability properties of aluminium alloys, combined with their lightness, make them an attractive material in all transport applications where reduced weight translates into energy consumption savings. In the car industry for instance, 90 % of cylinder heads and 25 % of engine blocks, gear boxes and wheels are made of aluminium castings. Many other components are made of rolled and extruded aluminium products (radiators, roof racks, ABS components, licence plates, ...).

New casting and body-frame techniques should allow further development of the use of aluminium by automobile producers: the metal is already widely used for frame parts in air, road and rail transportation as well as in commercial and cruise ships.

Construction is the second largest aluminium consumer sector, making up about 22 % of EU total demand for aluminium.

Aluminium products such as profiles, claddings, window and door frames, staircases, roof panels, greenhouse frames, smoke and fire protection systems, etc., find markets not only in new buildings but also in the renovation of old ones. They are selected for a number of qualities, such as resistance to corrosion, lightness, easy machinability and installation, low maintenance and repair costs, good formability and shaping along modern design requirements.

The third most important client sector for aluminium is packaging which accounts for an estimated 12 % share in EU aluminium demand. Packaging applications are numerous, not only in relation to foodstuffs and household products, but also for pharmaceuticals and cosmetics. Aluminium has the necessary properties to protect and preserve these goods and

to ensure their safe transportation and distribution as well as their convenient use.

Further progress can be expected in the use of aluminium in this sector as technical developments will further improve thin strip quality, down-gauging, lacquering and coating.

### Supply and competition

The world aluminium market has deteriorated considerably since 1991, following three years of near balance between supply and demand.

The imports from the CIS are playing a determining role under these circumstances. Until 1990, trade between the market economy and socialist countries resulted in net imports from the latter, which hovered around 300 000 tonnes per year. However, from 1991 onwards, the collapse of the Soviet system fundamentally changed the picture: the loss of the COMECON outlets, the sudden drop of domestic demand for military applications and a surge in the need for hard currency have propelled the former Soviet Union aluminium industry out onto the international market. Exports of the CIS increased by more than 100 % in 1991, and by a further 35 % in 1992. In 1993 exports further increased to reach an estimated 1.8 million tonnes. As a result, primary aluminium inventories on the LME have jumped from a mere 300 000 tonnes at the end of 1990 to five times as much at the end of 1992, and overstepped the 2.5 million tonnes mark by early 1994.

The EU market was the first to be hit, being situated nearest to the former Soviet Union. It is estimated that three-quarters of CIS exports have been directed to the EU in the first place.

The resulting price collapse on the LME has seriously affected the profitability of the aluminium producers in the market economy countries: in Europe, price levels dropped by more than 20 %.

In these circumstances in February 1993, the EU primary aluminium producers have lodged a request for safeguard measures with a view to curbing the CIS exports to the EU market. As a result, in August 1994 the European Commission imposed an import quota for a four-month period. This measure was subsequently extended up to the end of February 1994.

The "aluminium safeguard" measure had the effect of relieving the immediate pressure of CIS exports to the European market and has led to a multilateral dialogue with the major CIS exporter, i.e. the Russian Federation. In this dialogue, the governments of six nations took on, for the first time, the urgent and fundamental problem of the entry of a state-run industry of the former Soviet Union into the international market economy.

## INDUSTRY STRUCTURE

### Companies

In 1993, 22 primary aluminium smelters were operating in the EU but the number of producer companies is, in fact,

**Table 4: Aluminium semis

much smaller: the major ones are Aluminium Pechiney (F), VAW aluminium (D), Inespal (E), Alumix (I), Hoogovens (NL) and British Alcan (UK). Some of these companies operate plants in different EU countries or have subsidiaries or branches in other parts of the world.

The number of companies involved in aluminium processing is much larger, although there is a fairly good integration of the rolling activity into the smelting. The structure of the extrusion industry is, on the contrary, much less integrated, with about 170 production sites scattered on the EU territory.

## ENVIRONMENT

Aluminium has properties which make it increasingly competitive in an ecology-conscious world. As previously mentioned, its light weight is particularly effective in increasing energy savings in transportation applications. The high recyclability of aluminium is an additional important competitive advantage, particularly in packaging. Currently, 45 % of total EU aluminium output on average arises from scrap recovery. This proportion varies widely among Member States, however.

Aluminium projects for packaging will be affected by the planned "Directive on Packaging and Packaging Waste" which aims at reducing the amount of waste, and sets targets for recycling used packaging materials. In cooperation with other industries which are affected by this legislation, the aluminium

industry is prepared to play a leading role in minimising the impact of packaging on the environment, and is working together with public authorities to reduce the quantity of packaging waste going to landfills. At the same time, the industry emphasises the contribution of packaging to product protection and the safe transportation and distribution of goods.

Aluminium as a mineral is available in almost unlimited quantities: 7 % of the earth's crust is made of aluminium. The mining of aluminium-bearing ores, i.e. bauxite, can have negative effects on the ecological system, but reclamation of mined land is a top priority for the industry experiments and continuous efforts have yielded positive results in this area.

The reduction process for producing the metal consumes electricity and gives rise to emissions. The worldwide aluminium industry reduced its electricity consumption from 17 kWh per kg produced in 1980 to less than 16 kWh at the beginning of the 1990's. Major emissions were reduced by a factor of four or more during the same period, with the EU producers complying with stringent emission constraints.

---

## OUTLOOK

---

Primary aluminium consumption in the EU is expected to grow at an average annual rate of 2 to 3 % during the 1990s. Total aluminium demand, i.e. including secondary aluminium, should grow at a slightly higher pace as a result of the development of secondary uses, especially in the transportation and packaging sectors.

The packaging industry is expected to make considerable progress: the canning sector is far from maturity, and will give rise to considerable demand.

In the transportation industry the growth of aluminium demand is expected to arise chiefly from the automobile sector, where aluminium can further contribute to the lightness of cars, not only in castings, but also in wiring and body frames.

Increases in aluminium consumption in the construction industry is a function of the recovery of that client sector.

The industry is represented at the EU level by: Association Européenne des Métaux (Eurométaux). Address: Avenue de Broqueville 12, B-1150 Brussels; tel: (32 2) 775 6311; fax: (32 2) 779 0523.

# Copper

## NACE 224

The EU possesses few copper mine resources, but its copper metallurgical activities are highly significant. Its refining and semi manufacturing capabilities have developed in line with the requirements of its large consumption, using imported primary raw materials and domestic as well as imported scrap. EU copper demand follows the slow growth pattern of a mature market. Recycling is brought to a high level as, in many of its applications, copper can be reprocessed without loss of its intrinsic properties.

### INDUSTRY PROFILE

#### Description of the sector

The core of the EU copper industry is in refining and semi-manufacturing, in comparison with which the EU mining capabilities are negligible. Since the start-up of mining at Neves Corvo in 1989, Portugal has become the only EU country with a sizeable copper mine production (150 000 tonnes of copper in 1993). At present, with about 154 000 tonnes of copper extracted from domestic ores in 1993, the EU accounts for no more than 2 % of total market economy countries' copper mine output.

Annual refined copper production in the EU is in excess of 1.3 million tonnes. The largest facilities are located in Germany, Belgium and Spain. Refinery output essentially arises from electrolytic processes, in the form of cathodes, that are often melted and cast on the premises into "refinery shapes", i.e. billets, cakes. Some refineries also produce wire rod at the refinery location or elsewhere. About 60 % of the feed supplies to the EU copper refineries are purchased on the international market in the form of copper blister, anodes or scrap. The remaining 40 % come from the refiners' smelting operations whose feed consists of domestic and imported copper concentrates as well as copper bearing residue or scrap.

The products of the refineries are the major feed material for the copper semis manufacturers. The EU copper semis output exceeded 4.0 million tonnes in 1993. Owing to the recession this was 6 % below the record output of 1992. Germany, Italy and France accounted for about 71 % of EU output, with the Benelux countries, the United Kingdom and Spain making up most of the balance. The range of products supplied by the semis manufacturers is very wide. They consist primarily of rods, profiles, wires, sheets, strips, tubes, etc. with applications in such diverse sectors as electrical engineering, automobiles, construction, machinery, shipbuilding, aircraft, precision instruments, watches and clocks.

With an output which is three and half times that of EU refinery output, the EU copper semis manufacturers must turn to the international market to secure adequate volumes of supplies, together with the required alloying metals (zinc, tin and nickel for the most part).

The EU semis production is in excess of demand, and the EU copper semis manufacturing industry is a net exporter by about 300 000 tonnes per year.

#### International comparison

Nearly 30 % of the market economy countries 9.3 million tonnes demand for refined copper arises from the EU market. The EU consumed 2.8 million tonnes of copper, more than both North American consumption of 2.7 million tonnes and Japan's 1.4 million tonnes. Germany, France, Italy, Belgium and the United Kingdom are each among the top ten consumers

Figure 1: Refined copper  
Market economy countries consumption, 1993

Source: World Bureau of Metal Statistics, August 1994

together with the United States, Japan, Taiwan, South Korea and Canada.

In terms of production, the EU refiners account for about 15 % of the market economy countries' output. The EU's 1.3 million tonnes produced per year is slightly ahead of Japanese and Chilean production, each of around 1.2 million tonnes, but behind North American production (3.0 million tonnes). In the coming years, however, EU production will most probably lose its second place ranking to Chile, whose production is rising. For copper semis production, the EU countries hold by far a dominant position at world level, accounting for 38 % of the market economy countries' estimated 10.6 million tonnes output in 1993; the United States and Japan contribute 28 % and 20 % respectively.

### MARKET FORCES

#### Demand

Though lacking copper primary resources, the EU has a strong copper industry, being the largest consumer market among

market economy countries. Demand for copper mainly comes from the electrical and electronics industries, which absorb about 50 % of total EU consumption. These industries use copper primarily as a conductor material to carry electricity, in the form of wires, profiles and rods made of unalloyed copper. The construction sector is the second largest consumer: excluding building wire, it accounts for approximately 25 % of total EU copper demand. A wide variety of semi finished products, of both unalloyed and alloyed copper, is used in plumbing, roofing, decoration, etc. The remaining 25 % of demand arises mostly from industrial machinery and equipment, transportation equipment, and consumer products.

Copper's excellent thermal and electrical conductivity, corrosion resistance and malleability make it an ideal and safe choice for these applications.

Copper applications are well developed and the growth pattern of copper consumption closely follows the cycle of overall industrial activity at large. Copper demand on the EU market as a whole is growing slightly, as in most industrialised areas

in the world. Trends differ from country to country, however. Reconstruction in the east German Länder is contributing to produce higher than average copper demand.

### Supply and competition

EU copper refining activity has been able to grow primarily by securing raw materials on the international market and making use of the domestic "surface mine", consisting of copper scrap and residue generated by consumers and processors, as well as by demolition and obsolescence. Access to primary supplies has become increasingly difficult over the past few years, as copper mining countries have developed their own refining facilities close to their mines, thereby reducing raw materials availability on the international market. Furthermore, competition by rapidly industrialising countries for copper raw materials has increased as these countries develop domestic refining capacity to satisfy the requirements of their consumer markets.

Copper refiners in the EU face heavy international competition for their raw material purchases, especially from refiners in certain markets, mainly in the Far East, which benefit from protective measures. Furthermore, the trade in secondary materials is increasingly being restricted by environmental regulations such as the Basle Convention. These regulations are now starting to make a real impact on certain areas of the international copper scrap trade, with shipments of material held up pending the granting of relevant licences and other documentation. The major problems relate to:

- the notification and follow-up documents which have to be used;
- the financial guarantees which the Member States have a right to claim in order to cover the risks involved in these movements;
- the absence of bilateral agreements which are necessary in order to promote trade with a large number of non OECD countries.

All this has a negative influence on an intensive recycling industry like the EU copper industry with well established recycling circuits. According to industry sources, there is in fact the possibility that these rules actually discourage recycling rather than promote it.

The potential for expansion of copper refinery capacities in the EU is limited due to the difficulties of access to feed supplies as well as the heavy investment requirements and operational costs arising from environmental protection measures, which are far above the average world standard. Nevertheless, following the acquisition of Rio Tinto Minera in Spain by a major mining company, Freeport, with a world class copper mine in Indonesia, an expansion of the Spanish smelter and refinery is taking place. Besides, refinery modernisations have taken place at Norddeutsche Affinerie and at Hüttenwerke Kayser (D) and the Union Minière (B) refinery at Olen is currently being modernised. All are making use of the latest tankhouse technology.

Nevertheless, the structural shortage of EU refined copper output versus the manufacturing industry's consumption needs is expected to continue and the EU will remain a large net importer of refined copper. EU copper semis output, on the other hand, is large enough to adequately supply the EU consumer market towards which it is primarily geared. Excess capacity should enable the EU to remain a net exporter.

### Prices

The London Metal Exchange (LME) quotations for Grade A copper cathode generally govern the pricing of copper transactions made by the industry. The evolution of the LME copper prices generally reflects the market balance at world level, although the influence of large investment funds is increasingly felt in the market.

## INDUSTRY STRUCTURE

### Companies

There are ten major refineries in the EU and it is estimated that the copper refining industry employed more than 5 000 people in 1993. Two companies have facilities of over 250 000 tonnes of refined copper per year capacity. Union Minière (B) and Norddeutsche Affinerie (D). Two others, Hüttenwerke Kayser (D) and Rio Tinto Minera (E), produce more than 100 000 tonnes per year each. Production capacity at the other facilities in Spain, Italy, the United Kingdom, France and Belgium, ranges between 35 000 and 100 000 tonnes of copper per year.

**Table 6: Copper**  
**EU copper refineries, 1993**

Country	Company	Location	Theoretical annual capacity (tonnes)	Employment
Belgique/België	Union Minière	Olen	330 000	800
	Metallo-Chimique	Beerse	38 000	240
BR Deutschland	Norddeutsche Affinerie	Hamburg	350 000	2 000
	Hüttenwerke Kayser	Lünen	122 000	700
	MKM Mansfelder Kupfer und Messing	Hettstedt	55 000	230
España	ELMET	Bilbao-Berango	38 000	125
	Rio Tinto Minera	Huelva	150 000	600
France	Cie Générale du Palais	Le Palais	45 000	270
Italia	ENIRISORSE	Porto Marghera	60 000	200
United Kingdom	IMI Refiners	James Bridge	46 000	380

Source: International Wrought Copper Council, London, and industry statistics

Upstream integration into smelting operations, processing concentrates or low grade scrap varies from one refinery to another. Some are fully or partially integrated whilst others have no smelting facility at all. One company only has a smelting capacity which significantly exceeds its refining capacity (Metallo Chimique in Belgium). At EU level, there is a deficit in copper smelting capacity.

There are many more companies in the copper semis manufacturing industry, where about 100 companies are involved throughout the EU, employing some 75 000 people. However the industry is dominated by three large groupings, Europa Metall (I) with manufacturing subsidiaries in France, Germany and Spain, Outokumpu (SF), with manufacturing facilities in Finland, Sweden, and Spain, and Boliden (S) with plants in Sweden, Netherlands, Belgium and the UK. Other major independent companies include Carlo Gnutti (I), Wieland Werke (D) and IMI (UK). The industry suffers from overcapacity, making it very vulnerable to cyclical movements in demand.

## ENVIRONMENT

Recycling constitutes an important component of the raw material supplies of the copper refining and manufacturing facilities. Copper can be recovered from many of its applications and returned to the production process without loss of quality in recycling. Having very limited access to domestic primary sources of copper, the EU industry has traditionally given much attention to so-called "surface mine", relying to a large extent on scrap feed to reduce the large deficit of its copper raw materials trade balance. Altogether, secondary raw materials account for about 40 % of EU's use of copper, either by refineries as part of their feed and then by fabricators in the form of refined copper or by fabricators directly. In some cases, such as brass rods, the product is made entirely from recycled copper and brass, with only a small input of primary zinc.

The EU copper industry has developed advanced technologies and made considerable investments so as to be able to process a wide range of copper scrap, including complex, low-grade residues, and to comply at the same time with increasingly stringent environmental regulations.

# Zinc

## NACE 224

The EU zinc industry holds a top ranking position at world level not only in terms of production, but also in terms of know-how and consumer market basis. It is currently confronted with the effects of serious market imbalance created by both the lasting slump in demand and the sudden inversion of net trade with the Central and Eastern Europe countries, the CIS and China. As a result, the LME inventories have surged to unprecedented levels and prices have collapsed.

### INDUSTRY PROFILE

#### Description of the sector

Zinc is the third most used non-ferrous metal, behind aluminium and copper. Primary zinc production results from the processing of zinc ores into zinc concentrates of approximately 60 % zinc content which are then smelted and refined into zinc metal. Zinc production may also arise from secondary source materials such as metallurgical residue, ash from galvanising, new and old scrap. Zinc production from secondary sources accounts for 6 % to 7 % of refined zinc output in the market economy countries.

Zinc is supplied to the market in various qualities and shapes: metal ingots of various grades (the highest quality is SHG i.e. Special High Grade which rates 99.995 % Zn, whilst the poorest is only about 98 % pure); extrusion products such as bars, rods and wires; rolling products such as sheets and strips; casting alloys; powders and chemical compounds, such as oxides.

End-uses include a wide range of applications, the most important one in terms of volume being steel protection against rust through galvanising for the automotive, appliance and building industries. Zinc alloys (brass, bronze, die casting alloys, etc.) and zinc semis are respectively the second and third major consumption areas with applications in the building, appliance and car industries.

In 1993, the EU mine output dropped significantly to 397 000 tonnes of zinc contained in concentrates as a result of the exhaustion of reserves and lower ore grades at some mining operations. Metal production stayed above the 1.8 million tonnes mark which it had overstepped in 1992, while consumption of refined zinc stepped back to 1 640 000 tonnes, accounting for 30 % of the demand for zinc in the market economy countries.

#### International comparison

As shown in Table 1, the EU production of zinc concentrates is still significant at international levels, although it has been decreasing since the late 1980s, ranking in fifth position behind Canada, Australia, Peru and the USA.

Mine output in the EU is essentially accounted for by Ireland and Spain. In the other countries, mining is gradually being phased out as mine reserves are exhausting and operations are becoming uneconomic due to the high cost of labour and environmental protection, and the relatively low grade of ores. Considering these factors, combined with the persisting low prices for metal, zinc mining in the EU is bound to further decline in the coming years. While EU concentrates used to meet more than 45 % of the EU refinery requirements 10 years ago, they now account for less than one fourth of these. The deficit is filled in by increased imports, as mine production capacity is currently increasing in North America, Australia and some South American countries.

Figure 1: Zinc  
Breakdown of EU consumption by uses, 1993

Source: International Lead and Zinc Study Group, September 1994

In terms of refined zinc production, the EU definitely stands as the world leader, way ahead of Japan and Canada which rank on the second and third position respectively. In 1993, the EU output was recorded at 1 811 000 tonnes of metal, accounting for 33 % of the market economy countries total of 5 473 000 tonnes.

The EU is also the major consumer area of zinc among the market economy countries. The 1 640 000 tonnes zinc consumed in 1993 was 44 % above the second largest consumer market, i.e. the USA market, and 128 % above Japan.

#### Foreign trade

Zinc metal is a widely traded commodity as shown in Tables 4 and 5. Trade patterns have undergone a major change, however, with the opening of Eastern Europe. In the past, the countries of Central and Eastern Europe (CEEC) and the former Soviet Union were net importers of about 75 000 tonnes of zinc per year from the West. With the dismantling of the COMECON and the collapse of the State monopolies, the

Source: International Lead and Zinc Study Group, August 1994 Bulletin

trade flows which traditionally existed between those countries were knocked down. Also the rouble clearing system broke up, this phenomenon being accelerated by the rouble devaluation. Simultaneously, major production outlets in defence applications vanished, and as the conversion of the industry from defence to consumer products is a slow process, metal demand has dropped dramatically.

Due to these developments and the urgent need of these countries for "hard currencies", domestic production has been diverted from home markets: it is estimated that about 260 000 tonnes of refined zinc were exported from the CEEC and the CIS during 1993. Since the traditional 75 000 tonnes per year net export flow from the West to these countries dried up in fact at the beginning of the 1990s, it can be estimated that a supply of approximately 335 000 tonnes has been thrown on the Western market in 1993, with Europe bearing the brunt of it.

The EU zinc industry used to export significant tonnage of zinc on a regular basis to the former Soviet Union and, to a

lesser extent Czechoslovakia, while imports from the COMECON remained negligible.

By the beginning of the 1990's however, a drastic change occurred in these trade flows: EU exports rapidly decreased from more than 46 000 tonnes in 1988 to a mere 6 000 tonnes in 1991, and imports from the CIS and the countries of Eastern and Central Europe mushroomed from about 1 000 tonnes in 1989-1990 to nearly 27 000 tonnes in 1991 and almost five times as much in 1993. Figure 2 shows this development: the net trade surplus of the late 1980s has turned into a major deficit in 1993. Within four years, not only did the EU zinc industry lose a market outlet which it had ensured thanks to the superior quality of its product, but it also had to incur fierce inroads on its domestic market by lesser quality low price imported zinc products.

The move of the CIS and former COMECON zinc industry towards foreign markets, has destabilised the balance of the zinc market. This has a direct impact on the supply/demand balance and resulting market prices; but, more perniciously,

it also pulls the market value of zinc down as zinc from the CIS and former COMECON countries is offered at very low discount prices.

### Prices

Zinc is quoted on the London Metal Exchange (LME) where demand and supply regulate the price. As production remained slightly below consumption in 1990 and 1991, the price drop linked to business cycle factors was stopped in 1992 and prices increased during the first months of the year until the rising of stocks forced them to drop back.

The stagnation of consumption worldwide, the increasing exports from the former COMECON countries and the CIS and the unexpected surge in exports from China did in fact create a significant surplus which has been heavily depressing price levels since October 1992. On 29 September 1993, zinc was quoted on the LME at 859 USD per tonne, which is the lowest level since 1987 in real terms, and at the end of the year, the LME inventories were piling up at 907 000 tonnes, an unprecedented high level.

## INDUSTRY STRUCTURE

### Companies

Table 6 identifies the EU top zinc metal refiners with reference to their 1993 production capacity.

The major EU refiners have a diversified product list as they process part of their unwrought zinc output into value added products such as rolling products (sheets and strips of various dimensions), casting alloys or specialty products such as galvanising anodes, powders and callots for the battery industry, wires for the surface treatment of steel, dust, oxide. In the case of Union Minière (B) and Metallgesellschaft (D), value added products account for 50 % or more of output value and volume. The most diversified product list is Union Minière's.

Backward integration at mine level is limited and none of the EU refiners can rely significantly on its own mines' concentrate supplies, if any. A significant share of zinc mine production in the EU is not dedicated to any particular refinery. In Ireland for instance, Tara Mines has no integrated refinery and sells its concentrates on the market, and the current major mining projects or developments, in Ireland and Spain, are not geared to the exclusive supply of any EU zinc refinery.

## ENVIRONMENT

According to the European Zinc Institute (E.Z.I.), the market economy countries consume about 2 million tonnes of zinc from secondary sources either as refined metal or remelted zinc or through direct use of scrap at the fabricating stage. Estimates based on historical consumption and product life cycles indicate that the recovery rate of 80 % has been reached. The recyclability of zinc is far advanced, not only as zinc metal but also in several different forms.

Primary and secondary facilities in the EU operate under strict emission control and limit values with respect to air and water. The technology currently implemented is state of the art in this respect, making the EU production units the most environmentally friendly in the world.

## OUTLOOK

The oversupply of zinc metal, due to reduced consumption and increased exports from former COMECON countries and China, has resulted in extremely low prices which do not cover production costs for most mines and smelters, especially in the EU.

Source: Industry statistics

The integration of the former USSR and COMECON countries in the international zinc market appears to be the major determining factor for the future. This might lead to some fundamental restructuring of the industry worldwide, but the EU is more specifically affected as its geographic position makes it the closest target for the newcomers' exports. Meanwhile, the resumption of consumption might bring some relief in absorbing the current market surplus, although the latter has developed to unprecedented levels, and zinc being a mature metal demand, growth rates are not expected to be high.

The industry is represented at the EU level by : Association Européenne des Métaux (Eurométaux). Address: Avenue de Broqueville 12, B-1150 Brussels; tel: (32 2) 775 6311; fax (32 2) 779 0523.

# Lead

## NACE 224

The EU possesses few lead mine resources, but its lead metallurgical activities are powerful and competitive. During the last 10 years, EU consumption and production have experienced only modest growth, resulting in a decrease in the EU's world market share. Considerable restructuring has been taking place in the lead refining industry and in its major client industry, particularly the battery sector. Restructuring will require the build up of new relationships between suppliers and consumers. Secondary smelting is an increasingly important source of lead, particularly as environmental regulations become more stringent.

### INDUSTRY PROFILE

#### Description of the sector

Lead is the most abundant heavy metal in the earth's crust. It is normally found in mixed ores where it is associated with zinc and small amounts of silver and copper. Lead's softness, low melting point, chemical reactivity and resistance to corrosion give it great functional value, both in its pure form and in alloys or compounds. Mine production of lead has decreased slightly, as a result of the growing importance of recycling. Refined lead is derived from two sources: primary material in the form of lead ores and concentrates, and secondary material in the form of scrap and residue. Primary production requires the smelting of lead-bearing ores to produce refined lead bullion.

Secondary production may also require refining facilities if the secondary raw materials contain unwanted compounds. As a result of environmental and other regulations aimed at recycling of lead-bearing scrap, the secondary refining industry

now supplies more than 50 % of the lead consumed in market economy countries. As lead acid accumulators in cars are the main source of scrap for secondary refining, this proportion will increase as the world car population increases.

Primary refining is linked to the economics of mining lead-zinc orebodies. The bulk of lead mine production comes predominantly from operations in which zinc, and silver to a lesser extent, are the principal profit makers; less than a third comes from actual lead ore mining operations in which lead is the principal metal recovered.

The most important consumer of lead is the battery industry. Other uses for lead include: petrol additives (tetraethyl lead), paint, shot, glass, ceramics and plastics.

#### Recent trends

Consumption of lead rose significantly world-wide in the 1980s. From 1982 to 1992, consumption in EU Member States rose by some 13 % at an average annual rate of 1 %. In 1993, however, consumption of refined lead in the EU fell sharply to almost the same level as in 1985, at 1 347 000 tonnes.

The EU is not a major mining region. In 1993, only 104 700 tonnes of lead were mined in the EU, a fall of 19 000 tonnes from 1992. Metal production, however, is much higher and amounted to 1 355 000 tonnes in 1993, of which 50 % was from secondary feed materials. The industry is responding effectively to potential ecological problems by recovering ever increasing amounts of lead, resulting in a steady decline of primary production.

### MARKET FORCES

#### Demand

Consumption of lead generally follows business cycles, increasing during periods of high economic activity and falling during periods of recession. So it was in the EU from 1991

**Figure 1: Lead**  
**Production of primary and secondary lead in the market economy countries**

Production	1384	1 370	1 339	1 374	1 453	1 422	1 389	1 423	1 372	1 355

Source: World Bureau of Metal Statistics

to 1993 with the result that the average annual growth rate recorded over the 1980s dropped from 1.5 % to 1 % per year.

Regional trends in consumption are variable. For example, the share of EU consumption relative to consumption in market economy countries has fallen in recent years. The same is true for the USA. In contrast, most other areas of the world have increased their share in world consumption. Apart from the major influence of business cycles, consumption trends are largely driven by regulatory control on lead products (e.g. gasoline additives) and the cost and availability of substitutes.

Demand from the battery industry will continue to underpin consumption, largely as a result of rising demand for lead acid batteries for the automobile industry. Between 1979 and 1991, lead consumption in the battery industry increased by almost 43 %, at an average annual rate of 3.25 %. The vast majority of storage batteries are used in starting, lighting and ignition (SLI) applications in motor vehicles. Demand for such batteries depends on the number of vehicles built and, more importantly, on the number of batteries required to replace exhausted units. Demand has also increased for other types of batteries, such as those used in load levelling/peak sharing applications, as well as in electric-powered vehicles and standby power applications.

Environmental constraints and competition from other metals or materials have resulted in a stagnation or decline of lead demand in most of its other end-uses. Consumption of rolled and extruded products, shots, pigments and other compounds rose marginally, but contributed little to overall growth. In applications such as cable sheathing, alloys and gasoline additives, consumption has declined markedly: between 1979 and 1993 consumption in these three sectors fell by nearly 58 %. By the end of 1993, they accounted for only 8 % of the total, compared with 22 % in 1979.

In the case of cable sheathing and alloys, lead has suffered from substitution by other materials and the introduction of new technologies. Increasing awareness about the impact of polluting emissions on the environment is the main reason for the drop in lead consumption in gasoline additives. Over the period 1980 to 1993, consumption of lead for this end-use

fell by more than three-quarters, and it only remains of significance in the United Kingdom, which consumed 72 % of the total recorded in 1993.

#### Supply and competition

The market for primary lead and lead products is international in scope. Large consumer markets such as the EU are significant importers of lead concentrates and bullion. North America and Australia are large exporters of the same, after meeting their own market requirements. The market for secondary refined lead is more regional as secondary refining is predominantly carried out in the country where the scrap arisings occur and production is supplied directly to the neighbouring market. With the growing importance of secondary refining, from an environmental standpoint, the majors in Europe have a vested interest to be active in both primary and secondary refining. These companies are best placed to finance the investment that will be required to conform with increasing environmental legislation.

With the collapse of COMECON and the former Soviet Union in the early 1990's, increasing tonnage of refined metal of good to mediocre quality is being exported from these countries, disturbing the prevailing trade patterns in the Western European market, which it is the closest outlet to the now liberalised Eastern producers. The flow of Eastern material has enhanced the downward pressure on prices, which were already suffering from the slump in demand, and pushed metal stocks on the London Metal Exchange (LME) to sky-high levels. Competition from Eastern Europe is all the more damaging to the EU industry in that material prices do not take into account any comparable costs with respect to environmental protection, transport, or salaries, while EU producers bear the full brunt of heavy investment in R&D and for implementation of anti-pollution measures and environment-friendly technologies. At current price levels, the future of the industry is at stake and even secondary refining, though directly beneficial to the environment, is seriously threatened for no longer being economically viable.

## INDUSTRY STRUCTURE

### Companies

Within Western Europe there are ten primary smelters/refiners, ranging in size from 75 000 tonnes per year to 200 000 tonnes per year. The primary refineries are mostly multinational and spread throughout the United Kingdom, Sweden, France, Germany, Belgium, Spain, Austria, Yugoslavia and Italy. All plants, with the exception of Britannia Refined Metals (UK), smelt lead or lead/zinc concentrates before refining lead bullion. Britannia Refined Metals refines only crude lead bullion imported from its parent company MIM in Australia.

The secondary industry is characterised by a large number of smaller refineries, many of which are independent. There are approximately thirty secondary smelters/refiners in Western Europe producing from 5 000 to 65 000 tonnes per year. They recycle and refine scrap generated in their local area. The number of these refineries is decreasing as the large multinational companies, and the major battery manufacturing groups as well, acquire the smaller secondary facilities or set up their own new recycling operations.

The largest primary smelters/refineries in the EU include: Britannia Refined Metals (UK); Metaleurop (F and D); Metallgesellschaft (D); Union Minière's Business Unit Hoboken (B); and, Enrisorse (I). With the exception of Union Minière's Business Unit Hoboken, all of these primary refiners are involved in secondary recycling/refining as well.

### Strategies

During the last three years there has been considerable restructuring within the lead refining industry and its major outlet, the battery industry. The effects of restructuring can be noted within the battery industry, with the emergence in Europe of five major battery groups. These groups have become very powerful in their bargaining capabilities and some are competing with lead refiners by integrating their battery manufacturing facilities into lead recycling/refining opera-

tions. They process their own scrap collected from their own collecting networks for spent batteries, which are returned through their distributor networks.

In the future, secondary refiners will have to work more closely with major battery companies in order to maximise the recycling rate of battery scrap and to comply with national legislation implementing the EU Battery Regulation. Government approved collection schemes will be set up hopefully in close collaboration between the refiners and the battery manufacturers. Such schemes should be harmonised throughout the EU to allow fair competition on supply of lead and lead alloys between EU Member States and other European countries with similar schemes.

Environmental legislation will also require investment to reduce lead in air emissions. In recent years, several new technologies have been developed and implemented which offer more efficient, environmentally acceptable methods of smelting lead concentrates. These new technologies should rapidly gain ground because of their ability, in most cases, to handle secondary feed material. They integrate smelting and refining operations, offering many advantages such as economies of scale, synergy of the smelting and refining processes, concentration of lead production in fewer areas, closure of environmentally unacceptable plants, and lower lead emission levels.

It seems certain that new pyrometallurgical technologies will further increase their share of total lead smelting capacities over the next decade at the expense of the conventional blast furnace. Ultimately, looking further ahead, hydrometallurgical processes will probably make their way through also. In fact, there are already signs of such development in the treatment of battery paste. Undoubtedly, the number of operational refining sites will decrease in Europe. Consolidation and rationalisation are bound to take place as companies are confronted with facts and figures relating to possible return on investments.

**Figure 2: Lead**

## ENVIRONMENT

As lead is a toxic metal, it ranks high among environmental concerns. The metal has relatively little impact on ecosystems though and there has been much debate about the levels of lead which can actually cause harm. General policy is normally to restrict emissions to the lowest practicable levels given the state of technology. Recycling is normally conducted whenever appropriate and economic. Most control measures are concerned principally with human exposure (humans are most affected by lead exposure); although there are certain instances in which animals can be exposed to environmental lead.

Lead is increasingly recyclable in its major applications. Batteries, which created 49 % of lead consumption in Europe in 1990, are recycled with more than 90 % efficiency. Indications are that this efficiency rate should further improve in the future. Among other uses, tetraethyl lead (petrol additives), pigments and shots have declined dramatically or disappeared completely over recent years. This is partly a result of environmental legislation (e.g. tetraethyl lead), partly a result of voluntary reductions by industry (e.g. lead shots for fishing weights) and partly a result of substitution (pigments). As far as other uses are concerned, lead is mostly used in products from which it cannot be easily extracted, such as glass, ceramics, and plastics. In these cases, however, there is minimal risk for ecological impact. The net result is that uses of lead which really affect the environment are steadily disappearing.

During production and processing of lead there are inevitably occasions for emissions. These are kept to a minimum through the use of pollution control technologies and strict compliance to legal limit values on the amounts which are allowed to escape. Airborne emissions are controlled through efficient filtration systems and the implementation of design and management systems which prevent uncontrolled losses to the environment. Aqueous effluents are treated before discharge to ensure their compliance with limits imposed by water authorities. Finally, solid residues may not be disposed of indiscriminately. Depending on their lead content or their ability to dissolve into the environment, residues are designated as safe or hazardous and disposed of in authorised landfills.

## REGULATIONS

Regulations affecting lead fall into three main categories: occupational exposure, emissions from plants and controls on products. Occupational exposure is addressed under EU Directive 82/605/EEC of July 28, 1992 on the protection of workers from risks related to exposure to metallic lead and its ionic compounds at work. This directive sets allowances on the level of lead in the air in the workplace and on certain biological indicators which reflect the level of exposure of individual workers. The limit values are complemented by rules on the protection of the workforce providing for the use of protective clothing, respirators, washing facilities or specifying rules on eating, drinking, smoking, etc.

Emissions from lead works are normally controlled by national regulations relating to air or water. There are no universal European limits in these areas. However, lead in the general atmosphere is limited under Directive 82/844/EEC of December 3, 1982 which sets a limit for levels of lead in the air throughout the EU. Levels of lead are also controlled in a number of directives relating to water, depending on its type and use; e.g., water intended for human consumption, water for bathing, fishing waters, etc.

Regarding products, regulations do apply to a number of non-recoverable uses of lead. The use of lead in petrol, for instance, is controlled under Council Directive 85/210/EEC of March 20, 1985. Several Member States have their own regulations which impose tighter limits or which require the availability

of unleaded petrol for vehicles introduced to the market after a certain date. Another area in which legislation is applied is the use of lead in paints, which has been restricted under various national legislation for many years. Recently, lead carbonates and lead sulphates have also been controlled under EU Directive 89/667/EEC of December 21, 1989. This directive prohibits the sale of lead pigmented paints and prohibits their use in domestic buildings.

## OUTLOOK

During the past year the price of lead has improved. This has been brought about by shortages of clean concentrates and scrap batteries, coupled with a gradual emergence from recession. While LME stocks have continued to grow, the main European producers find themselves either short of finished product or in balance. This appears likely to continue through 1995 with all sectors of the industry experiencing improving order books.

The situation in the CIS has also changed quite dramatically. Refined lead production fell by 10 % and exports fell by 40 % between 1992 and 1993. This has been due to a lack of domestic concentrates coupled with a stronger domestic demand, especially from the battery sector.

Due to recent changes that have taken place in the industry's quality assurance requirements, the existence of a two tier market has become more apparent. The LME, on one side, requires little more than a 99.97 % min. Pb, without individual impurity limits, while the industry, in general, requires specific assurances on impurities, banding, dressing levels and general appearance. This leaves the LME, with few exceptions, as the market of last resort for industrial consumers. Hence, a two tier market.

# Nickel

## NACE 224

The nickel industry worldwide has developed a highly concentrated structure: about 60 % of the metallurgical production of nickel in the market economy countries comes from only four companies.

The EU is the third largest producing area for nickel products, with three companies operating on its territory, along with two other companies in Scandinavia (in Norway and Finland). With regard to nickel mine production, only two EU companies operate mining activities, one in Greece and the other in the overseas territories of France in New Caledonia.

Nickel demand is on a rising trend, determined to a large extent by the increase of consumption in the stainless steel sector, particularly in the newly industrialised countries (NICs).

### INDUSTRY PROFILE

#### Description of the sector

The EU nickel industry processes raw materials, either nickel ore or intermediate products, into nickel products. The range of products for nickel is wide: ferro-nickel, produced by Eramet (F) in New Caledonia and by Larco (GR) for use as a charge product in the fabrication of stainless steels; metal, produced by Inco Europe (UK) in form of pellets and Eramet in France in the form of cathodes for use as an alloying element in various applications (such as superalloys); salts, produced by Inco Europe and Eramet for use mainly in the catalyst and electroplating industries.

#### Recent trends

Since the mid-1970s, nickel consumption in the EU has increased at an average annual rate of 2.4 %. A record level of 240 000 tonnes was reached in 1990, but consumption fell by 9 % in 1991 and by a further 9 % in 1992, essentially as a result of poor economic activity. Demand picked up markedly in 1993, thanks to a production boom in stainless steel caused by increased demand from export markets.

The metallurgical production of the EU grew steadily during the 1980s, reached a peak in 1988 with 89 000 tonnes, decreased slowly thereafter down to 82 000 tonnes in 1992 but recovered to nearly 87 000 tonnes in 1993.

The number of employees in the EU nickel industry decreased by one third between 1982 and 1993, although mine production almost doubled and metallurgical production increased by more than 30 %.

#### International comparison

Among the top four companies producing nickel in the market economy countries, one is an EU corporation, Eramet in France, another owns a plant in the EU, Inco (Canada) in the United Kingdom, and a third has production facilities in Northern Europe, Falconbridge (Canada) in Norway. Table 4 shows the estimated share of the EU in world production of refined nickel. If reference is made to the market economy countries only, the EU share has diminished significantly over the past 16 years. The Canadian share decreased even more during the same period.

In 1993, nickel consumption in the market economy countries reached 667 000 tonnes, with the EU representing 33 % of the total consumption. This share of one-third has been relatively stable since the 1970s. Asia, however, increased its share of consumption from 24 % in the mid-1970s to 34 % in 1993, whilst the US consumption decreased from a 31 % share in 1976 to 20 % in 1993.

### MARKET FORCES

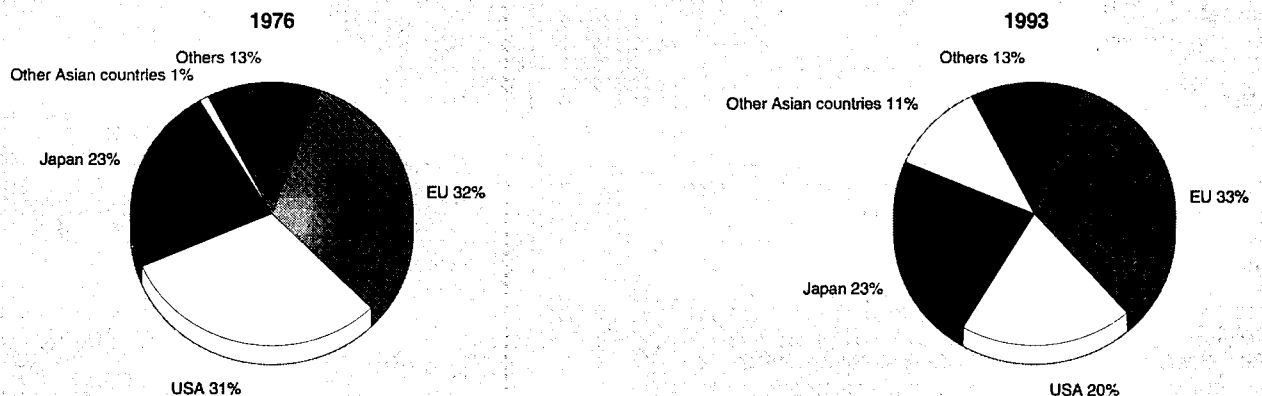

#### Demand

Nickel consumption in the market economy countries grew at an annual rate of 2.1 % between 1976 and 1992. EU consumption increased by 2.4 % per year during this period, while Japanese consumption rose by 3 % per year, and consumption in the USA decreased by 1.7 % per year. East Asian NICs were the fastest developing area from 1986 to 1992, with an average annual growth rate of 9.2 % as new nickel-consuming industries were being installed, especially in South Korea and Taiwan.

Among the various nickel uses, stainless steel plays the leading role. Nickel consumption for stainless steel represents more than 60 % of total nickel demand (63 % in the EU). It grew at a yearly rate of 4.3 % between 1976 and 1992, while nickel consumption in other sectors remained stable.

There are two primary reasons for this rapid evolution of nickel demand in stainless steel. Firstly, the production of nickel-bearing (austenitic) stainless steel rose at a higher rate than that of nickel-free (ferritic) stainless steel. Secondly, due to the improvement of the yield in stainless steel production,

the rate of growth of primary nickel consumption (4.3 %) was just a little higher than that of secondary nickel (4.1 %).

Production of nickel-bearing stainless steel is influenced both by the overall production of capital goods and by the intensity of use of nickel-bearing (austenitic) stainless steels in the capital and consumer goods sectors.

Over the past 15 years, the use of austenitic steel has increased at a higher rate than industrial production in the OECD countries. This increased use is mainly due to the technical qualities of austenitic steel, which, for many applications, has no acceptable substitute.

Recent developments in export markets show an extremely strong growth of nickel consumption in East Asia. Korea and Taiwan were the first markets to experience rapid growth, followed by China. Demand will increase strongly in the Eastern European countries around the turn of the century.

### Supply and competition

At the end of the 1960s, scarce nickel supplies led to a boom in investments by newcomers. Production, however, did not start until the mid-1970s. Most of these projects were located

in NICs and in Australia, where large nickel deposits were found. As a result, Canada and New Caledonia, which were responsible for around 75 % of the nickel mine production in the market economy countries in the early 1970s, accounted for about 45 % only in the early 1980s.

Up to 1970, about a dozen firms were engaged in nickel production, and increases in output were the result of expanding and modernising existing installations. At that time, all producers were working at near capacity level. Maximum capacity was reached at the beginning of the 1970s, but because of low demand, and subsequently very low nickel prices, producers had to significantly reduce their level of activity after 1975, bringing about a decrease in the rate of use of production capacity. Several facilities closed after 1984, as production costs were too high to enable firms to survive the depressed period of the first half of the 1980s. Real capacity also decreased due to reduced maintenance at most of the plants still in use.

Considerable progress in productivity has been achieved since the 1980s, including a significant reduction in energy consumption. This has enabled some companies to reduce pro-

Source: Marketing Eramet

duction costs so that they are in a better position to cope with the economic ups and downs which are affecting the capital and consumer goods sectors, the major driving forces of nickel demand. Many companies still suffered heavy losses, however.

Production costs decreased in constant terms, and the average break-even price for low cost producers, which was over 6.5 USD per kg at the end of the 1970s, decreased to a level between 4.5 USD and 5.5 USD per kg by the mid-1980s. The most competitive producers remained the sulphide producers in Canada and Australia which were less affected by the high price of oil at that time. After 1985, production costs increased significantly. Producers treating sulphide ore (e.g. Inco) faced increases in wages and social benefits for their workers and lower ore content in their mines due to the lack of extensive mining development work.

Producers processing lateritic ore, including the EU companies Larco and Eramet, also suffered an increase in costs, but to a lesser degree. The decrease in the price of oil and the depreciation of some currencies in Indonesia, Colombia and the Dominican Republic helped these producers to reduce the gap with the sulphide producers, and in some cases to take the lead in terms of costs.

As nominal production capacity was increasing in the market economy countries, net imports from former COMECON countries were also markedly increasing, particularly from the Russian Federation, which rapidly increased its exports to the West and especially to the EU, eagerly striving for hard currency revenues. As a consequence, the share of net imports from former COMECON countries rose from less than 11 % of EU consumption during the 1981-86 period to 19 % during 1987-92. The future trend of deliveries from the CIS will have a vital influence on the supply/demand balance over the coming years.

## INDUSTRY STRUCTURE

### Companies

Only three companies operate nickel production facilities in the EU. Inco Europe Ltd, a subsidiary of Inco Ltd of Canada, processes nickel oxide, an intermediate product supplied by its parent company, into pure nickel and nickel salts. Inco Europe Ltd markets its production throughout the world, although Europe is its most important market owing to its proximity. The American market is primarily supplied by Inco Canada.

Eramet is a 70 % subsidiary of ERAP, which is the holding company of the French state-owned company Elf-Aquitaine. Other shareholders are Elf-Aquitaine with 15 % and Imetal with 15 %. Eramet is the mother company of Le Nickel-SLN in New Caledonia which produces nickel matte and ferro-nickel. Its plant in Le Havre-Sandouville was built in 1978 to replace the facility founded in Le Havre in 1888. Matte shipped from New Caledonia is processed in Le Havre into pure nickel and salts. Eramet's sales program worldwide therefore includes a range of products, i.e. metal, ferro-nickel and nickel salts.

Larco, currently a state-owned company in Greece, was founded in 1963 for the mining of nickel ores and their processing into ferro-nickel. Due to the very small size of the Greek market, production is almost entirely destined for export. The EU market is the prime outlet for the Greek producer.

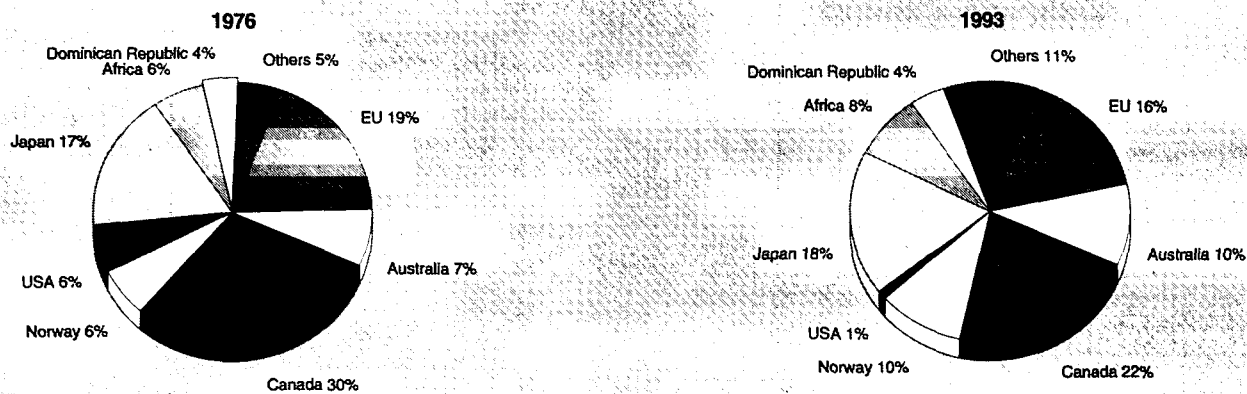

### Strategies

Nickel demand grows steadily and such a growth must be met by a corresponding sustained increase in nickel supply. To allow for such a development, investment in additional capacity at the lowest possible production costs must take place. Expansion at the existing mining and smelting facilities and improvements of productivity are generally lower cost options, but opening and building of new mines and production plants are also required.

Apart from economic considerations, long term stability of adequate supply can best be provided by giving priority to investments in integrated operations. Integrated nickel producers are not dependant on an external supply of nickel ore, and have their own refining facilities with a diversified range of products. They are therefore less dependant on cyclical market developments and are better able to withstand periods of recession.

Nickel producers must keep abreast of market developments: close cooperation between the nickel producers and consumers is necessary for both industries.

**Figure 2: Nickel  
Market economy countries production by area**

Source: Marketing Eramet

### REGIONAL DISTRIBUTION

The nickel market is a global one, but to a large extent, nickel mining areas do not correspond to nickel consuming areas. Major nickel consuming countries are net nickel importers, either in the form of nickel ore and intermediate products or in the form of finished products.

Nickel consumption in the EU represents approximately one-third of consumption in the market economy countries, but the production of the three EU nickel companies accounts for only 16 % of the corresponding output.

Germany is by far the largest nickel consumer in the EU, representing 34 % of total EU demand, but it has no domestic production. France is the second largest market, with a share of around 17 %. Other major nickel consuming Member States are Italy with 17 %, the United Kingdom with 15 %. Belgium (9 %) and Spain (8 %). The other EU countries are not substantial consumers of nickel.

Since the mid-1970s, nickel consumption in the EU has grown by 2.4 % per year on average, although growth rates vary widely among the various Member States. Belgium with a 14 % increase per year and Spain with a 5.8 % increase per year experienced the highest expansion in consumption, while

demand increased by only 0.8 % per year in France and only 0.3 % per year in the United Kingdom.

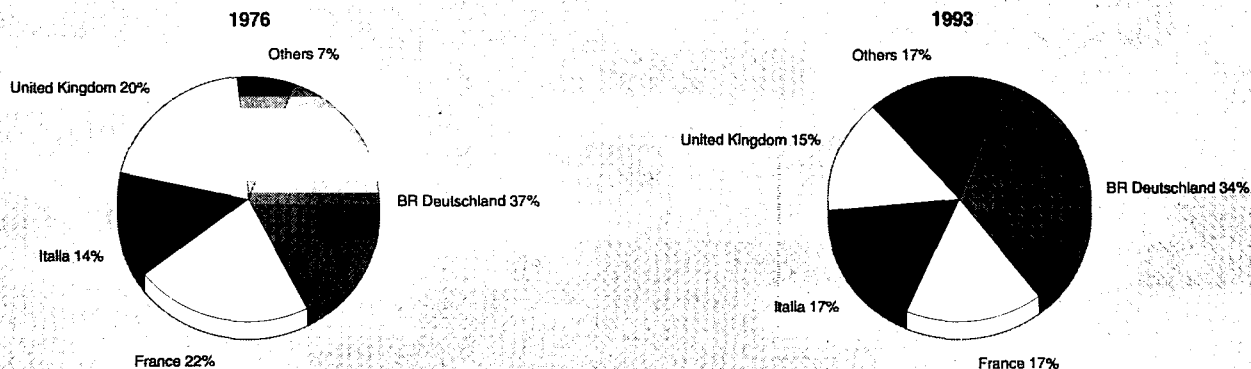

### ENVIRONMENT

Although nickel itself does not create environmental problems, some nickel compounds have properties which are dangerous to the environment and/or dangerous to humans. Most of the nickel producer and user industries have already reduced their emissions to an environmentally acceptable level. At EU level, atmospheric emissions have been controlled and reduced by means of the installation of efficient filter systems. Liquid effluents have been under control for many years now, and their levels comply with regulatory limit values. Solid waste containing water-soluble compounds such as nickel-bearing metallic hydroxides is still a concern. In most cases, however, it is disposed in controlled landfills. Nickel-bearing recyclables (stainless steel and alloy scrap, spent catalysts, etc.) are not an area of concern with respect to their nickel content.

### REGULATIONS

In spite of minimum specific risks for the general environment, nickel and some of its compounds are facing increasing regu-

**Figure 3: Nickel  
EU apparent consumption**

Source: Marketing Eramet

latory pressure at EU level. Skin-contact allergy is a clearly established risk linked to direct and prolonged exposure to nickel in some common products. The European nickel producers support the efforts of the EU Commission to establish rules for the protection of the fraction of the population at risk. Nickel is suspected of inducing respiratory cancer in workers in certain nickel refining processes. In addition, the classification of some nickel compounds as human carcinogens (Directive 67/548) will have a serious impact on industry and will require protective measures for workers exposed to these substances (Directive 90/548).

Like the rest of the non-ferrous metals industry, the nickel industry is concerned with the implementation of the EU regulation on transborder shipments of waste. Too many uncertainties regarding the essential administrative provisions of this legislation present a severe threat to the entire recyclables trade.

---

## OUTLOOK

---

Nickel consumption should continue to grow at a relatively sustained rate in the medium and long term, although it will fluctuate greatly in the short term due to cyclical variations in general economic activity.

The following factors could result in the continued development of nickel consumption:

- growth of nickel consumption in industrialised countries in connection with the development of new applications, most of them linked with the protection of the environment (Clean Air Act in the USA, Earth Summit of Rio de Janeiro);
- booming demand for nickel in the newly-industrialised countries (NICs), especially East Asian NICs, and in some Latin America countries due to the construction of new plants and the need for durable goods;
- reconstruction and reshaping of a civil industry in the former COMECON countries.

Production areas which show the greatest growth potential for the 1990s are located in the countries with the largest and richest mines, especially New Caledonia, Australia and Indonesia.

The recent creation of the "International Nickel Study Group" has improved the availability of reliable statistical information on the market thanks to the increased cooperation of the participating governments. This should help the decision process at all industry levels and significantly contribute to the transparency of the market.

# Precious metals

## NACE 224

The EU has the largest refining and fabricating capacity for precious metals in the world, even though its actual mineral resources of such metals are very limited. The recycling of precious metals from scrap and industrial residues has always been an important raw material source for the EU industry. EU environmental legislation now requires all new petrol driven vehicles to be fitted with catalytic converters to reduce pollution. This has stimulated EU demand for platinum group metals.

### INDUSTRY PROFILE

#### Description of the sector

Precious metals include well-known metals as gold and silver as well as the six platinum group metals: platinum, palladium, rhodium, iridium, ruthenium and osmium.

Precious metal activities can conveniently be separated under five headings: mining, refining and production of metals in unwrought forms; fabrication, i.e. processing, alloying and conversion of the metals into wrought or semi-manufactured forms, chemical compounds, catalysts and industrial components; manufacturing i.e. production of goods for retail sale such as jewellery, silverware etc.; trading, i.e. commodity dealing, investment bars and coins.

#### Recent trends

##### Mining

The twelve countries of the EU possess within their borders relatively insignificant sources of gold and silver and prac-

tically none at all for the platinum group metals. Primary precious metals which are actually extracted from ores mined in the EU are mainly by-products of copper or lead and zinc mining.

Among EU Member States, only Spain, France and Portugal appear in the world list of gold producing countries, and in 1993 they yielded under 0.5 % of total world output of 2 281 tonnes. Seven EU countries produce silver (Table 1), but only to a very limited extent: total EU production represents below 2.5 % of total world annual output.

#### Refining and recycling

The refining of gold, silver and the platinum group metals in the EU takes place either at the specialist refining and fabricating companies or at base metal refineries equipped to treat such metals either as by-products of non-ferrous metal refining or by recovering them from low-grade industrial residues and scrap materials. Total precious metal refining capacity of the EU firms is the largest in the world.

Consequently mines in all parts of the world still consign large quantities of precious metals in crude or by-product forms to the EU refineries, wherever local facilities do not exist, have inadequate capacity or are unable to treat the mine output satisfactorily to achieve optimal recovery rates or generally acceptable commercial quality.

Base metal refineries with significant precious metal capacities are to be found in Belgium, Germany and the United Kingdom. These typically recover precious metals from lead and zinc, copper or nickel ores, as well as low-grade scrap materials of all kinds, and they supply the pure metals in the form of unwrought "good delivery" bars or plates, grain or sponge.

The largest EU specialist precious metal refining firms are to be found in France, Germany and the United Kingdom. The specialist refiners are also fabricators, able to process the precious metals into alloys and chemical compounds and

to supply all forms of wrought materials such as wire, sheet, tubing and industrial components of many shapes and sizes.

Despite the lack of indigenous precious metal mineral sources, the EU can count on substantial "above ground" raw material supplies in the form of scrap and secondary materials sent for recycling both from within the EU and from the rest of the world. There are a number of EU companies who specialise in the collection, pre-processing and trading of such materials before the actual assay and refining stages take place. Typical items are discarded printed circuit boards, obsolete computers, old photographic film, X-ray plates and solutions, spent electro-plating baths etc.

The cost of recovery and recycling is more than justified by the high intrinsic value of the precious metals contained in these scrap and residues. It is not just the economic aspects that encourage the recycling of precious metals but also the environmental issues, where the regulatory authorities are setting ever stricter limits on the tolerable metal content of waste materials sent for dumping.

In this respect, it is unfortunate that as from Spring 1994 the valuable international business of recycling precious metals has been seriously unsettled in Europe by the application to such materials of the Basle Convention on Transfrontier Movements of Hazardous Wastes and the corresponding EU Directive.

The severe delays and high notification procedure costs imposed by the EU interpretation of the Basle Convention are having serious adverse effects on the EU precious metals refining industry and are hindering the obvious environmental and financial benefits to be gained from precious metals recycling and secondary refining in which the EU precious metal industry has developed exceptional skills.

None of the precious metal bearing feedstocks for secondary refining should be classified as "waste", in fact; the precious

metal content of these materials usually has a value far exceeding the cost of treatment and the owners of such materials want to realise the value as quickly as possible and with the maximum environmental safety.

Via its professional associations, the industry is working very actively to exempt transfrontier movements of all precious metal bearing materials from the application of the Basle Convention and in the longer term to redefine these materials as products rather than "waste". To this end, criteria should be established to allow a proper distinction between what should be considered as "waste" and what should not.

#### Trading

The major EU financial centres, particularly London but also Paris, Frankfurt and Luxembourg are significant markets for trading gold and silver both as commodities and for investment purposes. The daily fixing prices quoted by the London Bullion Markets and the London Platinum and Palladium Markets are those most widely used throughout the world as reference prices. "Good delivery" gold ingots and silver bars bearing the stamps of the major EU refiners are to be found in the vaults of banks and commodity traders in all the world's financial centres and international monetary agencies. Private individuals and other financial institutions generally prefer the smaller investment bars where once again it is the major EU refiners whose bars carry the most prestigious marks which are recognised everywhere as a guarantee of quality and accurate assay.

Market forces require the trading of the main precious metals on a 24 hours basis be organised so that forward cover and location swaps be provided for international customers. This push has caused many of the leading EU traders to set up facilities in North America and the Far East to complement their activities in Europe.

**Table 5: Platinum**

### *Fabrication*

Most of the precious metals are fairly easily fabricated either as pure metals or as alloys. Gold in particular is usually turned into specific alloys for jewellery or dental purposes in order to improve its wear-resistance or colour. Because of the high intrinsic value and the wide range of forms and alloys required, such metals are usually fabricated or processed in relatively small quantities compared with base metals. One of the few precious metal products manufactured in tonnage quantities is silver nitrate for the photographic industry. A product that has recently entered the multi-million unit scale of production in the EU is anti-pollution car exhaust catalysts, each containing just a gram or so of the platinum group metals, and some members of the EU precious metal industry are strongly represented in this field worldwide. The EU demand trend is discussed in more detail below.

### *Manufacturing*

Converting precious metal alloys into finished products to be sold to the retail trade, is largely the responsibility of the jewellery, silverware and tableware industries which is outside the scope of this article. These industries, however, are major consumers of gold and silver, especially in Italy, as can be seen from the accompanying EU consumption tables.

---

## **MARKET FORCES**

---

### **Demand**

The industrial and manufacturing demand absorbs the major share of precious metals fabrication, though gold and silver still play roles in coinage (now mostly commemorative coinage). Gold, of course, remains the main investment metal worldwide even in today's highly sophisticated financial circles, though part of its role as an internationally recognised store of value has been taken over by currency trading and futures. EU major precious metal outlets include: jewellery in the case of gold, photographic products for silver, automobile exhaust catalysts for platinum and dental alloys and electronics for palladium.

Consumption trends are closely linked to the outlook for consumer goods and industrial consumables. In the case of the platinum group metals, EU demand in recent years has, however, been driven by legislation and the Single Market. As a result since 1 January 1993 most new European automobiles have been fitted with catalytic converters to control exhaust pollution and reduce acid rain. Such devices have been compulsory since the 1970s in the USA and Japan but only recently has legislation been adopted by the EU and other states of Europe.

Gold and silver are able to rely on the jewellery and tableware markets as a fairly constant source of demand, although this does fluctuate with consumer purchasing power. There is also a small but growing demand for platinum jewellery and watches in the EU. In the case of palladium, world demand has risen recently because of increased use in autocatalysts and electronic components such as those used in mobile telephones.

All the precious metals except gold are consumed mainly in the industrial regions: North America, Japan and Europe. These three zones currently account for 90 % of market economy countries' consumption of platinum and palladium, about 75 % for silver but only slightly less than half of world gold consumption. More than 50 % of world gold consumption in 1993 is thought to have occurred in the developing countries.

### *Gold*

The EU accounts for just under 25 % of total market economy countries' demand for gold (Table 2). In 1993, EU utilisation is estimated to have decreased by 5 %, a reversal of the growth trend of the previous years. It is Italy which traditionally

dominates EU demand. The jewellery industry there used 447 tonnes of gold in 1993, which is about 75 % of the total EU usage for jewellery estimated at 593 tonnes. Much of the Italian production is exported to North America, the Middle East and other EU countries such as Germany and the United Kingdom, although it is Italy itself which is by far the largest jewellery market among EU member states. In 1993, Italian consumers bought some 110 tonnes of fine gold in the form of gold jewellery but this was in fact some 30 % lower than in 1992. This weak Italian domestic demand was compensated for by increased exports. Elsewhere in the EU, particularly France, Spain and Greece, the jewellery markets have shown signs of some recovery.

EU demand for gold for purposes other than jewellery also declined in 1993. The electronics industry and decorative uses had a lower take-off overall. The consumption of gold in dentistry fell back to more normal levels, largely due to the health insurance scheme changes in Germany which came into force on 1 January 1993 and which had caused a major acceleration of dental treatments there in 1992.

### *Silver*

Industrial demand for silver in the EU now represents under 30 % of the market economies countries' total (Table 3). One principal consumer sector in Europe is the photographic industry, where overall demand has grown steadily in recent years. The other major sector is jewellery, cutlery and silver tableware where Italy once used to be by far the largest manufacturer in the world. In the last couple of years however the reported Indian silver jewellery demand has doubled to some 3 700 tonnes and the Italian industry has been overtaken.

### *Platinum*

In 1993, the EU accounted for approximately 22 % of the market economies countries' platinum demand (Tables 4 and 5). Its main use is in catalytic converters for the car industry. As from 1 January 1993, all new petrol engine cars in the EU have to be fitted with such anti-exhaust pollution catalytic systems, all of which contain small quantities of the platinum group metals. EU car production in 1993 was substantially lower than in 1992 when 66 % of the new petrol engine cars in Western Europe were fitted with catalysts. As regards, new diesel engine cars, the proportion fitted with autocatalysts continued to rise in 1993.

Jewellery industry demand for platinum in Western Europe showed significant growth of nearly 25 % over 1992. The jewellery manufacturers of France, Germany and Italy enjoyed a growing demand for platinum products not only in their domestic markets but also in the USA and Japan.

Since 1992, Western Europe demand for platinum has exceeded that of North America mainly because of the EU legislation-driven increase in the requirements of the European car industry. Japan remains however by far the largest consumer of platinum, because there the demand for platinum jewellery is so high. In 1993, 42 tonnes of platinum were used by Japanese jewellery manufacturers compared with 87 tonnes of gold whereas in the EU jewellery trade the ratio was 3 tonnes of platinum to 593 tonnes of gold.

### *Palladium*

EU demand for palladium represents about 16 % of market economy countries' consumption (Tables 6 and 7). The use in dental alloys fell in 1993, especially in Germany following the 1993 health insurance scheme changes. However the volume of palladium used in the automobile industry started to increase significantly in 1992 as new technical developments in autocatalysts started to be exploited in Europe.

### **Supply and competition**

Gold is mined in most continents apart from Europe. The largest output still comes from the Republic of South Africa

**Table 6: Palladium**  
Breakdown of demand by application in Western Europe

(kg)	1987	1988	1989	1990	1991	1992	1993

Dental	7 460	8 240	7 780	8 090	9 330	9 330	8 240
Electrical/electronics	6 220	6 840	6 530	6 220	6 220	6 530	6 530
Jewellery	930	1 090	1 090	1 090	1 090	1 090	1 090
Other	2 330	2 490	2 640	2 800	2 490	2 800	1 710
<b>Total</b>	<b>17 100</b>	<b>18 820</b>	<b>18 200</b>	<b>18 360</b>	<b>19 290</b>	<b>20 990</b>	<b>21 460</b>

Source: Platinum 1994, Johnson Matthey

but mines with cheaper production costs have been opened up in America and the Pacific region. World supply from old gold scrap increased in 1993 by over 16 % to 516 tonnes as more old jewellery was recycled in the Middle East, India and the Far East, and was in fact the next biggest source after South Africa's 620 tonnes of primary gold.

Silver is largely a by-product of lead and zinc mines, particularly those in Mexico and Peru, as far as primary mineral sources are concerned. Over 25 % of total 1992 silver output however is thought to have been derived from secondary sources such as scrap and residues from the photographic industry.

Of the six platinum group metals it is platinum which dominates in the South African primary ores; rather smaller amounts of palladium and other precious metals are contained in the ore. However in the CIS and Canada where the platinum group metals are found in nickel ores, more palladium than platinum is actually recovered and the CIS is normally the largest supplier of palladium to the market economy countries.

Much of the platinum group metals used in industry is eventually recycled. As cars fitted with catalytic converters in the 1970s and early 1980s in North America and Japan reach the end of their useful life, a steadily growing source of platinum has been scrap car catalysts, which now yield the equivalent of about 17 % of the platinum currently required for new car catalysts.

The mineral sources of gold and silver are widely dispersed and mining activity is subject to only limited political risk. In the case of the platinum group metals, which rely to such an extent on the sources in the Republic of South Africa and the CIS, there is a risk that internal political events might affect supplies. However substantial stocks are held both by the refiner/fabricators of these metals and also the commodity markets which would be ample for short term needs.

## INDUSTRY STRUCTURE

### Companies

The principal precious metals refiners and fabricators of the EU operate on an international scale and are world leaders

in their field. Prominent names are Degussa and Heraeus in Germany, CLAL in France and Johnson Matthey in the United Kingdom. The US precious metals firm, Engelhard Corporation, is also well established in several EU countries. Major EU base metal refiners with significant precious metal involvement include Union Minière in Belgium, Norddeutsche Affinerie in Germany and Inco in the United Kingdom.

The installed precious metal refining and fabrication capacity controlled by the EU industry as a whole is the largest in the world and exceeds that of equivalent US and Japanese firms. It draws its supplies from all over the world both in the form of primary metal from the mines and secondary or recycled metal. It also delivers its fabricated products not merely within the EU, but also to the developing countries of Africa, the Middle East and Asia. It is such factors which give the EU precious metals industry its international character.

The EU precious metal firms form an advanced technology, high performance industry which is very strongly focused on research and development. This encompasses not merely new uses for the precious metals but also the discovery of techniques for economising the quantities of precious metals used in existing applications.

### Prices

The main precious metals are all traded on international commodity markets, in particular those of London, New York and Tokyo, and prices can be quoted on a 24 hours basis. Thus refiners and fabricators are able to hedge prices quoted to their customers to avoid the risk of price movements. Gold is the metal perhaps most affected by speculation and is usually sensitive to the world political and economic climate, largely because it is the precious metal of most interest to investors and speculators. Although silver and the platinum group metals are industrial metals to a much greater extent, and their prices are therefore subject mainly to supply and demand expectations, in practice they still move in sympathy with the price of gold.

For several years up to 1993, precious metal prices in US dollar terms tended to slide downwards as supply was generally ahead of demand. In the case of gold, the market had to absorb substantial sales by central banks who had surplus

**Table 7: Palladium**  
Demand by region

stocks or needed foreign exchange. Since 1993, precious metal prices have shown an upward trend as demand in some markets such as the US has recovered and there have been several surges in speculative and investment interest (Figure 1).

# Cobalt

## NACE 224

The EU cobalt industry is the world leader in cobalt powder and oxide production, and a major supplier of cobalt salts. The "cradle" of special cobalt products i.e. powders, oxides and salts is Belgium, where considerable production expertise has been developed since the beginning of the century in the treatment and processing of cobalt metal and raw materials originally coming from the Shaba copper mines in Zaire. Today, cobalt special products are a worldwide business with products originating from the EU, North America, China, the CIS, Australia, South Africa and others. However, the EU still retains a large proportion of the capacity (40 % to 45 %) to satisfy the market, with plants operating in Belgium, Germany, France and the United Kingdom, directly involving at least nine companies.

### INDUSTRY PROFILE

#### Description of the sector

Cobalt metal is shiny, grey and brittle with a closely-packed hexagonal (CPH) crystal structure at room temperature, which changes at 421 C° to a face-centred cubic form. Cobalt is usually supplied to end-users as powder or as oxides, salts. Cobalt is not used as a structural material, but always as an alloy or a binder in the case of sintered products.

Cobalt has unique properties which make it extremely valuable in many industrial applications. It has a high melting point, 1 493 C°, and retains its strength to a high temperature. It is ferromagnetic, like only nickel and iron. It is multivalent and easily enhances catalytic action.

As there are no longer any viable cobalt bearing ores in the EU, cobalt processors rely entirely on imported cobalt feed supplies, be these metal, mining or metallurgical residue or scrap.

All EU special products producers have to source cobalt outside their own business. Previously, cobalt supplies in the market economy countries were dominated by Zaire and Zambia, (70 % of metal production came from these two sources in 1990). This situation has drastically changed during the last few years due to the political turmoil in Zaire and the production problems in both Zaire and Zambia. Other factors such as net exports of Russian metal or the DLA releases (US Defence Logistic Agency) have resulted in Zaire and Zambia's share falling to less than 40 %.

Europe is a major market for EU cobalt special products producers, but they must also compete on export markets as their capacity far outweighs European demand. The main markets are the USA, Japan, Taiwan, South Korea and Pacific Rim countries. There are domestic competitors on these markets but other international companies compete there as well, as they do in Europe with the EU suppliers.

Figure 1 shows the overall cobalt market structure and the EU industry within it. Consumers of cobalt use the metal, as well as cobalt special products, to produce magnets, alloys (super alloys and hard facing), soft magnetic materials, hard materials, catalysts, speciality chemicals etc.

#### Recent trends

Due to a fundamental change in the supply structure, prices of cobalt metal and special products have doubled over the past two years and pricing will very likely remain quite volatile in the foreseeable future. While cobalt metal was the major feed material up to the late eighties, today's cobalt supply is much more diversified. There has been a trend towards the use of lower grade metal - especially of Russian origin or

from the DLA's releases - as well as by-products, scrap and residues.

The importance of trade is growing significantly and is interfering more and more with the traditional supply channels (direct producer-consumer relationships). Pricing is no longer dominated by the African Producer Price, but by the published prices of the Metal Bulletin (London) and Metals Week (New York).

Users of cobalt metal have been increasingly creative in switching to lower grade metal to compensate for the lack of availability of high grade metal. Either quality restrictions have been relaxed or additional refining steps have been introduced in order to cope with the lesser quality of the input material and henceforth remain price competitive.

**International comparison**

Demand for cobalt essentially arises in the industrialised countries. Europe, North America and Japan take the lion's share of total market economy countries demand which was estimated at 18 000 tonnes cobalt in 1993. The emerging markets

in the Far East (Korea, Taiwan) and China are slowly but surely becoming large users of cobalt. Today's geographic distribution of demand is shown in Figure 2.

The cobalt market is a mature one. For 4000 years cobalt has been used for ceramics; in the past 50 to 60 years, it has been used in superalloys and magnets. There are many new uses in electronic recording, anodising, batteries, amorphous soft magnets. However, these do not currently generate a large tonnage demand. The consumption curve has in recent years been declining, as shown in Figure 3. To some extent, this has been a technological rather than economic shift, although one must to some degree blame the uncertainty about supply which resulted from the late 1970s' turmoil in Zaire. Demand has fallen due to the development of substitute products which is illustrated by the following examples: nickel superalloys, albeit cobalt-containing, replaced cobalt alloys, cobalt-free high speed steels were developed, Alnico magnets were replaced by ferrites, etc.

## MARKET FORCES

### Demand

Until the 20th century, cobalt was only available or used as an oxide to produce blue colours. Its modern uses developed with Elwood Hayne's work on heat and wear resistant alloys (Stellite), the development of aluminium-nickel-cobalt (AL-NICO) permanent magnets in Japan, and the use of cobalt as a binding agent in tungsten carbide production in Germany.

Cobalt is consumed in various forms and in many different applications, which are summarised in Table 1.

About 18 000 tonnes of cobalt are consumed each year in the market economy countries. At present, demand from EU customers for special cobalt products is about 3 500 tonnes of cobalt per year (estimation based on the early 1990s), 36 % of which in the form of oxides, another 36 % in the form of salts, and the remaining 28 % in the form of powders. This demand mainly comes from the hard materials industry consuming powders, the pigments and ceramic industry consuming oxides, the metallic soap manufacturers consuming salts, the animal feed and fertiliser sector also consuming salts and the catalyst industry consuming salts and oxides.

It should be noted that cobalt demand in the EU includes an additional estimated 3 000 tonnes cobalt per year, consumed in the form of metal by the steel and alloy industry, the permanent magnet industry and some segments of the chemical industry. As there are no cobalt metal producers in the EU, these requirements have to be imported in full.

### Supply and competition

Competition between special cobalt product manufacturers is fairly strong in all three areas, salts, oxides and powders; the EU companies are world leaders in powders and oxides.

A summary description of the cobalt market at large helps to assess the relative position of the EU cobalt industry. It emphasises the diversity of its expertise taken account of the diversity of manufactured products and their industrial uses; it stresses the international "spread" of its enterprises, which import their feed materials from remote countries and export their products not only within Europe, but also to all parts of the world; it brings to light the challenges which it must face in order to maintain its leadership and market share when competition is tough and demand has basically reached full maturity.

### Mine production

Cobalt essentially arises as a by-product from the processing of copper and nickel ores, but it can also be associated with platinum or other non-ferrous metal ores. It only occurs as a major extracted element in the arsenide ores of Morocco (currently exported to China). African mines were historically by far the largest suppliers of fresh cobalt units from the ground, accounting for nearly 63 % of the market economy countries total output. The bulk of mine production is offered directly to the market in the form of metal which is produced in the integrated operations of Gecamines (Zaire), ZCCM (Zambia), Inco and Falconbridge (Canada). However in recent years a significant portion of the African output has been exported as low grade material (white alloy, slag, etc.). The balance of the output is supplied by other mining concerns, either in the form of oxide or salts, or in the form of cobalt-bearing primary raw materials. Figure 4 shows the development of cobalt supply in market economy countries from 1986.

### Metal production

There are five major cobalt metal producers among the market economy countries. Their 1993 capacity and output are outlined in Figure 5. In 1993 the Canadian company, Sherritt, started treating cobalt nickel sulphides produced at the Moa Bay plant of Cubaniquel under a long term arrangement.

Since 1992, Russia has become a significant supplier of metal to the market economy countries; however, its actual output, arising at four different refineries, is difficult to assess.

**Figure 4: Cobalt**  
Cobalt production in market economy countries

Source: Cobalt Development Institute

About 65 % of metal output is directly supplied to end-users in the special steels and alloys industry, the permanent magnet industry, and some segments of the chemical industry. The remaining 35 % are supplied to cobalt processors, i.e. producers of powders, oxides and salts.

#### Production of powders, oxides and salts

The market for special cobalt products - i.e. fine powders, oxides and salts - ranges from 9 000 to 11 000 tonnes cobalt content per year in the market economy countries. More than 50 % of supplies result from metal processing, some 9 % are the direct cobalt output of mining concerns (Inco's oxide, Eramet's chloride and Rustenburg Plat's sulphate), and the balance is produced from cobalt-bearing scrap, mining by-products or metallurgical residues.

More than 25 companies are active in the special cobalt product sector, though not necessarily supplying the full product range, and competition is fierce. Total installed capacity is estimated at 13 000 tonnes cobalt content per year, of which 34 % for powders, 37 % for salts and 29 % for oxides.

#### Prices

Cobalt has for many years been a producer priced material as shown in Figure 6, with Zaire and Zambia traditionally setting the quoted level (African Producers Price).

Free market prices are quoted by trading companies, some of which have become deeply involved in cobalt in the early 1990s. This phenomenon is largely due to the emergence of significant quantities of Russian cobalt. The volume of free market traded cobalt is difficult to assess but is probably at around 20-25 % of total supply.

## INDUSTRY STRUCTURE

### Companies

Although the EU has no cobalt mines or cobalt metal production, its industry is extremely strong in the processing of cobalt metal and of cobalt-bearing raw materials into special cobalt products, i.e. powders, oxides and salts. The rated capacity of the EU cobalt processing plants can be estimated altogether at about 6 500 - 7 000 tonnes per year.

All the companies listed in Table 2, with the exception of Eramet (F) which processes its own mining by-products from

New Caledonia, rely on feed supplies purchased on the international markets, be they metal, mining or metallurgical residues, or scrap. Their output is not only intended for EU customers but also for export, since their combined production significantly exceeds EU customer requirements. The EU cobalt processors have one major competitor in Europe, the Finnish plant of the OM Group. The OM Group was formed by Outokumpu (Finland) and has three operating plants, Vasset in France, Kokkola in Finland and Mooney Chemicals in the USA. In 1993, Outokumpu divested of this business, and the company was floated on the US Nasdaq Stock Exchange. The OM Group also competes with the EU cobalt-processing companies on the international markets, chiefly the Americas and Asia, which are significant outlets for the EU products.

Although there are not many competitors with international scope, those that do operate internationally are fairly significant. Some of them supply special cobalt products as a by-product of other base metal activities i.e. Inco's cobalt oxide is a by-product of nickel ore processing in Canada, and Rustenburg Platinum's cobalt sulphate is a by-product of platinum ore processing in South Africa.

A new producer of ultrafine cobalt powder, the Canadian producer Sherritt, started marketing its product in Europe in 1993.

## ENVIRONMENT

Cobalt is classified as non-carcinogenic in the EU (15th Modification to Directive 67/548/EEC). Material safety data sheets describing cobalt products are commonly available to the users from the suppliers, on request. Cobalt metal, oxides, sulphides and carbonates in the form of powder, are listed in the Seveso Directive (82/501/EEC), but will most probably be withdrawn from this list in the new version of the Directive. Current legislation, in force or proposed, regarding Health and Safety is closely followed by the industry, especially with regard to the setting of occupational exposure standards.

Cobalt metal and oxide (CO<sub>3</sub>O<sub>4</sub>) are on Annex I of EINECS (European Inventory of Existing Chemical Substances) (80/C2760) and the industry has collected data for submission to the European Commission, via a leading producer, by July 1994.

## OUTLOOK

The EU cobalt industry faces several challenges. Feedstock must be imported due to the lack of indigenous cobalt sources. These sources are changing as the political scene shifts. Currently, the industry must rely on Central Africa (Zaire and Zambia), Canada/Norway (the Norwegian refinery is linked to Canadian mining operations) and Russia. This latter source is not new, but consumption in Russia has fallen dramatically and surplus production plus stockpiles have rapidly appeared on western markets. To some extent, the new Russian material availability together with the DLA releases have made the industry less vulnerable to African instability.

The EU cobalt special product producers rely heavily on the availability of cobalt-bearing scrap and residue which they recycle. There is therefore great concern about the Basle Convention and related regulations on movements of wastes which, although well intentioned, should not be seen as causing the cessation of vital recycling.

EU producers always face competition but the changes in Russia, and also China, outlined above have also paved the way for sometimes erratic competition from these areas. The industry is, however, strong and expanding in some areas.

# Ferro-alloys

## NACE 224

*The very depressed state of economic activity in recent years, especially in 1993, has strongly affected the European ferro-alloys industry. Declining output of steel and aluminium in domestic markets, weakness of the industry's traditional export markets, and the appearance of new producers and strong competition have led to declines in the volume of output. Even so, the strengthening of structures and the recovery which will be forthcoming in 1995 allow the industry to look to the future with confidence.*

### INDUSTRY PROFILE

#### Description of the sector

The ferro-alloy sector in the EU covers the production of various metal alloys, generally from electric arc furnaces by carbothermic reduction of metallic oxides.

The two main product categories are bulk ferro-alloys and special products. Bulk ferro-alloys include: ferro-silicon, ferro-manganese, ferro-chromium, ferro-silico-manganese all of which are consumed in large quantities. Special products category includes: ferro-titanium, ferro-vanadium, ferro-boron, ferro-molybdenum, ferro-niobium, ferro-phosphorus, ferro-tungsten, as well as metals such as silicon, magnesium, vanadium, chromium, and other derivatives which are consumed in much smaller volumes.

A characteristic of ferro-alloys is that they are upstream of the production of other metal alloys, mainly steel and cast iron, and to a lesser degree aluminium, zinc, lead, etc. They enable alloying elements to be safely and economically introduced into metallurgical processes, thus giving certain desirable properties on to these alloys.

Bulk ferro-alloys are used almost exclusively in steel making and steel or iron foundries. Advances in metallurgy and increases in yield due to the growing use of continuous casting have contributed to limiting the consumption of bulk alloys. This trend, which has now slowed down, is counter-balanced by the growing proportion of steels using ferro-alloys, especially stainless steels, manufactured in electric furnaces.

The uses of special ferro-alloys are far more varied, and the proportion used in steel making has diminished over recent years in favour of those used in the aluminium and chemical industries, especially silicone products.

#### Recent trends

Consumption of ferro-alloys, which is closely dependent on iron and steel production, was at 3.3 million tonnes at the end of the 1980s. However, the slackening of economic activity in 1990-91 saw consumption decrease to 2.8 million tonnes. From 1992 onwards, economic recovery, coupled with re-building of stocks, has pushed apparent consumption back up to 3 million tonnes in 1993. For the years 1994-96, the more or less stable apparent consumption should grow in line with a slightly increasing demand for bulk ferro-alloys and more important growth of demand for special alloys.

This increase in demand has been met by a growing proportion of imports, at first from the newly industrialised countries and, in recent years, from the countries of Eastern Europe and the CIS. The rapidity of growth in the latter imports has radically changed the EU's supply structure. It has become evident, however, that this penetration has been based on economically unrealistic price practices, which have been penalised by anti-dumping duties, leading to a lesser growth of imports. However, the decisions to decrease output made during the recent difficult years mean that imports will continue to grow during the next years.

Output in the EU has been adversely affected by the repercussions of this penetration and has had to be adjusted downwards; especially in the case of bulk alloys. The number of bulk alloy production locations is decreasing, to the benefit of more productive plants, and use of these alloys is being adjusted accordingly, but with a certain time-lag. However, the special alloys production should benefit from the upturn of 1994.

#### International comparison

In the EU, the United States and Japan, the output of ferro-alloys, traditionally associated with the production of iron and steel, has tended to decline, while domestic consumption is increasingly provided for by imports. This movement has been more noticeable in the EU than in its trading partners, owing to the opening-up of its markets and the geographical proximity of the new exporting countries (especially the CIS). Furthermore, with the EU being the cradle of world production of ferro-alloys, it has always had a considerably higher level of export activity than the United States or Japan. This activity

is currently faced with a heightening of international competition and is tending to decrease as time goes by.

Domestic producers in the EU, the United States, and even in Japan, have reacted to the growth of imports at excessively low prices by lodging anti-dumping complaints with the competent authorities. In particular, these complaints have been aimed at countries which formerly had State trading systems. Investigations have led, in most cases, to severe anti-dumping duties, highlighting the unfair nature of some of these exports.

### Foreign trade

EU exports consist mainly (60 % by value in 1993) of the so-called special alloys, which are more difficult to produce, for which the consumers' quality requirements are higher and whose unit prices are higher. However, this leads to specialisation with greater value added for EU industry products. Special alloys exports go mainly to the industrialised countries whose export share is over 90 %.

Conversely, exports of bulk alloys to destinations outside the EU are tending to disappear as the world market is increasingly dominated by imports of low-priced products either from the newly industrialised countries or from countries which formerly had State trading systems.

The EU's internal requirements for bulk alloys are increasingly being met by imports from these same countries and from Scandinavia, where production costs have been kept down at relatively competitive levels owing to access to competitive sources of electricity.

While EFTA has maintained its overall market share in recent years, a disquieting increase in the share of the Eastern European countries is observable. These countries, especially the CIS, possess a very large amount of industrial plant capacity, although their productivity is not very high. The collapse of their iron and steel production has led to considerable quantities of ferro-alloys coming on to the market, which have been exported in order to obtain hard currencies. For logistical reasons, the greater part of these exports have gone to the EU. Consequently, the EU ferro-alloys industry has been exposed to considerable competitive pressure and has lost ground in its own market. Steps have been taken to bring about a re-establishment of fair competition, with a view to safeguarding the future of the EU industry. These steps should enable the industrial sectors to be independent in their procurement through the maintenance of a significant level of domestic production.

## MARKET FORCES

### Demand

Overall demand for ferro-alloys is connected with the trends of its main markets (i.e. iron, steel and aluminium) and is affected by the cyclical nature of their activities. However, there are also significant variations between the market sectors.

#### *Iron and steel production and iron foundry activity*

Almost all bulk alloys and one third of special alloys are consumed by the iron industry, within which a distinction must be made between iron and steel production (itself subdivided into oxygen steel-making and electrical steel-making) and iron foundry activity. The demand for iron foundry activity differs both in terms of types of product and of specific consumption.

Oxygen steel-making accounts for 66.5 % of the EU's steel output, but its share in the total is slowly declining. Considerable advances in productivity through continuous casting have been achieved in recent years, and its specific consumption of ferro-alloys has steadily declined (less than 10 kg per tonne of steel at present).

Countering the relative decline in oxygen steel-making, electrical steel-making is steadily increasing its share in production. Assuming a constant product mix, productivity has also improved; although this is another factor leading to a decline in the specific consumption of ferro-alloys. Yet, the increase in the share of high-alloy steels, especially stainless steels, has more than counterbalanced the decline in specific consumption. Demand for ferro-alloys has increased in this market segment.

Iron foundry activity consumes a large proportion of the special alloys used in iron working, and consumption has been more or less stable.

Overall, demand for ferro-alloys for iron metallurgy has moved in line with steel production and has led to a decline in demand for ferro-alloys compared with the high level reached in 1989.

### Aluminium

Ranking second as a customer for ferro-alloys (with only 5.3 % of the total), the aluminium industry is primarily a consumer of special alloys; such as silicon metal and magnesium metal. In special alloys, aluminium now represents nearly half of the market. After a steady increase in demand up to 1989, the aluminium industry was hit by the recession in the building and automotive industries, in particular, in 1992-1993. From the beginning of 1993 onwards, however, the increase in demand for aluminium has had a beneficial effect on demand for silicon and magnesium.

### Chemical industry

This industry mainly consumes silicon metal, which is the raw material of silicone chemistry. Despite the strength of the long-term growth of these products, consumption declined slightly in 1992-1993, but has recovered in 1994.

### Supply and competition

The EU ferro-alloys industry has been faced with a stagnation of its market for the last ten years. Long-term growth has been practically zero, due to the cyclical variations in demand which have led to cyclical variations in prices. In order to adapt supply to market trends and competition, EU producers have undertaken very thorough restructuring programmes. Since the end of the 1970s, the EU has witnessed a continuous process of concentration of production at the most productive locations. During 1990 to 1992 alone, 25 % of the industrial establishments were closed to permit this concentration. Furthermore, flexible management systems, such as winter stop-

Figure 2: Ferro-alloys  
Breakdown by application, 1993

Source: Euroalliages

pages, have been adopted in order to adapt operations to the constraints of a competitive energy supply situation.

Despite these measures, growth in supply from countries outside the EU has continued. However, supply from the EFTA countries (mainly Scandinavia) contracted in 1992-1993 as a result of competition from other exporting countries, especially the CIS, where there are considerable production capacities. With the fall of the CIS's steel production from 165 million tonnes in the mid-1980s to 95 million tonnes in 1993 and 77 million tonnes in 1994, the ferro-alloys which it has stopped consuming have been directed to western markets, especially Europe, for logistical reasons. This supply, provided at prices which are totally unrelated to economic production costs, has created serious distortions of competition.

As a result, European producers have lodged anti-dumping complaints with EU authorities to prevent the industry's efforts from being completely thwarted and the independence of the industrial sectors concerned jeopardised. These lines of action have led to the introduction of anti-dumping duties on a number of products, enabling a certain regularisation of the market to be achieved from 1994-1995 and permitting a revival of supplies from Scandinavia. At the same time, the EU industry has persevered in its activities aimed at improving its costs and offering its customer industries products and services which more distant suppliers are unable to provide.

---

## INDUSTRY STRUCTURE

---

### Companies

Thirty-two firms are engaged in the production of ferro-alloys in the EU. Some firms are subsidiaries of major industrial groups, such as VIAG in Germany and Pechiney in France, but they represent only a relatively small proportion of the groups activity. Many, on the other hand, are small firms concentrating on the production of a range of ferro-alloys, or merely on a single, very specialised product. All these European firms pay special attention to the quality of their products and to customer service.

### Impact of the Single Market

The impact of the creation of the Single Market on the ferro-alloys sector has been overall positive. Most relevant to the sector are the elimination of controls at internal frontiers and the liberalisation of the energy markets. The elimination of border controls has facilitated cross-border shipping. Other measures promoting the free movement of goods are less important. The products of the ferro-alloys sector have a commodity nature, so that technical harmonisation is not an issue. In contrast, any measures relating to the energy markets are important since ferro-alloys are generally produced in electric-arc furnaces and electricity constitutes one of the main cost items. Crucial is here that no legislation should be passed which would affect electricity prices differently across Member States, as this would distort the competition between producers in different Member States. An area for future policy initiatives of interest to the sector is the harmonisation of waste treatment regulations. Presently, these differ widely across Member States, leading to large variations in waste treatment costs.

---

## ENVIRONMENT

---

Production of ferro-alloys generally involves the use of open electrical furnaces into which natural products (quartz, lime, various ores, wood, etc.), with a relatively fluctuating physical composition, are loaded.

The European industry has endeavoured to reduce emissions of dust, by installing filtration equipment in its factories, and to recycle the by-products of what it produces to the greatest possible extent. The concentration movement of the last ten years has accelerated this process by making it possible to build larger furnaces with higher yields and emissions which can be more easily controlled than those from a multiplicity of small furnaces. However, these measures are extremely expensive. At present, the EU industry devotes a quarter of its investment capital to installations for protecting the environment, thus responding fully to the EU's priorities.

The ferro-alloys industry, whose basic tool is an electric furnace in which metal oxides are reduced by carbon, is a major consumer of energy and a producer of carbon dioxide (CO<sub>2</sub>). It has, therefore, always regarded reduction of energy consumption as a vital priority. However, progress made in this field is always limited by the laws of thermodynamics, which govern the reactions used. The imposition of a tax on energy consumption and/or emission of CO<sub>2</sub> would not act as an incentive, because the increase in the size of the furnaces has already pushed up yields to very high levels. On the other hand, this tax would have a direct and intolerable effect on the competitiveness of European producers and would give free rein to less efficient consumers in countries where awareness of ecological considerations is still to come.

---

## OUTLOOK

---

The recession of 1992-1993, which was particularly pronounced in Western Europe, has given way to a recovery which will benefit the automotive and building sectors, the main customer markets of the ferro-alloys industry. Expected to be confirmed in 1995, the recovery should continue throughout the next two years.

The hoped-for improvement in the iron and steel industry will be accompanied by a continuation of productivity gains, with a decline in the specific consumption of ferro-alloys; albeit to a lesser extent than in the recent past. In terms of volume, EU demand for ferro-alloys should stabilise. It looks as if some sectors, such as silicones, will enjoy more sustained growth. This would lead to an increase in demand for corresponding metals or ferro-alloys. Measures adopted by the EU to maintain fair competition within the internal market should allow EU production to benefit from cyclical improvements and permit the EU industry to remain independent of its external suppliers.

## Overview NACE 24

As non-metallic mineral products are strongly linked to construction, the fates of the two businesses is inextricably connected. Therefore, if construction industry forecasts are achieved, the second half of the 1990s should prove to be more favourable for the non-metallic minerals industry than was the first. And, while the EU industry already is technically advanced and generally competitive on a global level, the process of restructuring and modernisation will help it to move forward even further. Generally speaking, imports form a small part of total consumption, but for certain sub-sectors (particularly for certain glass and ceramic sub-sectors), imports have been growing in recent years, especially from countries with low labour costs. The sector is a major user of fossil fuels and is thus heavily involved in environmental issues regarding atmospheric pollution.

### INDUSTRY PROFILE

#### Description of the sector

Non-metallic mineral products are made up of the following groups: clay products (bricks and roof tiles - NACE 241); cement, lime, and plaster (NACE 242); concrete (NACE 243); glass (NACE 247); and ceramic goods (NACE 248). The working of stone is (NACE 245) is covered in Chapter 2 of the Panorama.

Clay products, cement, concrete, and plaster are used almost exclusively by the construction industry, which also figures prominently as a customer for lime, glass, and ceramic goods (particularly tiles and sanitary ware). The latter products are widely used across a broad spectrum of industries embracing metallurgy, chemicals, food and beverages, electronics, and even electrical and mechanical engineering. A number of glass and ceramic items are domestic consumer items.

#### Recent trends

EU production of non-metallic mineral products was valued at over 90 million ECU in 1994 and involved materials measured in hundreds of millions of tonnes. The real annual growth rate over the 1984-1993 period averaged 1.5 % for production and 2.0 % for consumption, although this hides the fact that the major growth occurred during the 1987-1990 period in response to the relative boom in construction activity. Overall, imports surged during this period and have continued to grow ever since, although to put things in perspective it should be noted that imports in 1993 amounted to 4.9 % of total consumption compared to 4.0 % in 1984. As an important exporter of many of the products in this group - particularly glass and ceramic goods - the EU maintains a positive trade balance even though the overall level has fallen over the period. Preliminary figures for 1994 suggest that both production and consumption of these products is growing again after two-to-three years of recession in the construction industry in the early 1990s.

#### International comparison

The EU is the world's leading producer of non-metallic mineral products and its 1993 production value exceeded those of the US and Japan by factors of 1.9 and 1.3 respectively. The industries of both the EU and Japan have grown in real terms whilst that of the US has contracted.

**Figure 1: Non-metallic mineral products  
Value added in comparison with related industries, 1993**

Source: DEBA

#### Foreign trade

Although foreign trade was only a minor part of the total picture - imports averaged almost 5 % of consumption while exports averaged 9 % over the 1984-1993 period - it is actually much more significant in some sectors than others. For this reason, the continuous fall in the export-import ratio from 2.99 to 1.96 between 1984 and 1993 has important implications for the EU glass, ceramic goods and cement sectors. During this period, each of these industries experienced dramatic growth in low-priced imports - from Eastern Europe and Turkey in the case of glass and cement, and from the Far East in the case of ceramic goods. Overall, the EFTA countries and the US are also important sources of non-metallic mineral product imports, although their shares have decreased in favour of Eastern Europe, Turkey and the Far East.

Source: DEBA, Eurostat

Meanwhile, the value of EU exports of non-metallic mineral products declined in real terms from 1984 to 1993. This is mainly due to the falling contribution of cement, since the level of exports for both glass and ceramic products remained more or less constant during this period. The destinations for these exports are spread throughout the world, although the EFTA countries and the US have consistently taken between 45-50 % of the total value each year.

Intra-EU trade expanded rapidly during the 1980s. Since then, it has levelled off at around 14 % of total activity.

## MARKET FORCES

### Demand

The construction industry accounts for over two-thirds of the consumption of non-metallic mineral products and thus the prosperity of the sector has tended to follow the somewhat exaggerated peak and trough pattern of the past six years. The current period of lower interest rates already appears to be contributing to a renewal of construction activity; and the correspondingly increased demand for non-metallic mineral products can be expected to continue for the short term. The demand for glass and ceramic goods also is affected somewhat by construction activity, but overall consumption is spread out more evenly across a range of industries from general manufacturing to food, beverages and catering. Advanced materials will continue to grow quickly from a small volume base.

### Supply and competition

Most of the products of this group (with the notable exception of flat glass, tiles and tableware) are major bulk items of relatively low value that are based on local raw materials and sold primarily to local markets. Transportation costs are always a major consideration and have generally deterred competition from distant sources.

Some of the higher value products in the glass and ceramics segments have been exempted from such considerations forever, but increasingly during the last decade or so major bulk items, such as cement, are being shipped long distances by sea. The enabling factor is the low cost of ocean transportation when large bulk carriers of 20 000 tonnes or more are involved. Thus, a modern cement plant close to a shipping point can supply markets at competitive prices on the other side of the globe, provided that there is a bulk terminal at the other end to handle and store the product. European producers were actually among the first to take advantage of these opportunities. However, as former importers (for instance, in the Middle East) have installed their own manufacturing facilities, not only have the markets disappeared but new exporters have emerged.

The market in the 1990s is, therefore, much more competitive than before; and certain regions of the EU have become more vulnerable to competition from countries with low labour costs (e.g. Eastern Europe or the Far East). Nevertheless, most EU producers are competitive and will continue to supply the vast bulk of the EU's construction and industrial requirements. The principal threats to this competitiveness would come from any future legislation which reduced the availability of raw materials or raised the cost of energy.

### Production process

Europe has been at the forefront of many technological advances in the processing methods employed by the non-metallic mineral products industries - from specific procedures such as the float glass process and ceramic forming and firing techniques, to energy-saving measures that apply to the industry as a whole. A close relationship exists between this industry and its equipment suppliers which can be expected to be just as fruitful in the future as it has been in the past.

**Table 6: Non-metallic mineral products  
Breakdown by size of enterprise, 1990 (1)**

(%)	Number of enterprises (units)	Share of number of enterprises	Share of employment	Share of turnover
Less than 20 employees	75 049	88.6	24.4	20.7
20-99 employees	7 906	9.3	22.4	21.8
100 or more employees	1 741	2.1	53.2	57.5

## INDUSTRY STRUCTURE

### Companies

The diversity of products contained in this group is mirrored by the diversity of the companies involved, which range from major international construction groups with turnovers measured in billions of ECU and tens of thousands of employees, to small, family-owned businesses with a handful of employees and a regional sphere of interest. Concentration is high in some segments such as cement and glass, but low in others, i.e. concrete products, bricks and ceramics. Similarly, concentration is high in some countries (e.g. the UK and France), but low in others (e.g. Italy, Spain and, surprisingly, Germany). However, the pace of concentration appears to be quickening as groups acquire a more obvious pan-European status. The top six companies - Saint Gobain (F), Lafarge Coppee (F), Holderbank (CH), RMC group (UK), Pilkington (UK) and Redland (UK) - account for about 25 % of total production

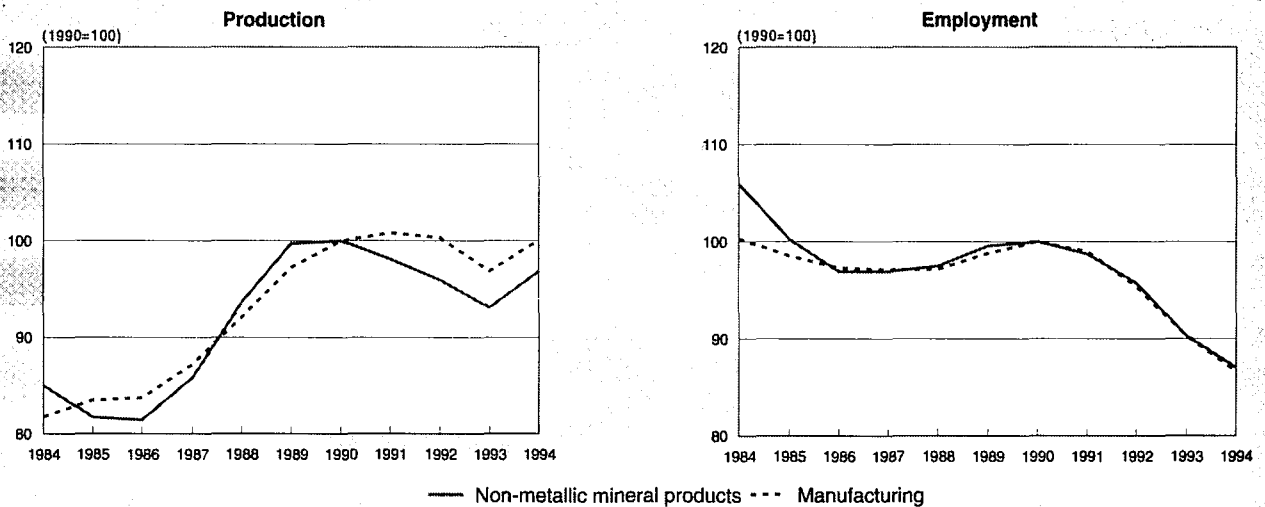

which is low compared to other industries. Nevertheless, it should be recognised that many of the smaller and medium-sized companies involved in non-metallic mineral product manufacture are highly efficient, modern, and deserving of international status in their own particular market niches.

### Impact of the Single Market

The creation of the Single Market is perceived to have had an important and primarily positive impact on the non-metallic mineral products industries in Europe. Sectors such as cement, glass, and ceramic goods had acquired a strong European mentality long before the Single Market programme began, but have seen the implementation not only as a confirmation of the process but also as a means to improve future development.

The free movement of goods, technical harmonisation, energy deregulation, competition policy, and environmental issues are of major relevance to all sectors. The importance of other

**Figure 8: Non-metallic mineral products  
Trade Intensities**

Source: DEBA

factors varies according to the sub-sector. For instance, intellectual property is highly relevant to the ceramics goods industries (tableware, ornamental ware, sanitaryware, walltiles, refractories, technical ceramics, etc.) where design or engineering influences are strong, but is only a minor consideration to the cement industry with its large volume commodity status.

With regard to the future a combination of energy, environmental, and competition policy issues are particularly relevant to these highly energy intensive (yet highly energy efficient) industries operating in very competitive international markets. The industries are especially concerned that EU legislation will increase costs to domestic producers and thereby open up European markets to suppliers from other countries which do not play to the same rules.

### REGIONAL DISTRIBUTION

EU production of non-metallic mineral products is widespread throughout the Community. The location of production sites is often governed by the raw materials used, e.g. cement factories based on limestone deposits, ceramics industries close to clay deposits, etc.

### ENVIRONMENT

The non-metallic mineral products sector is one of the major users of fossil fuels and is thus a focus of environmentalists concerned with atmospheric pollution. However, the sector has made major investments to comply with existing legislation and has a very good record in its control of sulphur dioxide and dust emissions. The various industries making up the sector also have been highly successful in introducing technical innovations to reduce unit consumption of energy. In particular, the glass industry is held up as a model for the ecologically sound practice of recycling. This notwithstanding, problems concerning the emissions of the oxides of nitrogen and carbon are proving to be a complex question. As a punitive carbon tax could be the death of much of the sector, efforts must be intensified to find a way to treat these gases by methods which do not themselves consume massive quantities of energy.

Source: DEBA

### OUTLOOK

Demand for non-metallic mineral products is expected to grow steadily in the latter half of the 1990s in response to the more favourable outlook for the construction industry. Generally speaking, although Eastern Europe has been regarded as a source of cheap imports in the past it is now being seen as a major area of opportunity for EU companies operating in this sector. However, also in this field there are wide differences among the subsectors involved, which are analysed in the following pages.

Written by: B.M. Coope & Partners

# Clay products

## NACE 241

Clay brickmaking is one of the oldest crafts in the world and the Ancient Greeks, Romans, and Etruscans can lay claim to being the earliest EU producers. Italy is still the largest producer in what is still the world's most important clay brick and tile producing region. Despite competition from a wide range of products based on concrete, wood, metal, and plastics, the modern clay brick and tile industry continues to be a major supplier to the EU building industry.

### INDUSTRY PROFILE

#### Description of the sector

The principal clay products for construction purposes are bricks and roof tiles. Clay extraction and treatment (Chapter 2) and brickmaking tend to be carried out by the brickmaking company itself, as a single integrated operation. Nevertheless, there are certain cases where large tonnages of clay are brought in from outside sources, for instance, when low cost by-product fireclays from open-cast coal mining operations are available. Products are sold to the construction and civil engineering industries (Chapter 19).

Bricks are available in a wide variety of types based on size, shape, colour, type of processing, end use, etc. They may be solid, perforated (i.e. with a large number of small holes), or hollow (e.g. horizontal core). Northern climates tend to use solid bricks whereas Mediterranean regions tend to use more hollow bricks. Perforated bricks are common along with solid bricks in Germany, Belgium, and Denmark. Another classification, particularly for solid bricks, divides bricks into commons (suitable for general building purposes, backing, etc.), facings (specially prepared with variations in colour and texture to provide an attractive appearance), and engineering bricks (high strength and low absorption for special load-bearing applications). Not surprisingly, there are strong regional characteristics in brick types, as well as national ones. Nevertheless, the industry has a long history of international dialogue on both technical and commercial levels. The European Tile & Brick Federation (TBE) has been in existence for over 40 years.

Principal producing countries in the EU are: Italy, Germany, and Spain which together account for about 75 % of total brick production and 65 % of total roof tile output. The UK, France, and the Benelux countries are also significant producers.

#### Recent trends

EU production and consumption of bricks and roof tiles grew almost continuously, in value terms, over the 1984-93 period (at an average 2.8 % and 3.2 % per annum, respectively). However, consumption, in real terms, has risen only marginally (0.14 %) and production has actually fallen (-0.12 %) during the same period. Over the last four years, there has been a decline of over 1 % in both production and consumption, although this trend was reversed in 1993/94. In volume terms, brick sales declined in 1992 and 1993, while roof tile sales grew.

Production patterns have been different for individual countries with Italy and Germany showing strong volume growth since 1984 while France and the UK showed initial growth followed by a clear decline. Future growth is likely to be uneven as well.

**Figure 1: Clay products**  
Value added in comparison with related industries, 1993

Source: DEBA

#### International comparison

Production of clay bricks and roof tiles in the EU is considerably higher than that in the USA or Japan, where other materials such as concrete, wood, and plastics are predominant. USA production in 1993 declined by 24.2 % compared to 1984, whereas Japanese production increased by 73.2 %. However, production in the USA increased in 1993 as its economy recovered.

#### Foreign trade

Foreign trade in bricks and roof tiles normally represents only a small part of overall consumption since the products are relatively high-volume, low-value products best suited to serve proximal markets. The types of products are also designed to meet particular building characteristics which tend to be of a regional or national nature. Thus, extra-EU imports represent less than 1 % of total consumption, although extra-EU exports are more substantial, averaging around 4 % of production in recent years. Export trade can be divided into regular trade with neighbouring EFTA countries and more single-project-oriented shipments to destinations such as the

Middle East and Far East. Over 25 % of exports are to EFTA countries, but with the inclusion of Austria, Sweden and Finland in the Union there will be a fall in extra-EU trade from 1995. Austria is also a major source of imports into the EU, second only to the Czech Republic which is the source of over 38 % of imports. Trade with the emerging economies of Eastern Europe is likely to increase as these economies develop and closer ties are forged with the EU. Meanwhile, intra-EU trade has more than doubled during the past five years, reflecting an increase in cross-border shipments in the regions of northern Germany, north-east France, and the Benelux countries.

**MARKET FORCES**

**Demand**

Bricks and roof tiles are consumed in building and construction and thus the construction industry is almost the sole customer of clay products. However, there is also a small volume of

sales to builders' merchants and the DIY (do-it-yourself) sector. Within construction, the main market for bricks and roof tiles is the new residential building sector. As bricks tend to be ordered at the beginning of the construction process, the level of new housing starts tends to be a better guide to demand than more general construction output figures. Bricks are also used in non-residential building for exterior cladding, as well as for walls, pavings, etc. The maintenance market for roof tiles tends to be more important than for bricks.

Other factors affecting brick and tile demand include climate, architecture, taste, and local availability. In addition, as previously suggested there are strong regional and national differences in demand patterns.

**Supply and competition**

Overall there is more than adequate capacity to meet existing and expected future demand for clay products in the EU; although, once again there are regional variations. In some

**Figure 4: Clay products**  
**International comparison of production in current prices**

Source: DEBA

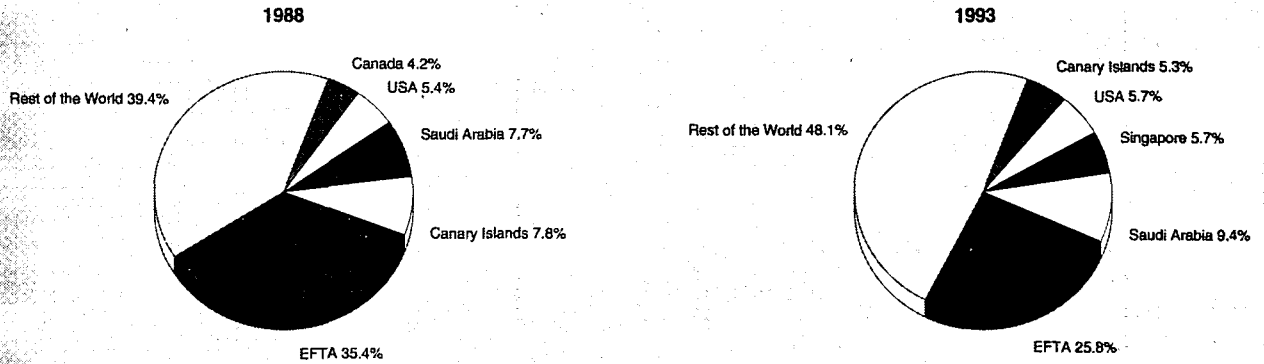

**Figure 5: Clay products**  
**International comparison of production in constant prices**

Source: DEBA

**Figure 6: Clay products  
Destination of EU exports**

Source: Eurostat

areas continuing overcapacity has led to the closure of older and less efficient brickworks whereas in areas such as former East Germany the boom in construction is likely to require the installation of new and modern brick and tile-making capacity.

The EU industry faces very little competition from foreign suppliers for reasons already stated in the trade section, but increasing intra-EU competition is a firm current and future trend. This has been helped by the process of standardisation now underway, a greater awareness of building practices from one EU country to another and the increasing international nature of the companies involved. Investments made by major producers in recent years have significantly brought down operating costs through savings in energy and labour costs and economies of scale. Consequently, the quality and range of products have both been extended.

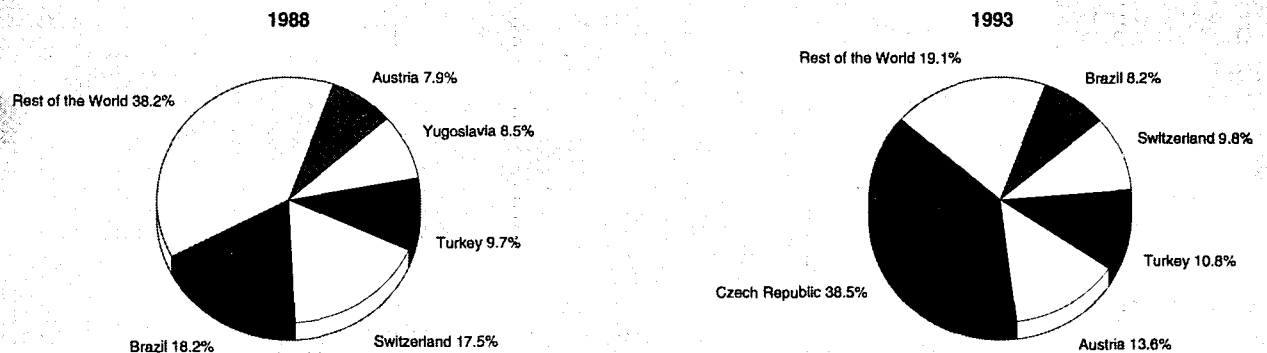

The most important competition that clay bricks and roof tiles have to meet is from competing materials ranging from bricks, blocks, and tiles made from concrete or other materials to completely different building systems.

### Production process

During the past decade the brick and tile making process has undergone major technological improvements at virtually all stages of the production process. A more precise understanding of the mineralogy of brick clays has enabled producers to improve properties and exercise greater control of product quality. In a modern plant, large scale mechanised extraction is followed by clay preparation which may now involve pre-treatment (e.g. weathering), blending, crushing, coarse grinding, fine grinding, and mixing. Additives may include plasticity modifiers (such as lignosulphonate to increase or crushed brick grog to decrease), wetting agents (soaps, etc.), colorants (such as manganese dioxide), deflocculants, and, last but not least, water. Prepared clay may then be extruded, surface-treated, cut (by wire), and dried before firing in a tunnel kiln.

Much effort has been directed in recent years to reducing energy consumption by applying best practice techniques at all stages of the production process. Although extrusion offers the most flexible and economical method to produce high quality bricks (including hollow bricks) other methods are still employed. These range from large factories based on dry or semi-dry presses to small factories using hand moulding techniques.

## INDUSTRY STRUCTURE

### Companies

Throughout most of the EU clay brick and roof tile production is in the hands of small or medium-sized companies; many

still privately-owned. In Germany, France, Benelux, and Italy the bulk of production is conducted by companies with annual sales in the 20-60 million ECU range. Most of these companies are based on highly efficient units with modern plants. The relatively small size is a reflection of the localised nature of the market. Nevertheless, the process of concentration is gaining momentum.

Concentration is most advanced in the UK where the clay brick and tile industry is now dominated (in production terms) by the conglomerate, Hanson Industries (through its subsidiaries, London Brick Co. and Butterley Brick); by two major diversified construction groups, Tarmac and Redland; and the large brick specialist, Ibstock Johnsen. Other companies of note include: Marshalls, Baggeridge Brick, and the building products division of Hepworth. In recent years several of these companies have expanded their activities in to other EU countries by acquisition. Redland, in particular, now operates on a pan-EU scale with its brickmaking in Germany and Benelux handled through a joint venture with Koramic of Belgium and roof tile activities operated through Braas in Germany and Italy and Coverland in France.

Meanwhile, other prominent companies operating in the EU include: Wienerberger Ziegelindustrie, Karl Bachl, Erlus Baustoffwerke, Roeben Tonbaustoffe, Josef Meindl, and F V Muelner in Germany; Guiraud Frères, Huguenot Fenal, and Sturm in France; Scheerders Van Kerchove in Belgium; and RDB Edilizia, Industrie Bitossi, and Moccia Irme in Italy. In response to increasing productivity the total number of employees in the industry has fallen steadily with the employment index (1990 = 100) at a level of 85 in 1994 compared with 126 in 1984.

Source: DEBA

### Impact of the Single Market

The impact of the creation of the Single Market on the clay products sector has been significant and primarily positive. Traditionally the brick and roofing tile industries of Europe have been drawn on national and even regional lines but over the past 10 years there has been increasing intra-EU activity involving trade, technical harmonisation, and countries operating in more than one country. The levels are still modest compared to other industries but the creation of the Single Market is seen as a contributory factor to the process and the free movement of goods and services as relevant to future development. However, many national and regional characteristics will remain and will generally be perceived as contributing to the cultural variety of the Union rather than as continuing internal barriers to trade. Meanwhile key issues affecting the industry which should also be afforded future priority include energy deregulation, public procurement policies, and policies affecting small and medium sized enterprises.

### REGIONAL DISTRIBUTION

The location of brick and roof tile manufacturing facilities is governed by the location of suitable clay deposits and proximity to major centres of building activity. Deposits of suitable clays are widespread throughout the EU wherever sedimentary rocks are in evidence. Thus, most operations tend to be concentrated in low-lying regions rather than in upland or mountainous regions.

### ENVIRONMENT

The principal environmental issues concerning the clay products industry involve reparation of former clay workings and emissions from the firing process. However, claypit restoration is essentially a mining activity, (see Chapter 2) thus the central issue concerns firing. Most modern brickworks tend to use gas as fuel, if available, although coal, oil, and certain waste materials are also used where local conditions apply. Thus, attention must be paid to both gaseous and dust emissions. It should be noted that in recent years the clay products industry has successfully devoted much attention to energy saving techniques based on recycling of waste heat, insulation, and best practice operating methods.

### OUTLOOK

There are signs of renewed growth in brick production and consumption in the UK, where the slump in brick sales has been most marked in recent years, although growth in the housing market has been modest. Recovery in other EU countries (apart from eastern Germany) is currently fairly modest, but the brick and tile industry should enjoy strong demand in the latter part of the 1990s in accordance with a generally good performance by the construction industry. Overall recovery from the recession in Europe has been cautious.

# Cement

## NACE 242

Economic activity in Cembureau member countries recovered slightly in 1994 due to an improvement in the construction sector. Trends in consumption and production showed marked differences between EU Member States. With a recovery forecast in the construction sector for 1995, the outlook for the cement industry is improving.

### INDUSTRY PROFILE

#### Description of the sector

Activity in the cement industry is connected to construction activity and is closely linked to the general economic situation. Cement is an important basic material for building and civil engineering works, representing major public and private investment.

Cement production consists of two essential phases:

- manufacture of a semi-finished product, so-called "clinker", obtained from the calcination in a high-temperature kiln (1 450°C) of raw materials (clay, limestone, etc.) which are previously prepared in paste or powder form, depending on the production process used (i.e. wet or dry); and
- manufacture of cement as a finished product, obtained by the homogeneous mixture of the ground clinker and calcium sulphate with or without, depending on the type of cement, one or more additional components: slag, fly ash, pozzolana, filler, etc.

#### Recent trends

In 1993, EU consumption amounted to 157 million tonnes, about 12 % of world production compared with 21 % in 1980. EU cement production amounted to 158 million tonnes in 1993.

After high economic growth in Western Europe in 1987-89, economic activity slowed dramatically in the second half of 1990 and growth virtually ceased in the first half of 1991. Consequently 1991, 1992 and 1993 marked a heavy downturn in consumption of cement for a number of EU countries. In 1993, total EU cement consumption decreased by a further 8 %, an 11 % decrease since 1990.

**Figure 1: Cement Consumption by Member State, 1993**

(1) Includes former East Germany.

Source: Cembureau

Differences in EU countries are, however, varied: Italian consumption decreased by 16 %, while French and Spanish consumption decreased by 11 % and 13 %, respectively. Germany, aided by the reconstruction works in the new Lnder, maintained its consumption, but increasing tonnage was imported from East European countries.

#### International comparison

World cement production has been estimated at 1 280 million tonnes for 1993. The major cement producing countries were: China (360 million tonnes), Japan (94.8 million tonnes), CIS (80 million tonnes, estimate), USA (74 million tonnes), India (55.8 million tonnes), South Korea (49.7 million tonnes), Italy (34.8 million tonnes), Turkey (32.7 million tonnes), Germany (32.5 million tonnes), Thailand (27.8 million tonnes), and Mexico (27.6 million tonnes).

In 1993 total world production of cement (excluding China) showed a slight decrease which was partly influenced by Europe. However, the overall market trend (including China) is increasing by about 3 %. European countries, as a whole, and Japan witnessed a new decline, while the USA showed an increase of about 6 %.

### Foreign trade

World trade in cement only accounts for about 6 % of total production, mainly due to the cost of ground transportation. The largest quantities are primarily distributed by sea and consumed at a limited distance from the port.

Moreover, foreign trade is marked by a very pronounced geographic polarisation. As in previous years, 40 % of imports were recorded in only six countries in 1993: the USA, Germany, Taiwan, Singapore, Spain and Italy, while more than 40 % of the world's exports came from five countries: Japan, Greece, Korea, Canada and Spain.

Japan increased its exports of cement by a further 14 % in 1993, with an export volume amounting to 13 million tonnes. In 1993, the USA, Taiwan and Germany each imported about 6 million tonnes. The amount of cement imported in Germany again increased, with tonnage coming mainly from Eastern Europe.

Recovery of consumption in the USA had a positive effect on their imports, which increased by 1 million tonnes to 7.1 million tonnes. However, the application of the ITC's (International Trade Commission) anti-dumping duties kept Mexican, Venezuelan and Japanese exports at 1992 levels.

Due to the consumption decrease in the EU, imports decreased slightly in 1993 to 20 million tonnes. However, the share of imports from Eastern Europe has increased four-fold since 1987, and continues to increase. Total imports from Eastern European countries represent about 13 % of EU consumption and about 30 % of total world trade. In 1993, imports increased in Spain and Italy up to 12.2 % and 8.5 %, respectively, of domestic consumption.

The EU's main exporter was Greece, exporting 50 % of its production.

### MARKET FORCES

#### Demand

As mentioned, consumption is linked directly to activity in the building sector and, more accurately, to investments made in residential and non-residential building and civil engineering works.

#### Supply and competition

EU capacity is currently more than sufficient to cover internal demand. Nevertheless, there is continued exposure to cement imports from East European and developing countries at artificially low prices (dumping conditions). Unfair competition from countries where environmental and social protection is non-existent could have a very damaging impact in the areas where these imports are concentrated. Consequently, the legal resources for defence against concentrated dumping at the borders have to be reinforced. Whereas overall economic harm to the EU may appear limited, the same does not hold true at the regional level where border dumping leads to a "knock-on" effect.

#### Production process

Productivity in the cement industry rose by about 30 % during the last ten years due to the introduction of more efficient and sophisticated production tools, with advanced automation of operations requiring higher qualifications from the staff.

Cement production requires large quantities of energy. Fortunately, significant advances have been made in recent decades in reducing the energy required to produce a tonne of cement. A recently published European Commission Report concludes that only a 2.2 % real energy saving potential exists within the cement sector. Average energy consumption per tonne of clinker produced in the EU today amounts to under 900 kcal/kg. However, this value may vary widely from country to country, depending on the production method applied. Energy consumption in relation to cement manufacture also depends on the policy pursued by the different national industries as regards investment and product development.

The industry continues its efforts to reduce energy consumption by:

- seeking cheaper energy (diversification of fuels); and
- rational use of energy (new manufacturing processes, development of composite cements, heat recovery, etc.).

## INDUSTRY STRUCTURE

### Companies

There are nearly 300 plants in the EU, belonging to 138 companies. Restructuring and market positioning of the leading companies is expected to continue.

There are no generally accepted criteria for ranking cement companies or groups, as both turnover and capacity can be defined in different ways. Published turnover in consolidated accounts may include non-cement activities and the existence of trading affiliates can lead to different quantities of cement being produced and distributed by a company. In addition, the calculation of capacity in part-owned companies can be treated differently.

Taking into account the above reservations, the largest operating companies in the world having cement interests in Europe are generally regarded to be (in alphabetical order): Blue Circle (UK), Cemex (Mexico), Dyckerhoff (D), Heidelberger (D), Holderbank (CH), Italcementi (I), Lafarge Coppe (F), Scancem (N/S).

### Impact of the Single Market

The impact of the creation of the Single Market on Europe's cement industry has been significant and positive. Cement companies tend to be large organisations with international operations and interests. For them the Europeanisation process was underway long before the Single Market programme was

introduced but it provides confirmation and a channel for future progress.

The transportation cost element associated with moving high-bulk, low-cost product by land means that most cement is consumed within 250 km of the point of production and thus intra-EU trade concerns less than 10% of total shipments. Nevertheless freedom of movement of goods is a highly relevant issue with particular reference to technical harmonisation, mutual recognition of rules, and competition policy.

As a major consumer of energy based on fossil fuels the cement industry regards the liberalisation of energy supply and pricing as highly important. Within this context indirect taxation and environmental protection issues are highly relevant with particular reference to the carbon tax.

The cement industry sees as future Single Market priorities the clarification of competition issues (dumping, subsidisation), and energy/environment factors, including the recognition by all parties that other countries must play the same rules.

## ENVIRONMENT

As public concern for the environment steadily increases, so does the activity of the EU Council, Commission and Parliament in tackling environmental issues.

A significant body of legislation is currently being developed which impacts on the industry. Particularly relevant to the sector are proposals for a CO<sub>2</sub>/Energy Tax, Integrated Pollution Prevention and Control, Waste Classification, and Incineration of waste and hazardous waste.

The industry has, at an operational level, invested heavily in environmental protection measures and strategically continues to work with the relevant legislators to develop appropriate legislative instruments in environmental protection.

## REGULATIONS

A European pre-standard for common cements, ENV 197-1, was adopted in 1992 by the members of CEN. This pre-standard will assist convergence of national standards as a full EN (Euronorm) is prepared. Pre-standard ENV 197-2 "Cement Conformity Evaluation", which sets out a European scheme for cement certification, was agreed by CEN members in 1994. Convergence of national certification schemes will now take place in anticipation of a final decision on the matter by the European Commission.

---

## OUTLOOK

---

Economic activity in Cembureau countries recovered slightly in 1994 with evidence of an improvement in the construction sector. According to Euroconstruct, the European construction sector shows flat output for construction in 1994 and a recovery of at least 2 % for 1995. The downward trend in demand for cement in the EU has apparently slowed down in 1994.

Written by: Cembureau

The industry is represented at the EU level by: Cembureau The European Cement Association. Address: Rue d'Arion 55, B-1040 Brussels; tel: (32 2) 234 1011; fax: (32 2) 230 4720.

# Precast concrete

## NACE 243.2

A fall in the precast concrete activity has been noted in most EU countries from 1990 onward. Precast concrete activity closely follows developments in the construction sector, which is virtually its only client. Drops in activity were strongest in France, Italy and the United Kingdom. Almost at the same time, a strong rise in precast concrete production was noted in Germany. Although the industry is mainly made up of small to medium-sized companies, some merger and acquisition activity has taken place. Stricter EU legislation on pollution control will influence the precast concrete industry, while the limited expansion possibilities for mining and quarrying might pose supply problems for the industry.

### INDUSTRY PROFILE

#### Description of the sector

The precast concrete industry is the collective name given to all enterprises that manufacture precast concrete products at specially equipped plants and which operate independently of weather conditions. Products are delivered to the construction sector ready to be put in place in building and road constructions, civil engineering works, etc.

Concrete is made from a mixture of sand, water, cement, gravel or other aggregates, and other possible additions. As an industrial sector, the precast concrete industry is situated between the suppliers (i.e. cement manufacturers and quarries) and the customers (i.e. the construction sector).

The precast concrete industry covers a wide range of products :

- products for road construction (paving flags, stones and blocks, kerbs, safety and sound barriers, sewerage and drainage pipes, accessories, etc.);
- elements for building construction (masonry units, cladding elements in architectural concrete, floor elements, beams and columns, wall elements for industrial, commercial and agricultural buildings, etc.);
- elements for civil engineering works (bridge girders, tunnel elements, etc.); and
- units for various other purposes such as flood protection, urban and garden landscaping, lighting poles, and agricultural installations.

Furthermore, the following general characteristics of the precast concrete industry can be highlighted :

- relatively low value-added content of certain mass-produced precast concrete units;

- strong dependence upon the efficiency of the business (i.e. the degree of mechanisation of the production process and the effectiveness of management); and
- a predominance of small and medium-sized businesses (in some countries the majority of the enterprises are still family-owned). Although some of these businesses have recently been bought up to form bigger concerns, the number of production sites remains largely unchanged (even after the inevitable rationalisation).

National and regional distribution in the EU precast concrete industry are very much interrelated and are influenced, to a large extent, by factors such as the demographic situation, climatic conditions and the traditional use of certain construction materials.

#### Recent trends

In 1993, it is estimated that turnover in the EU approximated 20 billion ECU and employment was at about 180 000.

In the industrialised countries, activity in the precast concrete industry largely depends on the overall economic climate and on activity in the construction sector in particular (99 % of production goes to the construction sector). However, trend differences can be observed between residential building, non-residential building and road construction (the latter absorbs roughly 30 % of precast concrete production).

In recent years, the general economic downturn has caused a considerable fall in overall precast concrete production, estimated at some 20 % (excluding Germany). However, the precast concrete industry is still doing well in Germany and this positive trend is expected to continue for the next few years.

Employment in the precast concrete industry follows overall production trends, but is more elastic, i.e. a considerable decrease in production does not necessarily lead to an equal drop in employment.

#### International comparison

Due to climatic conditions, prefabrication is in principle more developed in the northern countries. This explains the relatively high level of precast concrete activity in the Nordic countries. However, the recent economic crisis has had severe consequences for activity in Sweden and, especially Finland, where production in current prices has declined more than 50 % from 1990 to 1993.

Notwithstanding local competition from neighbouring East European countries, production volume in Austria remains satisfactory. Switzerland is a typically local industry with a very closed market which is probably due to the rather heavy weight of the product and the inherent transportation possibilities.

The level of activity in the North American precast concrete industry varies according to the product branch. However,

large structural elements for industrial applications, large-diameter pipes and paving blocks seem to be the most successful products of the last decade, while concrete masonry units have recently recovered some of the attraction lost in the early 1980s.

### Foreign trade

Generally, precast concrete products are heavy and bulky in relation to value. The average value of one metric tonne of precast concrete product is approximately 100 ECU (but for some standardised non-reinforced products manufactured on a large scale, this value can be as low as 40 ECU). Consequently, long-distance transportation of precast concrete products is unusual and trade is mostly limited to a single border crossing. However, there are exceptions. For example, technologically, highly-advanced precast concrete products (i.e. sophisticated cladding elements in architectural concrete) and certain speciality products (i.e. high-quality decorative tiles).

## MARKET FORCES

### Demand

Activity in the precast concrete industry strongly depends on activity in the construction sector, which in turn is dependent on the overall economic climate. As a consequence, periods of high activity in the precast concrete industry are succeeded by low-activity periods which leads to costly overcapacity.

Another factor causing variations in activity levels is the financial situation of public authorities. Approximately one-third of construction sector activity covers public works

(involving road construction, civil engineering works, etc.). Consequently, when public authorities experience financial difficulties, the construction sector is impacted which in turn influences demand for precast concrete.

In the German precast concrete industry it is evident that the current high activity level is a consequence of the immense reconstruction operations in the former East German states.

### Supply and competition

The precast concrete industry faces competition from traditional construction procedures with an intensity that varies from country to country and which is closely related to the marketing skills of the local industry. Indeed a wide range of substitution products are offered ranging from classical materials, such as clay brick and timber, to newer materials, such as PVC and glass fibre reinforced plastics.

However, some precast concrete plants have considerably improved their competitiveness through an extensive mechanisation and automation process. These operations make it possible to significantly compress the cost per unit. As a consequence, these plants have become competitively operational over a much wider geographic area. Moreover, the price of precast concrete products could be kept down to a remarkably low level, thus securing precast concrete products a strong position against substitution products.

Depending on their type, precast concrete products are either distributed by direct sale to building contractors, which accounts for at least 80 % of the total output, or through the sale to building material retailers, which accounts for the remaining 20 %.

## Production process

Over the last fifty years, mechanisation has changed the face of the precast concrete industry considerably. Before and in the first years after World War II, the manufacture of concrete was essentially a handicraft trade. Moreover, the material was mainly used for non-structural applications and was not reinforced.

Technological developments in the early 1960s in reinforced and prestressed concrete led to breakthroughs of various plant-manufactured structural elements for building construction and civil engineering. At the same time, light-weight concrete was applied in the precast concrete industry for the manufacture of masonry units, and wall and floor elements.

The construction boom in the late 1960s and early 1970s, as well as, the increase in building costs, led to a further industrialisation of the precast concrete industry. Profits were reinvested in to both plants and modern machinery, such as semi-and fully-automated batching and manufacturing equip-

ment. In addition, handling, packaging and transporting techniques were revolutionised.

Recent developments in the automation process (including the use of sophisticated soft-ware) have brought the industry to a new level of technical excellence which has further increased productivity.

The following are particular technological aspects for precast concrete manufacturing:

- precast concrete products are manufactured at a plant with a permanent location in controlled conditions;
- production is based on a proper scientific concrete technology, such as the use of 0-s slump concrete, hot concrete and pretensioning techniques, particular moulding and compaction techniques and accelerated hardening techniques;
- advanced quality control, which goes beyond the checking of the fresh concrete. Quality control includes the control of: dimensional accuracy, the properties of the hardened

Source: BIBM

concrete, and the position of the reinforcements. Control is done before the product has been incorporated into construction. This important factor should be taken into account when comparing precast concrete with other, traditional building methods; and

- not only are manufacturing methods and plants highly automated, but production is also characterised by an ever increasing level of industrialisation and standardisation.

These specific and scientific approaches in concrete technology help to guarantee a high and consistent quality of precast concrete products.

Basically, most "new" products in the precast concrete industry are evolutions of existing elements. Nevertheless, the industry has also developed (and is successfully marketing) valuable solutions in areas relating to environmental problems. One such development is sound barrier walls to protect residents living near highways or railways from noise hindrance.

## INDUSTRY STRUCTURE

### Companies

As already mentioned, the precast concrete industry remains predominantly composed of small to medium-sized enterprises (which in some countries are still family-owned), in spite of a recent rationalisation movement. This movement has been spurred on by two concurrent factors. First is the fragmentation of family-owned businesses (that had grown to considerable sizes since World War II) due to succession problems. And, second, in the context of the Single Market, is the trend towards concentration in view of allowing large construction companies to control supplies on the foreign markets they enter, or creating concrete companies large enough to deal with the big construction companies on an internationalised market.

The rationalisation movement inevitably reduced the total number of enterprises, but not to the extent expected. Most production sites remained in business, mainly because of the rather heavy weight of many precast concrete products and the transportation costs involved. For instance, after a company in one of the bigger countries had bought up 25 smaller enterprises, some 15 remained operational.

Even though there is not complete information on EU employment in the precast concrete industry, a reasonable estimate is around 180 000 people. The number of employees

is spread over nearly 5 000 precast concrete plants, of which approximately 600 employ more than 50 people.

Following years of growth up to 1990, employment has now come to a relative standstill in some countries. However, in some countries, such as the Nordic countries, the United Kingdom and Italy, it is falling as a consequence of the economic situation.

On the labour market, wage costs have risen in recent years as a result of reduced working hours, as well as, a shortage of skilled labour. The overall average hourly wage cost in 1993 was approximately 18.5 ECU. Skilled manual workers constitute about 25 % of employment in the precast concrete industry. These workers are involved in special production procedures such as reinforcement steel bending and netting and the finishing of architectural concrete (e.g. polishing).

In recent years, technological developments and automation have given rise to a considerable demand for highly qualified labour skilled in the latest technologies. In several Western European countries the limited number of these labourers are in high demand, as younger school graduates do not appear to be strongly attracted towards this occupation. To cope with the problem, the industry has set up specific programmes ranging from training courses for young adults and/or unemployed people, the publication of manuals, and campaigns designed to improve both the image of the industry and the attractiveness of jobs in precasting. For example, the industry in Germany regularly organises a nation-wide promotion day offering younger people the opportunity to visit precast concrete plants.

### Strategies

As mentioned, some degree of concentration has occurred in the industry in recent years. Besides mergers and acquisitions, the industry also aims to increase productivity (estimated to have risen by roughly 50 % over the last fifteen years) and improve quality. Towards these goals, the precast concrete industry has raised fixed investment by about 50 % from 1985 to 1993. These investments reflect significant efforts towards innovation in the sector and involve not only replacement of older equipment and installations but also an increase in capacity, thus enhancing the competitiveness of plants.

Precasters have also become aware of the market advantages of guaranteeing the adequate durability of products (implying both soundness and long-term appearance) and improved de-

sign. Hence, the active participation of the industry in EU harmonisation, certification and standardisation work in view of the implementation of the Construction Products Directive; the CE quality label.

Technological evolution also constitutes as an influential factor. Indeed, the technical realisation of new types of beams or girders with, for instance, larger spans would automatically create a higher demand for these structural elements. Furthermore, certain technological innovations that help avoid the carrying out of complex and difficult tasks on traditional building sites enable the precast concrete industry to offer attractive and efficient solutions to builders; e.g. elements for railway bridges with incorporated railway tracks.

### Impact of the Single Market

The impact of the creation of the Single market on the precast concrete industry has not been great but is regarded as positive due to the effect on general economic activity in the construction sector. Trade between countries tends to be limited since most of the products are large and heavy but some of the more specialist items do cross both intra-EU and extra-EU borders. Thus the freedom of movement of goods, services, and capital are all seen as relevant.

Where the Single Market is seen to have had the greatest effect is in the area of technical harmonisation, standardisation, and certification. This is seen as particularly important to the future development of the industry in Europe. Since the industry is largely made up of small to medium sized enterprises (often family-owned companies) issues concerning SMEs (access to finance and a lowering of the administrative burden) are highly relevant.

### REGIONAL DISTRIBUTION

National and regional distribution are narrowly intertwined.

The precast concrete industry is particularly important in the Federal Republic of Germany, relatively important and advanced in the Netherlands and Belgium, and, to some extent, in France and northern Italy. In some countries, there is a higher concentration of the precast concrete industry in certain regions; e.g. the South West of the United Kingdom.

Geographical factors also play an influential role in the precast concrete industry. The more densely populated a region, the more important and developed the precast concrete industry tends to be because these regions have a higher demand for building, water and road construction. Since precast concrete products are heavy and costly to transport, production takes place near the centre of demand. An example of this is the triangle of dense population in Belgium, the Netherlands and Germany, in contrast to the more sparsely populated regions in central France and Spain.

Climatic conditions also play an important role. In general, the further north a country is situated, the more developed its precast concrete industry. Traditional building activity in northern countries often has to be suspended during the winter due to bad weather conditions, while precast concrete products allow uninterrupted building activity.

Traditional use of certain construction materials has influenced the degree of development and strength of the precast concrete industry in various Member States. In the Netherlands, for example, a boom began for precast concrete pavers when traditional clay pavers became too expensive. This secured the Dutch paving industry a strong position which allowed large-scale production at a favourable cost. Another result of this situation was that transportation beyond The Netherlands' borders became possible. By contrast, the British precast concrete flooring industry has encountered great difficulty in breaking into the traditional timber floor market for low-rise housing.

The percentage of the precast concrete industry in total national cement consumption illustrates the actual penetration of the precast concrete products on the construction market. It shows a rather positive trend in most countries; especially in countries where the industry has successfully commercialised its precast concrete solutions. Indeed, by producing certain construction materials at fixed plant sites, instead of at building sites, construction costs may be significantly reduced.

### ENVIRONMENT

EU legislation on pollution control will have its influence on the precast concrete industry. National legislation concerning environmental protection is particularly aimed at reducing emissions from the raw materials and manufacturing industries. Hence, considerable know-how and capital investment in environmental protection are required of these industries. By means of modern techniques (such as waste-water treatment installations) the pollution of air, water and soil may be controlled notwithstanding growing production. Modern techniques will thus help dissociate industrial production and economic growth from environmental exploitation.

In the precast concrete industry, a noise problem may occur as increasing urbanisation encroaches upon precast concrete plants. However, the industry has already recorded some success in reducing noise levels. Unfortunately, machine manufacturers are not sufficiently aware of the problem and generally only take action when pressed by their clients, the precast concrete manufacturers.

Increased restrictions on gravel extraction, anticipated in a number of Member States, could affect the concrete industry by rendering raw material supplies more difficult in the long term. Raw material shortages might arise in some countries. In addition, the quarries supplying the precast concrete industry with sand and aggregates are either forbidden to extend further, or are threatened with closure. Since about 80 % of concrete is made up of sand and aggregates (1 m<sup>3</sup> concrete requires two tonnes of these raw materials), this may cause serious short-term problems, not only for the precast concrete industry but also for the construction industry as a whole.

Consequently, certain research programmes are being conducted with the aim of recycling concrete debris, crushed concrete and waste concrete. Due to requirements for high-quality inputs, however, the precast concrete industry has only limited opportunities for using such recycled materials. Moreover, high-quality aggregates are also a prerequisite to meeting the stringent performances demanded of precast concrete products. Furthermore, these aggregates play an important role in one of the major advantages of precast concrete, i.e. smaller dimensions of the components which reduce their weight, improving transportation costs.

### REGULATIONS

The Single European Market and the coming into effect of the Construction Products Directive (CPD) have emphasised the urgency of work on harmonisation, standardisation and certification.

Adoption of common standards and quality certification systems at the EU level are essential for the precast concrete industry. Consequently, the industry has a preference for the most stringent level of attestation of conformity involving product certification by an approved third party. Such certification would help to maintain client confidence in the high quality of the products, improve the quality image of the concrete products, and reduce the chances of having regulatory attestation exist next to a voluntary certification system.

Unfortunately, competent EU bodies do not share this view, but instead opt for a low-cost conformity attestation. This attitude is most regrettable since it could impede development of high-quality products.

---

## OUTLOOK

---

In general, 1994 and 1995 are expected to show mixed results in various Member States. Steady growth is foreseen in Germany and a near status quo in Belgium and the Netherlands, while France recovers slowly from a deep recession. In Italy, however, the situation is still rather bad and expectations remain low. This situation also applies to other Mediterranean countries due to an overall unfavourable economic climate which is discouraging investment in industrial buildings and, to a large extent, in private housing. As mentioned, activity in the precast concrete industry is largely dependent on construction activity. Thus, any improvement there will have a favourable impact on the economic situation in the precast concrete sector. The specific advantages of using precast concrete products for construction will, in the medium to long term, inevitably result in a larger share of the sector in overall construction volume.

Written by: **BIBM**

The industry is represented at the EU level by: **International Bureau for Precast Concrete (BIBM)**. Address: Bd A. Reyers 207/209, B-1040 Brussels; tel: (32 2) 735 6069; fax: (32 2) 734 7795.

# Ready mixed concrete

## NACE 243.6

With falls in production throughout Europe being more prevalent than increases, overall production fell by 9 % in 1993. Prospects for the immediate future will do well to recover this loss in production in the short term. The industry continues to work hard to ensure that current and prospective EU regulations will be those that the industry can meet in the normal course of business.

### INDUSTRY PROFILE

#### Description of the sector

The ready mixed concrete industry covers the off-site manufacture of fresh, unhardened concrete and its transport to the location where it is placed. It is, by definition, a local industry offering little or no potential for trade, even within the EU. In fact, the fresh product can only be transported for short distances, seldom more than a few tens of kilometres.

The European ready mixed concrete industry is a relatively new industry which has contributed substantially to the modernisation and efficiency of the building construction industry in each country. Although the use of concrete goes back to Roman times, the production of ready mixed concrete from an exclusively designed plant probably started at the beginning of this century with Germany leading production in 1903, followed by the USA in 1913. More widespread use of the product developed when the UK and France established their industries in the early 1930's. Today there are few countries in the world which do not have a ready mixed concrete industry.

Over the life of its 27 year existence, European Ready Mixed Concrete Organization (ERMCO) members have concerned themselves with improving the quality of their product and ensuring that concrete is designed for the purpose specified. They have also sought means for improving the marketing of the product against its main competitors: wood, bricks and steel.

#### Recent trends

The year under review is the second year following the completion of the European common market standards and the removal of many technical barriers to trade. Attendant activities have mainly been concerned with the drafting of EU directives covering construction products, certification and testing, and Eurocodes and CEN standards for concrete. These documents place a great emphasis on quality and should enable the standards already achieved by the industry to be fully recognised.

Production by EU Member States during calendar year 1993 totalled 225.58 million cubic metres, a fall of 9 % compared with the previous year. For the immediate future the industry will do well to recover to its earlier levels.

### MARKET FORCES

#### Demand

After the long period of uncertainty brought about by the Gulf war and the break up of the former Soviet Union, there is now a more hopeful and optimistic spirit in Europe. The general relief towards the end of 1993 at the completion of the Uruguay Round of the General Agreement on Tariffs and Trade has been followed by positive signs, including the continuing Israel/Palestine peace initiative, the possible end to

Figure 1: Ready mixed concrete  
Production volume by Member State, 1993

Source: ERMCO

hostilities in the former Yugoslavia and tentative improvements in the East European economies.

All this has led to a mood of growing confidence in the minds of authorities and businesses alike. As the overall level of trade struggles to improve, the European ready mixed concrete industry is ready to meet any increases in demand. ERMCO continues to be active in representing and defending the interests of the industry in the fields of Industry Policy, Standardisation, Certification and the Environment. However, any improvement in consumer confidence has yet to be reflected in increased construction investment and from there to production levels of the European ready mixed concrete industry. In addition, the future outlook is not evenly spread among Member States: while some countries are emerging from recession, many of the others, which have suffered recession for several years, are only hoping for a return to equilibrium in the year ahead. Likewise, the high level of unemployment still depresses the whole European economy, while inflation rates are, for the most part, at their lowest point for many years.

## INDUSTRY STRUCTURE

### Companies

The ready mixed concrete industry is a fragmented one, which not being organised into large monopolistic groups, can never achieve a dominant position in the market. Ready mixed concrete producers are typical of SMEs (small and medium enterprises) in Europe.

Despite its importance to the European economy, producers of ready mixed concrete occupy a very weak position between their customers and raw materials suppliers. On the one hand, their customers (contractors) can always manufacture their own concrete if they choose; while, on the other hand, ready mixed producers are totally dependent on supplies of cement and aggregate from producers of major groups who do not tolerate late payments.

A limited amount of progress has been made in the past year concerning the growing practice of payment delays by Public Administrations and Authorities for work done by the Prime Contractor. As a consequence of delayed payments, contractors are deferring payments to sub-contractors and suppliers to

the extent that the continued financial viability of many SMEs is being seriously threatened.

In its position paper submitted to the DGXXIII, Enterprise Policy and Distribution Trades, ERMCO strongly supports the introduction of a Community legal framework governing payment periods. Over the last year or two, ERMCO members have noted a marked increase in payment delays, some as long as 150 - 200 days. It must be explained that although the ready mixed concrete industry's main customers are private contractors and builders, some ready mixed concrete companies also sell directly to local and national public authorities. During the course of the year, the Directorate General XXIII, Enterprise Policy, Distribution Trades, started its own enquiries into such delays, which after consideration, resulted in a favourable resolution in the European Parliament. The subsequent public hearing on the subject resulted in, among a variety of other proposals, a proposed ERMCO sector agreement between the industry's suppliers and their customers. The proposals put forward have received an encouraging response from the Director General of DGXXIII.

## Impact of the Single Market

The creation of the Single Market has had little direct impact on the ready-mixed concrete sector in Europe. There has been an indirect impact, however, since the construction industry in general has benefited from the greater economic activity ascribed to Single Market measures. Not surprisingly some of the larger construction materials companies who include ready-mixed concrete amongst a range of interests see the Single Market as more relevant than small or medium sized companies operating in one country or region.

The local nature of the industry and the short distances involved in supply of the product means that the European dimension tends to focus on technical factors such as common standards, quality control, and environmental protection. The process of discussion of these issues was well advanced before the Single Market programme. With regard to the future, improved access to finance for small and medium sized enterprises is an important issue.

---

## ENVIRONMENT

ERMCO was early to recognise, through the establishment of its Environment and Consumers Task Group, that environmental performance and energy conservation would become major political/economic issues in Europe. Already, the Environmental Check List has formed the basis of many ERMCO policies and has received an emphatic welcome throughout those countries which have ERMCO representation. Liaisons have also extended further afield, notably to the United States and to Canada, where exchanges of documents have ensured that all knowledge is pooled.

Guide-lines on pollution control seek to ensure improved management and control of production processes including a system of licensing, linking all aspects of the chain of production and its use of resources. Efforts are being made to ensure a level playing field whereby site contractors, currently excluded from many technical and environmental controls, will be required to comply with the full range of environmental controls and waste management. This would ensure that site mixed, ready mixed and precast concrete are all subject to the same rules.

ERMCO has concluded that the question of CO<sub>2</sub>/Energy Tax is more related to cement production than to concrete; but, nevertheless has given its support to various submissions by Cembureau. It is considered that ready mixed producers can help achieve various targets by taking reasonable steps to include the use of less cement with more efficient mix design and replacement materials. The threats and opportunities of such taxes would significantly increase both cement costs and transport costs, but the present tax proposals could give concrete the opportunity to be promoted as a low-energy intensive product.

The launch of the European Environmental Agency with a set of priorities to coordinate information in areas of interest to the ready mixed concrete industry could be an arena for ERMCO to register its interests.

---

## REGULATIONS

Basic policies for ERMCO Members cover the main aspects of Standardisation and Certification.

For Standardisation, the same standards must apply to all types of concrete including ready mixed, site mixed and precast. For efficiency and economy, standards should, whenever possible, be expressed in performance terms. The industry's technical experts maintain a strong presence on the key CEN Committees and Working Groups and actively disseminate these policies.

Progress has been made in the past year by the European Standards Technical Committee (CEN/TC104) by achieving a majority vote for the pre-standard document prENV206 for concrete (including water, admixtures, additions and execution). To reach this compromise Agreement, in a number of cases, the pre-standard makes reference to national standards or regulations valid in the place of the use of concrete. Under CEN Rules, the pre-standard has only a limited life before a fully harmonised European Concrete Standard, document EN206, must be agreed. It is ERMCO policy to apply the same standards and principles to all types of concrete. It is also ERMCO policy that the ready mixed industry should not be asked to achieve standards which are technically inappropriate and commercially unrealistic.

Certification policy states that all concrete, including site mixed (contractors) concrete, ready mixed and precast concrete should be subject to the same levels of Quality Control and Attestation of Conformity.

Unfortunately, the past year has seen a marked slow down of progress on Certification matters. Few, if any, Member States have been able to fully implement the Construction Products Directive (CPD). One of the main difficulties has been the lack of direction on Attestation of Conformity given by the Standing Committee for Construction, which is responsible for the implementation of the CPD. Various ways and means of trying to solve this matter have been suggested, but further guidance from the Standing Committee is still awaited.

ERMCO priority tasks in the short/medium term still remain the preparation of a quality system for ready mixed concrete and the determination of an appropriate level of Attestation of Conformity. A framework document of the former has been prepared and approved by the ERMCO Meeting of Representatives. This will be circulated to all Members for use as a reference document to compare with existing factory production control procedures, or when preparing new ones. This document will, in due course, be submitted to CEN/TC104 for inclusion in EN206.

---

## OUTLOOK

The economic picture ahead indicates that the industry is poised and ready to meet increases in demand as trade struggles to improve. However, before the production levels of the ready mixed industry can appreciably increase, there needs to be an improvement in construction investment. Fortunately, the EU Growth Initiative has been of valuable assistance in encouraging investment in infrastructure and several Member States are benefiting from temporary loans.

The ready mixed industry, through the individual Members of ERMCO, is playing a significant role in establishing realistic standards for concrete manufacture, quality control and environment protection.

Nevertheless, annual production of EU Members of ERMCO will do well to recover this years drop in production over the next three years.

# Glass

## NACE 247

The EU is the world's largest glass producing and consuming region. After a period of restructuring and technological advance during the 1980s the EU industry is modern, efficient, and competitive in world markets. Good steady growth during the 1983-91 period was temporarily halted in 1992/93 but resumed in 1994 and is likely to continue. The industry has an excellent environmental record and is at the forefront of recycling developments. Although the new relationship with Eastern Europe is creating some problems of low-priced competition to EU producers they are likely to be outweighed by the mutual benefits of an expanded European market in the later 1990s.

### INDUSTRY PROFILE

#### Description of the sector

The glass industry can be divided into five main sections -- container glass (consisting primarily of glass bottles and also known as hollowware), flat glass (consisting primarily of window glass), tableware (domestic glass), glass fibre (for insulation and reinforcement), and special glass (such as optical and industrial glassware). In tonnage terms container glass accounted for 65 % and flat glass 25 % of total EU glass production of 22.9 million tonnes in 1993.

The principal raw materials for glass manufacture are mineral products such as silica sand, limestone, dolomite, soda ash, feldspathic materials, and borates as described in Chapter 2. The principal consuming industries are food and beverage processors (for container glass) and construction and motor vehicle industries (flat glass) although the full range of glass products find important applications across the whole spectrum of industry and construction as well as direct consumer items. By any reckoning the EU glass industry is a major sector, vital to the overall EU economy. The major producing countries are Germany, France, the UK, Italy, Spain, and Belgium.

#### Recent trends

The EU glass industry has displayed excellent growth - with production averaging 2.1 % and consumption averaging 2.7 % per annum in real terms - during the 1984-93 period. After falls in both production and consumption in 1993 there was strong growth of 4.3 % in 1994. The industry maintained a healthy trade balance with an annual average 12 % of production value being exported during 1984-93. However, imports have grown faster than exports, accounting for 8.7 % of consumption in 1993 compared to 6.8 % in 1984.

It should be noted, however, that different segments have behaved differently over the 1984-93 period. Average growth in production volume for the two major sectors - container glass and flat glass - was almost identical at around 2.5 % per annum but whereas flat glass growth was continuous (apart from a downward blip in 1991) the containers sector growth has been more irregular. Indeed 1993 container production at 14 932 000 tonnes represents a 3 % fall from the peak achieved in 1991. The best growth has been experienced in the speciality glass sector (including optical and industrial glasses) where growth has been continuous and has averaged over 4.5 % per annum. Growth in reinforcement fibres was strong (7.5 % per annum) during 1984-90 but has since declined. Meanwhile a recent decline in the tableware sector (9 % by volume between 1991 and 1993) has brought production down to levels only marginally above 1984-85 levels.

Figure 1: Glass  
Value added in comparison with related industries, 1993

Source: DEBA

#### International comparison

The EU is the world's largest glass producer with a total output of 22.9 million tonnes valued at 21.1 billion ECU in 1993. US glass production was just over under three-quarters and Japanese production just over two-thirds of the EU total in 1993. However, Japanese production has grown the fastest over the 1984-1993 period and the country now has a higher per capita output figure than either the EU or the USA.

#### Foreign trade

As suggested earlier, foreign trade plays an important though not dominant part in the EU glass market. Exports were of greatest importance to the tableware sector (where over 30 % of production was exported to non-EU destinations in 1993) and of least importance to containers (where the equivalent figure was less than 3 %). In between were the fibres and special glass sectors (20-25 %) and the flat glass sector (10 %).

Not surprisingly the tableware sector also records the strongest trade balance and export/import ratio - 131 000 tonnes and 1.9 respectively. Nor is it surprising that the trade balance

for containers and flat glass are both essentially neutral. However, negative trade balances and export/import ratios of 0.7 for fibres and 0.8 for special glass point to the influence of imports in these sectors.

The different unit value of glass in the different sub-sectors is responsible for the anomaly whereby the EU glass industry is a net exporter in value terms but a net importer in tonnage terms, albeit by a small margin. A major element of imports consists of large tonnages of cheap containers and unworked flat glass from eastern Europe whilst exports contain a major contribution from the domestic glassware sector with high value sales to the USA, Japan, and the EFTA countries.

In recent years over 50 % of the total tonnage (but only 40 % of the value) imported was sourced from Poland, the former Czechoslovakia, Hungary, the former Yugoslavia, and Turkey. Meanwhile the EFTA countries represented only 24 % of the tonnage but 29 % of the value in 1993. The USA is also an

important source of imports, notably for flat glass and glass fibres.

The principal destinations for EU exports in recent years have been the EFTA countries with 35-40 % of the tonnage and around 25-30 % of the value and the USA with 10-15 % of the tonnage and 20-25 % of the value) but the remaining 45-50 % of total exports is spread across a wide range of countries.

Intra-EU trade became an increasingly important element of the market during the 1980s and now accounts for about 25 % of total consumption. Belgium is notable as the principal net exporter of glass products in intra-EU trade.

## MARKET FORCES

### Demand

Glass is used by a very wide range of industries and furthermore up to 15 % of sales by value consists of private consumer products. At first sight, therefore, glass is not therefore tied too closely to a single or narrow range of consuming industries. However, the fortunes of the different sub-sectors are often strongly aligned to specific industries.

Glass containers, which account for around 65 % of total glass consumption by volume, are tied to developments in the food and beverages industry. Glass bottles and jars thus meet strong competition from other packaging materials but particularly from aluminium, plastics (mainly PET), and paper (aseptic cartons) in the beverages sector. After originally losing market share to these other materials glass has been performing strongly in recent years on grounds of performance, cost, and ecological advantages based on its recyclability.

Flat glass, which accounts for 25 % of total consumption, is heavily dependent on the construction and automotive industries for its sales. Insulating glass fibre is also very much a construction industry product.

Tableware and decorative glass products are widely used by the hotel, catering, and leisure industries as well as providing direct sales to private consumers.

Meanwhile many of the remaining sub-sectors have "high-tech" associations - e.g. optical and electronic glassware, industrial and laboratory glassware, reinforcing glass fibre for engineering plastics, etc.

### Supply and competition

As the world's major consuming region for glass the EU is a natural target for foreign companies wishing to expand their sales. In the case of the eastern European countries it is clear that the low labour costs and close proximity to markets have provided the platform for the growing export trade described above. In other cases foreign companies have gained major access to the market by acquisition (e.g. Asahi Glass in Belgium) or by building new plants (e.g. Guardian in Luxembourg). Thus EU producers undoubtedly operate in a very competitive environment although different factors come into play in the different segments of the market.

EU container glass producers meet some competition from the cheap European exports but would still see alternative packaging materials as the main threat. The rationalisation

**Figure 7: Glass  
Origin of EU imports**

Source: Eurostat

**Figure 8: Glass Trade Intensities**

Source: DEBA

programme which was carried out in the early 1980s to combat the twin ills of industrial recession and burgeoning demand for alternative products (e.g. PET bottles) has been highly successful.

Flat glass does not meet the same degree of competition from alternative materials but EU producers have had to meet competition from without (imports) and within (increasing foreign involvement in EU production). The industry has moved from high capacity utilisation in 1987 and 1988 to a situation of increasing surplus capacity which will become more acute as new float glass plants are brought on stream in Poland,

Spain, and France during the 1993-95 period. The stuttering recovery in car manufacturing and construction has not helped this situation but capacity utilisation may improve as the recovery picks up steam.

Glass fibre meets competition from a range of mineral and ceramic fibres (and flakes) for both reinforcing and insulating applications. Although there have been some closures of fibre glass plants in recent years, producers are now working at or near their operational capacity and companies are even starting to re-commission mothballed furnaces in order to avoid international shortage of fibre.

The more specialised industrial glasses meet competition from plastics in some applications although operating environments where products are subject to high temperature, reactive chemicals, or radiation tend to favour glass-based products.

### Production process

In the glass container sector the past 10 years have been marked by major advances to productivity, process monitoring and control systems, and quality, as well as recycling and lightweighting (the production of strong lightweight bottles). Major improvements have been made to furnace performance with regard to energy efficiency, high throughputs, and capability to take an increasing proportion of recycled glass (cullet) as feed material. The efficiency and throughput of automatic forming machines have also improved beyond recognition. Many of these factors also apply to other sectors of the glass industry including flat glass. The float glass process (originally launched over 30 years ago) continues to dominate flat glass production in Europe and has resulted in the closure of all but a handful of older technology sheet glass plants.

## INDUSTRY STRUCTURE

### Companies

The high degree of concentration in the EU glass industry is a reflection of the large scale and capital intensive nature of

modern glassmaking plant. The EU flat glass industry in particular is dominated by just five companies - Pilkington (UK), Saint Gobain (F), Glaverbel (B, a subsidiary of Asahi Glass of Japan), and the two US companies, PPG and Guardian - which together account for over 95 % of total output.

Saint Gobain is also a major factor in the container glass industry with major manufacturing operations in 6 EU countries. However, a large number of companies are involved in the container glass sector with smaller specialist companies coexisting alongside the larger groups. Other major producers include BSN (F), Gerresheimer Glas (D), Ruhrglas -- part of the VIAG group (D), Hermann Heye (D), Nienburger Glas (D), AVIR (I), PLM (S), Rockware (UK), and United Glass (UK).

The special glass sector is dominated by the German group, Schott Glas, which is a world leader in the manufacture of optical and industrial glassware. Other important companies in this sector include Corning of the USA (whose subsidiaries operate in France, Germany, and the UK) and Pilkington of

the UK. At the end of 1994 Corning sold out its European domestic glassware operations to another US company, Newell Co. Among a large number of decorative glass producers the largest would appear to be the Waterford Wedgwood group of Ireland although it should be noted that Venetian glass and the famous Murano producers are still highly influential in world markets.

#### Strategies

Although Saint Gobain and Pilkington are the principal companies operating on a European level a number of other such as BSN, PLM, Guardian, and Schott have important plants outside their home country. A number of companies operating in the EU have also formed alliances in Eastern Europe - notably Pilkington and Saint Gobain in Poland, Glaverbel (Asahi) in the Czech Republic (Glavunion and Obalunion), and Guardian Industries in Hungary (Hunguard).

### Impact of the Single Market

The impact of the creation of the Single Market on the European glass industry is described as "positive but mild". The mildness is because the programme is seen as the confirmation of an existing situation. Thus the free movement of goods, services, and capital are seen as of fundamental importance to the industry. Internal movement of glassware within Europe is a well-established activity and virtually free from all barriers. External trade with third countries is also a vital part of modern day trade and a number of barriers to European exports remain, either through high tariffs -- Brazil, Turkey, Israel, and the USA (luxury products) -- or through distribution "arrangements" -- flat glass to Japan.

As one of industry's largest consumers of energy, the glass industry not surprisingly sees energy deregulation as the main priority for future Single Market implementation. Other issues of importance include competition policy and small and medium sized enterprises policies concerned with the lowering of administrative burdens and improving access to finance.

### REGIONAL DISTRIBUTION

The location of glass manufacturing facilities may be governed by proximity to raw material sources (e.g. Belgium with its abundant supplies of high quality silica sand, limestone, and soda ash) or proximity to consuming industries (e.g. where bottle factories are located in wine-growing districts or close to major breweries) or even a combination of these factors tied to good communications.

### ENVIRONMENT

The glass industry is a major user of fossil fuels and is therefore subject to controls on gaseous and dust emissions. EU glass producers have a good record in dealing with the problems and operate within the limits of current legislation. The industry continues to work to improve existing practice, not only with reducing emissions but also to further improve energy efficiency. On another environmental front, recycling, glass is probably at the forefront of all major industries in its ability to use both process waste and use of waste glass. In countries such as the Netherlands, Germany, Belgium, Italy and Denmark the recycling rate exceeded 50 % in 1993 and great strides are being made by more recent converts such as the UK and Ireland.

### REGULATIONS

The industry is directly affected by EU Directive 85/360 concerning air pollution and provides an ideal example of how caution and foresight must be applied when introducing pollution control measures. New measures will add substantially to costs and put EU producers at a considerable disadvantage to competitors in countries with lower environmental standards. Through products such as double-glazed windows and glass fibre insulation, glass presents major energy saving opportunities and it would be ironic if a possible carbon tax were to penalise an industry making a positive contribution to the overall carbon dioxide equation.

### OUTLOOK

The EU glass industry is in good health and likely to benefit from improved industrial performance in the years ahead. Some concern is expressed concerning rising costs of complying with environmental regulations and the flat glass industry may be due for a period of oversupply due to capacity expansions in Europe as a whole. Nevertheless the potential for high growth, particularly in Eastern Europe, would soon minimise such fears. The inclusion of three new members to the EU in 1995 will increase the internal market, and although cheap imports from Eastern Europe may be seen by some as a threat in the short term, the longer term outlook is for greatly expanded markets as these countries develop.

Written by: B M Coope & Partners

The industry is represented at the EU level by: Standing Committee of the Glass Industries in the European Union (CPIV). Address: Avenue Louise 89, B-1050 Brussels; tel: (32 2) 538 4446; fax: (32 2) 537 8469.

# Ceramic goods

## NACE 248

The ceramic goods industry covers a range of products from tiles, plates, and toilets to refractories and advanced ceramics. It is difficult to think of another EU industry in which the type of company and state of technology covers such a broad spectrum - from small family companies producing clay-based products according to methods developed several millennia ago to important materials groups at the forefront of developments in advanced ceramics. Modernisation and restructuring will be necessary in some segments to maintain the EU's position as the world's leading producer of this group of products.

### INDUSTRY PROFILE

#### Description of the sector

The principal ceramic products covered under this heading are floor and wall tiles (NACE 248.3); sanitary ware (NACE 248.5); tableware and ornamental ware (NACE 248.6 & 248.7); industrial ceramics (NACE 248.8); and refractory products (NACE 248.1). Other ceramic materials covered in chapter 5 include bricks and roof tiles, cement, and concrete products. Products described are based on industrial mineral raw materials covered in Chapter 2, but in particular, on clays and other silicates (feldspar, talc, sillimanite, wollastonite, and zircon), silica (silica sand, quartz, and quartzite), and mineral oxides derived from such minerals as magnesite, dolomite, limestone, and bauxite.

Ceramic goods are consumed across a wide range of industries. Principal markets are building and construction (tiles, pipes, sanitary ware), domestic and leisure industries (tableware, hotelware, ornamental ware, etc.), electrical and electronic engineering (insulators); and metallurgy (refractories). The new breed of advanced ceramics (also known as technical ceramics or engineering ceramics) are also becoming of increasing importance to the mechanical engineering sector. Thus, ceramic products are not only consumer items but are also vital to a whole range of industrial processes.

#### Recent trends

EU production and consumption of ceramic goods showed steady growth between 1984 and 1991, followed by declines in 1992 and 1993. However, a recovery in production of 7.5 % is anticipated for 1994. In real value terms, production grew by an average 0.9 % per annum and consumption by 1.18 % over the 1984-1993 period. As this suggests, imports grew faster than exports, but the EU is still a major net exporter with sales to foreign countries consistently making up about 20 % of total production. Exports in 1993 grew by 10.4 % compared with import growth of only 1 %, reflecting a large drop in consumption. The contribution of imports to total consumption has grown from 7 % in 1984 to 10 % in 1993. The 1991/92 downturn in consumption was most severe in the construction-oriented ceramics and refractories segments.

#### International comparison

The EU is the world's largest ceramic producing region. But in the whiteware (wall & floortiles, sanitaryware and table & ornamentalware) segments the fastest growth recently has been recorded in the Far East, where China, Taiwan and the ASEAN countries have been displaying considerable growth during the past decade. The USA saw its whiteware production decrease in this period; in fact it is a major net importer of these products, and it is the main third market for European ceramic tiles and tableware producers.

Figure 1: Ceramic goods  
Value added in comparison with related industries, 1993

Source: DEBA

In industrial ceramics Japan is the most important producer, followed by the USA, with the EU industry in the third position.

Here competition on what basically is a world market, is very fierce.

The refractories industry is closely linked to a few basic industries which have a strong production basis in Europe. The EU refractories industry is the most important worldwide, but trade in this segment is rather limited.

#### Foreign trade

The EU industry is an important exporter of ceramic goods: in 1993 total exports to third countries amounted to nearly 4 billion ECU. Imports were considerably below this level with 1.5 billion ECU, but they are increasing more rapidly.

In the table- & ornamentalware segment the main export markets for the EU industry are the USA, Japan and Switzerland; imports mainly stem from the Far East (China, Taiwan, Japan and Hong Kong). For tableware exports to third markets in

Total	1 161.5	1 488.5

Source: Eurostat

1993 amounted to 502 million ECU, while imports reached a level of 321 million ECU. For ornamentalware the situation was less positive with exports of 246 million ECU against imports of 308 million ECU. This reflects the problem of high labour costs with which the highly labour-intensive EU industry has to cope.

In the wall & floor tiles segment the data show a healthy trade balance surplus, with EU exports of 1 457 million ECU against imports of 165 million ECU. Main export markets are here the USA, Switzerland and Saudi-Arabia; Turkey and the Czech Republic are the most important suppliers from outside the EU.

However, as some Eastern Asian countries are building up a big production capacity, there is no reason for the EU industry to be complacent.

**Figure 3: Ceramic goods**  
Production and employment compared to EU total manufacturing industry

The refractories segment accuses an important intra-community trade, with comparatively strong exports from the traditional steel producing countries.

**MARKET FORCES**

**Demand**

Building and construction is by far the most influential industry with regard to demand for ceramic wall and floor tiles and sanitary ware. Demand for these products is spread across a full range of structures and buildings from private dwellings to public buildings and industrial structures, and is not just limited by new building.

The maintenance and renovation market for tiles and sanitary ware provides an extremely important secondary market. The fact that both form a central element to interior design means that replacement takes place on aesthetic grounds, in addition to the more normal reasons of wear and tear. Sales of wall

tiles, in particular, take place on several levels, from large construction companies to the individual DIY (do-it-yourself) enthusiast. The latter may even buy from a shop devoted to selling tiles, tiles, and tiles.

The tableware and ornamental ware segment also takes more than a passing interest in new public building and renovation schemes since hotels, restaurants, hospitals, and the like are all major buyers of plates, dishes, bowls, cups, etc. Indeed, special requirements of the hotel and catering trade have given rise to the "hotelware" sub-sector with specially designed hard-wearing ceramics. Private buyers in this segment tend towards some of the more upmarket products designed by artists, made of prime raw materials such as porcelain and bone china.

The refractories segment is a fascinating industry in which technical advances continuously reduce the size of the market. Refractories are vital to high temperature processes required to produce metals, glass, cement, ceramics, and a range of other products. However, the tonnage growth of these products

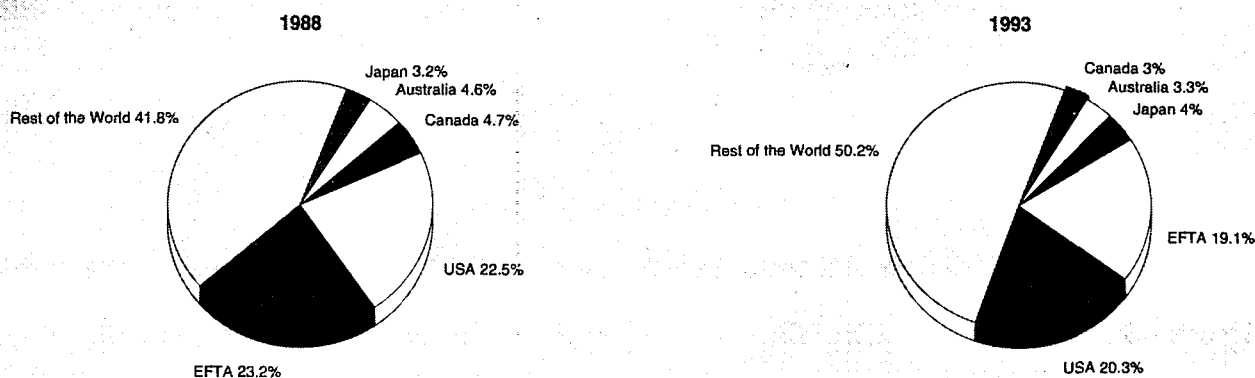

**Figure 4: Ceramic goods**  
International comparison of production in current prices

**Figure 5: Ceramic goods**  
International comparison of production in constant prices

**Figure 6: Ceramic goods  
Destination of EU exports**

Source: Eurostat

has never been enough to counter the decrease in unit consumption brought about by technical advances to processes and materials.

The technical ceramics segment is based, to some extent, on materials and techniques developed by the refractories industry and adapted towards engineering applications. Certain products, such as electrical insulators made of alumina or steatite, have actually been around for some time. But, some of the "newer" ceramics are becoming of increasing importance in electronics, chemical, mechanical, biological, and nuclear engineering applications. Very high growth rates are predicted for materials such as silicon carbide, silicon nitride, sialons, and partially stabilised zirconia, albeit from an initially low volume base.

### Supply and competition

The EU ceramics industry has centuries of tradition to draw on, ample supplies of high quality raw materials, a strong and continuously evolving technical base, and an enormous home market. Yet, it has proved to be vulnerable to competition from the geographically distant sources of the Far East. This has been due to a combination of the low operating costs of some of these countries (noticeably for labour and for meeting low environmental standards), and the fact that producers have embraced European processing technology to boost their own production. Many have also embraced European designs. This has exposed the high production costs and overcapacity which exist in much of the EU tableware sector. The impact has

been greatest at the lower quality end of the market, causing some EU producers to concentrate on more upmarket products, others to take major cost-cutting measures to remain competitive, and yet others to get out of the market.

The current downturn in demand has certainly reduced operating margins for even the most efficient producers. Yet, further efficiencies will no doubt be required to survive the worst in order to take advantage of the projected recovery.

### Production process

Although traditional ceramic industry symbols, such as the potter's wheel and the skilful hands of dedicated craftsmen still retain a niche in the "arts and crafts" end of the market spectrum, the modern ceramics industry is actually one of large scale, automated processes, close technical and quality controls, and a technically trained workforce. Among the new techniques introduced over the past 20 years are dry pressing, pressure casting, isostatic pressing, fast firing, roller kiln firing, plus the use of robotics in glazing and decorating.

## INDUSTRY STRUCTURE

### Companies

The EU ceramic goods sector has total production approaching 17 billion ECU and employs around 210 000 people involving over 2 500 companies. The figures bear out the predominance of small and medium-sized companies in the overall picture.

Some of the largest companies operate in the refractories sector where a high degree of concentration now exists. Five companies account for about 65 % of total European (EU plus EFTA) production: Didier-Werke (D) and Radex Heraklith (A) (which have recently announced that they are to join forces through a transfer of shares); Hepworth Refractories (UK); Sanac (I); and, SEPR (F). Other important mainstream refractory producers include: Refratechnik (D); the Wulfrath Group (D); Baker Refractories (UK); Dyson Refractories (UK); AMR Refratarios (E); Dr C Otto Feuerfest (D); and, VGT-Dyko (D). Significant specialist producers include: Ve-

suvius International (part of the Cookson group of the UK and a major manufacturer of concast refractories and crucibles); Lafarge Refractaire (part of Lafarge Coppee and a major producer of monolithic refractories); and, the Morgan group of the UK (crucibles, monolithics, and technical ceramics).

The tableware and ornamental ware sector contains a handful of large companies amongst a myriad of small ones. Major groups include three German companies, Villeroy & Boch, Rosenthal, and Hutschenreuther and two UK companies, Wedgwood and Royal Doulton, which all together account for around 40 % of total EU output.

**Figure 7: Ceramic goods  
Origin of EU imports**

Source: Eurostat

In the sanitary ware sector the two major groups operating on a European level are Ideal Standard (I) of the American Standard group of the USA, and the Sanitec group of Finland, whose interests now include Allia (F), Keramag (D), Pozzi-Ginori (I), and Eurocer (P), in addition to its Scandinavian activities. Other European companies of note include: Blue Circle Industries (UK) through subsidiaries Armitage Shanks and Ceramica Dolomite; the Roca group (E); Keramik Laufen (CH); and Sphinx (NL) which now operates plants in the Netherlands, Belgium, and France.

The EU wall and floor tile industry is dominated by medium-sized producers in Italy and Spain with annual turnovers in the 40-80 million ECU range. The small number of larger groups includes: Gruppo Ceramiche Marazzi, Iris Ceramica, and Cerim Ceramiche in Italy and Porcelanosa and Fabreza in Spain. Companies in other countries include: Villeroy & Boch in Germany and H & R Johnson (part of the Norcros group) in the UK.

Companies active in the technical ceramics segment include: Hoechst CeramTec, Hutschenreuther, Cerasiv, Wacker, and Didier of Germany; Saint Gobain (through its SEPR, Norton, and Stettner

subsidiaries), Pechiney, and Corning of France; Cookson, T&N, and Morgan of the UK; and Samatec of Italy.

### Strategies

The segment that has been most active on the mergers and acquisitions front is sanitary ware, particularly through the Sanitec group of Finland, followed by Sphinx (NL) and BCI (UK). It should be noted that Sanitec's expanding empire also includes plants in Poland and former East Germany. The continuous restructuring process of the refractories industry has been strongly in evidence through the amalgamation of the two Austrian producers, Radex and Veitscher, and the planned merger with Didier-Werke of Germany, which will create by far the world's largest refractory manufacturing group.

Nevertheless, it is clear from the foregoing that the process of restructuring has a long way to go in the tiles and tableware segments of the EU ceramics industry. It seems likely that further amalgamation, allied with investment in new equipment, will be necessary to improve competitiveness in parts of the industry. However, it should be noted that such streamlining will take place without sidelining the artistic element.

Flair and design play an important role in European competitiveness on both mass production and craft pottery levels.

### Impact of the Single Market

The impact of the single Market of Europe's ceramic goods industry has been significant and primarily positive. Though the industry maintains a strong, localised tradition it has always been very international in its outlook and intra-EU trade has long been a feature of the industry. Thus the free movement of goods, recognition of intellectual property (trademarks), and the liberalisation of energy supply are all seen as factors of fundamental importance to the industry. Much attention is also addressed to policies concerning competition rules, small and medium-size companies, and environmental protection.

Remaining internal barriers include national standards and certification schemes and environmental legislation is not applied equally across the EU countries. External barriers affecting EU exports include certification in central Europe, high import tariffs into the USA, and the problem of counterfeit designs being used on ceramic products in South East Asia.

Future priority should be given to common environmental standards and legislation, social flexibility, energy deregulation, checks on standards and technical requirements at external boundaries, increased access to third markets (USA, Japan), and, last but not least, improved internal trade statistics.

### REGIONAL DISTRIBUTION

A large number of ceramics manufacturing companies continue to operate in regions whose traditional location was based on the availability of raw materials and fuel. Thus, despite changing circumstances, areas such as Stoke-on-Trent in the UK, Bavaria and the Rhineland in Germany, Sassuolo in Italy, Valencia in Spain, and Limoges in France have maintained their status as major whiteware manufacturing centres. Although the raw materials availability argument also applied to the location of many refractories plants, more modern plants have tended to be built close to major metallurgical centres, such as the Ruhr region of Germany and Sheffield in the UK.

### ENVIRONMENT

The ceramics industry is a major user of fossil fuels and thus shares the same problems as other non-metallic mineral product manufacturers with regard to gaseous and dust emissions. The larger modern units are well equipped to deal with existing compliance levels, but further restrictions and the imposition of a carbon tax would have a major impact on the whole industry.

### OUTLOOK

Consumption of ceramic goods is expected to resume former levels of growth as EU industry, in general, moves out of recession. Those companies that have already modernised and restructured can be expected to perform well during the latter part of the 1990s. However, some of the smaller, high cost concerns will need to invest in new technology to remain competitive against imports. The technical ceramics segment will continue to grow and certain products may develop from "low volume, high value" to "medium volume, medium value" status by the year 2000. The addition of three new members to the EU will serve to reinforce the pan-European nature of the industry, as will growing ties with producers in Eastern Europe.

Written by: B M Coope & Partners and Cerame-Unie

The industry is represented at the EU level by: Liaison Office of the European Ceramic Industry (Cerame-Unie). Address: Rue des Colonies 18-24, Bte 17, B-1000 Brussels; tel: (32 2) 511 3012; fax: (32 2) 511 5174.

## Overview NACE 25, 26

The EU is a leading producer of chemical products. After several years of solid growth in the mid to late 1980s, depressed prices and overcapacity have characterised the performance of the industry since 1990, as the world's economies slowed down and additional production capacity came on stream. Despite an improvement in profitability in 1994, a high cost structure may undermine European profitability in the medium term. The strategy of major chemicals companies hinges on the creation of strategic alliances and joint-ventures to achieve rationalisation in research, production and access to markets.

### INDUSTRY PROFILE

#### Description of the sector

The chemical industry is an industrial branch of very heterogeneous character in which the main activities consist of chemically transforming materials into diverse substances, giving them new physical and chemical properties. For these activities, the chemical industry employs raw materials from the petroleum, mining and extractive industries such as oil, minerals, metals and certain agricultural products. The main activities of the chemical industry correspond to the following product groups: basic chemicals, which include basic organic and inorganic chemical products; fertilisers and nitrogen compounds; plastic in primary form and synthetic rubber; pharmaceutical and medical products; and specialty chemicals, which include pesticides and other agrochemical products, paints, varnishes, and other similar coating products, soaps and detergents, cleaning and polishing preparations, perfumes, toilet preparations, and man-made fibres.

The industry includes two upstream branches constituting basic chemicals (basic inorganic chemicals and basic organic or petrochemicals) and a series of downstream branches such as pharmaceutical products, agrochemicals, detergents, etc. The upstream sectors' outlets are almost exclusively the downstream sectors, which themselves supply either other industries (agriculture for agrochemicals, the plastics transformation industry for plastics in primary form), or end-users (soaps and detergents, for example).

In terms of value added, Germany is by far the largest EU producer of chemicals. With almost 34 billion ECU, the German chemical industry accounts for almost one third of EU value added in this sector. France and the United Kingdom almost tie for second place, with a value added of about 18 billion ECU. Other large EU producers are Italy (10 billion ECU), Spain (7 billion ECU), the Netherlands (5 billion ECU) and Belgium (5 billion ECU).

#### Recent trends

After a rapid expansion over the 1960s and 1970s, the first half of the 1980s was rather grim for the chemical industry. Stagnant production and overcapacity led to a drastic restructuring of the industry. The restructuring, accompanied by huge redundancies and cutbacks in capacity, enabled the chemical sector to start off from a much stronger base when the economic environment improved from 1983 onwards. The years from 1986 to 1989 were associated with high profits and strong expansion.

**Figure 1: Chemicals and man-made fibres  
Value added in comparison with related industries, 1993**

Source: DEBA

Prospects changed in 1990 with the economic slowdown in Europe and North America. Demand from the main clients weakened both at home and abroad. European industries were further hit by losses in market share on export markets, a trend that started with the fall of the dollar in 1985, which gave US companies a strong price advantage. The situation on the trade front improved significantly in 1993. The gains in the extra-EU trade balance (about 10 billion ECU) was however not sufficient to balance the fall of domestic demand (-15 billion ECU) in 1993.

Except for the pharmaceutical industry, profits started weakening in the first half of 1990. From 1990 to 1993, the profitability of the chemical industry has been poor in Europe, as witnessed by the low value of the gross operating rate in Table 5: it fell from 15.5 % in 1988 to about 11.5 % between 1991 and 1993.

**Figure 3: Chemicals and man-made fibres  
Production and employment compared to EU total manufacturing industry**

1994 are Eurostat estimates.  
Source: DEBA

In 1994, as the European economy started to recover, so did the chemical sector. In volume terms, production increased by 6.4%. This came as a surprise, as many analysts have very pessimistic expectations for 1994, even as late as at mid-year. This good result has been achieved thanks to an 8% increase of extra European exports, and a swing in the inventory cycle, with strong stock-building along the supply chain in 1994. Domestic demand remained weak, which brings some worries for 1995. As stock-building should rapidly stop, and exports are expected to subside, only a recovery in domestic demand could strengthen the current upturn in the chemical sector.

Employment in the European chemical sector shrank from 1 781 000 jobs in 1990 to 1 583 000 in 1994, an average fall of 2.9% per year. In 1994, employment fell by about 70 000 units. These job cuts are the results of an ongoing restructuring process in the chemical industry, aimed at reducing costs and improving productivity and efficiency, in order to maintain international competitiveness. As a result,

productivity has improved by an average of 2.9% per year between 1984 and 1993 (see table 5).

**International comparison**

The development of the US chemical industry differs slightly from that of the EU. American companies have experienced high growth rates during the second half of the 1980s, not only thanks to an increase in domestic demand, but also due to increased exports, as their competitiveness was boosted by a low dollar. Consequently, American companies did not experience the same incentives as their EU counterparts to develop downstream in sectors less sensitive to business cycles and exchange rate movements, especially as concentration is much higher in the USA than in the EU in many segments of the chemical industry.

In 1993, US production stood at 108% of EU production, and Japanese production represented some 63% of EU production.

**Figure 4: Chemicals and man-made fibres

**Figure 5: Chemicals and man-made fibres  
International comparison of production in constant prices**

Source: DEBA

**Figure 6: Chemicals and man-made fibres  
Destination of EU exports**

Source: Eurostat

In the USA, production of chemical products fell by 0.6 % in volume in 1991. Just as in Europe, the core of the problem was the overcapacity and the consequent falling prices of commodity chemicals, along with the specialities experiencing sliding demand, linked to the recession. The US chemical industry enjoyed a recovery since 1992, when production increased by 3.2 %. The industry kept its momentum in 1993 and 1994, with a 3.8 % growth rate in both years.

Markets for chemical products have developed fast, particularly in East Asia, but also in Brazil and the Middle East. New producers have rapidly appeared in these regions. The major share of world production, however, remains by far in the hands of European and American groups, which have developed their activities in these emerging markets.

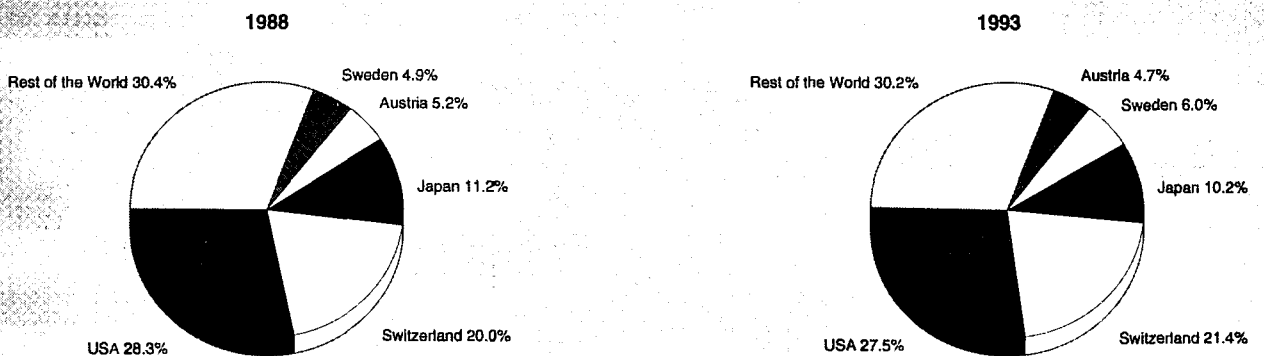

Increased competition from new chemical producers (in Asia, Latin America or the Middle-East, for example) risks eroding the competitive position of European producers whose structural and feedstock costs remain higher than in major competing regions in the longer term. A new opportunity exists, however, for west European manufacturers to gain new markets in eastern Europe. However, west European companies have until now shown only limited interest in acquiring production facilities in the east. The issues at stake are well known:

environmental cleanup has to be undertaken, obsolete equipment needs to be replaced, and the industry has lost the FSU markets, its main traditional export destination. Thus, even if some products, such as plastics, should show attractive growth rates, profits perspectives are mostly long term. West European companies are thus taking a wait-and-see policy, increasing their exports to eastern Europe before deciding on investment.

**Foreign trade**

The EU is the world's leading exporter of chemicals. In 1993, according to Table 2, EU companies exported 21 % of their production outside of the EU. Traditionally, the EU has a trade balance surplus (along with the EFTA countries). The surplus has been deteriorating since 1985, following the fall in the US dollar, the development of local capacity in many countries and the increasing market presence of export-oriented production capacity, notably in the Arab Gulf region. In 1993, however, following the depreciation of several European currencies and an overall improvement of the economy in foreign markets, exports have increased by 18 % in current prices. In the same year, the EU trade surplus against the rest of the world increased to 23 billion ECU. Figure 8 illustrates the dramatic growth of exports in 1993.

Source: DEBA, Eurostat

Overall, EU exports are specialised in refined chemicals, while imports are in basic chemicals. To a certain extent, the EU imports basic chemicals in order to export refined chemicals. Competitive discipline created by imports is therefore higher for basic chemicals than for refined chemicals.

The main destination for EU chemicals exports are the EFTA countries, the USA, the developing countries, eastern Europe. Compared to the average EU trend, it appears that Germany and Denmark are more oriented towards Western Europe. The United Kingdom and Ireland export more towards North America, while the proportion of exports towards developing countries is higher in France, Spain and Portugal than in the other EU countries.

On the other side, imports mostly come from the USA, EFTA countries, and Japan. With 21.4 % of extra-EU imports, Switzerland is the second largest exporter to the EU, because of its geographical proximity and the importance of the chemical industry in this country.

## MARKET FORCES

### Demand

About 65 % of chemical product demand stems from industry in the form of intermediate consumption. Apart from the chemical industry itself, which represents 36 % of its own demand, the principal client sectors of the chemical industry are (in

decreasing order) the rubber and plastics processing industry, agriculture, metals, mechanical and electrical engineering (the last three together), textiles and clothing, wood and derivatives and construction. This considerable self-consumption is explained by the high degree of industrial vertical integration in which the downstream elements, refined chemicals or specialty chemicals, are the almost exclusive outlets for components situated upstream, i.e. the basic chemicals.

The strong expansion of the chemicals sector over the last two decades can be explained in part by factors such as innovation and the replacement of traditional materials such as steel, wood, paper and glass by new materials derived from chemical processes. This substitution factor has enabled the chemical industry to experience premium growth rates, at a level much higher than the average manufacturing growth rates (10 % compared to 2 % over the period 1970-90). More recently, the contribution of this factor in the growth rate of the chemical industry has diminished, marking the industry's progressive evolution towards maturity.

An important factor in the creation of demand is the continuous effort towards product innovation. On average, European companies spend around 5 % of their turnover on R&D, although this number can be close to 20 % in some specific sectors, such as pharmaceuticals. In 1993, Hoechst, for example, the German chemical major, spent 6.6 % of its sales in R&D. In the same year, Swiss Ciba spent 9.2 % of turnover in research, and Bayer, which has important interests in pharmaceuticals, 15.3 %.

The most innovative fields of R&D include bio-technology and new materials (advanced composite materials, polymers, plastics and ceramics). As a general tendency, R&D efforts are more and more focusing on transformations of existing products rather than on true discoveries.

In some segments of the chemical industry, demand has declined steadily in the past few years. This is for example the case for fertilisers, for which demand is directly proportional to agricultural output. As production declined because of the reform of the Common Agricultural Policy (CAP), so did demand for fertilisers. Fertiliser demand is expected to decline further in the coming years.

Another example is the man-made fibres industry, of which many customers have moved to countries with cheaper production costs, especially in the Far East. Following their customers, fibre producers have reduced their capacities in Europe and invested in the emerging markets.

### Supply and competition

Global competition is increasing both in the bulk and specialty chemical industries. Producers located in South America, in the Middle East or in Asia have built a strong chemical industry in these countries. Export markets for European-based companies have shrunk as local industry developed. Furthermore,

**Figure 8: Chemicals and man-made fibres  
Trade intensities**

Source: DEBA

import competition has mounted in Europe, as these countries have cost structure that compares favourably to European producers cost. As far as European producers are concerned, they will increasingly have to focus on higher value-added and more specialised market segments in order to maintain margins.

Competition has been particularly strong in the early nineties, as the chemical industry (and especially the petrochemicals and plastic segments) were plagued by worldwide over capacity. This situation will subside in the coming years as demand grows. However, the European overcapacity situation will not recede as rapidly, as the industry did not achieve any significant cut in petrochemicals capacity in 1993/94. A number of old and uncompetitive plants are still operating, which makes average production costs higher in Europe than in other regions. Competition from imports is a determinant factor in the future evolution of the European basic chemical sector, as it is strongly export-oriented: export intensities amount to 50 % in Germany and the United Kingdom, and around 60 % in France.

Not all sectors of the chemical industry have such a poor outlook. The pharmaceutical industry, for example, will continue to benefit from rising standards of living and growing concerns for health on the demand side, and, on the supply side, from the high quality of European products and research in this sector. At the same time, the industry will suffer from government programmes aiming at checking social security costs and especially health care costs.

### Production process

While investment in nominal terms expanded by about 10 % between 1985 and 1989, investments have declined since 1990. As the industry suffered from over-capacity, especially in the basic products segment, European chemical companies refrain from building new capacity. Therefore, the greatest proportion of investment expenditure is at present directed towards rationalisation rather than towards capacity expansion.

The sector is an intensive energy user. The energy use is concentrated in the upstream basic chemical subsector. The biggest energy user is the petrochemical sector, with electricity and hydrocarbon (used both as energy source and as raw material) consumption of 35 % to 40 % of production costs. Other sectors with high energy contents are plastics (20 % to 25 %), inorganic chemicals and fertilisers (each about 15 %). The refined chemical sector is a relatively small energy consumer, but since the basic industry is its main supplier, it is bound to be affected indirectly by energy price rises. Profitability of basic chemicals is more vulnerable to oil price increases than that of specialty chemicals: as the basic chemical market is a very competitive one, it is difficult to pass price rises to purchasers.

## INDUSTRY STRUCTURE

### Companies

Six of the world's top ten chemical companies are EU based. With about 32 700 enterprises (including small enterprises, with less than 20 employees) in 1990, the chemical industry remains a concentrated sector, with 7.9 % of the enterprises representing 79 % of turnover. The top ten leading EU companies accounted for 48.6 % of total turnover of the industry in 1990, with the top five companies taking 32.6 % of turnover.

Economies of scale are particularly important in the basic chemicals subsector. It is a highly capital intensive sector that places commodity products on very competitive markets. Marketing large quantities is thus a necessity to generate sufficient margins. These economies of scale explains the existence of very large companies in the basic chemical segments, which have then expanded their activities towards downstream specialty chemicals.

Economies of scale are also important in the pharmaceutical sector. Fixed costs are important, in terms of research to find and develop new drugs, and then in terms of marketing. As the cost of producing a new drug is such that it has to be marketed on as large a market as possible in order to maximise revenue, pharmaceutical companies should therefore be present in all the large markets (EU, USA and Japan).

### Strategies

During the 1980s, larger companies were moving into specialty chemicals in order to improve margins and profitability. Mergers and acquisitions (M&A) activity leading up to the Single Market was intense, concentrating almost exclusively on downstream chemicals (plastic containers and film, specialty chemicals, pharmaceuticals, cosmetics, fertilisers) with the objective of strengthening and expanding market share. Also, the fall in the dollar exchange rate encouraged EU companies to undertake major investments in the USA during the second half of the eighties.

In 1994, after a significant slow-down of since 1990, M&A activity has been intense. In the chemical industry, it is the pharmaceutical subsector that has made the headlines. The main factors behind this are pressure on prices from governments, which try to control their health budgets, and the concentration of buying power in the United States. Among the most important deals were the purchase of US company Syntex by Roche of Switzerland, for 5.3 billion USD, the purchase of American Cyanamid by American Home Products for 9.7 billion USD, and the two purchases by SmithKline Beecham (UK/US): Sterling Health and Diversified Pharmaceutical Services, both companies from the USA. In January 1995, another important bid had just been launched, as Glaxo (UK) proposed to take over Wellcome (UK) for 9.2 billion pounds.

In other segments of the chemical industry, M&A activity has also been intense in 1994. While in the early nineties, many companies tried to disinvest from non-core businesses they had acquired in the eighties, in 1994, a number of com-

panies which had finished with their disinvestment program (although this has been less the case in France and Germany) were looking for ways to strengthen their core businesses, through acquisitions and joint ventures. Joint ventures are popular, as many companies do not want to sell out entirely, as they cannot yet obtain reasonable prices for outright take-overs.

### Impact of the Single Market

The European Single Market programme had a globally positive impact on the chemical industry. This is especially true for chemical industries which are closest to consumer markets, such as maintenance products, soaps, detergents, or paints, and where national regulations were still quite different before the programme was launched. In those sectors, the harmonisation has allowed the industry to restructure its activities, to target a larger market and benefit from economies of scale. On the other side, European harmonisation had less impact on the basic chemical industries (such as petrochemicals, fertilisers or basic chemicals) as most of these markets were already internationalised in 1985.

Much remains to be done before the Internal Market becomes reality, however. A number of Directives that would directly impact the chemical industry still have to be finalised. For example, the completion of the Internal Energy Market is an important step for the energy intensive chemical industry.

Where Directives exist, implementation is sometimes slow, or varies across Member States. This is especially the case of environmental regulations. The chemical industry is concerned that, under the principle of subsidiarity, some Member States would adopt more or less stringent regulations, re-installing de facto some barriers to intra-EU trade. The sector favours a harmonised business environment within the EU, and therefore believes that the principle of subsidiarity should be implemented with care. The chemical industry is also concerned about the persistence of State aids often to State owned companies, which help maintain uncompetitive capacities and distort competition.

### REGIONAL DISTRIBUTION

Proportionally to GDP, Spain, Belgium, Luxembourg, the Netherlands and Ireland have chemical industries bigger than that of other EU countries. With regard to product segmentation, the German, Dutch and French industries are more oriented towards basic chemicals and plastic materials, while the United Kingdom and Italy have a greater share of pharmaceutical and a few other every day consumer products.

### ENVIRONMENT

Environmental problems are particularly noteworthy in the case of the chemical industry. Environmental costs represent some 3.5 % of turnover for major European chemical companies, and 15 % of new investments. This latter percentage will increase to 20 % or more in the decade to come.

The problems raised by the chemical industry with regard to the environment can be separated into the pollution caused during the production process, and the downstream pollution occurring during consumption and disposal of the industry's final products. In the first area the industry is emitting harmful substances into water bodies and into the air, for example NOx and SO2, causing acid rain. The industry is also confronted with the scarcity of tipping sites to deposit solid waste. With respect to global environmental pollution, as a big energy user, the industry is a big emitter of CO2, one of the gases contributing to the greenhouse effect. The industry has opposed a tax on energy use or on the carbon contents of the fuels used, proposed by the EU Commission as a means to achieve stabilisation of CO2 emissions at the turn of the century, on the ground that energy taxes would undermine its competitiveness. However, the industry has supported an industry energy efficiency programme.

According to CEFIC, the observation of long term trends since 1960 reveals no correlation between oil prices and energy

Source: DEBA

efficiency. In other words, fuel and power energy consumption by the European chemical industry is not responsive to energy prices. International competitive pressure has been the real driving force behind the permanent and dramatic progress in its energy efficiency over the last 30 years. It follows that, according to CEFIC, energy taxes would further impair the international competitiveness of the EU chemical industry without bringing any progress in energy efficiency.

On the other hand, in the area of the environmental auditing of industrial installations, the industry has largely accepted the core principles of an EU Commission proposal on eco-audit, according to which industry would voluntarily allow such audits, checked by accredited auditors. The European Chemical industry has developed its own environmental programs, called Responsible Care.

Pollution linked to the use of chemical products can happen either at the time of actual use or at the time of disposal of waste. In the first case, examples relate to the use of solvents in paints and adhesives, and to the contamination of water tables by nitrates in fertilisers. In the area of solid waste disposal, the industry is faced with the successful implementation of plastics recycling infrastructure within 10 years, according to the EU proposal on packaging waste. This will stretch the plastic industry, as the recycling of plastics is generally less advanced than that of other materials used for packaging, such as paper and board, glass or aluminium.

---

## OUTLOOK

---

Investments should start increasing again in 1995, under the impulse of high and increasing operating rates. However, the structural problem faced by the European chemical industry is still present, especially in the basic chemical sector: an excess of capacity, and high production costs, which pushes companies to continuously press for productivity gains. In this regard, activity in mergers and acquisitions will remain important, especially in the pharmaceutical and basic chemical businesses, but also in a number of specialty chemical segments.

Written by: DRI Europe

The industry is represented at the EU level by: European Chemical Industry Council (CEFIC). Address: Avenue E. Van Nieuwenhuysse 4, B-1160 Brussels; tel: (32 2) 676 7211; fax: (32 2) 676 7300.

# Basic industrial chemicals

NACE 251, 252, 253

Despite good performances in 1994, the European basic chemical industry still faces structural problems. In addition, demand is declining in some segments, such as fertilisers. It is thus vital for the basic chemical sector to continue its restructuring process and to invest in new, modern productive capacity.

## INDUSTRY PROFILE

### Description of the sector

The data presented in this monograph correspond to NACE classes 251, 252 and 253, which cover basic organic and inorganic chemicals. The basic industrial chemicals sector includes units exclusively or primarily engaged in the manufacture of inorganic chemicals (including simple and complex fertilisers), electrochemical products, organic chemicals (including those obtained from petroleum and coal), synthetic rubber and plastics materials, mineral pigments and organic dyestuffs, etc., and in the distillation of tar and benzole. In this classification are considered not only the units producing such basic chemicals but also those units which both produce them and process them into finished products.

The petrochemical industry includes activities such as the cracking of ethylene and other olefins such as propylene and butadiene; the manufacturing of aromatic products such as benzene, toluene and xylenes; the manufacture of other products such as ammonia, methanol and carbon black. Petrochemicals also include the manufacturing of the intermediates products such as ethylene oxide or ethylene glycol, vinyl chloride, acrylonitrile, etc.

Taking the United Kingdom in 1991 as an example, petrochemicals accounted for 50.6 % of the production of the basic chemical industry. Petrochemicals are based on the processing on first derivatives of oil (such as naphtha) and natural gas.

The synthetic resins and plastics industry accounted for 21.1 % of production of basic chemicals. This segment of basic chemicals transform petrochemicals intermediates into synthetic resins, such as polyethylene, polystyrene, or polypropylene. The synthetic rubber industry transforms petrochemical intermediates into synthetic rubber, such as polybutadiene. It accounted for 2 % of basic chemical output.

Inorganic chemical industry is based on the processing of mineral products, and includes, among other, the production of acids, such as sulphuric or nitric acids, or the production of metal oxides, such as titanium oxides. Inorganic chemicals account for 10.3 % of basic chemical output.

Fertilisers accounted for 6.8 % of basic chemical production. Fertilisers produced in Europe are almost exclusively nitrous (N) fertilisers. Other fertilisers, either phosphates (P<sub>2</sub>O<sub>5</sub>) or potash (K<sub>2</sub>O), are imported.

Pigments and dyestuffs accounted for 9.2 % of basic chemical production.

Because of the relative importance of the petrochemical sector, which accounts for more than half of basic chemicals sales, development specific to that segment are covered in a specific monograph which follows. Another monograph is also dedicated to fertilisers.

Figure 1: Basic industrial chemicals  
Value added in comparison with related industries, 1993

### Recent trends

Two external events had a major influence on the fate of the basic chemical industry in the mid eighties: the depreciation of the dollar, which fell by 46 % against the ECU between 1985 and 1987, and the fall of the price of crude oil, which, in dollar terms, fell by 46 % since 1986.

One has to be careful, however, at reading the trade data published here. As trade data are published only in value terms, changes can be due to a change in volume actually traded, but can also be due to a change in prices. And indeed, in 1986, basic chemical producer prices fell by 10 % to 15 % in European countries. To understand what happened, we must thus consider figures in constant prices, or in volumes.

In 1986, European price competitiveness was directly hit by the fall of the dollar, and EU trade balance declined by about one third, with exports (in value) down 15.9 % and imports down 9.9 % in value. As a consequence, European production in the basic chemical sector fell by 3.4 % in volume (Figure 3), mostly because of this fall of exports. In the following years, strong domestic demand, as the European economy

1994 are Eurostat estimates.  
Source: DEBA

enjoyed one of its strongest booms, and a progressive recovery of exports allowed production to recover rapidly, at 7.9 % in 1987, 5.1 % in 1988, and 4.3 % in 1989.

The fall in the price of crude oil, on the other side, decreased dramatically the cost of producing basic chemicals. As selling prices remained relatively high, thanks to a fast growing demand, profitability was at its highest from 1987 to 1989 (on table 4, gross operating rate reaches a maximum of 16.4 % in 1988). The restructuring measures taken in the early eighties also helped enhance profitability in this period.

The situation changed after 1989. European economies entered a slow growth period, with an actual recession in 1993. Between 1989 and 1993, production of basic chemicals fell by 1.2 % per year on average in the EU.

Following the 1993 depreciation of several European currencies, the EU basic chemicals trade significantly improved in 1993 and 1994. In 1993, domestic demand of basic chemicals

remained weak, and offset the benefits of improving trade. However, in 1994, a swing in the inventory cycle allowed domestic demand to grow. Combined with good results on the trade front, this helped basic chemical production to increase by 6 % in volume terms.

Since 1985, employment has declined in the European basic chemical industry. Almost stable until 1989, employment fell by 3.5 % per year in 1989-93, as companies were launching restructuring plans and cost cutting measures to fight declining production and profitability.

**International comparison**

In 1993, the EU basic chemical output was worth about 100 billion ECU, about four fifths of US production in the same year. Japan is the third largest basic chemical producer, with an output worth 76 billion ECU in 1993. The importance of the Asian newly industrialised countries (NICs) is steadily growing, and their competition is affecting the position of the EU industry on the world market. Other countries, such

**Figure 4: Basic industrial chemicals

Destination of EU exports**

Source: Eurostat

as Saudi Arabia and Brazil also have developed important production capacities in petrochemicals.

Over the last ten years, from 1984 to 1993, it is in Europe that production of basic chemicals has grown the least, with an average annual growth rate of 1 %. In the US, average growth was 2.2 %, and in Japan 1.6 %.

#### Foreign trade

The European trade position in the basic chemical sector is on declining trend. Export performance by European companies are hindered by an uncompetitive cost structure and the development of new production capacity around the world. Previous export markets thus tend to become self sufficient, or served by other producers, at the cost of European export performances. On the other side, import penetration regularly increases in Europe. The ratio of exports to imports fell from 1.51 in 1984 to 1.03 in 1992. European markets are also under fierce competition from eastern European imports. Western Europe is indeed a prime target for eastern producers, whose domestic markets have shrunk rapidly in the last five years.

The export surge in 1993 and 1994 temporarily halted this trend. However, as they were mostly due to currency movements, we expect the deterioration of basic chemicals trade balance to continue in the future.

In 1993, the main export markets for the EU basic chemicals industry were EFTA countries and the USA. Together, they account for about 37 % of total exports. Japan accounted for 7.3 % of EU exports of basic chemicals. Imports mostly come from the USA (24 %), EFTA countries (more than 30 %), and Japan (9.1 %).

#### MARKET FORCES

##### Demand

The basic chemical sector is an intermediate goods producing sector, i.e. its products are mostly use as inputs by other industries. Only 4 % of basic chemicals output is sold directly to consumers and other final users. In Europe, more than 40 % of basic chemical products are sold directly to other chemical industries: pigments and dyestuffs are used by paint manufacturers, petrochemicals are used to make synthetic rubber and plastic resins, etc.

**Figure 7: Basic industrial chemicals  
Origin of EU imports**

Source: Eurostat

Another important client of the basic chemical sector is the rubber and plastic processing sector, that processes synthetic rubber and plastic resins into finished products, such as tyres, car components, pipes, packaging, houseware, equipment casing, etc. Demand for synthetic rubber and plastic resins was relatively low in 1991-93, as end-markets for plastic applications were shrinking: automotive sales were declining, thus tyres and auto components sales were low; activity in the construction sector declined. Retail sales increased only slowly in the last two years. Thus, despite an increasing use of plastics in packaging application, demand growth has been only moderate for plastic packaging. In the coming years, economic recovery and expected growth in plastic use should boost demand for plastic materials.

Agriculture accounts for about 7 % of basic chemicals sales, in this case fertilisers. The recent reform of the Common Agricultural Policy, for example the 15 % set aside measure, has reduced agriculture activities, thus demand for fertilisers. Fertilisers demand will continue to decline in the future. The Nitrate Directive, for example, will have a substantial impact on demand. Industry sources mention a 10 % fall in European fertiliser demand in the next five years.

The man-made fibres industry is another client of the basic chemical sector. However, as textile producers are moving their production base to countries in South-East Asia, the man-made fibres industry follows. Thus, very few capacity expansions are expected in Europe in the man-made fibres industry. Demand from this sector to the basic chemical sector will remain stagnant at best in the coming years.

### Supply and competition

The European basic chemicals industry has a strong technological base, and it compares favourably with the US and Japanese industry from the point of view of research and development. This represents an important strategic condition for a modern industry which depends on the use of more and more sophisticated materials and technologies.

A major problem for the European petrochemicals industry is its situation of outdated capacity (this situation is described in details in the monograph on petrochemicals). The situation improved in 1994, in part due to the coinciding maintenance and accidental shutdown, which reduced supply on a worldwide basis, and surge in demand, which was caused by some stock building activity and a rebound in economic activity

in Europe. European petrochemical operations were profitable in 1994.

The fertiliser industry is also under fierce competition from foreign producers, in this case eastern European companies. EU producers of fertilisers have a cost disadvantage: their main input is natural gas, which costs more in Western Europe than in other regions of the world, such as Eastern Europe.

Thus, the increasing market share and competitiveness of foreign producers previews a long term deterioration in the EU basic chemical competitive position.

### Production process

Petroleum products and first oil derivatives are used both as raw materials and as an energy source by the basic chemical sector. Fuel and power products represent the major input costs for the basic chemical industry. Therefore, profits in the industry depend to a large extent on oil prices. Other important raw materials are various mineral ores, that supplies the chemical substances needed by the industry.

High capital investments in machinery and technology are essential in this industry and represent, along with the availability of raw materials, a significant entry barrier. High competition, low product differentiation and heavy environmental constraints also increase the difficulties of the basic chemicals activity.

## INDUSTRY STRUCTURE

### Companies

The basic chemical industry is mainly composed of large companies. In the EU, the most important are : BASF, Hoechst and Bayer (D), ICI (UK) and Rhône-Poulenc (F). Other large European basic chemicals companies are the Swiss Ciba, Sandoz and Roche, the Finnish Neste (with Borealis, a joint venture with Statoil), the Norwegians Norsk Hydro and Statoil, Italian Enichem, or Dutch Akzo-Nobel.

Economies of scale are particularly important in the basic chemicals industry. It is a highly capital intensive sector that produces commodity products, thus with very few possibilities of product differentiation. Besides, markets are very competitive, especially because of import competition. Prices usually remain low, and profits margins meagre. It is thus necessary to market large quantities to generate sufficient earnings. It is because of the existence of economies of scale that concentration is high in basic chemicals.

### Strategies

The strategies of basic chemical industries follow four main axes.

First, rationalisation of production, in an effort to continuously improve productivity and cut costs. Together with a in-depth restructuring of activities, old and less efficient production units are closed, and employment reduced. The rapid fall of employment since 1990 (-3.5 % per year on average) is a consequence of this policy.

Second, restructuring of the portfolio of activities: the restructuring of activities also implies a restructuring of the king of businesses in which the various companies want to be active. Companies have focused on core businesses, while getting rid of peripheral activities in which they had no competitive advantage or where they were too small a player. This is achieved through assets sales and swaps, and mergers and acquisitions. The European petrochemical industry, through its association APPE, has tried to contribute to this restructuring, by promoting an industry-wide plan to cut petrochemical capacities in Europe, but it failed to attract sufficient interest. As targets for capacity reduction were not achieved, the plan was dropped in December 1993.

© SOURCE = Source: DEBA

Third, extension to pharmaceuticals and specialty chemicals, sectors which generate more value added, higher profit margins, and for which demand is less sensitive to the variation of the business cycle.

And fourth, establishment of joint-ventures in the rapidly growing Asian markets. South-East Asia is and will be the fastest growing region in the world, and opportunities are numerous in this region.

### Impact of the Single Market

The basic chemical industry was already a global industry when the Single Market programme was launched. The direct impact of 1992 has thus been minimum on this sector. However, there are a number of issues which still need to be addressed, and which the European basic chemical industry sees as major tools to enhance its competitiveness. In particular, state aids and other uncompetitive behaviour should be closely monitored, as they often contribute to maintain uncompetitive plants, in a sector where capacities are in excess.

Transport is another issue where progress could be made, especially in rail transport. Rail transport is almost not used by the European basic chemical industry, because of the perceived excessive administrative burden and delays in international rail transport. In the US, in comparison, a majority of products is moved by rail.

The completion of the Internal Energy Market, which would introduce a higher degree of liberalisation of the sector, is also a priority for the future as it would help to keep energy prices down and would likely result in greater price harmonisation across the EU, an important issue for a very energy intensive industry.

### ENVIRONMENT

The chemical industry has launched its own voluntary program, Responsible Care, to improve its health, safety and environmental performances and the public perception of it. Within this framework, several actions has been developed, such as: the VEEP programme, to reduce specific energy consumption; the ICE programme to improve safety in distribution of chemicals; the publication of annual Environment Reports to meet the European requirement on Environmental Reporting (EMAS).

The publication of environmental reports and audits, certified by independent agents recognised by the authorities, is seen by the chemical industry as a major step to gain greater trust from the public. The chemical industry, under the coordination of CEFIC, has already organised environmental reporting on a voluntary basis, within the Responsible Care program. Various countries has also published National standards (for example BS7750 in the UK, the Netherlands and Finland, or NFX30-200 in France).

The EU regulation on eco-management and auditing (EMAS) comes into force by Spring 1995. The EMAS regulation requires the publication of an environmental statement after any environmental audit, which should be done at least every three years. CEN, the European standards body, is working on an environmental management standard for auditing and reporting under the EMAS regulation, and should come up with a European standard by April 1996. This standard is likely to be ISO14001, from the International Standard Organisation. However, EMAS include elements, such as an initial review and environment statement, which are not part of ISO14001. CEN might thus need to write additional standards to complement ISO14001.

Initiatives from the chemical industry and from various countries should be consistent with European standards, which hopefully will remove the burden of applying for several certifications. In the long run, it is likely that only the European standard will remain.

Other environmental issues at the European level are: the setting up of a polluting emission register from industrial sites; the revision of the Seveso Directive on major accidents hazards, the proposed Air and Water Quality Directive; a Volatile Organic Compounds Directive.

The role of the environment in international trade is now recognised as a major potential issue, although no concrete case of trade-related environmental problem has actually been recorded in the chemical industry. A committee on Trade and Environment has been set up by the World Trade Organisation (WTO). The issues at stake are to avoid the creation of trade distortions from environmental issues; and prevent relocation of polluting production to countries where environmental legislations are less restrictive.

### OUTLOOK

The future of the basic chemicals industry is clouded by rising competition from producers in other parts of the world, particularly in developing countries. Outdated capacity will remain in the industry for several years to come. EU companies will continue to focus on cost cutting leading to a further reduction in employment. The boost in demand registered in 1994 (+6 % in volume) should subside in 1995, as export demand slow down and inventory build up stops, while domestic demand is not expected to take over as the engine for growth.

# Petrochemicals

## NACE 252

The petrochemicals industry represents more than two-thirds of the basic chemicals sector and a quarter of the total chemicals industry turnover. Petrochemical market conditions improved significantly in 1994, with a return to profitability for European companies. However, long-term structural problems of the European petrochemicals industry, such as uncompetitive plants, remain largely unresolved.

### INDUSTRY PROFILE

#### Description of the sector

The petrochemicals industry is defined as the industry that uses raw materials derived from oil or natural gas to manufacture the following products:

- primary petrochemicals: olefins (i.e. ethylene, propylene, butylene, butadiene, acetylene), aromatics (i.e. benzene, toluene, xylenes, naphthalene) and methanol;
- petrochemical intermediates: vinyl chloride, acrylonitrile, cyclohexane, ethyl benzene, styrene, phenol, etc.;
- petrochemical products: plastics, synthetic fibres, solvents, surface active agents, additives, synthetic rubber, fertilisers and agricultural chemicals.

This monograph does not deal with the last categories, which are the subject of separate monographs in these and other sectoral chapters. The lack of a common data base for petrochemical products is the main reason for the absence of complete statistical data.

The petrochemicals industry is concentrated in Germany and the Benelux countries, which hold 27 % and 25 % of the Community's olefin cracker capacity of ethylene production respectively, followed by France, the United Kingdom and Italy, with 18 %, 15 % and 12 %.

#### Recent trends

Over the last ten years, the production of basic petrochemical products has increased steadily, as shown on Table 2. On average, ethylene production and consumption in volume terms

Figure 1: Petrochemicals  
Value added in comparison with related industries, 1993

(1) DRI Europe estimate.  
Source: DEBA

has increased by about 3 % per year, propylene by about 4 % per year and benzene by about 1 % per year. Butadiene is the exception, with a 0.1 % annual decline of production, while consumption increased by an average of 2 % per year.

Despite the poor economic environment in the last two to three years, production and consumption of basic petrochemical products in the EU increased in 1992 and 1993. Ethylene production increased by 5.3 % in 1992 and 1.7 % in 1993, to reach a total production in 1993 of 14.5 million tonnes. Propylene production increased by 7.3 % in 1992 and 3.8 % in 1993, to reach a total production of 9.5 million tonnes in 1993. Production of butadiene and benzene, however, declined in 1993.

The prospects for 1994 look much brighter. According to the Association of Petrochemical Producers in Europe (APPE), the production of all major petrochemical products increased significantly in the first half of 1994. For example, output

Origin of EU Imports**

Source: Eurostat

of ethylene increased by 10.4 % over the first half of 1993. Activity remained buoyant in the summer, as temporary capacity shortages abroad, caused by maintenance shutdowns and accidents, boosted export demand.

In terms of basic and intermediate products, the petrochemicals sector accounts for approximately one-quarter of the total value added of the chemical industry, i.e. 26 billion ECU in 1992. Eurostat figures show that total employment in the basic chemical sector (including NACE 251 and 253) reached a level of 607 000 in 1992, with a decrease of more than 8 % from the 1985 peak.

#### International comparison

The EU is a major player in the world market for primary petrochemicals, being the largest producer of butadiene and benzene and the runner-up to the USA, for the production of ethylene and propylene. EU production, in volume terms, is about twice that of Japan. Recently, new producers have emerged on the world scene, particularly in south-east Asia (e.g. Korea), Brazil and the Middle East.

#### Foreign trade

The EU's trade balance with the rest of the world is positive and increased sharply in 1993 because of favourable currency

movements in Spain, Italy and the UK. From 2.2 billion ECU in 1992, it rose to more than 6 billion ECU in 1993, attributed mostly to a rise in extra-EU exports, from 16 billion ECU in 1992 to 19.3 billion ECU in 1993. This is a reversal of the trend observed in the recent past. From 1984 to 1992, the EU trade surplus in petrochemicals declined from 5.9 billion ECU to 2.2 billion ECU.

In the medium to long term, however, the EU trade surplus should resume its downward trend, as European-based production cannot completely overcome its cost disadvantage in global markets relative to US, Middle East and Far Eastern producers.

A breakdown by Member States shows the predominance of Germany, which is both the major exporter and importer in the EU, accounting for 41 % of extra-EU exports and 23 % of extra-EU imports. In this respect, other significant countries within the EU are the United Kingdom, whose figures are respectively 13 % and 14 %, France (10 % and 14 %), the Netherlands (10 % and 12 %), Italy (9 % and 15 %) and Belgium (7 % and 10 %).

Before the recent enlargement of the EU, the EFTA countries and the USA were the main end markets for extra-EU exports as well as the primary source of EU imports. In fact, together

they made up 41 % of total extra-EU exports and 60 % of extra-EU imports. Non-OECD countries, which account for most of the "Rest of the World" category in Figure 2 (44 % of exports), also represent an important market for the EU.

## MARKET FORCES

### Demand

The products of the petrochemicals industry are used mainly by other branches of the chemicals sector, especially specialty chemicals, synthetic resins, plastics and synthetic rubber, used in virtually all segments of our industrialised economies (such as packaging, construction, electronics, or transport); pharmaceuticals; paints varnishes and inks; and man-made fibres.

The industry is traditionally very cyclical. Based on Table 2, the two most recent low points of the cycle occurred in 1986/87 and 1990-92. Surprisingly, despite the overall poor economic environment (GDP fell by 0.6 % in the EU in 1993), demand for ethylene and propylene grew in 1993, although more slowly than in 1992.

The demand for primary and intermediate petrochemicals depends mostly on the growth in end markets, which in turn relies on several factors. First, the economic environment; second, inter-product competition (i.e. among plastics and other materials like steel); third, the emergence of new products; fourth, the influence of environmental restrictions; and finally, changing trends in the global petrochemicals industry.

### Supply and competition

The European petrochemicals industry is currently suffering from a combination of problems which contribute to a lack of competitiveness in a global context. An important feature of this is structural overcapacity.

During the period 1986-1991, lower feedstock prices and strong economic growth motivated the industry to invest heavily in increasing both capacity and flexibility of choice of feedstocks. However, new capacity only came in 1991 and after, when the demand growth rate started slowing down. In the last three years, ethylene production capacity in the EU has increased by 21 %. Three new olefin crackers became operational recently. Furthermore, the removal of bottlenecks added the equivalent of another three olefin crackers. Consequently, the capacity utilisation rate fell to 83 % in 1993.

At the same time, capacity of production has increased rapidly worldwide, especially in south-east Asia and the newly industrialised countries, such as Korea and Taiwan. Between 1990 and 1993, world ethylene capacity increased by 10.1 billion tonnes, against an increase of demand of 6.3 billion tonnes.

This has posed problems for European-based producers, who operate at a competitive disadvantage. A ton of ethylene produced in Europe can cost up to twice as much as a ton produced in the Middle East, because the latter uses ethane whereas in Europe naphtha is typically used. However, while European ethane-based producers have higher raw material and labour costs, in the Middle East distribution costs are higher. Additionally, new producers in the Middle East increasingly will have to use naphtha or liquefied petroleum gases, where they will lose their raw material cost advantage.

This, unless they introduce raw material discounts. The practice of "dual pricing" in Saudi Arabia, for instance, has caused concern within the industry, as it threatens to distort the world market.

Already, the increasing market share and competitiveness of foreign investors has had long-term consequences for European petrochemical producers. Thus, while a brief increase in the trade surplus of European producers was experienced in 1993 (due mostly to exchange rate fluctuations), a longer

term decline in the level of trade surplus is clearly shown in Table 2.

Market prices for petrochemical products have remained low in the recent years, as the situation of excess capacity forced producers to lower prices to keep their market share and to keep their factory running at as high a utilisation rate as possible, in order to lower the influence of important fixed costs. As a result, margins and profits have been under serious pressure, and the petrochemical operations of many European companies lost money in 1993.

The situation improved in 1994, in part due to the coinciding maintenance and accidental shutdown, which reduced supply on a worldwide basis, and surge in demand, which was caused by some stock building activity and a rebound in economic activity in Europe. European petrochemical operations were profitable in 1994.

### Production process

Most of the petrochemical crackers being built around the world today are based on naphtha, or mixed streams. In this context, Europe is not at a technological or structural disadvantage, as long as manufacturing costs are competitive. Unfortunately, in many cases they are not. Nowadays, naphtha-based ethylene cracking can be as much as 20 % more expensive than LPG or natural gas-based cracking.

In recent years, there has been considerable investment in Europe to allow cracker operators to select the feed most appropriate for their particular circumstances. For instance, major European petrochemical companies have sought to take advantage of rapid growth in the industrial gases' market, by setting up pipelines to feed petrochemical sites. A case in point is the BP cracker at Grangemouth in Scotland.

However, in the medium term, there is no real alternative to naphtha as principal feedstock for ethylene production in Europe. In any case, the investment to improve operating costs and efficiency has improved the overall competitiveness of the European industry.

## INDUSTRY STRUCTURE

### Companies

Activity in the petrochemicals field is performed by large-scale European and international groups, which have undergone extensive restructuring following the oil crises and the slowdown in economic growth that characterised the end of the 1970s and the beginning of the 1980s. The restructuring has prompted a reduction in the number of producers and sites as well as a shift in emphasis with regard to certain products. For example, during the 1980-1986 period, eight EU producers of ethylene disappeared through the closure of 30 sites representing a capacity of 4.7 Mt. At the end of 1993 there were 52 olefin crackers operating in western Europe, owned by 27 companies.

Among the five leading EU chemical firms (BASF (D), Bayer (D), Hoechst (D), ICI (UK) and Rhône-Poulenc (F)), three are involved in the production of basic and intermediate petrochemicals (Rhône-Poulenc and Bayer are the exceptions). The proportion of activities involving basic chemicals varies among these three: according to 1991 data, Hoechst can ascribe a share of 12 % of its turnover to petrochemicals, BASF 20 % and ICI 19 %. Among the ten non-EU leaders, Dow Chemical (USA) and Exxon (USA) are firmly installed in the European petrochemicals sector.

The petrochemicals sector is closely related to the oil refining industry for its supply of raw materials. This has engendered the development of petrochemical activities on their own from the refining industry, as part of a strategy of downstream integration. It is worthwhile to note that among the top 15 chemical groups at the world level, four of them are petro-

chemical subsidiaries of larger oil companies: Shell Chemical (NL/UK), Enichem (I), Elf Atochem (F) and Exxon Chemical (USA). Traditionally these companies focus their production more on basic chemicals than on refined chemicals.

### Strategies

Faced with a situation of excess, costly, capacity in Europe and the world, European companies have accelerated the concentration of the petrochemicals sector. The European market is still characterised by a large number of producers. In the ethylene market for example, there are 27 producers in Europe, much more than in the USA.

The existence of structural excess capacity should encourage European-based producers to press ahead with the restructuring process. This would allow the shut-down of the oldest facilities, which are now uneconomical to operate, and which contribute to the European petrochemicals sector's uncompetitiveness. However, companies seem reluctant to take initiatives in this regard.

In 1993, given the dimension of the inefficient capacity problem, the APPE developed a plan - later aborted - for the closure of uneconomic plants. The idea was to create a fund, financed by all ethylene producers in Europe, to help companies closing cracker capacity. However, it appeared that the target of 1.5 million tonnes of capacity to shut down would not be achieved, and the plan was abandoned.

Since then, one cracker, with a capacity of 335 thousand tonnes per year, has been closed, by BP (UK/NL) at Baglan Bay, South Wales. This followed the expansion of a BP ethylene cracker in 1992, at Grangemouth in Scotland, thus increasing Europe's global ethylene capacity. A cracker at Leuna also has been closed.

In 1994, the ethylene and petrochemical markets have improved, as explained above. As a result, the incentives for companies to close some capacities have faded.

However, the primary structural problems remain largely unchanged: a great number of uncompetitive plants and high operating costs. Other factors, not directly linked to market fluctuations, also affect the petrochemicals sector in the EU: i.e. the presence of too many players with too many manufacturing sites; a lack of integrated pipelines; the need to complete the integration of the European market, and a poor pricing mechanism.

Competition from East European producers has declined recently. As they now have to buy their feedstock in hard currencies, their operating costs have increased dramatically. They must improve their cost structure before exporting again on European markets. Although this should not influence the West European market in the short run, in the medium term, imports from Eastern Europe may add to the existing overcapacity problem in Western Europe.

### Impact of the Single Market

The petrochemical industry was already a global industry before the Internal Market programme was launched. The impact of the 1992 programme on this sector has thus been relatively limited. Nevertheless, there remain a number of issues which should be addressed and which the European petrochemical industry considers to be important to enhance its competitiveness.

One of these is a closer monitoring of state aids and other regulatory measures taken in some Member States. These aids often contribute to the maintenance of uncompetitive plants, in a sector where there is already excess capacity.

Improving transport networks is another area in which progress could be made, especially for rail transport. At present, road transport dominates in the European petrochemical industry, because of excessive administrative burden and delays in in-

ternational rail transport. This contrasts with the situation in the US where a majority of petrochemical products are moved by rail.

On the other hand, the harmonisation of European energy markets and a higher degree of liberalisation in this sector could have a beneficial effect on energy prices, reducing them and ensuring greater price convergence across the European Union. This would remove national (input) price distortions for a very energy intensive industry.

---

### ENVIRONMENT

---

Four main factors have helped to greatly diminish the level of pollution produced by the petrochemicals industry over the past two decades. First, the closure of plants whose environmental performance was not satisfactory and their replacement with units using clean technologies; second, modifications to the production processes to make them less contaminating; third, the set-up of effluent processing plants downstream of the polluting units; and fourth, the Responsible Care programme, launched by the chemical industry, aimed at progressive improvement in environmental performance for the entire chemical industry.

Another main concern for the industry is the proposed energy/carbon tax. The industry already faces higher prices for energy and feed-stocks than do its main competitors (the USA and the Middle East) and is afraid it would be taxed more heavily than other regions in the world.

---

### REGULATIONS

---

The industry's trade association (APPE) fully supported the proposal made by the European chemicals industry at the Uruguay Round of the GATT negotiations to lower tariffs on chemical goods at a level of 5.5 to 6.5 %.

Other trade agreements include the Community's Generalised System of Preferences (GSP) as well as Association Agreements with East and Central European states. The former was originally designed to help developing countries by granting them duty-free access to the EU. The industry now complains that some of these countries have reached a stage of economic development that does not justify that privilege anymore.

The Association Agreements concluded with most East European neighbours aim to create a free trade area within ten years and will grant free access for their products as of January 1, 1995. The industry is particularly worried about the Community institutions that might not apply trade measures whenever justified. These fears arose from a few cases where dumped Eastern European imports have made spectacular progress on the Western market (e.g. PVC, melamine). However, the EU saw its chemicals trade surplus with this region grow from 708 to 1 012 million ECU between 1991 and 1992.

---

### OUTLOOK

---

The factor that will influence the petrochemicals industry the most in future is a lack of competitiveness within the global market. The causes of this situation are structural rather than cyclical. An immediate problem which must be addressed is the existence of a number of production units in the EU with a cost structure which is no longer competitive in the global market.

The situation of lack of competitiveness will be alleviated by the following remedies: first, an improvement in the European cost structure; second, a reduction in the number and ownership of crackers through joint ventures and alliances; and third, the rise of flexible crackers able to receive propane, butane or ethane. However, without significant further re-

structuring of the industry, this problem is unlikely to be solved until the late 1990s.

Another influence will be that investment in environmental protection is steadily increasing, and is expected to have risen by about 15 % between 1991 and 1994. Legislative requirements, such as the Integrated Prevention Pollution Control, are the main driving force behind this increase.

Finally, during the next decade naphtha is forecast to remain the bulk feed stock, with LPG at best playing a major role only after 2010.

# Paints, varnishes and printing inks

NACE 255

The market for paints, varnishes and printing inks is not recession-proof, as the industry's 1993 drop in production demonstrated. In any case, prospects for 1994 and 1995 are positive, as the EU economy shows signs of recovery. Like other industries, the industry for paints, varnishes and printing inks is, to an increasing extent, governed by the growing concern for environmental issues. Although EU legislation is still sparse, country-specific regulations have forced the industry to search for environmentally friendly materials to replace hazardous substances, reduce damaging emissions and minimise the use of raw materials. The more efficient use of raw materials is also stimulated by increasing prices for these materials. In order to meet these requirements and attain a competitive advantage, companies are spending more on R&D. As a result, new technological developments are expected in the next years.

## INDUSTRY PROFILE

### Description of the sector

NACE 255 includes the production of paints, paint fillers, varnishes and printing inks. Within this wide range of products with various applications, four main categories can be distinguished:

- architectural coatings, including exterior and interior house paint, primers, finishing coats, pore fillers, varnish and dyes;
- coatings used for a whole series of industrial products and consumer products (e.g. wood or metal furnishing, automotive industry, aircraft industry, machinery and equipment, household appliances, electrical insulation, film, paper and foil, toys and sporting goods);
- special coatings designed for specific applications or for use in special conditions, including products for the re-

painting of cars and machines, high-performance maintenance, road markings, bridge maintenance and metallic coatings; and, finally,

- printing inks used for a series of printing processes (e.g. letter pressing, offset/litho, engraving, flexography, screen printing, etc.).

Paints and varnishes account for around 90 % of production measured in volume and 83 % of production measured in value of the sector. In 1993, production reached a level of nearly 15 billion ECU, which is expected to be surpassed in 1994. Germany is the largest producer accounting for an estimated 31 % of total production value. The United Kingdom, France and Italy follow at a distance with shares of 20.3, 19.5 and 13.7 %, respectively.

### Recent trends

Over the period 1983-1992, the industry recorded average production growth rates of more than 7 % per annum. 1993 also showed an overall growth of 6 %, but the recession caused a drop in the production of some Member States. There have been sizeable falls in the output of France, Italy, Spain and the Netherlands. Germany has managed to increase its production, mainly because of the new demand from the former East Germany, while the United Kingdom maintained output as the result of an upturn in demand by the automobile industry, particularly the Japanese companies located in the United Kingdom. In most other EU-countries, the production of coatings has been virtually static.

### International comparison

The EU is the largest producer of paint, varnishes and printing inks if compared with the USA and Japan. In the latter countries, production levels reached 12.5 billion and 10.1 billion ECU respectively. On a global scale EU-based multinational companies have the highest market shares. The top six European paint producers hold a total 25 % share of the global market, with the overall European share of world demand approaching 45 %.

### Foreign trade

The EU is a net exporter of paint, varnishes and printing inks. The recession and the resulting slow growth in EU-demand is reflected in the zero growth of extra-EU imports in

1993. Extra-EU exports, however, still recorded a growth of 8 %. These developments together caused the trade surplus to increase by more than 13 %, equalling an amount of 1 555 million ECU.

In 1993, 29 % of EU production was exported to EFTA countries, with Austria, Switzerland and Sweden being the major clients. Exports to the USA totalled 129.5 million ECU or 5.9 % of EU exports. This relatively low export amount is caused by the fact that some European companies have their own production facilities in America. Remarkable are the growing export markets in Eastern Europe. Together, Poland, the Czech Republic, Russia and Hungary accounted for more than 12 % of total EU exports in 1993. Similarly, extra-EU imports originated mainly in Austria, Sweden and Switzerland (accounting for 59 % of extra-EU imports combined). The USA and Japan make up 23 % and 12 %, respectively.

## MARKET FORCES

### Demand

Market demand for paints and coatings is very complex. Paint products are used in numerous situations and applications. They prevent the corrosion and deterioration of various materials, such as wood used in buildings, metal used in cars and concrete used in construction. Paints fulfil the more common function (for both professionals and average consumers) of colouring walls, buildings, etc., constituting 50 % of demand. Other market sectors follow at a distance with shares ranging from can coatings and wood finishes (7 %), to car refinishes (4 %) and anti-corrosion materials (3 %).

Some clear trends in buyer preferences have emerged in recent years. Wood care products are taking an increasing share of the decorative market, at the expense of paints. Powder coating is estimated to be the fastest growing paint market in the world; as powders contain no solvents and therefore tend to be less toxic. In 1994, an overall 13 % increase in the use of powder coatings was induced by the conversion to powder technology in metal office furniture and other markets. Finally, demand for high-solid paints has grown, causing a corresponding reduction in the use of non-water-based solvents.

A breakdown of market demand for printing inks can be made according to the applied graphical processes and the material to be printed. As such, the following categories can be distinguished: offset printing (brochures, posters, magazines); flexoprinting (packaging, wallpaper); book printing (magazines, periodicals, promotions); newspaper printing (newspapers, weekly and other paper editions) and other printing techniques. As the relative importance of these printing processes may differ drastically between countries, demand cannot be translated into separate market shares.

As demand for paints and printing inks, tailor-made solutions are increasingly needed. Manufacturers respond to this trend by demonstrating a problem-solving attitude and continuously searching for product improvements. The growing environmental concern has stimulated the industry to develop new formulas for their products in order to reduce the potential harmful environmental effects.

### Supply and competition

A relatively small number of large multinational companies operate worldwide. The intensifying global competition between them concentrates on new product development (the application of safer and environmentally friendly materials) accompanied by large expenditures on R&D and promotion (especially for consumer products). Manufacturers try to improve their market positions by finding and/or creating new trends in market demand, which has led to a flood of new products.

These developments lead to further price reductions, higher concentration of supply, a growing number of product varieties and large R&D-expenditures on new product development and promotional activities.

The large manufacturers also try to establish growth by exploring new geographical markets and taking over small and medium-sized companies. Increasingly in recent years, the domestic markets also have been affected by the trend among chains of do-it-yourself stores (DIY) towards own-brands and generic brands, resulting in an intensification of price competition.

### Production process

During the 1980s, the paints and varnishes industry developed new products and adopted new applications driven by rationalisation in its client industries and environmental problems.

High raw material prices, which applied to titanium dioxide in the late 1980s, have led to the development of new raw materials technology, which aims for products designed not only to perform better, but also to comply with environmental regulations. In this market, where price competition is so important, raw material prices have become a crucial factor. Therefore, manufacturers are aiming for better and more efficient raw material performance and for improved product quality.

## INDUSTRY STRUCTURE

### Companies

The top ten EU coating companies account for an estimated 40 % of total world supply. The top six European manufacturers account for 25 % of world supply. They tend to operate on an international basis, in contrast with most major US-based producers.

Akzo Nobel is by far the largest manufacturer of paints worldwide, accounting for more than 7 % of global sales, with a turnover of 2.4 billion ECU. Another European-based manufacturer ICI (UK) ranks second in the world, with a market share of 6.8 % and sales totalling 2.2 billion ECU. Other major EU-paint producers are BASF (D), Herberts (D) and Courtaulds (UK).

The European paint manufacturers operate on a broad country base, which is demonstrated by the market shares of these companies in other parts of the world. The five leading EU manufacturers have strong footholds in North America, with company-specific turnover shares varying from 20 to 49 %. In addition, a European presence has been established in the Asia and Pacific regions, where ICI and Courtaulds record more than 20 % of their sales.

### Strategies

The large multinationals try to establish growth either by developing new markets for existing products (the exploration of the East European markets for instance), developing new products or product varieties for existing or new markets and performing mergers and take-overs.

The smaller companies, active in one or two market niches, are often limited to local markets. Only if they possess a patent for a certain product are they able to operate on a larger scale. The backward integration tendency towards own-brands and generic brands is a retail strategy that directly affects market forces at the production level.

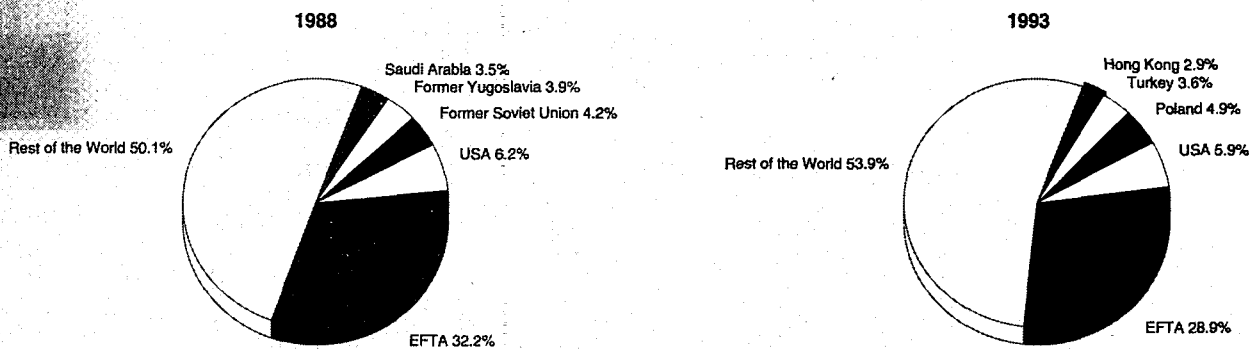

The industry has now entered a period of rationalisation and consolidation, with an increasing number of paint companies identifying their core business sectors. As a result, there has been a considerable number of divestments in the recent past, the most notable being the withdrawal from the automotive OEM market of Akzo Coatings and ICI. The Akzo business has been acquired by PPG Industries (USA), while DuPont (USA) has bought the 50 % holding of ICI in their joint venture, IDAC, headquartered in Bonn. As a consequence of these moves, the automotive OEM market in Europe is now held by only four companies - PPG and DuPont (USA), and BASF and Herberts (D). There are also a few smaller specialised companies operating in limited geographical areas. Among other recent major divestments are the sale by Manders (UK) of its architectural coatings business to the French Group Total, which enables Manders to concentrate on inks. Similarly, Courtaulds sold its general industrial coatings division to

Destination of EU exports**

Source: Eurostat

Croda (UK). Divestments by some companies have been offset by the acquisitions of others. The most far-reaching of the recent acquisitions in Europe is that by Akzo Coatings of the Swedish-owned Casco operations of the Nobel Group.

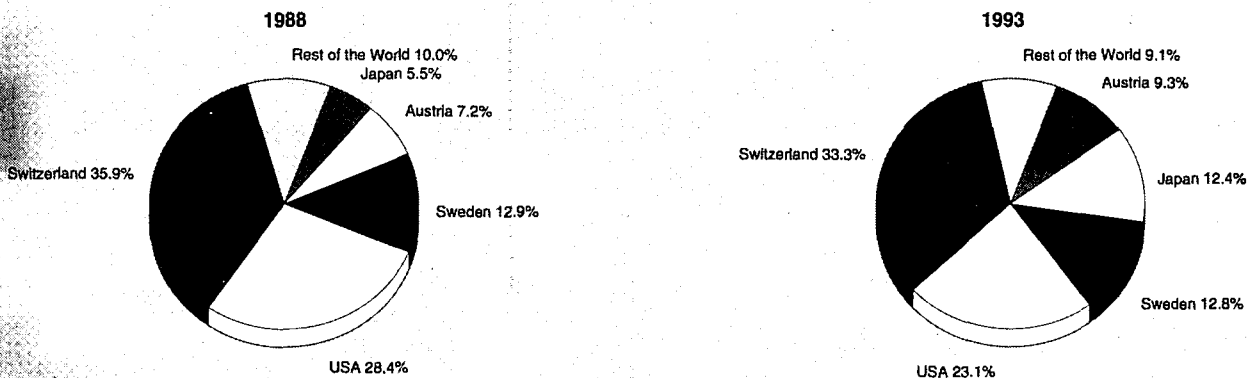

The search for new geographical markets for European companies is seen from the plethora of new plants, that have been established recently in Asia and the Pacific. Courtaulds Coatings is one of the leaders in this region and established new paint production units in China, South Korea, Malaysia and Indonesia in 1993. A joint venture was recently set up in Vietnam and more units are currently being built in China and India. Similarly, ICI has become heavily involved in China, Thailand and Malaysia. Other EU-based firms looking to Asia and the Pacific are Total in Vietnam, where a joint venture with a local producer has been set up. Herberts (D) has formed a joint venture with a Hong Kong-based firm.

The involvement of EU paint companies also has increased in Eastern Europe. Akzo Nobel and Total already have joint ventures in Hungary. Akzo has further established a joint venture in Russia with the largest local paint producer. Herberts has set up a joint venture with Nobilias for automobile coatings in Poland.

### Impact of the Single Market

Paints, varnishes and printing inks are not subject to any significant restraint to trade within the EU, nor to trade with non-EU countries. Free movement of goods is an accomplished fact. Among the set of measures which constituted the so-called "Internal Market" programme, those which had most impact on the industry were those related to environmental protection. The products of this sector are indeed subject to European directives on the marketing, use, classification, packaging and labelling of dangerous substances. Emissions and hazards during the production process are also partly regulated by EU directives (for instance the regulation of hazardous waste shipments), though most of these aspects are still covered by national regulations (for instance related to the emissions of solvents). The sector favours a harmonised business environment within the EU, and therefore believes that the principle of subsidiarity should be implemented with care. In particular, it is important to avoid that subsidiarity would result in a reversal of harmonisation. The packaging and packaging waste directive for instance is considered to be leaving too many issues to be determined by the Member States. This could result in the emergence of new internal barriers if Member

States choose different approaches to implement the objectives of the directive.

## ENVIRONMENT

As stated earlier, the growing environmental concern among clients, the general public and policy makers - in some cases resulting in regulatory pressures - has stimulated the industry to develop new formulas for their products in order to reduce harmful environmental effects. High solids, water-based products, powder coatings and UV-technologies are all innovations which offer solutions for the environmental problems. Volatile organic compounds (VOCs) are being reduced to an increasing extent. The industry is devoting a considerable share of its R&D expenditure to solve this problem and already has had some success, e.g. water-based coatings. Other examples of less hazardous techniques are the electrostatic application of powder coatings, which - like most radiation curing-systems - does not contain any solvents. Although these techniques have advantages and are a good alternative, they also have some disadvantages. For example, water-based products are still more expensive and less durable than solvent-based varieties.

Printing inks are almost entirely used by professional clients. For industrial appliances it is possible to limit or even prevent emissions of solvents, especially where solvents are used in order to increase the speed of printing the industry succeeded in stopping emissions. The printing industry also uses less hazardous systems, such as water-based products and UV-systems.

## REGULATIONS

The EU Commission has put forward several directives on environmental pollution which concern the paint and varnish industry, most of them concerning titanium dioxide. However, solvents are not yet subject to any directives, although country-specific regulations do apply to their use. Legislation in this area varies widely across the EU. German legislation calls for limits of 150 mg/cubic metre of carbon emissions, while in the United Kingdom the limit is set at 50 mg/cubic metre.

Country-specific regulatory pressures and the involvement of the association which represents the European industry (CEPE) have contributed to the current debate on solvents, which likely will be the starting point for a new directive. The issue of solvents, however, is only one of the subjects which are being discussed. Other proposals and directives deal with the control of hazardous waste shipments, the control of major accident hazard preparation and the provision of information on emissions and waste to the public.

## OUTLOOK

In the recent past, the industry has demonstrated cyclical movements. The recession in 1992 and 1993 seems to have come to an end. For 1994, there are signs of global economic recovery. Within the EU the upward movement during 1994 is likely to carry on well into 1995. For both years an average annual production growth of 4 % is expected. For the years until 1998 even higher growth rates are forecast. Regulatory pressures will further encourage R&D expenditure for the search for new formulas to reduce negative environmental effects together with a more efficient application of raw materials.

# Other specialty chemicals

NACE 256.1-256.7

The market for other specialty chemicals is to an increasing extent controlled by the growing awareness of environmental issues. The manufacturers who succeed to develop environmentally friendly products, which are good alternatives for existing products in terms of quality and price, can create substantial competitive advantages. Proper commercial exploitation of these advantages can lead to higher profits. In order to achieve these advantages, R&D expenditures are increased, in some cases forcing companies to cooperate or to merge. In the coming years relatively high growth rates and new technological developments are expected.

## INDUSTRY PROFILE

### Description of the sector

The manufacture of other specialty chemicals includes a number of products, mainly for industrial purposes. A subdivision can be made into the:

- manufacture of compressed gases (NACE 256.1);
- manufacture of glues and gelatine (NACE 256.2);
- chemical treatment of oils and fats (NACE 256.3);
- manufacture of essential oils and of natural and artificial flavouring and perfume materials (NACE 256.4);
- manufacture of explosives, pyrotechnic articles and matches (NACE 256.5);
- manufacture of auxiliary products for the treatment of leather and textiles; manufacture of tanning agents (NACE 256.6).

### Compressed gases

Compressed gases are mainly destined for the engineering industry. They include air gases, acetylene, propane, carbon dioxide, gas mixtures and various specialty gases. Liquid nitrogen finds its destination in the medical sector and is used

for the conservation of blood and organ transplants. Compressed gases are mainly supplied in small steel cylinders. Gasworks and the distribution of gaseous fuels via mains destined for the steel, chemical and glass industries are excluded (NACE 162). Gases in liquid form are also excluded (NACE 256.5). In 1993, worldwide compressed gases sales accounted for 34 % of total gases sales, corresponding with an amount of 5.2 billion ECU.

### Glues and adhesives

This subsector includes gelatine, modified starches, peptone and glues. The glues can be subdivided into liquid glues and solid glues. Liquid glues consist of a glue-based material liquefied with a solvent, that evaporates after gluing. Solid glues have to be activated by water, solvent or air before they can be used. Within Europe, 60 % of glue production is concentrated in Germany, France and the United Kingdom. In 1992, the total world market for glues and gelatine was estimated at 12 billion ECU. The manufacture of glues for office and household uses is excluded (NACE 259).

### Chemical treatment of oils and fats

Oleochemicals are mainly made from beef tallow, fish oils and from vegetable oils extracted from palm fruits, coconuts, rape seeds, sunflower seeds, soya beans and from the seeds or fruits of other oil-bearing plants. Some oleochemicals are also made from tall oil, a paper industry by-product. These oils and fats are chemically converted into a wide range of chemical products for use in eco-friendly lubricants, soaps and detergents, cosmetics, medicines, food additives, leather, paints and coatings, printing inks, rubber, plastics, metalworking and many other industries. Worldwide production of basic oleochemicals is estimated to be over 3.5 million tonnes, out of which more than one-third is produced in Western Europe. The oleochemicals industry uses about 5 % of the worldwide production of natural oils and fats, the major share of which is recovered material.

### Essential oils, natural and artificial flavouring and perfume materials

These materials include essential natural oils such as lemon, orange, lime, geranium, jasmine and lavender; flavourings, anti-oxidants, colourings, emulsifiers, stabilisers, and enzymes; all to be used as food additives. The worldwide production of these materials was estimated at 7.7 billion ECU in 1993.

### Explosives

The manufacture of these products includes propellant powders, detonators, fuses, matches, flares and liquid gas fuels.

### Auxiliary products for the treatment of leather and textiles

These products include surface agents, lubricants, leather and skin treatments. Tanning and dressing of leather, however, is excluded (NACE 441).

### Miscellaneous chemical products for industrial purposes

These products include abrasive compounds, auxiliary products for use in mechanical engineering and metallurgy, natural resins and their derivatives, etc. All these products deal with the production of activated carbon and earth.

This chapter includes a wide variety of heterogeneous products, for application in a tremendous number of industrial and household uses. Each substance finds its application in distinctively different market niches. While the substances themselves are not necessarily complex, the applications can be. R&D activities mainly focus on finding new applications and markets.

In contrast with commodity chemical markets, the market for specialty chemicals is highly fragmented. To a growing extent, manufacturers have to meet the specifications of particular clients in a niche. This requires a service-oriented market approach and an excellent understanding of the clients' products or production process. This custom-tailored approach also provides the opportunity for higher profit margins.

### Recent trends

The growing interest in environmental issues will cause shifts in production and demand. Changing consumer re-

quirements are met by new or modified products which in turn lead to a shift in industrial demand for raw materials, such as specialty chemicals. The resulting trend towards more environmentally-friendly products leads to an increasing willingness and effort to apply natural-based products instead of synthetic products.

The economic recession in recent years has resulted in pressures on product volumes and prices in commodity chemicals. As a consequence, many chemical companies have cut costs and sold their non-strategic businesses. Conversely, despite the recession, most subsectors of the specialty chemicals industry have demonstrated economic growth, keeping up the level of employment.

### International comparison

In 1993, 33 % of all gases (including compressed gases) was sold in Europe. North America accounted for 35 % and Japan ranked third with 14 % of all sales of gases worldwide. In sales of flavourings, Europe accounted for 45 % against North and South America (25 %) and the Asia-Pacific region (26 %). Demand for glues and adhesives mainly originates from the USA (38 %), Europe and Japan (together 32 %).

### Foreign trade

Extra-EU exports have demonstrated an average annual growth of 4.9 % over the 1984-1993 period, while extra-EU imports increased by an average annual rate of 5.7 %. In 1993, a growth of exports of nearly 19 % was recorded, while imports increased by only 2 %. Thanks to a buoyant growth on its export markets, the specialty chemicals industry has been able to counter-balance the weakening domestic demand, thus avoiding the consequences of the recession.

Germany, France and the United Kingdom are the main exporting Member States. In 1993 they accounted for 71 % of

total Extra-EU exports. Germany is by far the largest market for Extra-EU imports. The USA and Switzerland are the main suppliers of the EU market for specialty chemical products with respective shares of 42 % and 17.5 % in 1993.

## MARKET FORCES

### Demand

#### Compressed gases

The market for compressed gas is highly fragmented, and less sensitive to cyclical downturns than the market for liquefied gases such as oxygen and nitrogen, whose markets are concentrated in the chemical and refining industries. Weak demand in total industrial gases negatively influenced sales and profits in this sector in 1992 and 1993. An upturn is expected for 1994 and after. European manufacturers expect major opportunities for expansion into the Eastern European markets.

#### Glues and adhesives

World demand for glues and adhesives is expected to grow by an annual rate of 2.5 to 3 % in the future. This growth will stem chiefly from growing demand in Latin America and the Far East. The major applications for glues and adhesives can be found in the construction industry, the paper and packaging industry, the woodworking and furniture industry, and others e.g. the electronic, shoe, cigarette, aeroplane and automotive industries. Demand for glues and adhesives in the automotive industry is increasing rapidly, as steel is replaced by plastics and aluminium. Consequently, the ongoing upturn of the European automotive industry will have a strong positive influence on the market for glues and adhesives.

In recent years, environmentally-friendly products such as melting glues, dispersions and water-based systems have been introduced. Despite the fact that the application of these products often requires new investments, these products are expected to account for the highest growth figures in the next few years.

#### Chemical treatment of oils and fats

Coupled with a general upturn in economic market conditions, demand for chemicals derived from natural oils and fats has improved considerably. It is expected this trend will progress as long as the recession continues to recede.

Other factors also have contributed to the improvement in the market for oleochemicals. For instance, formulation changes in powder detergents, has increased demand for fatty alcohols steeply. Similarly, new products have had a positive

affect on fatty acids, where new demand has subsequently been created. Refined glycerine has made gains from other polyglycols stemming from reformulation.

An encouraging upturn in volume has been moderated to some extent by a rapid and sustained increase in the cost of raw materials, which is not always recoverable. This trend is almost without exception: coconut, palm kernel, tallow and oilseed rape are among the most prominent of the world commodities to have undergone such price increases. A better utilisation of indigenously produced natural oils derived from the cropping of set-aside land is quickly becoming an economic necessity.

#### Essential oils, natural and artificial flavouring and perfume materials

The industry's performance has been much better than that of the chemical industry overall. For instance, in the Far East double-digit growth rates are common. Demand for flavours and fragrance is highly fragmented, reflecting the large variety of flavour products.

With respect to fragrances a rough subdivision can be made between applications. Household products are the biggest users of fragrances (30 %) with sales amounting up to 1 billion ECU, followed by cosmetics, toiletries (23 %), fine fragrances (19 %), soaps (18 %) and oral hygiene products (10 %).

#### Explosives

The development of the explosives industry is strongly linked to mining activity. In Europe the mining sector is in a situation of long-term decline, hence the outlook for this EU market is poor.

#### Auxiliary products for the treatment of leather and textiles

The European textiles and clothing industry is suffering from a further increase in import penetration, as treatment activities are now mainly executed in low labour cost countries. As a result, sales of auxiliary products for the treatment of leather and textiles are declining in Europe.

#### Supply and competition

As the market for specialty chemicals is highly fragmented, the service and quality aspects are the most important competitive factors. The higher margins in the specialty markets have drawn the attention of the large chemical companies, which used to focus only on commodity chemicals. Following a wave of mergers and acquisitions in the past few years, many small and medium-sized specialty chemical producers have been integrated into larger companies, with varying de-

**Figure 2: Other specialty chemicals  
Origin of EU Imports**

Source: Eurostat

gress of success. As a consequence, R&D has intensified and has become a crucial instrument, not only to develop but also to protect existing positions in market niches. R&D expenditures were also stimulated by new demands from the market, especially because of growing environmental concerns.

## INDUSTRY STRUCTURE

### Companies

Investments by European industrial gas companies have been particularly important in the recent years. The two major European manufacturers of compressed gases, Air Liquide (F) and BOC (UK) invested in the Far East by taking over three plants in China, India and Australia and by starting up a new plant in Thailand. In Europe, capital expenses of these companies, together with AGA (S) and the Messer Griesheim (D), were mainly directed to Eastern Europe, where the European manufacturers of industrial gases invested in 12 new plants, take-overs or joint ventures. The expansions in Eastern Europe are now in a consolidation mode, with the most recent investments being used to modernise the factories.

In the market for flavours and fragrances, some large companies (either subsidiaries or large multinationals) are operating, such as Quest of Anglo-Dutch Unilever, German Haarmann & Reimer (Bayer), Swiss Givaudan (Roche). There is also one publicly-traded flavours and fragrances company, which accounts for about 13 % of total industry sales.

The major companies in the market for specialty surfactants are Hoechst (D), Henkel (D), Rhone-Poulenc (F), Clermont-Tonnerre (UK) and ICI (UK).

### Strategies

The higher profitability of specialty chemicals over basic products has pushed many large chemical companies to extend their activities in the specialty business, mainly by taking over specialty chemical companies. This strategy has not always been successful, as producing and selling specialty chemicals is a very customer- and service-oriented activity. In recent years, a new restructuring took place, as companies reorganised their activity portfolio and focused on core businesses.

In flavours and fragrances, as well as in specialty surfactants, R&D expenditures have increased, partly to cope with stricter environmental regulations. The important expenditures in R&D have forced companies to cooperate, in order to benefit from economies of scale and to reduce their individual research

bill. Thus, there has been a number of mergers, mainly between large and medium-sized companies. A sizeable number of small to medium-sized companies remain in this business, which are increasingly forced to operate in specific geographical or market niches.

### Impact of the Single Market

Like other chemicals, specialty chemicals are subject to extensive regulation concerning their production and use. This applies in particular to the specialty chemicals that are used in the production of consumer products, such as foodstuffs, pharmaceuticals or cosmetics. The Internal Market programme has led to the harmonisation of product regulation, as well as of methods to test toxicity. Even where harmonised legislation is still absent, the Internal Market programme has increased contacts between Member States, thereby promoting a movement towards agreement on common standards, and exchange of information on safety issues. The implementation of the Single Market programme is still in progress, so that some specialty chemicals segments have not yet benefited from the full impact of European integration. For instance, the pressure equipment directive, important to the industrial gases industry, and the directive on flavouring substances are still in the drafting stage.

## ENVIRONMENT

Stricter environmental regulations and demand from the public are pushing specialty chemical producers to develop environmentally-friendly products. On the one hand, this increases R&D costs. On the other hand, it is an opportunity for increasing revenues, as demand for the new "green" products is increasing. It is important, however, to provide substitutes which are of comparable price and performance.

## REGULATIONS

The proposal on eco-audit from the European Commission has been approved by the environment council of ministers. Although the eco-audit is not compulsory, activities with high environmental impact are expected to carry out eco-audits once a year. Other proposals and directives deal with the control of hazardous waste shipments, the control of major accident hazards preparation and the provision of information on emissions and waste to the public.

In 1994 a new directive came into force concerning additives in food, containing procedures and regulations for the use of

additives. New uses should be authorised, environmental risks and other technical details should be specified. The European Council further adopted a directive concerning the use and marketing of enzymes, micro-organisms, and their preparations in animal food.

---

## OUTLOOK

---

The outlook for specialty chemicals is favourable. This heterogeneous and highly fragmented market still offers growth rates and profit margins higher than the market for commodity chemicals. Large chemical companies will increasingly try to penetrate these profitable segments. Large companies will try to cover customer needs in several types of applications, small producers will focus on particular markets or specific products. In order to penetrate the existing segments or explore new markets, R&D-efforts will become increasingly important. These efforts are more and more directed towards the development of environmentally-friendly products as the markets for these products will become highly profitable in the near future. Production of other specialty chemicals is expected to increase by 3 % in 1994 followed by slightly higher growth rates in the years until 1998 (3.5-4 %). Extra-EU exports are expected to reach an average growth rate of 6 % until 1998.

# Agrochemicals

## NACE 256.8

The European Union, which shows a favourable trade balance for crop protection chemical products, is the leading region for the manufacture of these products. However, demand of agrochemicals within the EU has suffered from the effects of the 1993 reform of the Common Agricultural Policy. Nevertheless, taking into account the increased demand in developing countries, it is now possible to look forward to medium term growth in the EU production of agrochemicals for crop protection.

### INDUSTRY PROFILE

#### Description of the sector

As defined in NACE 256.8, the agrochemicals sector covers the manufacturing of agrochemicals for agricultural purposes. It includes two major sub-sectors: fertilisers and chemical products for crop protection. This monograph covers crop protection chemicals. The fact that compound fertilisers are covered in another monograph of the Panorama (under NACE 256.8) introduces a slight distortion in statistics. The problem is limited, however, as compound fertilisers represent only a small share of both the fertiliser and agrochemical markets.

Crop protection chemicals include insecticides, herbicides, fungicides and plant growth regulators, as well as products derived from biotechnologies designed to protect plants against diseases and parasites. Worldwide, cereals accounted for 17 % of agrochemical use, fruit and vines 13 %, maize 10 %, cotton 7 % and other products 25 %.

#### International comparison

Representing close to 40 % of the world's production, the European Union is the largest region for agrochemical production, ahead of Asia, Eastern Europe and North America.

In the 1980s, Western Europe ranked as the leader in crop protection markets. Nevertheless, since 1990, with the reform of the Common Agricultural Policy (CAP), demand in Europe has markedly dwindled. In 1993, the West European market ranked third worldwide, behind North America and Asia (including Japan). The sector's share in the world market declined from 30 % in 1990 to under 24 % in 1993.

France, Germany, Italy, the UK, Spain, the Netherlands and Denmark are the main EU agrochemical markets. The EU's number one crop in terms of pesticides sales is cereals, followed by vines, fruits and vegetables. The pattern of consumption according to product type varies significantly from

one European country to another, depending on climatic conditions. For example, insecticides are used more frequently in southern Member States, such as Spain and Greece, than in northern countries. In contrast, fungicides used to fight fungal diseases, particularly for high-value crops, are increasingly used in northern European countries, where there is a damper and cooler climate.

#### Foreign trade

The European Union is a major exporter of crop protection products, especially insecticides. The countries with the highest export levels are Germany, France and the United Kingdom. These three countries account for nearly 80 % of the total export values of pesticides from the EU.

Alongside a 12 % drop of imports in 1993 associated with shrinking demand in the EU, there was a 10 % increase in exports. Overall, foreign trade in crop protection chemicals showed a positive balance of about 1 billion ECU in 1993. However, this favourable trade balance remains short of the level reached in the mid-eighties.

Herbicides, fungicides and insecticides represented respectively 43 %, 32 %, 25 % of total agrochemical imports in 1993. The leading competitors of EU agrochemical companies are to be found in the EFTA countries (with just under 50 % of imports), which are ahead of the United States (about 25 %).

### MARKET FORCES

#### Demand

Demand for agrochemicals is closely linked to shifting dynamics within the agricultural sector, as well as to the search for technologies that are likely to increase profitability per hectare. Statutory, economic or even environmental constraints also exert a noticeable influence on developments in the demand for agrochemicals in Europe.

Following a period of steady development during the seventies and eighties, the 1993 reform of the CAP brought about a drop of nearly 20 % in the demand for agrochemical products. Following this reform, the surface area devoted to cereal cultivation decreased by almost 11 % in the EU, thus causing a reduction in total surface areas for potential treatment. Poor weather conditions in the early nineties and mediocre earnings in the agricultural sector also contributed to weak demand.

Certain economically-related factors, such as labour costs - which vary from one country to the next - are liable to generate demand that differs between countries. For example, herbicides are used more in those countries where labour is more expensive.

The overall reduction in demand led some companies to cut back production, and, in some cases, even to shut down their production facilities.

Source: Eurostat

### Supply and competition

Since the early nineties, more intense competition has been observed in the context of reduced demand within Europe. Because of price competition and slack demand, agrochemical producers have seen a setback in revenues. Although European manufacturers are in the lead in the field of research and development, international competition will nevertheless force them to create new alliances in order to reach the "critical size" and benefit from economies of scale. Compared with the United States market, there is still some scope for concentration in Europe: whereas only four major agrochemical manufacturers remain in business in the United States, in Western Europe there are still seven.

American groups are trying to strengthen their position in Europe, and are attracted by potential opportunities in Eastern Europe. Dow Elanco (USA) has launched an investment programme in France and Germany, while Dupont de Nemours is opening a research centre for plant protection products in Europe.

### Production process

Research and development is a crucial competitive factor in agrochemicals, in order for companies to adapt to changes in agricultural practices and increasing environmental pressures. Research and development costs in the top 20 agrochemical companies worldwide represent nearly 10 % of their turnover.

One aspect of the research is to develop more environmentally-friendly products. Seed treatment is another focus of research. It involves coating seeds with a film of an active ingredient while at the same time allowing exchange with the atmosphere. The goal is to increase the seed resistance to pests. Finally, there is a growing interest in biological and biotechnological methods to increase resistance. Genetic engineering techniques have strengthened the effectiveness of the traditional selection of cultivated plants and made it more complex. New varieties have been developed with charac-

teristics that include, for example, resistance to disease and parasites, as well as to weed killers, frost and drought. The initial results of biotechnological research are likely to appear on the European market at the beginning of the next decade.

As in the pharmaceutical industry, the patent protection of agrochemicals is severely limited in time. It is thus crucial for the competitiveness of a particular product to shorten its development time as much as possible, as development is usually carried out after the patent has been registered, thus shortening the useful commercial life of a product.

## INDUSTRY STRUCTURE

### Companies

The crop protection chemicals company sector is relatively concentrated at the international level, with the top 12 companies controlling more than 80 % of the market. They are based mainly in the United States, Western Europe and Japan.

The four leading European companies in the sector, Ciba-Geigy (CH), AgrEvo (D), Zeneca (UK) and Bayer (D) are also among the six leading manufacturers worldwide. Zeneca is a result of the ICI split, whereas AgrEvo is a joint venture in the field of plant protection products created by Hoechst (D) and Schering (D) at the beginning of 1994.

### Strategies

In recent years, agrochemicals producers have had to significantly enhance their R&D expenditures, in order to face the challenge of new regulatory frameworks - especially in the environmental protection area - and to take part in the latest developments in biotechnology. This trend is expected to continue, and will force the sector into a further wave of mergers or acquisitions, in order to benefit from further economies of scale and to increase the potential market of their product. Concentration will thus continue to increase in the agrochemical sector, both in Europe and worldwide.

**Table 3: Agrochemicals for crop protection**  
**Breakdown of external trade by product**

Source: Eurostat

**Figure 1: Agrochemicals  
Destination of EU exports**

Source: Eurostat

At the same time, favourable market prospects in Asia, especially China, and Eastern Europe are inciting agrochemical companies to prepare the ground in these countries. In 1994, AgrEvo, already active in China, announced the formation of AgrEvo China to expand its business activities in that country and, in the same year, bought out the South Korean firm, Misung. Meanwhile, Zeneca is planning an agrochemicals joint venture with three local partners in Nantong, just north of Shanghai. In Poland, Sumitomo (JPN) has set up a subsidiary to market its products.

## REGIONAL DISTRIBUTION

Large differences exist between regions and countries in terms of their use of pesticides in arable crop production. They range from 3 kg (Germany) to 22 kg (the Netherlands) of active ingredients per hectare. The use of pesticides is highest in areas with intensive horticulture (northern Italy, the southern coast of France, the south-east coast of Spain, and the Netherlands). Lastly, the use of fungicides to grow grapes is highest in regions with relatively high precipitation levels.

## Impact of the Single Market

The completion of the European Internal market had a mixed impact on the agrochemicals industry. New restrictions were imposed on the sector, while the industry perceives that the positive effects of the Single Market programme did not yet fully materialise. On the negative side, the reform of the CAP in 1993 brought about a reduction of the area under cultivation, which caused a substantial drop in the demand for agrochemicals. In addition, European regulations imposed strict environmental requirements on the production and use of plant protection products. Finally, reduced expectations have prompted some European producers to de-emphasise further development in the EU and to shift research activities to other world regions, particularly to the USA.

On the positive side, the free movement of goods is considered to be very important for the sector. When realised, it is expected to yield substantial gains. Unfortunately, and although much progress has been realised, this has not yet become reality. The directives on the harmonisation of the regulation of plant protection products are slowly being implemented, though some Member States continue to enforce divergent national rules. Further progress in the area of technical harmonisation

**Figure 2: Agrochemicals  
Origin of EU imports**

Source: Eurostat

and a consultation on environmental policy are considered to be policy priorities in this sector.

---

## ENVIRONMENT

---

The placing of agrochemicals on the market is regulated by Directive 91/414/EEC which lays down stringent requirements for the protection of the environment and of human and animal health. This directive ensures that agrochemicals, when used according to label instructions, do not represent a hazard to man, animals, or the environment.

Agrochemicals are designed to be biologically active in order to control undesirable target species in food crops. Therefore, it is essential that users of agrochemicals respect label instructions and good agricultural practices so as not to cause any environmental harm.

In this context, the agrochemicals industry is placing much emphasis on the development of Integrated Crop Management (ICM) techniques. ICM is a sensible, economical way of farming which combines the use of selective modern agrochemicals and technologies with traditional methods, thus encouraging the respect of the natural environment. The goal of ICM is not to destroy every last weed, pest or disease in a crop, but rather to keep infestation at a level that does not cause economic damage. If any control treatment is needed, whether biological or chemical, or a combination of both, it is applied only when a pest population reaches a damaging threshold.

---

## REGULATIONS

---

Reform of the CAP has strongly affected the agrochemicals market in Europe. This reform, implemented on 1 July 1993, reduces price support in favour of compensation paid directly to farmers. This reform has had a notable impact on the arable sector. The intervention purchase prices of cereals have dropped by nearly 25 %, and these reductions have been compensated for by direct aid per hectare. At the same time, aid payment is contingent on 15 % of the surface area devoted to cereals and oil and protein-yielding crops.

In July 1991, the Council adopted a directive concerning the registration of agrochemicals. The directive is aimed to harmonise the registration of agrochemicals in the EU and should contribute to the introduction of high standards of protection for man and the environment throughout the Community.

The Commission has been working on a certificate giving a longer patent protection for agrochemicals. (Proposals will be made in early 1995).

---

## OUTLOOK

---

Agrochemical consumption in the EU should display a slight growth over the medium term. Despite reform of the CAP, which reduced cultivated land area and thus agrochemical demand, production volume should benefit from dynamic export markets in Asia and North America.

Key issues for the European agrochemical industry are use reduction, environmental protection (in particular, factors linked to the quality of water) and intellectual property rights (i.e. the restoration of an effective patent term certificate via a supplementary protection).

# Fertilisers

## NACE 256.8

*Demand for fertilisers in Europe is suffering from recent developments in agricultural and environmental policy. Furthermore, the EU industry is confronted by stiff competition from East European countries. The sector's restructuring should continue in Europe into the medium term.*

### INDUSTRY PROFILE

#### Description of the sector

As included in NACE 256.8, the agrochemical industry can be defined as the manufacture of chemical products for agricultural purposes. There are two major branches within agrochemicals: fertilisers and chemical products for crop protection. This section of the Panorama is concerned with the first of these, fertilisers.

The fertiliser industry manufactures and markets products which contain one or more of the three primary plant nutrients: nitrogen (N), phosphorus (P) and potassium (K). Of the total nutrient volume applied in the EU (15.7 million tonnes of nutrient in 1992/1993), nitrogen fertilisers accounted for 54 % (8.5 million tonnes of N), whilst potash fertilisers (3.8 million tonnes of K<sub>2</sub>O) and phosphate fertilisers (3.4 million tonnes of P<sub>2</sub>O<sub>5</sub>) accounted for 24 % and 22 % of the total, respectively.

All fertilisers containing more than one primary are called multi-nutrient or compound fertilisers. Single-nutrient fertilisers (which contain only one of the three primary nutrients) are also called straight fertilisers. Whilst the majority of phosphate and potash fertilisers are applied as multi-nutrient fertilisers, nitrogen fertilisers are mainly supplied as straight fertilisers.

Fertilisers are usually sold as solids, in piled or granulated form. Between 5 % and 10 % of all fertilisers are, however, in liquid form. These require special storage and handling equipment.

The use of fertilisers follows a seasonal pattern. Fertilisers are mainly used in the growing season, from February/March to June, while fertiliser use is at its lowest in July. Sales follow a similar cycle, starting in December/January, with a peak in April/May. Price movements reflect this cycle, in order to cover the cost of storing fertilisers produced in the low demand season. Prices are thus lowest in July, and then grow regularly until they reach their peak in the Spring.

#### Recent trends

The market for fertilisers has been depressed for years, with overcapacity problems and weak demand. Since 1988, fertiliser demand has decreased steadily, with a drop of 20 % and 27 % in nitrogen and phosphate consumption, respectively. One of the main reasons for this decline was the reform of the Common Agricultural Policy (CAP), which imposed a 12 % freeze on arable land. Another reason for this decline is the setting up of new environmental legislation, which aims at reducing the releases of nitrates and phosphates into surface and underground water.

#### International comparison

In 1992/1993, consumption in Western Europe represented 14 % of the total world consumption of fertilisers while 60 % was accounted for by China, the former Soviet Union (FSU), the United States and India. Between 1989 and 1993, worldwide consumption of fertilisers declined by almost 12 %. This was most significant in Western and Eastern Europe and in the FSU. At the same time, North American demand remained stable while that of developing countries grew by nearly 10 %.

As regards production in general, ammonia nitrogen fertiliser is produced in almost all the main consuming areas of the world. Production of phosphate and potassium fertilisers tends to be located near regions rich in minerals: Canada, Germany and the FSU for potassium fertilisers and North America, the FSU and Asia for phosphate fertilisers. Taken as a whole,

Source: EFMA

the European Union represents about 12 % of worldwide fertiliser production and ranks fourth behind the FSU, the USA and China.

### Foreign trade

Since the end of the eighties, the European Union has posted a trade deficit in fertilisers. In 1991, it reached 788 million ECU. This deficit lessened somewhat in 1992 and then in 1993, mainly thanks to a strong decline of imports (-17 % in two years). As European demand for fertilisers declined steadily in recent years, this affected both domestic production and imports.

Overall, Western European producers, which now mainly produce nitrogen fertilisers, have a cost disadvantage vis-à-vis their foreign competitors, as they have to pay a higher price for natural gas, the main raw material in nitrogen fertiliser production.

## MARKET FORCES

### Demand

In Europe, demand for fertilisers is directly linked to the implementation of the CAP reform: for example the 15 % set aside policy for eligible arable land already had a significant

impact. Furthermore, environmental legislation like the nitrate Directive, will have a substantial impact on demand.

France is the largest single fertiliser market, followed by Germany, the United Kingdom, Italy and Spain. Concerning the fertiliser application rates per hectare throughout the EU, the highest application rates are found in the Netherlands, Germany, Belgium and Denmark.

### Supply and competition

Profitability of European fertiliser producers has been particularly low since the eighties. This stems from two factors: on one side, the demand for fertilisers has been particularly low in the EU, and on the other, an increasing share of the market has been covered by low-priced imports from Central and Eastern Europe and the former Soviet Union.

In an attempt to bolster its profitability, the European fertilisers industry undertook an extensive restructuring and downsizing. Employment, which in 1983 stood at 140 000 jobs in this sector, fell to only 40 000 jobs in 1991. However, despite massive restructuring European capacity of production still exceeds demand. Since 1980, European production capacities have been particularly cut in compound fertilisers, while capacities of ammonium nitrates have been left mostly intact. In the rest of the world, capacities of production have increased

**Figure 2: Fertilisers**  
Destination of EU exports

Source: Eurostat

**Figure 3: Fertilisers  
Origin of EU imports**

Source: Eurostat

in all segments of the fertiliser market, with ammonium nitrate being the segment that has grown the least.

The fertiliser industry is a global industry. Given that natural gas constitutes a large part of the input costs, the main competitors tend to come from regions with access to cheaper gas. In recent years, Eastern Europe and the FSU have become increasingly important players on export markets. Several factors contributed to this situation: a subsidised gas supply, a desire to earn foreign exchange and, more recently, a drop in fertiliser demand in their domestic market. As Eastern European economies have moved toward market economies, producers in these countries have had to pay international market prices. Thus, they lost most of their cost advantage, and fertiliser prices from these countries have risen. However, this is not yet the case in the former Soviet Union.

Given the state of the market, the question of fair international trade is becoming increasingly important. In the past, cases of dumping have been proven; and this is still an area of concern to the industry.

### Production process

Fertiliser plants are often large integrated operations that produce many important products, including fertilisers, for other industries. Typical products of a fertiliser plant include ammonia, urea, ammonium nitrate, nitric acid, sulphuric acid and phosphoric acid.

Although the components of finished fertiliser products are relatively simple chemicals, the technologies used are highly developed. The sector is capital intensive.

Continued improvements in production technology have reduced the amount of natural gas required to produce a tonne of ammonia, the basic intermediate for nitrogen fertilisers, significantly. Energy efficiency in the EU compares very fa-

vourably with that of ammonia producers in other regions such as the former Soviet Union.

## INDUSTRY STRUCTURE

### Companies

The fertilisers industry has become increasingly concentrated: from 1980 to 1991, a wave of mergers and acquisitions took place. The major producers of fertilisers in Western Europe are: Norsk Hydro (N), Kemira Oy (SF), BASF (D), Grande Paroisse (F), Enichem Agricoltura (I), DSM (NL) and Fertiheria (E). Norsk Hydro and Kemira have the largest capacities in Europe. At the end of 1994, the group Freeport McMoran Resource Partners (USA) acquired the Spanish manufacturer Fertiheria.

### Strategies

Given the decline in demand and the increasing competition from regions that enjoy considerable competitive advantages, further restructuring of the European fertiliser industry is expected. The EU fertiliser industry is committed to a huge restructuring and rationalisation process, both within national borders and at the EU level. Sales networks have been developed in all countries. Plants have been shut down and production concentrated in terms of supply and outlets at the most favourable locations. Investments have been made in order to improve efficiency and productivity (especially to optimise the use of energy), to produce the best fertilisers and market them in the best way.

### Impact of the Single Market

There are no significant barriers to trade in fertilizers within the EU. The largest steps towards European integration had already been taken with the creation of the Customs Union

**Table 2: Fertilisers

Source: Eurostat

and the subsequent elimination of internal tariffs. Recent measures to improve the functioning of the Internal Market have had in comparison less impact on the fertilizer industry. This does not exclude, however, that several areas of European legislation are relevant to the fertilizer industry. Indeed, in some segments internal barriers to trade remain. This applies in particular to ammonium nitrate (AN), which is subject to regulations on its use and transport that vary greatly across Member States. Furthermore, the transitional VAT system imposes a considerable administrative burden on cross-border shipping, especially if goods are not exported directly to the country of destination, but first transit another Member State. Being one of the largest consumer of gas in Europe (4% of EU gas consumption), the fertilizer industry stands to benefit from initiatives liberalising the natural gas market. Finally, fertilizer manufacturing is subject to extensive environmental and safety regulations. In this area, EU rules are progressively replacing the individual national regulations of the Member States. The fertilizer industry favours an extension of the harmonisation of environmental protection regulation within the EU to the countries of Central and Eastern Europe.

## REGIONAL DISTRIBUTION

In the past, production capacity for each type of fertiliser has been widespread across the EU. However, this is less true now, due to the rationalisation of the industry. This had the effect of concentrating production for the different types of fertiliser in a smaller number of countries.

In the finished nitrogen (N) fertilisers segment, France, the Netherlands and Germany each account for around 18 % of total EU capacity, whilst Belgium, Italy, Spain and the United Kingdom each account for nearly 10 %. Potash (K) is directly mined in a limited number of regions in Europe. There are still some mines in France, which will soon be exhausted. The largest producing area in the EU is in central Germany. Phosphates are now mainly produced outside of Europe, for example in North Africa.

## ENVIRONMENT

Since the early 1980s, there has been considerable concern about the impact of agricultural chemicals and fertilisers on the environment.

In particular, there has been concern about the level of nitrates in water supplies and phosphorus in water sources and the sea. In December 1991, the Council adopted a directive on the protection of waters against pollution by nitrates from agricultural sources. The objectives of the directive are to ensure that the nitrate concentration in freshwater and groundwater supplies does not exceed the limit of 50 mg NO<sub>3</sub> per litre, as imposed by the EU Drinking Water Directive, and to control the incidence of eutrophication (i.e. enrichment of water by nutrients, such as phosphates and nitrates, which, under specific circumstances, may cause algae to bloom).

For its part, the industry is concentrating on producing high-quality products that ensure an even distribution of fertilisers and therefore minimise the leaking of excesses into the environment. However, the consumers also have a key role to play in this. Fertilisers have to be used in an appropriate way to achieve the most efficient results. It is thus necessary to ensure that the user is properly informed before applying fertilisers. The reform of the CAP, by reducing the agricultural surplus production, will help to reduce the amount of fertiliser used in farming.

## REGULATIONS

Regulations covering most aspects of fertiliser production and use already exist. In addition to normal health and safety regulations, fertiliser producers are subject to emission standards and product quality specifications.

The European fertilisers industry is considerably affected by legislative measures such as the reform of the CAP. This reform, implemented on 1 July 1993, abandons price support mechanisms in favour of compensation paid directly to farmers. It has had a notable impact on the arable land sector: the intervention purchase prices of cereals have dropped by nearly 25 %, and these reductions have been compensated for by direct aid per hectare. At the same time, aid payment is contingent upon a 15 % freeze of the surface area devoted to cereals, oil and protein-yielding crops. As the cultivated area was reduced, demand for fertilisers declined by about the same proportion.

Finally, the fertiliser industry is willing to contribute to the promotion of legislation concerning the use of its products.

## OUTLOOK

In view of current developments related to the ongoing changes to the Common Agricultural Policy and to the awareness of environmental concerns, EU production of fertilisers should stabilise in the years to come, with a return to growth and output reaching around 3.3 million tonnes in 2005.

The industry is represented at the EU level by: European Fertilizer Manufacturers Association (EFMA). Address: Avenue E. van Nieuwenhuysse 4 Bte 7, B-1160 Brussels; tel: (32 2) 675 3550; fax: (32 2) 675 3961.

# Soaps, detergents, perfumes and toiletries

## NACE 258

Most products covered by NACE 258 are considered non-luxury goods. A growing public awareness of environmental issues has led to the development of more and more environmentally acceptable products and product accessories. The large multinational companies which operate on the global market try to establish growth not only by new product development, but also by entering new geographical markets, taking over smaller companies, spending large amounts on promotional activities, following a strong brand strategy and choosing mass distribution channels. Also, in recent years, the trend towards own brands and generic brands in the soaps and detergents market has resulted also in an intensifying price competition. In the market for personal care products, own brands are expected to be limited to low-end markets. The economic downturn in recent years caused a drop in demand. However, this trend is not expected to continue, as the current economic recovery will increase free disposable incomes in the years to come.

### INDUSTRY PROFILE

#### Description of the sector

NACE 258 is divided into two product categories:

- the manufacture of soaps and synthetic detergents (NACE 258.1) which covers toilet, household and industrial soaps and washing products; and
- the manufacture of personal care products (NACE 258.2) which covers beauty products (skin care, sun care, cosmetics, etc.), bath and shower products, hair care products, perfumes and fragrances, deodorants, etc.

The manufacture of soaps and detergents is closely related to maintenance products (NACE 259.2). Whilst sanitary cleaners, bleaches and air fresheners are categorised under maintenance products, sanitary water fresheners are categorised under soaps and detergents. Soaps and detergents and the market for personal care products differ substantially in market demand, supply and development. Therefore, these categories will be considered separately.

Compared with related industries, the sector as a whole has a relatively low level of value added. Within the EU market, demand for personal care products was estimated at between 25-30 billion ECU in 1994, whilst sales of soaps and detergents amounted to an estimated 8-12 billion ECU in the same year.

#### Recent trends

Over the 1984-1993 period the industry grew at an average rate of more than 6 % per annum. In 1993, however, the economic recession in most Member States resulted in a drop of demand. In contrast, the largest EU market, Germany, recorded growth rates in 1993: consumer spending on personal care products rose 4.4 %, whilst sales of soaps and detergents recorded a growth of 2.7 %. The most recent German figures indicate a stabilisation of overall sales, with personal care products slightly falling (-0.3 %) compared to soaps and detergents (0.2 %). This trend, however, does not represent a clear picture of the EU market as a whole. For most other Member States, production and sales increases are expected for 1994.

Figure 1: Soaps, detergents, perfumes and toiletries  
Value added in comparison with related industries, 1993

Source: DEBA

### International comparison

The industry is relatively large: total production for 1994 is estimated at nearly 40 billion ECU. The industry employed over 185 000 that year, although this amount is decreasing. Another 430 000 jobs in related areas (e.g. distribution, transport and retailing) can be attributed to the industry.

The EU is the world's largest producer of soaps, detergents and personal care products, with the USA and Japan following at a distance. Within the EU, Germany is the largest market accounting for 26 % of total sales. Germany is followed by France (22 %), Italy (18 %) and the United Kingdom (13 %). If the consumption per capita is considered, the rank order is changed, and France appears to be the leader with nearly 136 ECU per inhabitant. Germany and Italy are tied for second, with 106 ECU per person. The other EU countries follow at a distance.

### Foreign trade

The EU is a net exporter of soaps and detergents. With Extra-EU exports and imports totalling 4 645 and 930 million

 Source: DEBA

ECU respectively, the trade balance demonstrated a surplus in 1993. More than 26 % of total EU exports find their destination in EFTA countries. Compared with 1988, the total value of exports to these countries increased by 61 %. The USA is another large export market, which also has been increasing in value since 1988. Noteworthy are the increasing exports to Eastern Europe, especially Poland and Russia. Extra-EU imports mainly find their origin in Switzerland and the USA. The import shares of these countries are 34 % and 31 % respectively.

**MARKET FORCES**

**Demand**

*Soaps and detergents*

The sales of laundry detergents, dishwashing liquids etc., are estimated at 10 billion ECU. With an annual capita consump-

tion of 21 kg, the European use of these products was about 10 million metric tonnes in 1993. In value terms, nearly 40 % of this market is made up of heavy-duty detergents. Growth rates in the EU market, however, are modest. The trend towards super concentration and lower wash temperatures will continue, causing the market share of compact powders to increase. Also with respect to compact powders, the Netherlands has taken the lead, recording a domestic market share of 80 % followed by Germany with 52 %. The other EU countries follow at a distance, with domestic market shares of compact powders of less than 30 %.

While demand for powders looks healthy, the market for liquid detergents is decreasing. Liquids appear to have peaked in 1989, when they claimed an overall market share 14 % in the EU. The level has fallen to 9 %, although market shares vary across the region.

**Figure 4: Soaps, detergents, perfumes and toiletries**

**Cosmetics, perfumes and toiletries**

The personal care market includes a wide variety of products of which hair care and skin care products are the major segments with shares between 20-25 % of total EU demand. Other important segments are perfumes and fragrances, men's toiletries, cosmetics, oral hygiene products, bath and shower products and deodorants.

Demographic trends have made the more mature consumer the target market for the 1990s. This has led to an emphasis on more expensive products, especially in the skin care market.

In this segment, consumers now demand a range of skin care products wide enough to suit every skin type and capable of alleviating dermatological problems. In addition, there has been an increased demand for more and varied skin care products for men. The picture is the same across Europe. There is an increased demand for multi-functional products which are safe, made of natural products and either recyclable or biodegradable. A special key growth area is for products which claim to have distinct benefit to the skin, such as anti-wrinkle, anti-ageing or fat reduction. Recent trends show that the gap between the premium and mass markets has closed, in par-

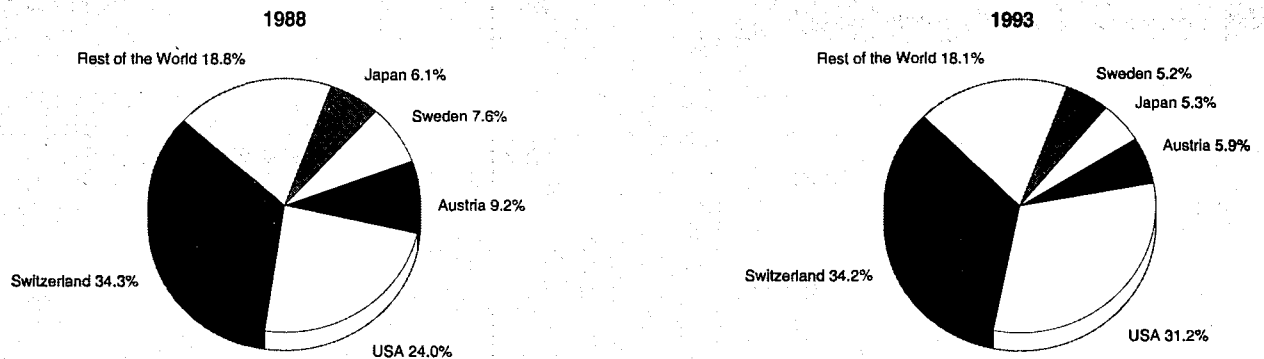

ticular for skin care products. Ingredients once restricted to an exclusive corner of the market have found their way into mass market products, sales of which have increased dramatically.

With respect to hair care products, demand for convenience has resulted in increasing sales of two-in-one (i.e. cleaning and conditioning) shampoos. Three-in-one formulations (additionally either strengthening the hair or providing sun protection) are likely to be a future growth area. The shampoo sector is highly fragmented with a variety of niche products. Styling products are the fastest growing sector of the market for hair care products.

**Supply and competition**

The fragmentation of both markets on the demand side is not fully reflected in the structure on the supply side: many companies are operating in both markets. In their attempt to dominate each market segment, a few large, globally-operating, multinational companies are active both in segments of the market for soaps and detergents and in several segments of the market for personal care products.

**Figure 7: Soaps, detergents, perfumes and toiletries  
Origin of EU imports**

Source: Eurostat

**Figure 8: Soaps, detergents, perfumes and toiletries Trade intensities**

Source: DEBA

One important link between the two markets can be found in the channels which are used for the distribution of the products. To an increasing extent, soaps, detergents and personal care products are sold through supermarkets, for instance. Another link is the importance of the brand image created by the manufacturer.

#### Soaps and detergents

A relatively small number of large multinational companies operate worldwide in the market for soaps and detergents. The intensifying global competition between them concentrates on new product development accompanied by large expenditures on R&D and promotion. Manufacturers try to improve their market positions by finding and/or creating new trends in market demand. The emphasis on new product development is reflected in an increasing flood of new products or new product varieties.

The large manufacturers also try to establish growth by exploring new geographical markets and by taking over small and medium-sized companies. In recent years, the international market for soaps and detergents has also been increasingly affected by the use of generics and own brands.

The intensifying competition brought about by these developments is reflected in price competition, a further concentration of supply, a growing number of product varieties, large R&D expenditures on new product development and, finally, on advertising and promotional activities.

#### Cosmetics, perfumes and toiletries

More companies operate in the personal care market, although in recent years the concentration in supply has increased. As in the market for soaps and detergents, competition is fierce, with the emphasis still on sales, the distribution of personal care products and advertising.

Fine fragrances are considered to be luxury items. This is reflected by the attention manufacturers pay to their exclusive distribution and creative presentation. Experience has shown that mass distribution may eventually lead to a loss of prestige resulting in a reduction in demand. Faced with the reality of the economic downturn, traditional independent perfumeries in France have responded by forming their own voluntary chains and franchises and by increasing their sales points. They have geared their strategy around product quality, pres-

tige and also self-service, recognising that customers sometimes prefer to choose products on their own.

Following the trend towards more mass distribution, more own brands and generic brands can be expected, which will result in an intensification of price competition.

The industry is dedicated to continuously meeting the needs of its consumers and improving the performance of the business overall through intensive market research. This, in all areas of the industry (cosmetics, toiletry and perfume) - from the capture of the exquisite ingredients which give a luxury perfume its undefinable qualities, to the testing of new ingredients for the increasingly sophisticated skin care market, and the creation of new and seductive packaging designs.

#### Production process

As a result of rationalising production and cost reductions, the industry's labour productivity has been increasing at a higher rate than unit labour costs. On the one hand, this development demonstrates the growing efficiency of production. However, on the other hand this rationalisation has resulted in a drop in employment despite production increases.

### INDUSTRY STRUCTURE

#### Companies

The world market for soaps and detergents is led by five major multinational companies, of which three are EU-based: Unilever (NL/UK), Henkel (D), Benckiser (D), Colgate Palmolive (USA) and Procter & Gamble (USA). The flood of mergers and acquisitions seems to have reached its peak in the late 1980s and early 1990s.

Unilever and Procter & Gamble are also competitors on the market for personal care products. Both companies have been expanding their presence in the personal care market. However, in this market more large companies are operating, e.g. L'Oréal (F), Shiseido (J), Avon (USA), Wella (D), Sanofi (F), Schwarzkopf (D), Beiersdorf (D), to name just a few.

#### Strategies

The large multinationals try to establish growth either by developing new markets for existing products (e.g. Eastern Europe) and, subsequently, new products for these markets; or by developing new products or product varieties for existing markets; or, finally, by mergers and take-overs.

The smaller companies, active in one or two market niches, are often limited to local markets. Only if they possess a patent for a certain product are they able to operate on a larger scale. The backward integration tendency towards own brands and generic brands is a retail strategy that directly affects the market forces on producers.

The acquisition turmoil of the 1980s and early 1990s has undermined the once clear demarcation between the cosmetic industry's distinct markets: class (prestige), mass and direct sale. The arrival of multinationals such as Unilever (Fabergé, Elizabeth Arden, Calvin Klein) and Procter & Gamble (Max Factor, Old Spice, Santa Fe, etc.) introduced much more financial muscle to personal care products. The multinational companies try to move some of their strong brands towards the mass market by choosing other distribution channels. As a result, customers are buying more and more personal care articles in drugstores and supermarkets, thus putting pressure on profit margins as sales volumes increase.

Furthermore, some backward integration towards own brands can be expected in this market, especially for low-end personal care products which are distributed through supermarkets. For luxury perfumes and fragrances, however, the strong image surrounding the products makes it more difficult for retailers to create their own successful brands.

(1) Ratio of production in the sector compared to manufacturing industry for each country, divided by the same ratio for the EU. Estimates.

Source: DEBA

Between 10-20 % of all luxury products in the world are sold through duty-free sales outlets. With the possibility that this channel could be abolished in the EU as of June 1999 - since it is seen as being inconsistent with the Single Market - the issue has become a priority for the industry. The IDFC (International Duty-Free Confederation) made up of national duty-free associations in all EU Member States (except France) and the EFTA countries, has achieved its goal of retaining intra-EU duty-free sales in the short term, and is now developing a new five-year strategy plan. The industry has recently suggested the idea of introducing "free zones" with special fiscal advantages, as an alternative to the current duty-free system. This would allow duty-free sales without jeopardising the credibility of the Single Market, and will be investigated further.

### Impact of the Single Market

The overall impact of the Internal Market on this sector has been positive in that it has led to cost savings (more efficiency in trade and decreased bureaucracy) and to an increase in competition as the free movement of goods has improved market access in other Member States, and has offered the industry the opportunity to rationalise production by reducing the number of products being offered in different EU markets. For large multinational companies, this has meant a concentration of production and thus an increase of 'crossborder' transport. SME's, which were previously not able to operate internationally due to a lack of resources and other barriers, can also benefit from the increased trade possibilities and from decreased paperwork. Still, many things need to be done such as a greater enforcement of EU measures at the Member States level and the break-down of current monopoly positions in upstream markets. This could eventually lead to additional cost savings.

### ENVIRONMENT

Growing consumer concern for the environment has been reflected in their increased demand for more environmentally acceptable products. Of particular interest to the industry is the ecological debate on the use of aerosols for deodorants, body sprays and hair sprays. With the rejection of CFC (chlorofluorocarbons) aerosol propellants, and VOCs (volatile organic compounds) on environmental grounds, the industry's initial response was to introduce pump sprays as a more environmentally acceptable alternative. However, pump sprays have proved to be less popular with consumers as they give a lower level of performance and are more difficult to use.

Even in countries which first embraced pump sprays, the trend is a return towards aerosols. The industry has been quick to respond to these new demands in other ways and has given its full cooperation to the EU market-based initiative in which products are awarded an eco-label if certain environmental criteria are met.

Another aspect of the ecological debate has focused on packaging. The cosmetics industry is in favour of initiatives aimed at reducing unnecessary packaging, and fully supports the goals of the proposed Packaging Directive, which was adopted in December 1994. The text of the directive recognises that some exceptions should be made in certain cases for luxury packaging. It is clear that the packaging of a luxury product is an integral part of the whole product image, and this is maintained by using the best technologies and highest quality materials.

In the market for soaps and detergents the use of more compact product formulas already has resulted in less packaging. Reuse has been encouraged by the introduction of refill bags, resulting in even greater packaging resource savings. Several companies are actively participating in the recycling of plastics used in the production of detergent bottles.

### REGULATIONS

#### Soaps and detergents

This sector of the industry is covered by the Directive 88/379 concerning dangerous preparations. In December 1993, the Commission Directive 93/112 was adopted, which delineated the arrangements for the system of specific information relating to dangerous substances and preparations.

Other recently adopted or drafted directives concern the assessment of risks to man and the environment of substances notified in accordance with Directive 67/548 on dangerous substances (Directive 93/67); the assessment of the effects of certain public and private projects on the environment; and the incineration of hazardous waste.

Furthermore, the Commission's eco-audit proposal has been approved by the environment council of ministers. Although the eco-audit is not compulsory, activities with high environmental impact are expected to carry out eco-audits once a year. Where appropriate, the industry is expected to carry these out alongside existing eco-audits.

#### Cosmetics, perfumes and toiletries

The European cosmetics industry guidelines for consumer and manufacturer safety are contained in the European Union Cosmetics Directive. The creation of an ingredient inventory and a potential ban on animal testing represent two areas among others raised in this directive (it its sixth amendment) wherein the industry will need to adapt quickly.

Ingredient labelling is an area which has rightly received much attention. COLIPA, with support from the Commission, is developing a common ingredient nomenclature, the result of which will be that a particular ingredient will appear under the same name on every cosmetic product that contains it, no matter where in Europe it is sold. In this way it will be possible for ingredients to be rapidly and correctly identified from the list of ingredients on the product label and thus enable consumers to purchase products most well-suited to their needs. A similar system is already in use in the soap and detergent industry.

The early 1980s saw a change in public attitudes towards the use of animals in laboratory experiments, which resulted in increased international demands for this practice to end. The cosmetics industry is unanimously in favour of ending animal testing but is guarded against a premature ban. The difficulty in this complex issue lies in the fact that any alternative method not only has to be reliable but also validated and approved

by the regulatory authorities. Meanwhile, the industry remains committed to ensuring that ingredients and products are safe for consumers.

In fact, tests on cosmetic products currently represent only 0.3 % of all animal experiments and the number of animals used in cosmetic testing continues to fall. Already many companies have developed *in vitro* methods for the early screening stages of new products.

The industry has set up a specific steering committee to create a pool of expertise on the development of alternative testing methods. It is also involved, with the Commission and the European Centre for the Validation of Alternative Methods (ECVAM), in carrying out programmes and generating data which will contribute to the speedy validation of alternative methods.

---

## OUTLOOK

---

The growth of the market for soaps and detergents and personal care products is expected to continue at a modest but constant rate. According to our forecast, overall production and consumption of these products will increase by about 1.5 % per annum for the period 1994-1997 after a remarkable recovery in 1994. As a result of environmental pressures, even more environmentally acceptable products and product accessories will be developed and marketed. More shifts in demand can be expected from the ongoing demographic developments (especially in the cosmetics market). The growing demand for convenience and the distribution strategies of the large multinationals will further increase the use of mass distribution channels. As most products covered by NACE 258 are considered as being necessary items, it is not expected that any changes in demand or in the regulatory environment will lead to a considerable decrease in overall demand.

# Pharmaceuticals

## NACE 257

The EU is both the largest world producer and the largest exporter of pharmaceutical products. Total EU output amounted to 68.9 billion ECU in 1993, of which prescription pharmaceuticals accounted for a share of close to 85%. R&D accounts for a large part of investments in the pharmaceutical sector. At 11.8% in 1992, the R&D/turnover ratio of the top pharmaceutical companies in Europe is the highest of all manufacturing sectors. This is also higher than the R&D/turnover ratio of the top US pharmaceutical producers, which was 10.5% in 1992. There are, however, major challenges facing the pharmaceutical industry. The sector has to adapt to the changing regulatory environment for health care, which takes different forms in different countries. In Europe, this effectively puts limits on the volume of pharmaceuticals sales and prices. Other challenges confronting the industry include stiffening world-wide competition and the continuously increasing costs of research and development. As a result, many companies are restructuring their operations, with the research-based firms trying to expand their presence in the self-medication market and changing the way they operate, sometimes making major changes in their distribution systems or in the organisation of R&D.

### INDUSTRY PROFILE

#### Description of the sector

In the EU, medicinal products are defined according to Article 1 of Council Directive 65/65/EEC (see Official Journal L 22 of 9.2.65 for more details):

- Proprietary medicinal products: any prepared medicinal product placed on the market under a special name and in a special pack;
- Medicinal product: any substance presented for treating or preventing disease in human beings or animals;
- Substance: any matter irrespective of origin (i.e. human, animal, vegetable, chemical).

The sector includes both pharmaceuticals for human consumption and for veterinary use. Although from a scientific and technical point of view there are strong similarities between the two categories, there are significant differences in the social and economic framework within which they operate. For this reason a separate section is dedicated to the veterinary sector at the end of the monograph.

The market for pharmaceuticals is sometimes divided into two categories, according to the way the products are purchased: the first is prescription pharmaceuticals, i.e. products which can only be sold on the basis of a medical prescription, and the second covers non-prescription pharmaceuticals. Non-prescription pharmaceuticals can be both prescribed by a doctor or purchased directly by the patient without a prescription. Non-prescription pharmaceuticals which are bought directly by the patient without being prescribed by a doctor are commonly defined as over-the-counter (OTC), or self-medication products. Non prescription pharmaceuticals are considered to be OTC products when the four following criteria are fulfilled:

- the product is registered;
- the product is used for a minor ailment;
- the product is advertised to the public;
- the product is not subject to prescription.

Figure 1: Pharmaceuticals  
Value added in comparison with related Industries, 1993

Source: DEBA

Relevant to both the prescription and the non-prescription pharmaceuticals markets is their division between branded pharmaceutical products and generics. At the expiry of the exclusive period of marketing granted by patent laws and the supplementary protection certificate to the inventor, generic medicines may be put on the market. They are copies of original products and are usually less expensive than the original branded products.

Pharmaceuticals are either made from chemicals or, increasingly since the mid-1980s, from biotechnological processes. Biopharmaceuticals are now estimated to command more than 4% of world pharmaceutical products' sales.

#### Recent trends

Following a period of rapid growth in real production between 1987 and 1991, the production of pharmaceuticals started decelerating in 1992 and actually fell in the first months of 1993 before reaching a turning point towards the middle of the year. On a year over year basis, however, 1993 production

**Figure 3: Pharmaceuticals**  
Production and employment compared to EU total manufacturing industry

1994 are Eurostat estimates.  
Source: DEBA

volumes were 2.3 % higher than in 1992 (Table 2). Growth accelerated further in 1994, in line with the general economic recovery in Europe. In 1994, production in the EU is estimated to have increased by close to 4 % in volume.

Apparent consumption of pharmaceuticals in the EU also decelerated in 1993, its rate of growth falling to 1.6 % in real terms from an average annual growth of 6.7 % between 1984-93. Again, growth recovered partly in 1994. The two main sub-segments of the market (prescription pharmaceuticals and non-prescription products) posted very different performances, however, as explained in more detail in the section on Market Forces.

In 1993, employment in the EU pharmaceutical sector decreased for the first time in ten years, by 2.6 %. All Member States recorded diminishing or stable employment figures. The trend continued in 1994, with employment down by 4.2 %. This represents a loss of 28 500 jobs compared to the peak 1992 employment level of 425 200. Hurt by the fall in demand

and by the multiplication of cost containment measures adopted by Member States in order to keep health care costs under control, which negatively affected their profitability, most pharmaceutical producers restructured internally and took measures to reduce costs, in particular labour costs. This is confirmed by the trend in labour productivity, which increased by 5 % in 1993 despite the slowdown in production, and which continued growing at a high rate in 1994.

Partly thanks to this rapid growth in productivity, unit labour costs fell by 3.8 % in 1993 and total unit costs were down by 3.7 % in 1993 compared to the year before.

#### International comparison

The EU is the leading world producer of pharmaceuticals. In 1993, the value of production in the EU was 24 % higher than that of the USA and 68 % higher than that of Japan. Between 1984 and 1993, the EU recorded an increase in production of 46 % (measured in constant prices), at a time when the USA and Japan posted production growth of 29.5 % and 20.6 % respectively.

Until recently, the Japanese pharmaceutical industry was mainly focused on its domestic market, an attitude encouraged by the national health insurance system which provides the entire population with access to low-cost health care. This resulted in growing demand for medicinal products and in a steady expansion of the Japanese pharmaceutical industry. As in other countries, this has, however, also increased the burden of health care in total public spending. In order to control spending the government introduced limits on the official drug reimbursement prices. In April 1992, reimbursed prices were thus cut by 8.1 %. As elsewhere, downward pressures on domestic prices progressively reduced profits on all drugs. Partly as a result of this, the Japanese industry is now increasingly turning to other world regions, expanding its presence in the USA and Europe through acquisitions and the setting up of production units in Asia. Investment in research and development by the top Japanese firms is also rising rapidly, although total R&D in this sector in Japan is still well below the levels recorded in the US or in Europe.

In the US, where the market is much less regulated than in either the EU or Japan, producers furthermore benefit from a large, unified market on which they can generate a sufficient turnover of new drugs to pay-back R&D costs during the

**Figure 4: Pharmaceuticals**  
International comparison of production in current prices

Source: DEBA

**Figure 5: Pharmaceuticals**  
International comparison of production in constant prices

period of patent protection. Pharmaceutical product prices in the US have also grown faster than in other world regions, and downward pressures on profits have been less obvious. Between 1984 and 1993, the value of USA production rose by 69.6 %, while production volumes grew by 44.2 %. This implies that the growth in prices was about 17 %. In the EU, over the same period, production value increased by 97.4 % and volumes by 71 %, implying a price rise of 15.4 %.

#### Foreign trade

The EU is a net exporter of pharmaceutical products. In 1993, 18 % of EU production was exported, whereas the share of domestic consumption which was supplied by imports was 10 %. Within the EU, the major exporter is Germany (with a share of 27 % of extra-EU trade) followed by the UK (17 %), France (16 %) and Italy (11 %). Only Italy has a negative trade balance, which dates back to the early 1980s. However, when calculated at ex-factory prices, the cover ratio (production/consumption) for Italy was 1.14 in 1992.

On average, growth in EU exports between 1984-93 was 2.6 % p.a., while growth in EU imports has been stronger, at 4.8 % per year on average. This has led to a steady decline in the

export/import ratio, from 2.65 in 1984 to 1.86 in 1992. The latter increased again in 1993, to 1.99, as a result of a strong export performance in that year.

The EU's net surplus on the pharmaceuticals trade balance has nevertheless increased steadily over time, rising from 3.4 billion ECU in 1984 to 4.9 billion ECU in 1992, and to 6.2 billion ECU in 1994. Notwithstanding this positive performance in the EU's trade balance, there are signs that the industry's competitive position is at risk in world markets. In addition to the steady decline in the export/import ratio, which only reversed in 1993, the EU's trade position is slightly less favourable for active substances, which generate more added value and which are more closely related to research than finished or semi-finished products.

EU imports overwhelmingly come from western industrialised countries, with the USA accounting for 25.8 % of total imports in 1993 and Switzerland for 37 %. Austria and Sweden, two new EU members, were the source of 20.1 % of the EU's pharmaceutical imports in 1993.

The export markets of EU pharmaceutical producers are more dispersed. Developing countries, which account for most of the "rest of the world" category in Figure 6, take up nearly half of extra-EU exports. Their share is slowly decreasing over time due to the expansion of pharmaceutical production within those countries which has taken some market share from exports from western Europe. Partly as a result of this development, the share of total exports which is destined for the USA and EFTA countries has been growing in importance.

### MARKET FORCES

#### Demand

Based on official statistics, the total EU market for pharmaceutical products was worth 62.6 billion ECU in 1993, about 2.5 % less than in 1992 (Table 1). It is difficult to provide a breakdown of the European Union market for pharmaceuticals into prescription and non-prescription medicines as the rules governing the sale and reimbursement of individual products vary. For example, pharmaceutical products which are available without a prescription may also often be reimbursed if prescribed.

Within the EU, an estimated 85 % of all pharmaceutical products sold in 1993 - including on the hospital market - were prescription pharmaceuticals. The different categories of purchasers of prescription pharmaceuticals are patients, along

with medical doctors, hospitals and other institutions operating in the health-care sector.

Sales of non-prescription medicines in the eight larger EU markets amounted to 18.3 billion ECU in 1993, 2.8 % more than in 1992. The non-prescription share of the total ambulatory pharmaceutical market at public price level was just under 25 % in 1993. The hospital market is dominated by prescription pharmaceuticals.

The recent initiatives by some governments to control spending on health-care by reducing the reimbursement rates of medicines or putting limits on prescriptions have seriously limited the growth in sales of prescription pharmaceuticals. In some countries (for instance Germany and Italy) the tightening of government controls and regulatory changes have effectively resulted in a reduction in the overall volume of pharmaceutical sales. In Germany, sales of prescription pharmaceuticals dropped by close to 15 % in 1993, while in Italy the rate of decline of prescription pharmaceuticals' sales in the first half of 1994 was 7 % (compared to the same period in 1993).

Estimates of the share of the total pharmaceutical market which is accounted for by generics vary significantly depending on the data source considered. It is nevertheless estimated that generics sales account for about 20 % of the market in Den-

mark, 13-15 % of the market in Germany, and about 10 % in both the United Kingdom and the Netherlands. These countries are also the ones in which pharmaceutical products are considered to be comparatively expensive, and in which the development of the market for generics has been partly encouraged by the health authorities. The market share of generics is much lower in the other EU Member States.

The relative size and rate of growth of the non-prescription pharmaceuticals market, and, within it, of the self-medication market, varies greatly from country to country. Self-medication products are generally used preventively and for benign disorders, so that the market is dominated by cough and cold products and analgesics. However, whereas the practice of self-medication is generally well established in the northern Member States (including France), it remains somewhat underdeveloped in the southern Member States. Until recently, self-medication was, at least officially, non-existent in Greece.

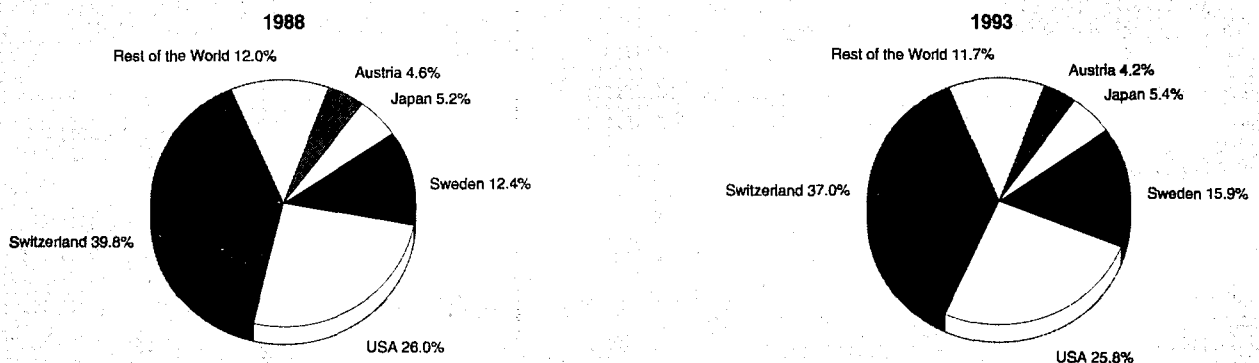

Whereas non-prescription pharmaceuticals sales grew by 8.4 % per year on average (in value terms) between 1989 and 1993, the self-medication market grew by 10.2 % per year on average. In 1993, when total sales of pharmaceutical products were falling in value terms, the self-medication market remained buoyant, growing by 8 % over 1992. Similarly fast growth was experienced in 1994. The self-medication market is expected to remain one of the most dynamic demand segments in the medium term.

### Supply and competition

Although the EU remains the largest producer of pharmaceuticals at world level and accounts for about one third of the total world market in pharmaceuticals, competition has stiffened and EU producers are progressively losing ground to competitors from other countries, in particular the USA and Switzerland. At present, EU companies account for roughly two thirds of the EU market, one third of the market in the USA and 10 % of the market in Japan. The US pharmaceutical industry has similar market shares in the EU and Japan, while the Japanese industry, which controls 80 % of its domestic market, only has a market share of about 1 % in both the EU and the USA. The Japanese pharmaceutical industry is nevertheless expected to increase its penetration of the world market with new medicinal products researched and developed in Japan and purchased under licence by companies from the USA and Europe.

As in other industries, competition within the sector takes place on two fronts: internationally and between companies

within the sector. The nature of competition between companies, however, differs from that in other sectors.

In most Member States, indeed, there is a price control system for reimbursed medicinal products, in some cases even for non-reimbursed medicines. The market for medicines which are available without a prescription and which are not eligible for reimbursement by social security is highly competitive. In this market, companies compete in terms of prices as the market is much less administered. In the area of reimbursed medicinal products, however, where many prices are regulated, companies channel competitive efforts into therapeutic innovation and continued improvements to existing products. Enterprises in this market thus compete less on prices and rather concentrate on their costs, finances and sales volumes, as well as on the development of new products.

Another area of competition in this market is between generics and original drugs which have come off-patent (i.e. for which the patent has expired). It is currently estimated that when a high-selling drug comes off-patent, sales revenue can be cut by up to three quarters in only a few months as non-branded rival products are launched. This makes it ever more important for the innovative drugs producers to maintain a continuous flow of innovation.

#### Research and development

The pharmaceuticals sector is thus one whose survival depends on a continuous stream of innovation. This, in turn, requires that:

- The financial means for undertaking research and development are available;
- There is a healthy regulatory environment for developing new drugs and bringing them to the market.

Pharmaceutical research is both long and costly. It takes 10 to 12 years to develop a newly-synthesised active substance into a marketable medicine which can be used in current medical practice. The average cost of researching and developing an entirely new medicinal product, several dozen of which

are launched each year on the world market, was estimated in 1993 at 275 million ECU.

Because such investments can only be financed if companies are able to generate the necessary cash flow during the period of patent protection, it is essential to launch the medicinal product on as large a market as possible as quickly as possible. On the other hand, because the costs associated with research are high as well as the risks, only the bigger pharmaceutical companies can afford to spend large sums on R&D. On average, 95 % of R&D spending is currently financed by the industry itself.

Most European companies are smaller in size than their USA competitors. From the start, their relative disadvantage in terms of launching R&D projects is the lower level of financing available. Although both the average size and the average profitability of the top EU pharmaceutical producers have increased in past years, this has not enabled the industry to compete on equal footing with the leading USA manufacturers. Hence, whereas 20 years ago 50 % of new medicines were developed in the Community, today this share has fallen to about one third. Over the same period, the USA continued to discover about a quarter of all active substances, whilst Japan increased its share from 10 % to 22 %.

The picture is even more worrying in respect of biotechnology.

This segment of the market is the fastest growing of the industry. Medicines derived from biotechnology have seized 4 % of the world market in less than a decade. Among the 50 new medicinal products appearing each year on the world market, 10 to 15 are derived from biotechnology methods. This share is expected to continue to grow over the next years.

In this market segment, however, 65 % of patents are American, 15 % are European and 13 % Japanese. Although the European companies' interest in biotechnology is growing steadily, as indicated by the number of acquisitions of biotechnology companies by European firms in the USA market in past years, R&D expertise in biotechnology still predominantly lies in the USA where more than 1 000 firms were active in

the pharmaceutical field in 1993, compared to about 30 in Europe.

Most pharmaceutical companies have invested heavily in this domain, either directly in R&D or through participation in emerging biotechnology companies.

There are signs that the R&D situation of the top European producers is improving, however. In 1990, the share of R&D to turnover amongst the top 500 west European pharmaceutical companies was 10.8 %, compared to Japan's share of 10.1 %, and the USA's share of 9.5 %. By 1992, despite the slowdown in production growth and domestic sales in Europe, the share of R&D in turnover amongst the top firms had risen to 11.8 %, again higher than the USA's 1992 share of 10.5 %. Given that total sales by the top European pharmaceutical companies are less than those of their US competitors, however, this still means that the total nominal value of investment in R&D in Europe is lower than that by US firms, though the difference is shrinking. Recent changes to the regulatory environment should help to further improve these figures.

## INDUSTRY STRUCTURE

### Companies

The pharmaceutical sector has a complex structure, with about two dozen large companies responsible for most of R&D operating alongside a large number of medium-sized companies whose activities are not world-wide but are nonetheless international. These medium-sized firms exploit both the products of their own research and other companies' products under licence. There is also a large number of small companies, some working in promising specialised fields (such as biotechnology) and others producing only a selected range of products, essentially for local markets.

Contrary to the situation in Japan and in the US, small European firms concentrate on traditional production, which implies that not all the innovative potential of the sector is fully exploited.

The pharmaceuticals market is one in which strong competition exists both within Europe and worldwide. Although there are only a few companies present in the drugs market, no single company has a dominant position. Taken together, the top ten pharmaceutical producers represent 22 % of the world market, based on turnover, and no single company has a share of more than 3.9 % of the world market.

The larger European pharmaceutical companies are relatively well placed in the world ranking. In 1993, there were seven European companies amongst the top 10 firms: three from Switzerland and the other four from the EU: Glaxo (UK, n°2), Hoechst (D, n°4), Roche (CH, in 5th position), SmithKline Beecham (UK, n°6), Ciba-Geigy (CH, n°8), Sandoz (CH, n°9) and Bayer (D, n°10). Other leading west European com-

panies are Sandoz (CH), Rhône-Poulenc Rorer (F), Boehringer Ingelheim (D), and Zeneca (UK). The largest Japanese pharmaceutical company, Takeda, re-entered the world top 15 ranking in 1993 after a four-year absence, thanks to a 15.5 % growth in turnover in that year.

Recent acquisitions and restructuring moves amongst the top firms have, however, already changed the rankings presented in Table 9. Roche moved to 4th position after its merger with Syntex, whereas the combined American Home Products/Cyanamid operation moved up to third position. American Home Products previously ranked 11 in the world ranking of the top pharmaceutical producers. The most important change in 1995 was Glaxo's acquisition of Wellcome of the UK, which has turned it into the largest world pharmaceutical producer, ahead of its rival Merck of the US.

In the biopharmaceuticals market, the top companies are mainly from the USA. Several of the top European pharmaceutical producers are increasing their stake in this market, mostly through acquisition. In 1992, Genentech of the US had sales (including licensed-out products) of about 1.1 billion ECU, followed by Amgen with 0.7 billion ECU. In the EU the main player is Novo Nordisk (DK). Rhône-Poulenc Rorer is one of the companies increasing its stake in the biotechnology market, through the creation of its new division RPR Gencell, which will concentrate on the treatment of genetic diseases. RPR has set up a network involving cooperation with 14 companies and research laboratories, and already has a number of products in clinical trials.

Another example of EU pharmaceutical manufacturers' increased involvement in the biopharmaceuticals market is Glaxo's acquisition of the USA based biotechnology company Affymax.

### Strategies

There are four main challenges facing the EU pharmaceutical industry. These are (1) heightened competition at world level due to the emergence of new technology; (2) downward pressure on prices and profits from governments trying to reduce the growth in health spending; (3) rising R&D costs; and (4) increased market harmonisation.

To respond to these challenges, the world's largest pharmaceutical producers typically follow one or another of two types of strategies. One of these, which has recently been adopted by Glaxo with its acquisition of Wellcome, consists in buying drug companies (as opposed to distributors) and expanding into the OTC market. Other companies having recently pursued this strategy are American Home Products, with its purchase of Cyanamid in the US, and Switzerland's Roche which acquired its California rival Syntex in 1994. The second type of strategy, which is more frequently adopted in the USA, is that which has been followed by Merck, SmithKline Beecham

and Eli Lilly, and which consists in taking over drug distributors.

Both in Europe and in the USA, many large pharmaceutical companies are also putting the emphasis on the development of products for the self-medication segment of the market, in order to respond to the change in behaviour of patients and to increase their share of a market which is perceived to be fast growing. To fend-off competition and limit sales losses after patents expire, some innovative-drugs producers even engage in the production of their own generics.

In the research-based segment of the market, the pressure on prices imposed by governments in Europe and the changes in national reimbursement systems are impacting the type of research underway. Emphasis is increasingly put on those compounds or molecules that are directly therapy oriented, that respond to broad medical needs and that have a large potential market. The change in emphasis is sometimes accompanied by a separation between the "research" and "development" functions within the companies. Efforts are also made to make a more thorough analysis of the potential market for new drugs between the "research" and the "development" stages, with a view to prioritising those products with a high potential turnover and a rapid rate of return on the initial investment.

Although a great number of enterprises are active in the pharmaceutical industry, large multinational firms are each pre-eminent in only a few of the many market segments constituted by diverse therapeutic indications. Consequently, the trend for large companies to link up or merge is likely to gather pace.

Finally, in some countries, collaboration between firms, e.g. through co-marketing ventures, and investment by major multinationals in local research and development and/or manufacturing units, has helped to hatch a local research industry later able to position itself on world markets. Technical collaboration between world class research and undertakings closer to the culture of their markets often results in marketing agreements or in more elaborate joint venture programmes which themselves provide development opportunities in a growth industry from which these countries would be excluded without the contribution of know-how essential to a successful start-up.

As competition continues to grow in this market, this puts continuous pressure on margins and creates a difficult operating environment for the innovative drug producers. Increasingly, the maintenance of high profit ratios will be conditional on companies being both innovative but also "more efficient" than their competitors at controlling costs or distributing their products on a large market.

### Impact of the Single Market

Prior to the implementation of the Internal Market programme, pharmaceutical markets in the EU were very fragmented, as there were numerous non-tariff barriers to trade such as differences in marketing authorisation rules and different classification systems across Member States. As indicated elsewhere in this monograph, most of the technical barriers to trade have now been eliminated. Since the new marketing authorisation system only became effective January 1st, 1995, however, it is still too early to measure its actual impact on production or trade in Europe.

The creation of a truly integrated EU market for pharmaceuticals is nevertheless reliant on a further harmonisation of national health systems. Although transparency has been much improved in this market, differences across Member States in the lists of products that are subject to reimbursement, or in terms of types and levels of price control still create important market distortions.

Although the process is not yet completed, the greater harmonisation of the EU pharmaceuticals market has already

influenced the strategies of firms, mainly of SMEs. Thus, although the mergers and alliances which have taken place in past years amongst the bigger firms are more the result of globalisation trends in the industry than of increased EU harmonisation, the same cannot be said of a number of cross-border mergers amongst medium-sized firms. There have also been implications on the geographical location of production, with some countries such as Portugal and Ireland in particular benefiting from increased investments by the larger companies in this sector. The number of production facilities has also gone down as companies are concentrating production in fewer production sites to cut costs.

An emerging trend which many have implications on the future structure of the industry in a harmonised EU market is the increased concentration among wholesalers. This is discussed in more detail in the Chapter on wholesale and retail trade.

## REGULATIONS

Until recently, the EU pharmaceutical market was very segmented, due to the existence of numerous and varied national regulations which often constituted important barriers to intra-EU trade. The situation is now changing rapidly, following the adoption and implementation of a set of EU Directives relating to technical harmonisation, to market access and to increased transparency. The creation of a truly integrated market for pharmaceuticals in Europe is, however, reliant on a further approximation of national health care systems.

EU regulations, which are spelled out in more detail below, cover all industrially-manufactured medicines, including vaccines, blood products, radiopharmaceuticals and homeopathic medicines. These regulations reflect two key objectives: the first is to harmonise the essential health protection rules across Member States, and the second is to remove barriers to trade within the EU by defining the conditions for market access. By 1993, all measures relating to technical harmonisation of products, to product approval and to marketing authorisations had been adopted and are now being implemented. Progress has been slower in terms of convergence of national measures on price and reimbursement.

### Technical regulations and marketing authorisations

On January 1st, 1995, a new system for marketing authorisation and supervision of medicines entered into force, and a European Agency for the Evaluation of Medicinal Products was set up (Regulation (EEC) 2309/93 and Directives (93/39/EEC,

**Figure 8: Pharmaceuticals  
Trade intensities**

Source: DEBA

93/40/EEC and 93/41/EEC). The new marketing authorisation system gives medicines a quicker and simpler access to the whole of the EU market, while guaranteeing an evaluation of high scientific quality. The new marketing authorisation procedures respond both to the specific needs of the companies and to the public health requirements in the EU. Thus, since January 1995, two procedures are available for pharmaceutical companies giving a quicker and easier access to the whole of the EU market:

- a centralised procedure, leading to a single authorisation for the whole of the European Union, designed for certain new medicinal products and mandatory for those derived from biotechnology;
- a decentralised procedure designed for most medicinal products, based on mutual recognition of national marketing authorisations (with disputes to be settled by binding Community arbitration).

The European Agency for the Evaluation of Medicinal Products which has been set up to operate the system is an administrative and technical secretariat with substantial scientific support provided by the competent authorities of the Member States. Once a product has undergone one of these authorisation procedures, the Commission will turn the Agency's opinion on it into a binding decision.

The new marketing authorisation system should give firms access to the large internal market they need to recoup their research and development costs. Sharing the workload between the European Agency and existing national authorities should also reduce the time it takes to authorise a product from several years to 300 days, and halt runaway increases in registration fees.

The research-based pharmaceutical industry has an obvious interest in the quality of protection afforded by industrial property rights to new medicinal products.

In theory, patents granted under the Munich Convention, to which all EEC Member States are party, afford 20 years' protection, which runs from the date the patent application is filed. In practice, by the time a medicinal product has been developed and a marketing authorisation obtained, only 8-10 years' protection remain.

To remedy this anomaly, the Council adopted Regulation (EEC) 1768/92, creating a supplementary protection certificate

for medicinal products to provide up to 15 years' protection from the date of the first marketing authorisation in the Community. This gave the European industry better protection, similar to that obtained in the USA in 1984 and in Japan in 1986.

### Price controls and reimbursement regulations

Progress in terms of harmonising national legislation in the area of pricing and reimbursement of medicine has been slower, as Member States remain responsible for the organisation and financing of their social protection system. The divergence of national pharmaceutical pricing and reimbursement systems, however, makes the European market for pharmaceutical products more fragmented than is the case in the USA and Japan.

There are differing reimbursement rules for products in the different Member States, different approaches to controlling prices or volumes sold, and different lists of products qualifying for reimbursement. Historically, national regulations were developed to address concerns about public health and social conditions. Over time, however, they have become increasingly focused on public financing issues, in particular on how to reduce the burden of health care in total public expenditure. In most Member States, the entire population benefits from a publicly financed health care coverage which includes pharmaceuticals. The reimbursement rates for pharmaceuticals vary across countries and according to the individual medicine, but can be up to 100 %. Total spending on pharmaceuticals is estimated to represent about 14 % of total health care costs in the EU.

The proportion of the price of a medicine which is not covered by social protection is borne either by private insurance, or by the patients themselves. The reimbursement rate is typically higher (i.e. about 60 %) for products which are only available on medical prescription, and therefore for innovative products.

In past years, national authorities have multiplied cost containment measures. These have included price cuts (in Germany, Ireland, Italy, Portugal, Spain, the UK and Japan), price freezes (in Belgium, Denmark, Germany, Ireland, Portugal and Switzerland), reductions in the rate of reimbursement (France, Belgium), limits on the value of doctors' prescriptions (Germany), restrictions on the categories of products reimbursed (Italy), tightened controls on the industry's advertising practices (France), and measures to encourage national prescribing and use of medicines. These have resulted in a fall in demand for (and sales of) prescription pharmaceuticals in some Member States, triggering a new wave of restructuring in the industry.

Although price controls and reimbursement systems fall within the competence of Member States, they create distortions in the market, preventing pharmaceutical manufacturers from reaping the full advantages of a unified EU market. To limit these distortions as much as possible, the Commission has adopted the so-called "Price-Transparency" Directive, which lays down the transparency rules to which Member States must conform. The price transparency directive establishes that national measures must be based on objective and verifiable criteria, and that all individual decisions must be duly motivated. A Committee has been instituted by the Directive (Council Directive 89/105/EEC), which constitutes an important forum for discussion and exchange of information in this field, and which should help further improving the situation in this area.

### OUTLOOK

Pharmaceutical products are non-durable goods for which the demand is only moderately influenced by the business cycle, as has been confirmed during the last economic downturn. The demand for these products is thus dominated by structural developments.

There are a number of factors influencing structural trends in demand for pharmaceutical products. Looking at the market in general, the predominant factors are the ageing of the population, combined with technological progress in medical science. These two factors are slowly changing the levels and structure of demand for pharmaceutical products. Along the same lines, the opening-up of Eastern Europe has created new market opportunities for the EU pharmaceutical producers. The need for more advanced medicinal products in those countries has already resulted in a growing trade surplus of the EU with Eastern Europe. The potential for increased EU exports to other world regions is enormous, provided EU producers can gain access to these markets.

In line with the "natural" trend in demand within the EU, however, is another factor working in an opposite direction. This is the desire of government authorities to limit growth in health care spending, particularly public spending. Although this mainly influences developments on the drugs market, it has implications for other segments as well. Largely as a result of these government pressures, the past years have seen a gradual change in the organisation of the market, with a shift of products from the prescription to the non-prescription pharmaceuticals category, and with limits on the sales (and prices) of certain drugs. This has translated into a major slowdown in the rate of growth of the prescription pharmaceuticals market, a trend which will likely persist over the rest of the 1990s.

Partly as a result of this, the market for non-prescription pharmaceuticals and in particular for self-medication products is likely to expand rapidly in the coming years. Governments are also encouraging the development of this market, by increasingly recognising the need to support self-medication through pro-active measures.

Although future trends in production and sales are likely to differ across the different market segments, the pharmaceutical sector as a whole is expected to remain one of the fastest growing manufacturing sectors in Europe, as a result of both the continued dynamism in demand from an ageing population, and medical progress and innovation.

## VETERINARY PRODUCTS

Sales of therapeutic products for veterinary use amounted to 1 527 million ECU in 1991, a share of the total pharmaceuticals market of about 2.5 % in that year. This share, however, is growing progressively over time. Between 1989 and 1991, sales of therapeutic products for veterinary use grew at an average annual rate of 7.5 % per year.

The total market for veterinary products includes both therapeutic products, such as antibacterials, antiparasites, biologicals and medicines for metabolic disorders, and feed additives, which cover antibiotics, coccidiostats and vitamins. Antibacterials accounted for a little over 36 % of total EU sales of therapeutic products for veterinary use in 1991, followed by antiparasites (22.6 % of total sales), and biologicals (20 % of total sales).

Within the EU, the largest markets for therapeutic products for veterinary use is the French market, followed by the German and UK markets.

As the remainder of the pharmaceutical industry, this sector is very R&D intensive. On average, the share of sales devoted to R&D in the top thirty animal health and nutrition companies was 8.3 %. The industry estimates that the total amount that needs to be spent on R&D is 100-150 million ECU, which is a very high figure when compared to the average size of the market. Whereas the top pharmaceutical products for human consumption can record sales figures of up to 3 billion ECU, only half a dozen veterinary products have ever exceeded annual sales of 120 million ECU.

In general terms, the highest R&D to turnover ratios are recorded by those firms which are principally involved in biologicals and pharmaceuticals, whereas those companies which mainly produce feed additives have lower R&D to turnover ratios.

Several of the larger companies producing pharmaceuticals for human consumption are also involved in the production of therapeutic products for veterinary use or feed additives. In 1993, the five major animal health and nutrition companies were Hoffmann-La Roche, followed by Rhone-Poulenc, MSD, SmithKline Beecham and Mallinckrodt Veterinary. Together, these accounted for 33 % of the sales of the animal health industry's thirty largest producers, but only 3 % of the total sales of Europe's five largest pharmaceutical producers. Amongst the top 30 animal health and nutrition producers, 10 also rank in the world's top 15 pharmaceutical companies.

The EU market for veterinary and animal health products is currently undergoing major shifts and rationalisation as a result of two factors: the creation of the Single Market and stringent regulations aimed at ensuring safe residue levels in food and in the environment (these have resulted in a considerable reduction in the number of products).

In recent years, a number of major pharmaceutical producers have divested from the animal health and nutrition sector to generate cash to finance their restructuring or new acquisitions in the human health sector. Given the enormous difference in market size and turnover value between the human drugs businesses and animal health products, the animal health divisions are indeed not perceived to be a strategic enough asset for the larger pharmaceutical firms to want to keep them in their group. This represents a new threat to an industry which is already faced with relatively slow growth in demand.

# Maintenance products

## NACE 259.2

Maintenance products have been influenced by changing demographic and lifestyle patterns which, along with the growing public concern for environmental issues, have led to the development and marketing of new products and new product varieties. The large multinational companies which operate on the global market for maintenance products not only try to establish growth through new product development, but also by entering new geographical markets, by taking over smaller companies and by large investment in promotional activities.

### INDUSTRY PROFILE

#### Description of the sector

Maintenance products are defined as preparations designed to meet the cleaning, preserving and protective requirements encountered in a wide range of domestic, institutional and industrial applications. The maintenance products can be subdivided into four categories: scourer and surface cleaning products, polish products and waxes, bleaches and sanitary cleaners and air fresheners and insecticides. Soaps and detergents, classified under NACE 258, are not considered in this chapter.

Scourer and surface cleaning products include all-purpose cleaners, scouring powders and preparations for specific applications, such as car, oven and window cleaning products. Their market size is estimated at nearly 2 billion ECU. Polish products and waxes include polishes for wood, shoes, leather etc. For these products, sales are estimated at more than 800 million ECU. Bleaches and lavatory cleaners include both powder and liquid products. They are chiefly used for the cleaning and disinfecting of sanitary ware. Their market size is estimated at nearly 1.5 billion ECU. The market for air fresheners and insecticides is estimated at more than 500 million ECU. Air fresheners appear in an aerosol or solid form; insecticides in powder, solid or liquid form. Electrically-operated products (NACE 34) are excluded.

Compared to the soap and detergents industry, the market for maintenance products is relatively small. With sales totalling an estimated 36 billion ECU the soaps and detergents industry

is six to seven times larger than the market for maintenance products.

#### Recent trends

Over the period 1987-1992 the EU market for maintenance products grew at an average annual rate of 5%. In real terms, however, consumption only increased by 1.2%. In 1993, the industry suffered from the economic recession.

#### International comparison

Some large multinational companies are operating on the international market for maintenance products. With their headquarters located in the USA or in Europe, these companies have branch offices and production facilities around the world, often close to the local markets. As the same competitors can be found in different countries, country performance is directly related to company performance.

#### Foreign trade

In 1993, extra-EU exports in value were 18.3% up from the year before. Meanwhile, extra-EU imports jumped by 24.6% in value, keeping the sector's trade balance positive at 101 million ECU in 1993.

The USA has become the major supplier of maintenance products to the EU market, raising its share in EU imports from 19% in 1988 to 40.5% in 1993. This growth, however, might be distorted by the inclusion of the agricultural and horticultural applications of insecticides and pesticides into the trade figures. The EFTA area is the major market for EU-manufactured maintenance products.

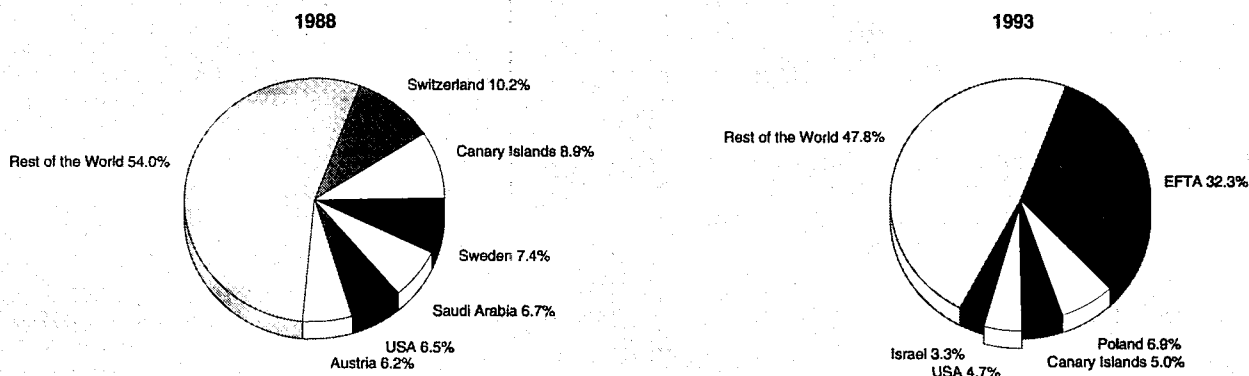

### MARKET FORCES

#### Demand

The long-term development of the demand for maintenance products is linked to a number of demographic factors. The ageing of the population brings with it the need for more intensive use of space and thus more frequent maintenance. The number of households is increasing, with more smaller (e.g. single person) households, pushing up demand. The increasing number of women working outside the home has changed the nature of demand: more practical and convenient products designed to help save time are needed.

The demand for convenience is reflected in the growth of liquid products and the increasing demand for multi-purpose products, or on the contrary for task-specific products. For

instance, in their search for new market niches manufacturers have developed low-abrasive products for particular areas of the house, such as the kitchen or the bathroom. Other marketing elements, which increasingly impact on consumers' purchasing behaviour, include the technical performance of preparations, a convenient packaging, along with strongly scented and coloured products.

The patterns of consumption vary regionally from one country to the other, according to the climate, local customs and the degree of environmental concern. For example, the per capita consumption of domestic hypochlorite in Germany is 0.14 kg and in Denmark 0.5 kg, while the corresponding figures for Portugal and Spain are 8.2 kg and 12.2 kg respectively. In the surface cleaners and scourers subsector, the highest per capita consumption in value is in Italy (8.75 ECU) and Switzerland (7.71 ECU), while the Swedish and the English consume the largest volume (8.1 kilos and 6.7 kilos, respectively). The main users of air fresheners and insecticides are the French (2.12 ECU) and Portuguese (2.06 ECU). Finally, in 1992, Belgium and Sweden were the two countries where per capita sales of shoe polish were the most important (1.47 ECU and 0.96 ECU, respectively).

### Supply and competition

A relatively small number of large multinational companies is operates worldwide in the maintenance products segment.

Intensifying global competition has forced the industry to concentrate on new product development, which has involved large expenditure on R&D and promotion. The emphasis on new product development is reflected in an increasing flood of new products on international markets. The large manufacturers, however, also try to generate growth by exploring new geographical markets and by taking over small and medium-sized companies. In recent years, the international market for maintenance products has also been increasingly affected by the rise of generics and own brands by some retailers, resulting in an intensification of price competition.

## INDUSTRY STRUCTURE

### Companies

A few large multinationals are active on the international market for maintenance products, including the two US-based companies Colgate-Palmolive and Procter & Gamble, and the Anglo-Dutch group Unilever. However, on the markets for air fresheners and insecticides their market positions are weak. Other companies which are also operating in one or more segments of the market for household cleaning products are Reckitt & Colman (UK), SC Johnson (US) and the German companies Henkel and Benckiser.

(1) The significant increase in the number of employees for 1993 is because the figure include sales, marketing, distributional activities and not only production activities as in 1992.

Source: FIFE

Beside these major international companies, many small and medium-sized firms are active in manufacturing and selling maintenance products throughout the EU. Their number is estimated at around 600. The total number of employees in the sector, estimated to be at least 60 000, remains fairly stable.

### Strategies

The major multinational companies try to generate growth either by developing new markets for existing products (the exploration of the East European markets for instance), developing new products or product varieties for existing markets and by developing new products for new markets. Mergers and takeovers are also often made in order to benefit from growing markets and to diversify into new markets.

Smaller companies, active in one or two market niches, are often limited to local markets. Only if they had an exclusive patent for their product would they be able to operate on a larger scale.

### Impact of the Single Market

The European Single Market programme has been a success for the maintenance products industry. A unified market, with harmonised standards has indeed emerged, while in the past, product specification had to adapt to each national set of regulations. As a result, large multinational companies (about 80% of the market) have restructured their operations. They have been able to concentrate production in a small number of large factories, each specialised in a limited number of products, from where they serve the entire European market. Small and medium size enterprises have also increased their specialisation, developing their presence in niche markets.

As far as this industry is concerned, two important Directives remain under discussion: the biocides directive, and the actualisation of the directive on biodegradability which dates back from 1973.

### ENVIRONMENT

In the maintenance products industry, environmental protection is at the forefront of the research and development of new products. EU and national environmental regulations are becoming increasingly strict as the pressure of public opinion is intensifying. Minimising toxicity has thus become not only mandatory, but also a criterion for success. The industry is devoting a considerable share of its R&D expenditure on more environmentally acceptable products. Actually, a large number of toxic products have been phased out, as the more environmentally acceptable substitutes have started to pay off.

Specifically, in accordance with EU regulations and following public opinion, major efforts have been made to develop new types of propellants for aerosols and containers that do not involve the use of pressure.

The use of products containing active chlorine is also under scrutiny. Under the EU legislation on dangerous preparations, hypochlorite products that contain below 5 % of active chlo-

rine are not classified; products containing 5 to 10 % of active chlorine are classified as irritants, and those above 10 % are classified as corrosive. Although the average hypochlorite solution contains around 5 % of active chlorine (or less) and thus not classified as dangerous, a possible hazard can arise from the improper use of hypochlorites in a very limited number of situations (which represents 0.12 % of household accidents). This can occur if the products are mixed with other cleaners of an acidic type. Accident statistics further show that direct contact with eyes and skin does not cause permanent injuries and that ingestion very seldom leads to serious or permanent injuries.

Although the risk of having an accident linked to the use of hypochlorite products is very low, the industry has strongly supported improved labelling to ensure that hypochlorites are not used incorrectly and has developed a public information programme on their benefits and safety when used correctly.

The industry also has implemented measures aimed at reducing packaging waste, thus contributing to energy savings. Reductions are being achieved through lightweighting (using less material to make the packs), concentration (using a formula to deliver performance from smaller volumes of product), refilling (using the pack more than once), recycling (reusing the material from the pack). These measures not only lead to waste reduction, but to energy saving as well.

### REGULATIONS

Some 200 regulations, directives and amendments are relevant to the maintenance products industry. Subjects covered include dangerous substances, dangerous preparations, solvents, pesticides and insecticides, consumer protection, environment, waste, water quality, biodegradability, eco-labelling, eco-auditing, risk assessment, packaging, taxation and transport.

The industry is mainly covered by the Directive 88/379 concerning dangerous preparations. In December 1993 the Commission Directive 93/112 was adopted, defining and laying down arrangements for the system of specific information relating to dangerous preparations.

Other recently adopted or drafted directives concern the assessment of the risks posed by substances to human beings and the environment in accordance with Directive 67/548 on dangerous substances (Directive 93/67), warnings for products containing more than 1 % of active chlorine, the assessment of the effects of certain public and private projects on the environment and the incineration of hazardous waste.

### OUTLOOK

Given their secure integration into many aspects of daily life, the use of maintenance products is unlikely to be reduced. The growth of the market for maintenance products is expected to continue at the same modest, but constant rate. According to our forecast, overall production and consumption of these products will increase by about 1.5 % per annum for the period 1994-1997. As a result of environmental pressures, an increasing volume of more environmentally acceptable products and product accessories will be developed and marketed.

The industry is represented at the EU level by: International Federation of Associations of Maintenance Products Manufacturers (FIFE). Address: Square Marie-Louise 49, B-1040 Brussels; tel: (32 2) 238 9711; fax: (32 2) 230 8288.

# Man-made fibres

## NACE 26

World production of man-made fibres grew by 2 % in 1993 to a record level of 20.3 million metric tons. However, production in Western Europe declined by 3 %. The sector's major outlets, were hit by a combination of recession and structural change. With stronger demand during 1994, prospects seem to improve in the near future.

The manufacture of man-made fibres in the EU is confronted with intense competition, particularly from developing countries and NICs in Asia. Thus, the European industry is turning its attention to higher value added products, continued work on modernisation to lower production costs, and restructuring to trim excess capacity and the number of producers.

### INDUSTRY PROFILE

#### Description of the sector

The man-made fibres (or chemical fibres) industry covers three different types of fibres: synthetic fibres, cellulosic fibres, and mineral fibres.

Chemical fibres mainly consist of synthetic fibres, which accounted for 85 % of world chemical fibre production in 1992. The main synthetic fibres, with their share of total 1992 world production, are: polyester (54 %), nylons and aramids (20 %) and acrylic (13 %) fibres. Cellulose-based fibres, which are made from natural sources, such as modified wood pulp that has been dissolved into a liquid, include: acetates, rayon, triacetate and viscose. They account for 13 % of world chemical fibres production. Although mineral fibres are also part of the chemical fibre sector, they are excluded from the statistics presented in this chapter.

All of these fibres are divided into sub-categories according to their physical form. Filament is a polymer which is remilled in its molten state via a fine strainer and then solidified by cooling. It is then processed in a variety of ways, depending on how it is to be sold. It can also be cut up into short fibres.

These short fibres often have very similar characteristics to those of natural fibres.

The preponderance of synthetic fibres over cellulosic products is becoming more pronounced. Short synthetic fibres represent the bulk of EU production, with 54 % of the total. Synthetic filaments come second with 33 %. Cellulosic fibres, which represented about 22 % of total chemical fibres in 1980, now only represent 13 %.

Among EU Member States, the largest producer of man-made fibres is Germany (34.1 % in 1993), followed by Italy (22.5 %). Benelux and the United Kingdom are also important producers, each accounting for about 11 % of EU production, followed closely by Spain (9.2 %).

#### Recent trends

Between 1986 and 1991, EU production of man-made fibres had grown at an average annual rate of 2 %. In 1992, however, EU production in volume decreased by 5.2 %, the first decline since 1986, followed by a 3 % decline in 1993. These declines were mainly driven by an equal fall in consumption, due to a downturn in the textiles and clothing and automotive industries, which were hit by a combination of recession and structural change. This output fall is significant when compared to world production which grew at 4.6 % in 1992 and 2 % in 1993.

The EU chemical fibres industry has undergone extensive restructuring since the late 1970s. The low rate of increase in European textile consumption during the late 1970s (following the first oil crisis) contributed to the structural change. Other reasons for restructuring were: the growing deficit on the EU's textile and clothing trade balance; the development of chemical fibre production capabilities in the rest of the world; and, numerous investments made by EU firms in other parts of the world. In fact, two waves of production capacity reduction have occurred. During the 1978-85 period, over 900 000 tonnes was cut, or one-third of the total West European capacity. Another development has been technological changes which reduced manpower requirements. Employment has been falling gradually since 1980, except for an increase of 7.8 % in 1991, due to the inclusion of eastern Germany. However, employment in the industry has continued to fall from 77.4 thousand in 1991 to 62.4 thousand employees in 1993, i.e. 10 % yearly. This decline was accompanied by a significant

upgrade of apparent labour productivity and an increase of utilisation rates from 74.4 % in 1991/92 to 77 % in 1993.

#### International comparison

Over the past decade the production of man-made fibres has decreased by 9 % in both the USA and Japan. Although total production in the EU increased, the industry has been losing ground in relative terms in the production of all kinds of fibres. Between 1992 and 1994, estimated man-made fibre production capacity declined by 1 % in Western Europe, mostly because of the capacity reduction which took place in East Germany during this period; while it increased by 23 % in the developing countries (excluding China). During this period, production capacity hardly increased at all in the US and Japan. The relative decline is particularly strong in the field of synthetic filaments, where the EU represented

less than 12.4 % of world production in 1992, down from 20.6 % in 1977.

The US man-made fibre industry remains one of the largest in the world, with a market share of 19 % in 1993, compared to 16 % for Western Europe, 11 % for Taiwan and 9 % for Japan. Production in the newly industrialised countries (NICs) accounts for an increasing share of world output, displacing the former pre-eminence of the USA and some EU Member States. In 1993, already 49 % of man-made fibres were produced in Asia, while combined production of Taiwan, China and South Korea reached 29 % of world output.

The NICs are becoming crucial actors in the industry. The most dynamic region is Southeast Asia, which includes: Taiwan, South Korea, China and the ASEAN countries. For example, while the East Asian countries represented only 22 %

**Figure 2: Man-made fibres**  
International comparison of production in volume

Source: CIRFS

of world production of polyester in 1980, this share jumped to 40 % in 1992 and could rise to 60 % of world production by 2001. Overall, the Southeast Asian industry should see its share of synthetic fibres grow from 28 % in 1992 to 31 % in 2001.

### Foreign trade

The EU has a strong rate of import penetration, while its share of exports in production remains weak. The EU trade balance on man-made fibres has declined steadily since 1983, falling into deficit in 1988, when imports jumped by 23 % to 614 000 tonnes. Meanwhile, exports declined from an average of 560 000 tonnes between 1984 and 1988 to an average of 431 000 tonnes between 1990 and 1993. Combined with imports peaking at 653 000 tonnes in 1990, after which they declined again to 1988 levels, the cover ratio (exports/imports) fell from 1.54 in 1984 to 0.66 in 1990, after which it steadily increased to 0.72 in 1993.

After an increase of 5 % in 1992, extra-EU imports decreased by 4 % in 1993. As a consequence, EU imports as a percentage of consumption decreased slightly; a ratio that has shown an increase from 14 % in 1984 to 20 % in 1992. Comparing

1993 to 1988, the USA and EFTA countries lost ground in the EU-market (origin of EU imports from these countries declined from 57.3 to 50.7 %), while Japan increased its share in EU imports from 2.9 to 4.5 % and the "Rest of the World" increased from 29.6 to 34.7 %.

Extra-EU exports, after an increase of 9 % in 1992, decreased by 2 % in 1993. EU manufacturers exported roughly 15 % of their production in 1993 to non-EU markets. However, declining demand, along with increasing supply from other regions of the world, put pressure on prices as the weakness of the dollar continued to negatively affect extra-EU exports.

Germany is by far the largest exporter of man-made fibres, accounting for 53 % of extra-EU exports. It is also the leading importer, with 19 % of extra-EU imports. Italy (15 % of exports, 19 % of imports) and the United Kingdom (13 % of exports, 16 % of imports) are also big trade players. However, only Germany recorded a trade surplus outside of the EU in 1992.

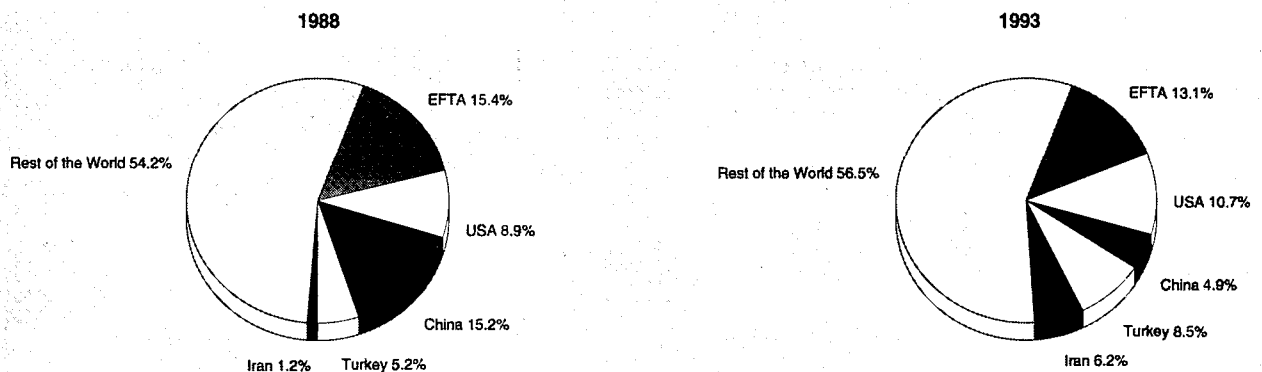

The USA is the EU's foremost national trading partner. Over the period 1988 to 1993 the share of exports to the USA increased from 8.9 to 10.7 %, while imports from the USA decreased from 16.3 to 12.9 %. Exports to China decreased dramatically, from 15.2 % in 1988 to only 4.9 % in 1993. This fall has been partially compensated for an increase in exports to countries such as Iran (6.2 %, up from 1.2 %) and Turkey (8.5 %, up from 5.2 %). Eastern Europe has also been an important EU export market. Until 1990, this region had been more important in terms of exports (with about 25 % of total extra-EU exports in 1986) than the EFTA countries. However, since 1990, EU exports to Eastern Europe have fallen drastically, in spite of a decline of synthetic fibre output in Eastern Europe of 14 % in 1992. In that year, total consumption in Eastern Europe had still not reached the peak of 1980.

## MARKET FORCES

### Demand

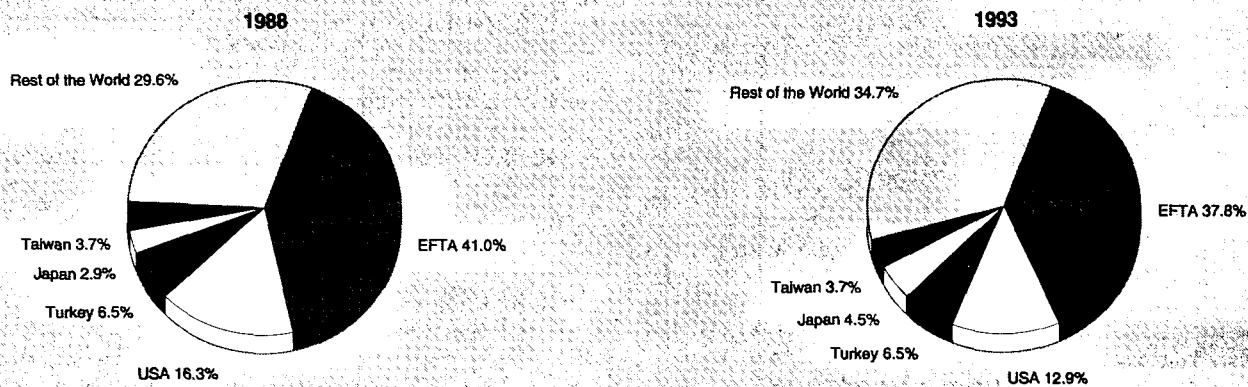

The main end-market for man-made fibres is the clothing industry, with 47 % of total consumption, while interior furnishings represents another 35 % and industrial applications 18 %. As consumers account for an important share of demand, overall economic activity and personal disposable income are overriding factors in the dynamics of the man-made fibres industry. Chemical fibres represent an important share (approximately 66 %) of total fibres consumption in the EU.

**Figure 3: Man-made fibres**

**Figure 4: Man-made fibres**  
Origin of EU imports in volume

Source: Eurostat

Growth recorded throughout the 1980s in the textiles sector mirrored the overall increasing trend in consumption of man-made fibres. Technical textiles is the sector with the most favourable market prospects in the EU, as the sector is continuously finding new markets; not least because of a high rate of innovation. On the other hand, synthetic fibre consumption for spun-yarn production has fallen back to the levels of the late 1970s, and further declines are expected for the coming decade. The main reason for the decline are increased imports of apparel, primarily made from cotton.

As the seventies were the decade that created pan-European markets, the past decade implied the globalisation of markets. The barriers between Europe and the rest of the world being swept away have required, once more, a radical reassessment. The reduction of the European market for man-made fibres has been partially driven by the fact that several textile clients have shifted operations to extra-EU countries. Another minor factor was the change in the tyre market, which saw increasing buyer power and falling market boundaries. Within five years, a dozen major world tyre manufacturers merged to form five.

Combined with oversupply of fibres, the industry's margins have decreased.

### Production process

Enhancements in the technology of yarn and fabric manufacturing have been major factors in the increasing dominance of synthetic fibres over natural fibres. Some processes, such as tufting for carpet manufacture, were initially made possible by developments in synthetic fibres technology. Given their particular suitability for a variety of end-uses, man-made fibres, in particular synthetic fibres, have been able to capture a significant part of the fibres market.

The production process is increasingly capital intensive, following the need for higher technology products.

Two recent innovations have been developed in the clothing industry. Microfilaments, which have properties similar to silk, geared towards casual wears, and Lyocell, a new man-made cellulosic fibre developed by Courtaulds (UK), AKZO Nobel (NL) and Lenzing (A), aimed at the high fashion market. The latter's manufacturing process is an important chemical simplification over that of rayon and viscose and environmentally more friendly; because of the use of a renewable raw material and the recycling of solvents.

## INDUSTRY STRUCTURE

### Companies

The global man-made fibres market is dominated by a small number of big companies. Companies are specialised and concentrate on speciality fibres in order to avoid competition from developing countries.

With a production capacity of 1.1 million tonnes, Hoechst AG (D) is the world's largest producer of polyester. Its turnover, in chemical fibres, amounted to 6 945 million DM in 1992. In polyamides, the joint venture between Rhône-Poulenc (F) and SNIA Fibre SpA (I) controls about a third of the West European market, followed by DuPont (USA) with 25%. The latter is also the first world producer, followed by Allied Signals (USA) and BASF (D). For acrylic fibres, Enichem (I) and Bayer (D) are the main world producers, recently joined by the joint venture between Courtaulds (UK) and Hoechst (D). As far as polypropylene is concerned, two EU companies belong to the world top ten, Moplefan (I) and Danaklon (DK). Courtaulds (UK), Lenzing (A) and AKZO Nobel Fibres (NL) are other major players in the sector.

**Figure 6: Man-made fibres**  
Consumption growth of man-made fibres and textiles

Source: CIRFS, Eurostat

### Strategies

Globalisation of markets and increasing pressure from Asian competition had a profound impact on the strategies of EU companies. The latest strategy is one of specialisation in one type of fibre through asset swaps, sales and/or alliances. As a result, the major firms in the industry are increasingly operating with a global perspective. For example, ICI's tyre cord business moved from having a strong market share in Europe to a weaker position in the global market. However, its quality advantage was less easy to realise over a wider geographical spread. In spite of a major restructuring programme, doubling labour productivity without increasing capital employed, it became clear that profitable investments would only be possible in conjunction with DuPont. In July 1993, ICI completed the sale of its fibres business to DuPont in exchange for a cash sum and for DuPont's interests in acrylic materials.

Polyamide alliances have been concluded between Allied Signal and Akzo and between Rhône-Poulenc and SNIA. Another important joint venture between Courtaulds and Hoechst, announced in May 1993, concerns their acrylic and viscose operations. In viscose, the new company will command a strong position in both the industrial and textile end-uses. It will also provide Courtaulds with a wider platform to launch its new Tencel fibre on the European market. BASF also illustrates the drive towards specialisation. After divesting from viscose and acrylic, which it sold to Lenzing and ICI (respectively) in 1992, it is now planning to do the same for its polyester operation in the USA, in order to focus on polyamide. On the eastern front, Rhône-Poulenc has set up a joint venture with Chemlon SP of Slovakia, the leading producer of polyamide yarn in Central Europe.

An increasing number of fibre producers are following textile demand to Southeast Asia. This trend is not because of the lower level of labour costs per se, but rather to be nearer major sources of apparel manufacture, which can subsequently be exported to Western Europe. In the beginning of 1994, DuPont and China Worldbest Development Corp. agreed to explore the possibility of a joint venture to make and market Lycra elastane fibres in China. Lycra can be combined with other fibres to enhance the fit and shape retention of garments. DuPont recently doubled its capacity for Lycra in its Singapore plant. Akzo Nobel is also exploring investment opportunities in China and other Southeast Asian countries.

### Impact of the Single Market

The legislative measures taken to create a Single European Market are considered to have been globally positive by the man made fibre industry. One of the measures which the industry considers to have been particularly relevant is the creation of a centralised system to monitor and approve mergers and acquisitions at the European level. As this sector is mostly composed of large multinational companies, and because restructuring activity (through M&A, asset swaps, etc.) has been and will continue to be important, the existence of a centralised authority is essential to allow a fast completion of restructuring agreements.

In order to have a balanced competitive environment within the EU, it is, however, also important for the man made fibre industry that state aid to nationalised or other producers be carefully monitored and regulated. Another important competitive factor is the cost of energy, which accounts for more than 5% of total costs. The set up of the Energy Internal Market and a further liberalisation of the energy sector would help keeping energy price down and would harmonise prices across the European Union.

### ENVIRONMENT

Firms in the industry will have the choice to apply or not for the Eco-label award, depending on whether they can and want to fulfil the requirements developed by the competent body and approved, in the last instance, by the Council of the EU.

The UK's Chemical Industries Association (CIA) reported that its members' "green" spending for environmental protection, energy conservation, and health and safety is expected to hold steady at 27 % of total capital spending.

### REGULATIONS

The industry is carefully following extra-EU imports to detect cases of "unfair" trade. Under the auspices of its industrial association, CIRFS, it has already won several anti-dumping cases.

The Uruguay Round package brings trade in textiles and clothing gradually back to more liberal GATT rules. With regard to tariffs, European tariffs are being trimmed to about 4 %, recently in India tariffs have been reduced up to a maximum

**Figure 7: Man-made fibres**  
Production in volume by Member State, 1993

Source: CIRFS

of 65 % in 1995 and will be reduced to 20 % at the beginning of the year 2000, Pakistan will reduce its tariffs in July 2000 up to a maximum of 30 %. The structure of the textile phase-out will have a major influence on textile industries all over the world, causing restructuring of the textile and fibre industries. In the short term, international trade may not be affected, but between the fourth and eighth years, major influences will impact exporting and importing countries. In the long term, the biggest benefit is expected to accrue to China.

A framework agreement, with the European Commission, covers national subsidies for investments in the man-made fibres industry. The Commission must be notified, in advance, of all government subsidies to the synthetic fibres sector, and any subsidy assistance for increasing capacity is forbidden. Where subsidies are granted for modernisation, the funds should be linked with restructuring and reducing capacity.

---

## OUTLOOK

---

The EU man-made fibres industry is expected to perform slightly better in the 1995-1997 period. The bulk of the growth will be accounted for by synthetic fibres, especially nylon (about 5 % yearly), polypropylene (4 % yearly) and polyester (2.5 % yearly). Development of new cellulosic fibre variants may reverse the decline of cellulose production in Western Europe.

Demand from the industry's main clients is expected to improve in the second half of the decade. The automotive industry is expected to start recovering by 1995, thus contributing to a stronger production performance in the man-made fibres industry. Industrial applications, including geo-textiles and nonwovens, seem to be a solid growth area, while the prospects for household textiles and carpets are also healthy. The textiles industry will witness a slight increase in production, with customers looking for materials with specific, higher value added, qualities. Import growth is expected to benefit from the growth in textile consumption, and restructuring is expected to continue as a result of import pressure from Southeast Asia. NEI also estimates that at least one-third of the European textile industry will be relocated by the year 2000, probably resulting in a similar, but less profound, relocation of the fibre industry.

Written by: Netherlands Economic Institute

The industry is represented at the EU level by: International Rayon and Synthetic Fibres Committee (CIRFS). Address: Avenue E. Van Nieuwenhuyse 4, B-1160 Brussels; tel (32 2) 676 7464; fax (32 2) 676 7454.

# Biotechnology

*Biotechnology is a small but fast growing, high technology field. The European Union's 1993 White Paper on Growth, Competitiveness and Employment recognises that biotechnology is one of the key technology for Europe future prosperity. At present, most commercial biotechnology production occurs within the pharmaceutical sector. Other areas of increasing importance are the agricultural sector, the food processing sector, renewable energy production and environmental and waste management.*

*The EU is an important player in biotechnology. However, comparatively favourable market conditions in terms of financial arrangements, intellectual property protection, regulation and public acceptance in the USA makes this country the world leader of the field. Many European companies invest in the USA.*

*According to Ernst & Young, the market for biotechnology products in Europe, reached 38 billion ECU in 1993, with about 27 000 jobs where biotechnology is directly applied, and 184 000 jobs in biotechnology-related activities. By 2000, Ernst & Young expects this market to reach 80 billion ECU.*

---

## INDUSTRY PROFILE

---

### Description of the sector

Biotechnology can be broadly defined as the application of scientific and engineering principles to the processing of materials by biological agents. Biotechnology consists of two segments. Classical biotechnology is comprised of fermentation and preservation processes used in the production of beer, wine, cheese, bread, vinegar, etc., where advances have been made predominantly without the use of genetic engineering. Modern biotechnology is characterised by the utilisation of genetic engineering and is a small but rapidly growing segment. Only modern biotechnology will be considered here. Modern biotechnology is based predominantly on recombinant DNA (rDNA) and cell fusion techniques and has considerable potential for a wide range of applications. So far, around 400 genetically modified organisms (GMOs) have been released in the environment worldwide. Major impacts are expected in pharmaceuticals, agriculture and food processing, health (diagnostics), renewable energy, environmental management (including waste management). Large growth in biotechnology equipment is expected to impact on relevant high-technology fields of the electronic engineering sector.

According to a recent study by Ernst & Young, the European market for goods which are dependent on the successful application of biotechnology is about 38 billion ECU. About 27 000 jobs depend directly on modern biotechnology applications, and about 184 000 people have jobs where biotechnology is involved to some degree. According to the European Commission, the number of employees in modern biotechnology firms is slightly higher than estimated by Ernst & Young, and would be between 35 000 and 40 000. The Ernst & Young study also shows that research and development expenditure by European biotechnology firms amounted to more than 1 billion ECU in 1993. This is significantly below US biotechnology investments

### Recent trends

Over the eighties, there was a 10.6 % per year increase in the number of patent applications in the area of biotechnology in the EU. The structure of biotechnology inventions (i.e. those with patent applications in at least two countries) remained roughly stable over the second half of the 1980s. While Germany had the highest share, this fell slightly towards the end of the decade and the United Kingdom was among

those that increased their share. Since 1993, because of easier access to capital in the United Kingdom, the biotechnology sector has developed more rapidly in this country, thus reinforcing the trend noted above.

In 1994, according to Ernst & Young, employment in biotechnology-related activities increased by 1 %. However, employment increased more rapidly in small companies (less than 1 000 employees), at 6.5 %, than in large companies, where employment only increased by 0.5 %.

### International comparison

Ernst & Young estimates that the number of biotechnology companies in Europe at about 400, including university research programmes and pharmaceutical companies subsidiary. This compares to about 1 500 companies in the United States, which remains the dominant country in the field. Even European companies are now investing more in the USA in the EU. The Ernst & Young survey mentions that, while European companies realised about 60 % of their investment within Europe in the past few years, and only 20 % in the US, current plans for future investments by European companies show a balanced split between investments planned in Europe and in the US.

Mergers and acquisition activity gives another sign of the leading role of US companies in the biotechnology sector. An analysis by Roche, the Swiss pharmaceutical company, shows that, over the 55 major R&D alliances formed by the pharmaceutical industry in 1993, 52 of the 55 "technology providers" were US biotech companies, and only three were European.

European companies have historically tended to specialise in different product areas than their US and Japanese counterparts. In the USA, biotechnology companies focus their interest on diagnostic agents, pharmaceutical products and equipment. In Europe, there is no marked specialisation. In Japan, there are proportionally more biotechnology companies active in applications for the chemical industry.

In the pharmaceutical market, all three main players are developing and using rDNA and cell merging techniques to produce proteins for a wide range of pharmaceutical products. In the agro-biotechnology market, there are marked differences in product specialisation. European expertise is fairly broad but particularly strong in the area of agro-chemicals. The USA is superior in its level of development in seeds, geared towards oil and cereal crops. Japan concentrates mostly in fermentation products and biotechnology directly related to horticulture.

### Foreign trade

At present, trade in biotechnology-derived products is principally for pharmaceutical applications. Compared with the pharmaceutical sector as a whole, where slightly less than half of extra-EU exports goes to countries outside the USA and EFTA, biotechnology derived pharmaceuticals are much less traded with countries outside these two foreign markets. The biotechnology pharmaceutical products tend to be high value, specialist drugs designed for ailments prevalent in the industrialised world. Trade in agro-biotechnology is small in comparison and is largely of seeds. Non-compliance with intellectual property rights is a barrier to trade, as companies only export to countries where their products are protected by effective patent regulations.

---

## MARKET FORCES

---

### Demand

At present the market for biotechnology derived products is almost totally in the North America, Japan and western Europe. Although potential developments in industrialising countries are enormous, especially in the agriculture sector, sales to

these countries are very limited. The market fails to take advantage of developing biotechnology products, pitched at demand from the developing world for two main reasons. Firstly, the return on the large investments in R&D that would be needed to bring the products to commercialisation would be too small to justify. Secondly, if the product was brought to commercial status, the risk attached to non-compliance with international intellectual property rights would be very high. Technology for equity deals may be one viable way forward as a mean of technology transfer in the less high-tech industries, particularly agro-biotechnology.

Factors hindering demand include concern over the safety of genetically engineered organisms on the natural environment. In Europe, a certain distrust of the public in some Member States towards biotechnology is a handicap for the development of the sector.

A promising sector for biotechnology applications in Europe is environment management. Demand in this field is likely to increase with the growing concern over the environment in the EU and the rest of the world. An example of possible application has been developed by Brixham, a subsidiary of Zeneca (UK). The company is working with the University of Luton (UK) to develop a biosensor to detect and monitor toxicity levels at sewage works.

Products of biotechnologies can also be used in agriculture, where productivity gains and cost reductions are important in a heavily subsidised sector in the EU.

Agro-biotechnology products have taken longer to be brought to the market than biotechnology derived pharmaceuticals for at least three reasons. Firstly, in the EU and other developed countries, high technology pharmaceuticals are part of a more profitable and faster growing sector than the agricultural sector. Secondly, basic research in agro-biotechnology takes longer than for bio-medical products, partly because of the scale (genetically altering a whole organism compared to cells used to produce proteins for a new drug) but also because testing of new strains of crop is limited by seasonal factors and in animals, testing is constrained by the gestation cycle. Thirdly, the delay in adopting EU-wide regulations on the marketing of biotechnology-derived agricultural products (Novel Foods, animal feed, seeds, plant protection products, etc.) may have some impact on the sector's development.

An estimated 872 transgenic plant trials have been achieved in Europe and North America between 1988 and 1993. Oilseed, rape, potato, tobacco sugar beet and maize accounted for most of these trials. Over the last three years, the number of trials has been stable in Europe (from 79 in 1991 to 93 in 1993), while they have doubled in North America (from 83 in 1990 to 177 in 1993). Furthermore, trials are limited to a few experimental sites in Europe (175 in 1993), while in North America, trials are achieved in a large variety of sites (1300 in 1993), which indicates that many transgenic plants are in the final stages of testing in the US, while still in preliminary test in Europe.

### Supply and competition

The world leader in the biotechnology-derived pharmaceuticals' market is Amgen (USA) with sales of about 1.6 billion USD in 1994. In Europe, Switzerland (with Roche), Germany (with Bayer and Hoechst) and Denmark (with Novo-Nordisk) are particularly well placed in the market. As far as attracting investment is concerned, the Netherlands, where many US owned companies have settled, and the UK, with an easier access to stock market, are amongst the most attractive business environments. However, other countries' environments, due to lower public acceptance, are perceived by the industry as less favourable.

Several factors contribute to the preference for European companies to invest in biotechnology outside the EU: the relatively

low level of subsidies to biotechnology R&D (in the ten years to 1992, the EU provided 600 million ECU in to improve basic knowledge and reinforce biotechnology in Europe); public mistrust and interest group opposition, both higher in Europe than in the USA or Japan; the level of bureaucracy that is high compared to USA and Japan, and finally trade restriction, such as a relatively low level of intellectual property protection.

Indeed, in Europe, the non-uniformity of intellectual property rights remains a stumbling block for producers of biotechnology derived products, within the EU domestic market and also in many export markets. The very high levels of investment that are necessary to bring the product to the market necessitate some form of generic licensing enforced through patents. In the past, an estimated 14.5 billion ECU per year have been lost on the world pharmaceutical market due to the non-recognition of patents by many large export markets such as Brazil, Hungary, India and Thailand. If international intellectual property rights were enforced it could increase world pharmaceuticals' sales revenues by up to 8.5 billion ECU. On the other hand, a recent report on biodiversity commissioned by the UN Development Programme estimates the value of Third World plant species to the pharmaceutical industry at more than 30 billion USD per year, as 90 % of the earth's remaining biodiversity is located in non-industrialised countries.

### Production process

Biotechnology has made great strides in the field of human health since 1980 when insulin became the first product of genetic engineering and modern biotechnology to reach clinical trials. In the pharmaceutical sector, biotechnology is used in three ways: to produce drugs and vaccines using rDNA technology, to make intelligent screens for new compounds and to apply techniques for rational drug design by understanding molecular structures. Since the early 1980s biotechnology has also branched into other areas.

In the field of diagnostics, kits are available that use monoclonal antibodies (MABS) to diagnose such diseases as the AIDS virus. MABS can also be used to direct treatments or attack a target themselves which have important consequences for the treatment of cancer and other diseases. In the chemical sector, biotechnology research is mainly in the field of enzymes (which act as catalysts) with markets such as washing powder.

In the agricultural sector, developments have been in the areas of pesticides, plant and animal health and the increasing of yields. Bio-pesticides are produced using strains of a bacterium *Bacillus thuringiensis*. They have been in commercial use for over 30 years and, over this period, biotechnology has increased the range of target pests. Plants and animals have been selectively bred for generations to bring out useful traits. However, it was not until 1983 that the first rDNA engineered plant was produced. Since then there has been much research and development in the area (known as transgenic plant technology) and over 50 species of crop plant can now be genetically transformed. In addition to increased yield, biotechnology has also enabled increased resistance to pests, diseases and to herbicides, which allow a more selective and effective use of herbicides.

In the food sector, developments have included the genetic modification of plants to improve flavour and smell, lengthen shelf life and eliminate toxins. Also, genetically engineered enzymes can be used to enhance the efficiency of certain areas of food production. For example, Bovine Somatotrophin (BST) increases milk production of cattle, and a rennin substitute (Chymosin) eliminates problems of supply and infections from animal sources of rennin. BST is currently commercialised in the USA. In Europe, the Council of Ministers has decided to ban BST use until the end of the nineties.

Non-food uses of animals and plants will become important for the production of antibodies and therapeutic proteins. In June 1994, Genzyme (US), has launched the first "transgenic farm". The thousand goats raised in the farm have been genetically modified to produce humane proteins in their milk. These proteins can then be used to create new drugs. Genzyme's plans include the production of a new anticoagulant, or drugs against multiple sclerosis and cancer.

The areas in which biotechnology could play a key role in environmental and waste management are: treatment of contaminated land and water; reducing the cost of effective pollution control for hazardous industrial effluent; a reduction in the volume of household, agricultural and industrial waste through bacterial digestion and the use of biodegradable packaging. In addition, the use of biotechnology to engineer organisms to increase the rate of digestion of woody matter would enable the yield of biogas from landfill sites, sewage works and agricultural digestors to be increased.

## INDUSTRY STRUCTURE

### Companies

European biotechnology has developed primarily within large pharmaceutical companies and in non-profit research institutes such as universities. The typical European biotech company is thus quite different from the often quoted US biotech company, typically a small research company, whose financing rely essentially on investor's confidence and thus on announcing as widely as possible every achievement. In Japan, the players on the market are almost exclusively large companies.

The first biotechnology survey published in March 1994 by Ernst & Young reports about 400 European biotechnology companies, about a third of what can be found in the USA. However, the average size of a biotechnology company is larger in Europe than in North America. In the USA, the typical biotechnology company is a small entrepreneurial young companies. In Europe, biotechnology has developed primarily within large pharmaceutical or chemical groups, or in universities.

European biotechnology companies are especially active in pharmaceuticals and food businesses. On total biotech-related sales of 38 billion ECU in 1993, pharmaceuticals account for 15 billion ECU, and food for 10 billion ECU (according to Ernst & Young). Other sectors of activity are chemicals, agriculture supplies and diagnostics and equipment.

In the few years of its short history, the biotechnology industry has developed in a few specific locations, such as Oxford, Cambridge, Scotland and London in the UK, or in the areas around San Francisco and Boston in the US. According to the Ernst & Young's study, the most important factors are the availability of skilled staff, the regulatory environment, the proximity of scientific institutes and the cost factor. Other factors that influence the location of an investment are access to capital, a favourable tax regime, easy access to airports and highways, the quality of the environment.

Most of these factors are slow to change, and it is likely that the same regions will continue to attract biotechnology companies in the future, if only because biotechnology companies gain from being next to each other, so new ideas can move around and develop quickly.

Many companies also set up in the US because it is the largest and most profitable market for biotechnology products. The entry into force of the new marketing authorisation system for medicinal products, run by the European Agency for Evaluation of Medicinal Products (EAEMP), will help in attracting more biotechnology companies to Europe.

The European regulatory environment is likely to undergo changes in the near future. A number of European companies

are reported to have established new laboratories in the US largely because of stringent regulations in Europe. This is for example the case of Bayer, Boehringer Mannheim or Hoechst in Germany. On the other hand, the EU regulatory framework is currently reviewed, in order to incorporate scientific progress and gained experience on work with genetically modified organisms (GMO). This is expected to bring about the added benefit of a positive impact on European competitiveness.

Access to capital is a crucial factor for the development of the biotechnology industry. Indeed, it often takes 10 years before a biotechnology company becomes profitable, if ever. Until now, on the 2 000 or so biotechnology companies in the Europe and North America, less than a dozen have shown any profit. Despite this, there is a highly dynamic entry of new firms in this domain. Capital is a necessity for a biotechnology company, not only to pay the bills and salaries, but also because it provides a strong asset when negotiating strategic agreements with potential partners such as large pharmaceutical concerns.

However, accessing capital is difficult. In the US, biotechnology companies raised 3.4 billion USD in 1991, but this amount declined to 2.5 billion in 1992 and 2.8 billion in 1993. Capital raised through flotation on the stock markets also declined in the US, from 33 million USD in 1991 to 26 million in 1992 and 22 million in 1993. One of the main reasons which explain the decline in interest for funding biotechnology companies is the fear of healthcare reforms, which cast doubts on the ability of new biotechnology products to generate large profits once they reach the market.

Another important reason is the change of mood among investors. While optimism over a buoyant future for the biotech industry was the rule in the early eighties, the results achieved by the industry has somewhat watered down that optimism. Many biotechnologically-developed drugs did not live up to expectations, as they were either dropped by their developer (such as Synergen of California abandoning its sepsis treatment Antril), or had only limited success.

In Europe, cash raised through public offering has been more limited, but the situation is slowly changing. In the UK, the London Stock Exchange has adapted its rules for biotech companies. Normally, to obtain a quotation on the stock exchange, a five year track record and three years of profit were required, a technical impossibility for young biotechnology companies, which usually do not show profits for years after their creation. Now that more appropriate criteria have been set, the number of flotation has dramatically increased in the UK. In March 1994, 11 biotechnology companies were quoted on the London Stock Exchange. That number was expected to double a year later.

As the venture capital and stock market source do not provide enough capital to finance the cash hungry biotechnology industry, new sources of capital have to be found. The industry is now turning to large pharmaceutical companies, which are always keen to spend their resources to increase their research and new drug portfolio. The drawback, for small biotechnology companies, is that they often have to give up a lot in terms of marketing and manufacturing rights, or in equity and management responsibilities.

### Strategies

Because the field has a large capital requirement and it is difficult to raise capital in the EU for a biotech venture, large companies are prominent in the field. On the other hand in the United Kingdom there are a larger than average number of smaller companies due to exceptional arrangements that have been in force since 1993, allowing biotechnology companies to be floated on the London stock exchange without the usual three years record of trading profits.

For the average European pharmaceutical company, alliances or minority shareholdings are generally preferred over acquisitions in the biotechnology field. Large companies see this as a way of allowing smaller, innovative companies the freedom to bring a novel technology to the market, whilst widening their technical knowledge and increasing the opportunities for spin offs. During the late 1980s, European companies spent about 2-3 million ECU sounding out the US biotechnology market by investing in small, specialised Californian companies. The testing period ended when Roche (CH) acquired a 60 % share of Genentech (USA), adopting an aggressive apprenticeship strategy. Since then, European activity in the USA has been increasing. Recently, for example, Ciba (CH) secured a 49.9 % holding in Chiron, a 13 year old biotechnology company in the USA.

For smaller companies, two strategies are possible. Some companies, such as Synergen (US), want to develop a product on their own. While this strategy can bring high rewards, it is also highly risky. In the case of Synergen, the company recently announced it was abandoning the development of its main product, Antril, laying off half of its staff, and putting the company up for sale.

One of the structural problem of the small biotech companies is that they only master a limited numbers of the numerous technologies that constitute biotechnology. Alliances or mergers between small companies, or company networks such as the one set up by Rhône-Poulenc recently, would create entities better able to face the arduous task of developing a new biotechnology product. The new entity can also benefit from economies of scale.

Example of this strategy are Chiron (US), or Celltech (US), which developed a network of alliance, especially with large, cash-rich pharmaceutical companies. Although this involve some loss of independence, they bring new resources, in terms of knowledge as well as in terms of capital, and secure somewhat the future of the biotech companies. This is done at the clinical trial or manufacturing stage for example, where large financial resources are needed. Small companies are then used as a subcontracting laboratory, that creates the new drug, while the large pharmaceutical concern takes care of the testing and marketing, which needs large investments. This structure makes sense as in the pharmaceutical sector, the average development costs for a new drug in smaller companies average is almost 50 % of those of a large pharmaceutical company.

### Impact of the Single Market

It is difficult to assess the impact of the European Single Market programme on biotechnology, as this is more a technology than a product. Indeed, a large number of industries use - or will soon use - biotechnologies in their normal production process (agriculture, pharmaceuticals, food and drink, chemicals, environmental services, etc.). Furthermore, the rapid development of technology has been the dominant factor of evolution in the past 10 years, dwarfing any impact European harmonisation could have had.

However, directives on the release of genetically modified organisms (90/219 and 220) have put a burden on the development of biotechnology in Europe, and several European companies have invested abroad. The definition of new rules on intellectual property rights is viewed as important for the future of biotechnology in Europe. A major concern of the industry is the lack of European harmonisation in regulations linked to biotechnology. Even when directives exist, differences remain important between Member States, as they only set minimum standards to be met.

**Table 1: Biotechnology**  
**Geographical distribution of major pharmaceutical biotechnological companies in Europe**

## ENVIRONMENT

The pharmaceutical sector is presently the largest market for biotechnology and this application has the least impact on the environment.

Biotechnology can benefit the environment directly in several ways. Using biotechnology to improve the ability of bacteria to digest woody material could improve biogas production from sewage works, landfills and agricultural digestors, boosting renewable energy production. It could also reduce the volume of waste from domestic, agricultural and even industrial sources. Bacteria could be designed to provide effective effluent pollution control at much reduced costs. The decontamination of polluted land and water is another possible application. In oil spills, for example, the use of detergents and the consequent detrimental effects to the environment could be avoided through the use of biotechnology.

In agricultural applications, biotechnology could transform modern farming methods. Consequences for the environment are still difficult to assess. On the one side, genetically engineered resistance to pests and diseases will reduce the necessity for artificial pesticides (and improve the environment); resistance to specific herbicides will allow a more effective and selective use of herbicides. On the other side, there are fears that the resistance to herbicides could, in the long run, increase herbicide usage. For example, a genetically modified rapeseed, tolerant to Hoechst herbicide Basta, recently gained marketing approval in the UK. The application is currently in discussion at the EU level. Fears have raised that rapeseed could become a weed if in subsequent years a field is planted with a different crop and farmers may then resort to using even stronger or multiple herbicides.

The safety of GMOs on the environment is another important issue. The industry is highly regulated, both in R&D and in the clinical or field testing of genetically engineered organisms before commercialisation. Currently moves are underway to set out more clearly the procedures applicable for the marketing of biotechnology products.

---

## REGULATIONS

---

On one level, biotechnology is a new set of techniques that modify the way in which a number of industrial sectors are approaching R&D and production. It is therefore subject to all pre-existing regulations controlling those industries.

There have also been various Council directives and regulations specifically in the field of biotechnology.

Registration of biotechnology-derived pharmaceutical products has been the responsibility of the Committee for Proprietary Medicinal Products (CPMP) and the Committee for Veterinary Medicinal Products (CVMP) as regulated by Council Directive 87/21/EEC. As from January 1, 1995, these two bodies constitute the scientific support of the European Agency for the Evaluation of Medicinal Products (EMEA). This new European body will allow for a single application for a community-wide marketing authorisation for new medicines. This should significantly shorten approval cycles for new drugs.

In the area of health and safety at work, Council Directive 90/679/EEC has been adopted to protect workers against the risks to their health and security from exposure to biological, irrespective of whether these are biotechnology-derived or not, agents and to promote the harmonisation of the regulations applied by Member States in this area.

Council Directive 90/219 covers the contained use of GMMs (genetically modified micro-organisms), while Council Directive 90/220 deals with the deliberate release of GMOs in the environment. Both directives require a risk assessment to be carried out before operations with GMMs and GMOs are undertaken. Directive 90/219 foresees different administrative procedures for the several categories of micro-organisms and operations established. A Member State is competent for authorising contained uses and R&D releases taking place in its territory. There exists a European procedure (with the participation of national authorities) for authorising the marketing

of GMOs. After receiving marketing approval, GMOs can circulate freely in the EU.

As announced in its Communication "Biotechnology and the White Paper on Growth, Competitiveness and Employment: preparing the next stage (COM(94)219, 1st June)", the Commission is currently reviewing Directive 90/219, in order to incorporate the wider range of available knowledge and experience, which should result in more risk-based administrative provisions. This is equally expected to bring about the added benefit of a positive impact on European competitiveness.

On the other hand, the EU is currently making an effort to complete biotechnology's regulatory framework by implementing the "one door, one key" policy for the marketing of GMOs. This policy integrates the environmental risk assessment foreseen under Part C of Directive 90/220 in the relevant vertical product legislation. This will eliminate administrative burdens for operators wishing to market biotechnology-derived products. The policy has been fully implemented in the fields of pharmaceuticals and animal feed additives, and is at different stages of development in the areas of food, seeds, plant protection products and feed.

As concerns the juridical protection of intellectual property, the Commission adopted in 1992 a regulation on a supplementary protection certificate for medicinal products, while the regulation on community plant variety rights was adopted in 1994. The conciliation committee between the European Parliament and the Council has recently adopted a common project for a Directive on the legal protection of biotechnology inventions.

Additional proposals under consideration refer to transgenic animals and to the transport of GMOs. The Council of Ministers for Agriculture recently decided on the extension until 1999 of the moratorium on the use of BST (bovine somatotrophin).

A move by the European Commission in 1992 established standards in the field of biotechnology with a program conducted by the European Committee for Standardisation (CEN). The standardisation will complement existing legislative actions, and will allow to reflect technical progress. By building a common approach on technical questions, the program should strengthen the competitiveness of the European biotechnology industry.

Community support is given to the biotechnology research through a number of research programs, including BEP, BAP, BRIDGE, ECLAIR, FLAIR, HUMAN GENOME ANALYSIS, VALUE, and MONITOR, that have been designed to improve basic knowledge and reinforce biotechnology in the EU. The Fourth Framework Programme (1994 to 1998) of the EU allocates 552 million ECU to R&D in biotechnology.

---

## OUTLOOK

---

Given the front-ranking position of the USA, it is expected to continue to act as a magnet for investment. The Japanese industry, too, should experience high growth. Investment is likely to continue to flow out of Europe.

In Europe, according to Ernst & Young, a large proportion of companies expect sales of biotech products to remain flat until 2000. Only 20 % expect their sales to double before the end of the decade. Overall, sales should increase from 38 billion ECU in 1993 to 80 billion ECU in 2000.

## Overview NACE 31

The metal products industry, consisting of many small companies, is a relatively large industry employing approximately 2 million people. During 1984-1991, the EU metal products industry demonstrated a growing trend in production and consumption. In 1992 and 1993, however, the industry was confronted with production and consumption declines due to the economic recession. In the near future, increases in consumption and production are expected as demand from downstream industries has started to recover. Fierce international competition urges EU manufacturers to rationalise production processes and improve quality. To an increasing extent, technical know-how and high product quality constitute the core of EU competitive power.

### INDUSTRY PROFILE

#### Description of the sector

The metal products industry as defined by NACE 31 can be subdivided into seven sectors:

- Foundries (NACE 311) include ferrous metal foundries like iron and steel foundries, and non-ferrous metal foundries like copper and aluminium foundries;
- Forging (NACE 312) includes drop forging, closed die-forging, pressing and stamping;
- Secondary transformation, treatment and coating of metals (NACE 313) includes the manufacture of articles on turning machines, such as lathes, screws, bolts, nuts, springs (except furniture and watch springs) and chains (except articulated link chains); the sintering, treatment and coating of metals; and general mechanical engineering on a subcontract basis;
- Structural metal products (NACE 314) include the manufacture of metal structures and parts of structures (such as bridges and frames); metal doors or windows from rolled angles, shapes and sections; pit-propping equipment; and standard-gauge railway track, fixtures and fittings;
- Boilers and metal containers (NACE 315) include the manufacture of large boilers (including complete furnaces) and other boiler house products, reservoirs, tanks and other containers;
- Tools and finished metal goods (NACE 316) include the manufacture of hand tools and agricultural tools; kitchen and tableware; general hardware like locks and fittings; heavy and light metal packaging products; domestic and kitchen heating appliances; metal furniture (including safes); domestic articles of base metal; small arms and ammunition thereof; and other finished metal products; and
- Other metal workshops (NACE 319) include soldering, welding, smithery, blacksmithery and rural workshops for the repair of agricultural equipment.

It should be noted that there is much overlap between some of these sectors. Aggregate figures on production and consumption should therefore be treated as giving an idea of size rather than stating exact levels. In 1992, tools and finished metal goods accounted for the largest share of total production with approximately 40 % of total EU production of metal products. The shares of the other sectors were much smaller with the manufacture of structural metal products at 16 %,

**Figure 1: Metal products**  
Value added in comparison with related industries, 1993

Source: DEBA

followed by secondary transformation (13 %), boilermaking (12 %), foundries (10 %) and forging (8 %). More than 41 % of total value added of the EU metal products industry originates from Germany. Other major producing countries are France (17 %), the United Kingdom (12 %) and Italy (11 %).

#### Recent trends

From 1984 to 1991, the metal products industry demonstrated a growing trend in production and consumption. In 1992 and 1993, however, the industry was confronted with decreases in production and consumption as a result of the recession. Some downstream industries, such as the building and construction sector were severely hit by the recession, resulting in weak demand for metal products. To prevent EU production

Source: DEBA

from declining as much as consumption, the EU industry increased its extra-EU exports.

The trade surplus has decreased since 1984 as extra-EU imports have grown faster than extra-EU exports. However, an increase in extra-EU exports and the simultaneous stagnation of extra-EU imports have stopped this trend. In 1993, the trade surplus grew by 15.7 % against 1992.

During the 1984-1987 period, employment in the metal products industry declined, but was followed by three years of increases. From 1991 on, however, the industry has been faced with a continuously declining workforce. This decrease is due to cyclical movements and the rationalisation of production within the industry.

Overall labour productivity of the metal products industry has increased at an annual average of 2.6 % from 1984 to 1992. Labour productivity differs among the sectors, however, with tools, boilermaking and forging scoring above average

values, and foundries and secondary transformation accounting for relatively low values.

### International comparison

In recent years EU production of metal products (in constant prices) has declined. While US production recovered in 1992 and 1993, EU production has only started to grow again in 1994. In contrast, the Japanese metal products industry has seen production increase by 25 % since 1990. From 1984 to 1993, the average annual growth rate of Japanese production (in constant prices) amounted to 9 %.

Japanese production in 1993 (in current prices) was almost as high as EU production. The Japanese workforce, however, is only half that of the EU; 963 741 against 2 041 371. If comparing value added per employee, the EU has the lowest value at 3 400 ECU per employee in 1993, while figures for the US and Japan were 5 100 ECU and 7 800 ECU, respectively.

**Figure 4: Metal products**  
International comparison of production in current prices

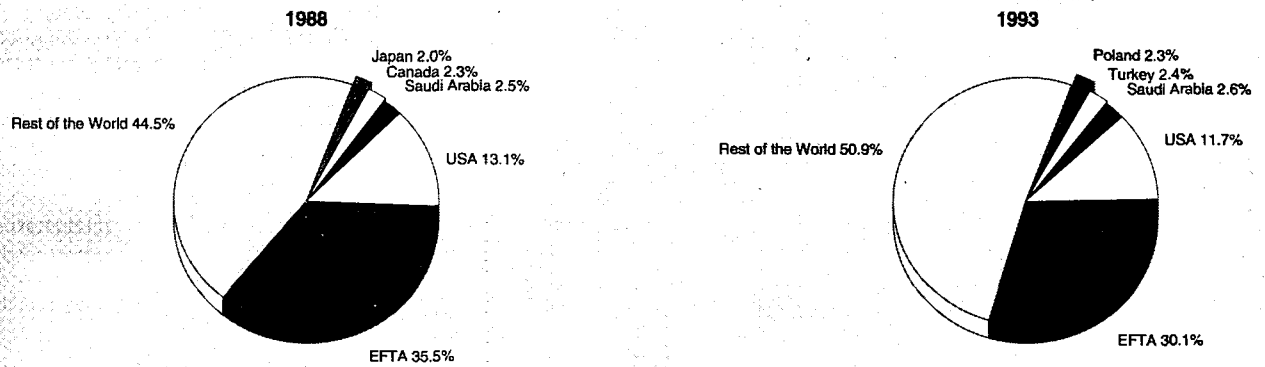

Source: DEBA

**Figure 5: Metal products**  
International comparison of production in constant prices

Source: DEBA

**Figure 6: Metal products  
Destination of EU exports**

Source: Eurostat

From 1984 to 1993, the US saw its production, in current prices, decline by 14 %. Consequently, it has lost its leading position on the global market.

### Foreign trade

The EU is a net exporter of metal products, although the trade surplus has decreased during the 1984-1992 period. In 1993, 30 % of total extra-EU exports was destined for EFTA countries. Other major destinations, though much smaller in share, were the US (11.7 %), and Saudi Arabia, Turkey and Poland, together accounting for 7.3 % of total extra-EU exports.

Extra-EU imports mainly originated from EFTA countries (37.6 %) and the US (12.8 %). Far Eastern countries, like Japan, China and Taiwan accounted for 20.7 % of total extra-EU imports.

The trend in trade is to export high value added products and import low value added items. Hence, there is relatively little extra-EU trade in sectors such as foundries and forging, whereas there is much more in structural metal products, boilers and metal containers, and tools and finished metal goods. Since 1985, the import/consumption ratio has increased from 3.94 % to 6.01 % in 1993. The overall export/production ratio

in 1993 was lower than in 1984, although it has been increasing since 1991. The export/production ratio is highest in tools and finished metal goods (12.3 %), while in forging a relatively low share of production is exported (4.2 %).

## MARKET FORCES

### Demand

The industry manufactures metal products for a wide range of industries. Important client industries are: the automotive sector; the construction industry; mechanical engineering; energy industries; chemical industries; iron and steel industries; household appliances; electronics; transport industries; and, agricultural and horticultural industries. Due to a downturn in these downstream markets, demand for metal products was weak in 1992 and 1993. However, the relative importance of downstream industries varies between Member States. For example, major client industries of the boilermaking industry in France and Germany are chemical industries, while in Italy and the United Kingdom harbour and shipping industries are major clients.

As product processes in client industries are continuously being technologically improved (e.g. automation and robotisa-

Terms of trade index	183.9	178.0	151.2	130.3	107.9	104.5	100.0	87.3	84.8	89.0	N/A

Source: DEBA

tion), demand for standard metal products is increasing. The market has been subject to significant changes in demand, including shifts in the relative importance of major clients. Some of these changes are heavily influenced by environmental developments. With respect to the manufacture of boilers, for instance, demand from the nuclear power industry collapsed, while attention to co-generation or the simultaneous production of power and thermal energy from a common fuel source has grown.

### Supply and competition

There is an ongoing tendency towards concentration in the client industries of metal products. Together with the growing market power of client industries, mutual dependency of the supplier and client industries is increasing.

Due to weak demand in most downstream industries and worldwide overcapacity, prices have come under pressure. Furthermore, competition from former East European countries, where labour costs are relatively low, has intensified. In mass markets with standard products, price competition is fierce. Prices of metal products are somewhat higher, but still competitive, if compared with prices of alternative materials, such as plastic parts, stamping, roll-formed metal and composite components.

The core of EU industry competitive power is sophisticated, high quality, specially designed products. Competitiveness of the EU industry can be further improved if increasing efforts are directed towards R&D. Increased demand for higher efficiency in downstream industries and growing environmental concerns will stimulate manufacturers to direct more efforts

to R&D, which in turn will lead to increasing know-how and comparative advantage in the long run.

### Production process

Production processes in the industry are being technically improved in two ways: rationalisation and specialisation in quality products. Technical criteria are not the only decisive factors in international competition though, products must also be competitive from a cost angle.

Developments in labour productivity, unit labour costs and total labour costs indicate that efficiency increased during 1984-1989. Labour productivity, in current prices, increased at a faster rate than unit labour costs. Weak downstream markets, accompanied by lower capacity utilisation, have caused a stabilisation of labour productivity in the early 1990s. The resulting decline in employment, however, could not prevent an increase of unit labour costs. From 1990 to 1993, these costs rose by 14.7 % against a stabilisation of the labour productivity index. As a result, profitability of the industry has increasingly been put under pressure.

Costs have given rise to a trend for mergers as larger minimum plant sizes are required to cope with necessary investments. Further specialisation is also encouraged by environmental requirements. For example, companies which formerly galvanised their products themselves now leave this to specialised plants. By servicing a number of companies unit costs can be reduced.

## INDUSTRY STRUCTURE

### Companies

In 1990 the EU metal products industry counted 229 087 manufacturers, of which 88 % employed less than 20 employees and 1.8 % employed 100 or more employees. Nowadays, the majority of metal products manufacturers are still small or medium-sized. The large enterprises accounted for 55 % of total turnover and almost 43 % of total employment, while the small firms constituted 19 % of total turnover and employed 28 % of the total industry's workforce.

Among the top ten companies in the world metal products industry four were Japanese, four were US and two were German firms in 1992. Three of the four Japanese companies were involved in structural metal products manufacturing; Tostem, Hitachi Metals and Sanwa Shutter. The US and Japanese companies have subsidiaries in the EU. In terms of turnover, Gillette (US) and Tostem (J) were three times larger than the two top ten German firms (GEA and Buderus). The largest companies in hand tools are Gillette (US) and Stanley (US).

Only one of the ten largest EU firms in the boilermaking industry is located in Germany (Deutsche Babcock). In Germany, there are many medium-sized enterprises. Other large firms involved in the boilermaking industry include: CLN (I); Degremont (F); Saboe Refrigeration (DK); Alsthom (F); Industria Cantieri Metallurgici (I); Dexicon International (UK); Ponticelli (F); and, Aalborg (DK).

The secondary transformation industry is, like the metal products industry as a whole, characterised by many small and medium-sized enterprises. There are only a few companies that could be classified as medium to large enterprises, with sales over 100 million ECU.

### Strategies

In recent years, the metal products industry has: trimmed inefficient capacity, introduced raw material cost-control measures; installed new-technology processors; improved productivity; and, started to emphasise niche-marketing, concentrating either on high-volume work or specialised low-volume products.

Fierce price competition, due to increasing volumes of cheaper imports, urges manufacturers to improve productivity and re-consider their product-mix. In addition, saturation of the EU market urges manufacturers to look for new markets, possibly to be found in Eastern Europe.

Rationalisation of production processes and establishment of production capacity in low wage countries will enable manufacturers to lower production costs. Quality improvements and after-sales service are particularly important in high-income Western industrialised countries. In a recessive economy, in which consumers tend to concentrate on prices, rationalisation is increasingly being used as a strategic tool to remain competitive.

### Impact of the Single Market

The overall impact of the Internal Market programme on the metals products sector has been globally positive. The main positive effects have been from the necessary reorganisation of the sector and from the fact that firms have started to act more globally. The other positive effects which were aimed for are, however still to come. Technical harmonisation according to international standards, the clarification of directives and the transposition of the EU legislation into national laws are considered to be the next priorities in this sector.

### REGIONAL DISTRIBUTION

The industry has local, regional and global aspects. Manufacturers who operate on a small scale and depend on demand from downstream industries, tend to be located in areas where these industries are concentrated. Because of the small scale of many firms, long distance transport is not viable in general. Furthermore, to lower transportation costs, most metal parts industries are located near their clients; e.g. near major industrial centres. At the same time, however, large firms in the industry, for example in the hand tools industry, have a global orientation.

### ENVIRONMENT

The European Union's (EU) Working Party on the Definition of Waste has endorsed a proposal stating that if a material may be used by a third party after a transformation, it can be considered a product. Industry groups in Europe, however, are still concerned that the EU's regulation for implementing the Basle Convention will hinder the trade of scrap metal and other materials.

In technology development, the metal products industry pays a lot of attention to environmental issues, such as reduction of emissions. For recycling metals out of waste disposal, most small and medium-sized enterprises use third party firms. Regarding intra-EU competition, a coherent approach in ecological issues is necessary, otherwise distortions in competitive power will arise. The EU has become more active in this area with the carbon tax proposal and, more general, its fifth action programme on the environment: "Towards sustainability. A European Community programme of policy and action in relation to the Environment and sustainable development".

Some environmental issues especially apply to downstream industries and, therefore, indirectly affect the upstream metal products market. In an attempt to meet the needs of their clients, manufacturers of metal products put efforts in to product innovations concerning safety and environmental issues.

**Table 7: Metal products**  
**Breakdown by size of enterprise, 1990 (1)**

(%)	Number of enterprises (units)	Share of enterprises	Share of employment	Share of turnover

 Source: DEBA

The Machine Directive (89/392/EEC) will attain its definite character in 1995. In response to customer requirements for a safer working environment, the industry has put much effort into R&D for improvement of safety conditions of equipment. This Directive defines essential requirements concerning machine safety, health provisions for people and the environment. Manufacturers that comply with the provisions of the Directive may affix the CE-mark on their products.

## REGULATIONS

Standardisation is important to this industry. DIN standards, a German quality standard, and ISO standards are used to indicate quality. Most companies in the metal products sector support the initiative to make ISO 9000 standards compulsory, not only for EU manufacturers but also for importers.

EU energy policy will have a major impact on upstream industries of the energy sector, like the metal products industry. The debate on the introduction of a carbon tax in the EU is an issue which deals with EU energy policy. In the long run, such a tax might affect total energy consumption and could, therefore, lower demand for metal products. At the same time, however, the metal products industry could also benefit from

a growth in demand for more efficient processing techniques in downstream markets.

---

## OUTLOOK

---

In the downstream industries of the metal products industry a further recovery of demand is expected. At the same time, structural measures (rationalisation and quality improvement) will have a favourable impact on the industry's competitiveness and performance. Therefore, in the short and medium term, EU production and consumption in the metal products industry are expected to grow. Extra-EU imports will benefit from an upswing of EU demand and are expected to grow slightly faster than extra-EU exports, which will result in declining net trade.

It is further expected that despite the upswing, the workforce in the EU metal products industry will continue to decrease. Despite favourable prospects in the short and medium term, future risks for the industry include: too much dependence on downstream industries and intensifying international competition. However, an expected increase in demand for innovative equipment will stimulate the industry to retain a comparative advantage against other countries resulting from better know-how.

# Foundries

## NACE 311

The EU is one of the world's largest producers of castings with an annual output valued at about 20 billion ECU. The greater part of this output is supplied as components to the motor and machinery manufacturing industries.

The structure of the foundry industry is characterised by small and medium-sized enterprises. Many foundries are part of a larger company and produce castings for internal requirements. The substantial fall in employment while output has largely remained constant clearly shows the rise in labour productivity over the past ten years.

The EU's trade balance is in surplus. Up to 1992, however, imports rose faster than exports. Only in 1993 was there a reversal of the trend.

### INDUSTRY PROFILE

#### Description of the sector

Foundries are industrial suppliers. The castings they produce are normally used as intermediate products in other industrial companies. Cast end-products remain the exception.

Castings obtain their shape from the pouring of molten metals into a mould to solidify. This leaves the designer basically free to determine their shape, with the result that both the surface and the cavities may be very complex. Depending on whether the molten metal is given the shape corresponding to the desired product under the influence of gravity, centrifugal force or pressure, in other words, depending on the technique used for making the mould, the following types of casting are distinguished: sand casting, shell moulding, gravity die casting, pressure die casting, centrifugal casting, continuous casting, investment casting, precision casting, and art casting.

Another possible classification is to make the distinction in terms of the materials used. This classification forms the basis of this paper and also of NACE. A distinction is made in NACE 311, foundry products, between:

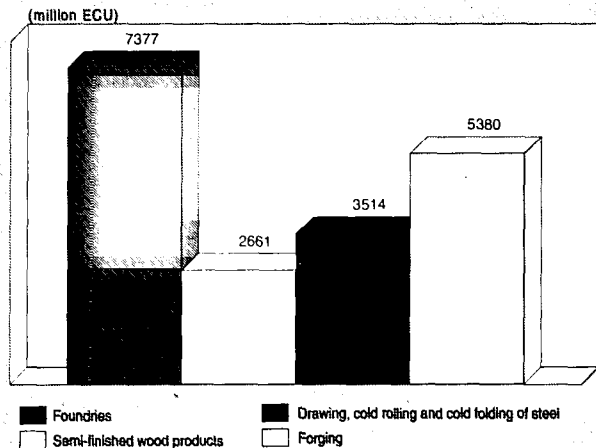

- ferrous metal castings (NACE 3111): grey cast iron, ductile cast iron (nodular cast iron/malleable cast iron), steel castings and stainless steel castings;
- non-ferrous metal castings (NACE 3112): mainly aluminium, copper and zinc.

For each group there are innumerable alloys. Some are standardised. Many are specially developed to meet the customer's specific requirements. Foundries quite often offer up to 200 different qualities or alloys.

The availability of statistical data and their degree of detail vary greatly among individual EU countries. Particularly unsatisfactory is the foreign trade data. Many foundry products do not have a commodity number of their own in the foreign trade statistics. They are grouped together with other products under "miscellaneous products". This applies particularly to components supplied to the automobile industry.

In the past, many foundries were established in the vicinity of coal mines or close to iron and steel production locations. In other words, the locations of the foundry industry were raw-material-oriented. Over the course of time, the raw-material orientation has been increasingly replaced by customer orientation. Concentrations of foundries are now found in areas near the locations of their major customers, the automobile and mechanical engineering industries.

#### Recent trends

As manufacturers of intermediate products and components, foundries depend to a great extent on the business conditions in the markets of their (most important) customers. For example, in the late eighties the strong growth in the automotive and mechanical engineering manufacturing industries resulted in an equally strong growth performance of the foundry industry. On the other hand, the drop of demand for cars and machinery at the beginning of the nineties caused a sharp decline in foundry production, by as much as 40 % in some cases. Since 1994 production has been rising again and this trend should continue in 1995.

This should also bring an end to the shedding of labour. However, even in the case of a sustained recovery only a very small number of new jobs can be expected. Most of the almost 60 000 jobs that have been cut since 1990 - around 20 % of the total - have probably been lost permanently.

The deep recession and the time lags inherent in all employment restructuring measures have obscured long-term trends

Source: DEBA

if production and employment. The available data suggest, however, that over the past ten years the volume of output per employee has risen by 20 %, and the value added per employee even by 30 %.

This highlights the trend towards higher-quality castings. Firstly, the share of non-ferrous metal castings in the total output has risen from 13.1 % to 16.8 %. Secondly, the castings have become increasingly thin-walled, lighter and more complex to manufacture.

The EU's foreign trade balance is positive. In the years up to 1992, however, the surplus has shrunk steadily. In 1984, the quantity of cast products exported was 2.9 times as great as that of imports. In 1992 the corresponding figure was only 1.6. In 1993 export/import ratio rose again to 1.7, and will in all probability stabilise at this higher level.

Regionally, the industry is strongly concentrated within the EU. Germany alone accounts for 40 % of the value added

of the European foundry industry. It is followed by France with 17 %, the UK with 15 %, Italy with 14 % and Spain with 7 %. The five largest manufacturing countries account for 93 % of total EU production.

Personnel costs in the foundry industry represent 50 % of production costs. The ratio of the sector's value added to the value of its output is correspondingly high.

**International comparison**

There have been and still are great uncertainties concerning production in the former USSR and its successor states. According to the latest publications, the output of the Commonwealth of Independent States in 1992 was 14.3 million tonnes. 60 % of this was accounted for by Russia alone. There are equally great uncertainties about the production of the People's Republic of China, which is said to have risen from 8.9 million tonnes in 1990 to 11.6 million tonnes in 1992. Even the es-

International comparison of production in constant prices**

Source: DEBA

**Figure 6: Foundries  
Destination of EU exports**

Source: Eurostat

timates for the production of the USA show considerable variation depending on the source.

Consequently, any statements about the world ranking of EU production must inevitably be imprecise. At 10.7 million tonnes in 1992 the production of the EU was approximately equal to that of the USA. Japan produced 7.2 million tonnes in that year. It is certain that the shares of the individual materials are similar in these three economic areas. This applies especially to the share of non-ferrous-metal castings in total production, which is between 14 and 17 %. This share is expected to increase over the next few years.

#### Foreign trade

Cast products are made to order according to the customer's specifications and on his behalf. Furthermore, they have to meet increasingly stringent demands. Both these factors necessitate close co-operation and intensive communication between the foundry and the customer. In addition, consideration of the high specific and sometimes absolute weight of castings and their value to weight ratio, together with "just in time" delivery difficulties greatly restricts transportation possibilities (or trade, for that matter) over great distances.

The importance of foreign trade is correspondingly slight in comparison with other branches of the economy. In the five most important EU countries, exports represent barely 15 % of the value of output. The share of imports in consumption is less than 5 %. By far the largest proportion of foreign trade takes place with neighbouring countries: either EU Member States, EFTA countries, and, since recently, Poland and the Czech Republic.

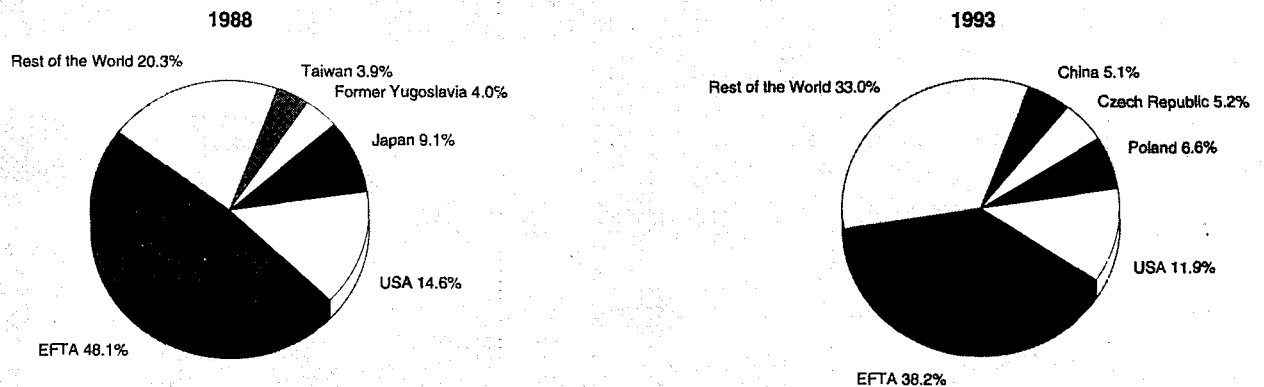

Shipments to distant countries are the exception. They chiefly consist of components or spare parts for plant construction and their value is, as a rule, very high.

#### MARKET FORCES

##### Demand

By far, the largest customer of the foundry industry is the automobile industry. Over 70 % of the output of light-metal castings (chiefly aluminium alloys) become components for road vehicles. In the case of ferrous metal castings, the percent of total EU production shipped to the automobile industry is approximately 35 %. In Germany the corresponding figure is even 42 %.

(2) DGV estimates.

Source: CAEF, "Modern Casting"

Next, is the mechanical engineering industry. Due to the strong world positions of the German mechanical engineering and plant construction industries, supplies of castings to these industries attain their highest levels in Germany. In 1993, 750 000 tonnes of grey cast iron and spherical graphite cast iron, representing 28 % of all deliveries, went to the mechanical engineering industry; at the end of the 1980s this share was over 30 %. In Italy the share of deliveries to the mechanical engineering industry in total deliveries by the foundry industry also equalled 28 %, but represented here a lower absolute volume than in Germany.

Pressure pipes, pipes and castings are the most important end-products of the foundry industry. They played the greatest role in France where they accounted for 30.1 % of total output of grey iron and of nodular iron. Their value (ECU/kg) is, however, fairly low.

The foundry industry cannot actually be said to be a growth industry. If business cycle influences are eliminated, hardly any change has taken place in the tonnage produced during the past ten years. The fact that the value of production has risen during the same period reflects the shift towards higher-value, through lighter, thinner-walled, and complex cored component castings and towards lighter alloys, especially aluminium-based ones.

**Figure 8: Foundries**  
**Trade intensities**

Source: DEBA

Casting, as a basic forming process, is in direct competition with sintering. In practice, however, particular competitive processes are those of metal reshaping, specifically: forging (hammer forging or drop forging), rolling, pressing (extrusion), drawing and deep drawing. There are also the processes of connection technology comprised of welding, bonding, riveting and bolting.

By far the most important factor in recent years, has been the competition between metals and substitutes such as plastics. The proportion of the latter in motor vehicle manufacture, the making of household articles, pipes or connecting pieces has grown steadily in recent years at the expense of metals demand. The reasons which are leading to the replacement of one material by another include: weight, tensile strength, resistance to pressure and wear, resistance to heat or to rust and acid, ageing behaviour, price and recycling possibilities.

In the future, mineral products such as ceramics or composite materials appear likely to gain market share held by foundry products. Whether they can become generally acceptable will depend chiefly on their price and whether their ability to meet stated specifications.

### Supply and competition

As material intensity is decreasing in practically all branches of the economy, specific consumption of castings is also declining, as evidenced in the automobile and mechanical engineering industries. The growth rates of the foundry industry are lower than those of their main customers (as became evident, for instance, at the end of the 1980s) and resulted in an appreciable decrease in the long run quantity produced when compared to the quantities produced in 1970 or 1980.

Accordingly, the existing melting, moulding or fettling capacities are more than sufficient to meet demand. This leads to intense competition between foundries, and also makes their market position weak in relation to their main customers. Because of the overcapacity and strong buying power of the major customers, foundries do not have much leeway in price setting, thus creating a low profit to sales ratio.

In view of the EU's single market, the most important repercussions are likely to result from international calls for tender for public contracts. They affect, in particular, manufacturers of pipes, pressure pipes and moulded conduits. Furthermore, liberalisation in the transport sector may lead to lower freight rates. Both of these factors not only widen the foundries' range of action, but also shift the competition between foundries from the national to the international plane. To ensure that this competition takes place under fair conditions environmental protection regulations and non-wage labour costs must be harmonised.

Most of the production of the foundry industry is delivered directly to customers. This is particularly true in the case of mass-produced castings for the motor industry, where just-

**Table 6: Foundries**

Source: CAEF

in-time deliveries on the basis of long-term contracts are common. In this case the marketing costs, measured as a proportion of the cost of production, are relatively low. On the other hand, marketing costs are far higher in the case of single-piece production or short production runs for the mechanical engineering industry (unless assembly and conversion take place in-house, within the same firm). The foundry must then maintain its own field sales force, and sometimes even branch offices. Usually in distant regions and abroad sales representatives are employed on a commission basis.

### Production process

The making of castings continues to be very labour-intensive. Even where the production process is highly mechanised, for example in large-scale series production, the proportion of personnel expenses in the production costs is 40 %. In the case of hand casting, i.e., individual production, the proportion of personnel expense to total cost is as high as 55 %. As a result, efforts made to step up labour productivity and reduce personnel expenses have been correspondingly great.

Metal materials account for 15 to 25 % of production costs. The range is due to the differing nature of the materials to be produced, as well as to the ore mix, which in turn depends on the melting equipment. Factors affecting the proportion of raw material costs in the total production costs are: whether an initial melt is being produced; whether a material is merely being re-melted; and the proportion of scrap, pig iron, (ferrous) alloys or high-grade pure metals contained in the melt. Lastly, the influence of market prices should not be underestimated. Between 1989 and 1993 the foundries benefited from a decline in raw materials prices, but they are now confronted again with rapidly rising raw material prices.

The proportion of capital costs, depreciation and interest costs fluctuates between 10 % and 15 % of total production costs. It depends chiefly on the production technique and is naturally larger in the case of highly automated large-series production than in that of hand-moulded individual parts.

Finally, energy costs must be discussed. Here, foundries still operating with cupola furnaces are the most economical since coke is the main source of energy. Rising quality demands, the decline in the share of grey iron castings and, conversely, the increase in the amount of cast iron using nodular graphite are, however, causing many foundries to switch to electric furnaces. The share of energy costs for foundries using electric furnaces can rise 15 % of total production costs.

## INDUSTRY STRUCTURE

### Companies

The foundry industry has been able to retain its character as a sector mainly composed of small and medium-sized firms. More than half of all foundries still have fewer than 50 employees, and many are still family-owned. Some of them, as jobbing foundries, work only for other companies. Often, however, they are also part of a larger undertaking, which predominantly produces castings "to meet its own requirements", for instance for use in mechanical engineering and plant construction.

There is no observable trend towards larger company units. Investment in recent years has been mostly for the purpose of increasing labour productivity. A breakdown between iron, steel and malleable-iron foundries and non-ferrous-metal foundries reveals that on average, the former have an appreciably larger number of employees than the latter.

Nevertheless, technical progress has led to the emergence of a few large companies in the foundry industry. For instance, the production of large series has become much more economical due to the development of automatic moulding plants. The increase in capital-intensity, however, has necessitated two or even three-shift operations. This has led to the creation of production plants with up to a thousand employees. These usually specialise in making castings for the automobile industry.

### Strategies

Rationalisation and automation has brought about, among other things, automation of sand preparation, the development of automatic casting plants and the development of induction and holding furnaces. In the future, the greatest successes will probably be achieved by the use of CAD/CAM in pattern making and fettling.

The demands made of castings are becoming increasingly high and varied. This will necessitate the development of new materials with ever-narrower dimensional tolerances. Castings are becoming thinner-walled, lighter and harder to core with the cavities and surfaces becoming more complex. Other castings are required to be made in ever-increasing size and thus of ever-greater weight. The result is that foundries, too, are specialising more and more and that the industry is steadily becoming more heterogeneous.

Therefore, one cannot speak of general or uniform foundry strategy. An important current topic is the extension of the value added chain from the raw material phase to the end product. The enterprises involved in production (in different industries) may be faced with the need to restructure the distribution of functions within the chain. For foundries, this could mean taking over research and development functions, taking over mechanical processing operations and, via the supply of ready-to-fit components, increasing their own value added.

Where foundries are taken over by other companies, they typically continue to be operated as profit centres of the new owner. The size and equipment of the production plant does not usually change much. That being the case, there are two main reasons for a take-over: the acquiring company's need for castings for their own production to make them independent of other suppliers; and the need to offer customers the complete range of the foundry sector's products, from light-metal to

fine-steel castings, from hand-moulded to automatically moulded castings, and from small to large castings, etc.

### Impact of the Single Market

The impact of the creation of the Single European market on the foundries industry has been rather limited, and certainly not as high as in other industries as most companies in this sector are mainly regionally oriented. Only a few operate internationally, and those which do have been doing this for many years. The industry mainly consist of SME's and is very flexible. The SME's are being threatened by low-priced imports from Eastern European countries, however, as these countries have access to cheaper raw materials (the EU supply of steel is not enough for self-sufficiency). Wages are also much lower in these countries. In spite of these competitive advantages, dumping has been observed in some cases. The industry has high expectations with respect to the application of the new anti-dumping directive. Priorities to be addressed include the end of state aid for operational losses.

### ENVIRONMENT

Great importance has always been attached to recycling in the foundry industry. This applies particularly to the most important materials used, namely sands and metals. Sands are reconditioned, and metals re-melted. Used castings are returned to the production circuit as cast scrap via trade channels.

Even so, total avoidance of waste is not possible. Certain residual materials, especially thermally exhausted moulding sands, which have to be disposed of at tips, will always accumulate. Nevertheless, the foundry industry is in the process of devising economically defensible methods of further reducing the quantities of such residual materials.

Keeping the air clean, particularly dust removal, is presently the foremost environment protection measure for many foundries. Strict regulations have to be met. In most cases this will require substantial investments.

All foundries may not have sufficient financial resources to afford the requisite investment. These companies may have to stop production after the regulation phase-in period. For most foundries, earnings will deteriorate further if the costs entailed by environmental protection cannot be passed on to customers. In this respect, the regulations should be well considered and balanced, at least within the EU to curtail the loss of competitiveness of foundries located in countries with stricter environmental policy.

### REGULATIONS

There are no specific EU directives or regulations which apply exclusively to foundries. Foundries are, however, affected by all provisions relating to: protection of the environment, non-wage labour costs, trade with associated countries in Eastern Europe, energy prices and public charges (e.g., for waste disposal) and taxation (local business taxes, property tax, corporation tax).

## OUTLOOK

The recession from 1990 to 1993 hit the foundry industry hard. In 1994 prospects for the industry finally improved. During the recession radical measures were taken to restructure capacity and employment, and capital investments were made to rationalise production processes and improve environment protection. As a result the industry looks ahead with a fair degree of optimism. Nevertheless, the volumes reached in 1989, the peak of the last cycle, will probably not be attained. Moreover, 20 % of employment in the industry has been permanently lost since 1989.

The performance of the foundry industry will remain very dependent on the performance of downstream industries, particularly the automotive and mechanical engineering industries.

In the future, it will be important for foundries to further improve quality and develop new materials and production processes. The distribution of functions between individual enterprises participating in the value added chain from the basic product to the finished article present foundries with additional opportunities. For example, they could focus on increasing their value added by supplying ready-to-fit components.

Against the background of the labour-intensive production, investment will aim towards rationalisation, further raising the productivity of labour. Progress can be expected to result from the use of CAD/CAM systems in pattern making and fettling since both remain very labour-intensive manufacturing stages.

**Table 11: Foundries  
Expected real annual growth rates**

(%)	1993-94	1994-97

Production	2.0	0.1
Extra-EU exports	-0.3	1.0

Source: DGV

Reducing the production cycle length, minimising production rejects, attainment of "just in time" delivery and quality improvement will be important for the future international competitiveness of EU foundries.

# Forging

## NACE 312.1

The forging industry is a typical sub-contracting industry consisting largely of medium-sized businesses. Important customers for these firms are the motor industry, mechanical engineering, electrical engineering, aircraft constructors, etc. With a production volume of just over 2.7 million tonnes the forging industry in the EU surpassed both the United States and Japan in 1993. From 1990 to 1993 a drop in the forging industry's output was recorded due to the economic situation in Europe. At the end of 1993, and especially during 1994, not only was the downward trend halted, but it was possible to increase the output of forged parts once again as a result of strong demand. Comparing 1994 with 1993, we can expect an increase in output of at least 10 % for forges in the EU. Prospects for 1995 indicate further upward movement.

### INDUSTRY PROFILE

#### Description of the sector

The majority of forges are sub-contracting firms. In addition to their own products, such as crankshafts, tensioning systems for the construction industry and shaped components for pipelines, they usually offer finished products based on customers' drawings on the free market. Hammer forges are, in some instances, production departments of larger enterprises such as steel works. Drop forges and manufacturers of extruded parts, flanges and shaped components for pipelines are mostly medium-sized undertakings. Only where the repetitive manufacture of very large quantities is involved do some motor vehicle and bearing manufacturers produce individual items in their own production shops.

The following groups of products are included under the heading of "forged parts": hammer forgings; drop forgings, including hot extruded and upset parts; flanges and shaped components for pipelines; and, cold extruded parts. In most cases, forgings are semi-finished products which still require further processing such as heat treatment, surface treatment or machining. When special forming processes are used, items ready for installation can also be manufactured.

Forgings are manufactured with or without preheating of the blanks (usually sections of rectangular or round bars or shaped parts from thick sheets) by means of shaping tools that are brought together. Hammer forgings can be produced with simple, flat or round tools and incorporate a machining allowance of several millimetres. With drop forgings, flanges, shaped components for pipelines, and extrusions an attempt is made to get as close as possible to the final shape of the workpiece by means of a correspondingly high expenditure on tooling. Working surfaces or forged products ready for installation can, in many instances, be produced by a combination of manufacturing processes.

A wide range of steels and also non-ferrous metals (Al, Mg, Cu, brass, Ni alloys, etc.) can be shaped by forging. Differences in the deformability of the various materials determine the type of manufacturing process to be used and also set limits on the shapes and precision that can be achieved. The desired characteristics of the products with regard to strength, structure, ease of machining, etc. are obtained either through the production process itself (heat treatment from the heat of forging, strain hardening, etc.) or through subsequent processing (annealing, quenching, strengthening shot-blasting, etc.).

The forging industry manufactures products of high quality which offer substantial advantages for users, particularly from

**Figure 1: Forging**  
Value added in comparison with related industries, 1993 (1)

the point of view of weight, resistance to breakage, service life and consistently high quality.

### MARKET FORCES

#### Demand

Countries belonging to EUROFORGE produced over 2.6 million tonnes of steel forgings in 1993 and were the largest producers of forged parts, ahead of Japan and the USA. By far the largest share of forged products (67 %) consisted of drop forgings. Since 1990, however, the trend in the volume of production has been downward in most Member States (see Figure 4). The reasons behind this are, essentially, the poor economic situation in mechanical engineering and the decline in motor vehicle production.

In 1994, thanks to the general economic revival in the EU, output of forged parts has been able to increase. Comparing 1994 with 1993 we can expect an increase in output of at least 10 %. For 1995, there are also indications of a further

rise in output in the forging industry. This outlook is based on the favourable economic forecasts issued by its main customers, the motor vehicle, mechanical engineering, and electrical industries.

## INDUSTRY STRUCTURE

### Companies

The structure of the forging industry is predominantly based on medium-sized companies. However, it is apparent that concentration and cooperation activity across national borders is increasing.

About 150 forging companies are active in the Federal Republic of Germany. They account for about 55 % of the EU's output and are the top producers in the Western world. The companies are based in: North Rhine-Westphalia (75 %), Baden-Württemberg (11 %), with the remaining 14 % divided equally between the West German Länder and the former East German Länder. These companies exhibit the following size structures: 36 forges employ over 200 people, 31 have

between 100 and 200 employees, 32 between 50 and 100, and 51 employ fewer than 50 people. The large companies include Thyssen, Gerlach and Peddinghaus.

In Italy, which accounts for 20 % of EU output, most companies are based in the North. In particular, Piedmont, the Turin area, Lombardy, the Como, Varese and Brescia regions, Veneto and Emilia Romagna. The most important firms are Teksid, a Fiat subsidiary (90 % of its production goes to the motor industry), the Erber Group, Riganti and Casartelli. In Lombardy, 10 % of the companies produce 50 % of the total output. Apart from Teksid, most of the forging companies are family businesses.

In the United Kingdom, which represents 8 % of EU output, the majority of the manufacturers of smaller forgings are based in the Midlands and the Birmingham area. Large forgings are mostly manufactured in the Sheffield area in South Yorkshire. The largest undertaking is the forging business of United Engineering Steels Ltd which produces about 45 % of UK output. Other important forging companies are Firth-Rixson, the INCO Group and Wyman-Gordon Ltd.

In France, 72 companies are active in this sector and they represent 11 % of EU output. The forging companies are distributed among the regions as follows: 25 in the Ardennes, 6 in the Loire region, 14 in Eastern France and 27 in other regions. Three groups dominate the sector: Ascometall, Forges Stéphanoises and Forges de Courcelles.

In Spain, 37 companies are engaged in this sector and account for 5 % of EU output. Most of them (about 30) are based in the Basque country, while the others are distributed among Catalonia, Aragon, Madrid and Galicia. Eight companies employ over 150 people, 5 between 100 and 150, 9 between 50 and 100, and the remainder have fewer than 50 employees. The most important companies are: P. Echeverria SA, La Forge Casanova SA, Forgas de Villalba SA (Gekanor Group) and Forges de Galicia SA which together produce about 60 % of Spain's total output volume.

**Figure 3: Forging Sales by end market, 1993 (1)**

(1) NACE 312.11.  
Source: Euroforge

In Belgium, which only accounts for 1 % of EU output, there are eight companies working in the forging sector. All the companies are small or medium-sized businesses. Drop forgings in steel are produced by four companies, while two forges specialise exclusively in non-ferrous metals forgings and two are engaged only in hammer forging.

No account is taken of the Netherlands, Ireland, Denmark, Greece or Portugal in this report, as they do not have significant forging industries.

### Strategies

The severe pressure of competition, brought about by excess capacity, price reductions demanded by customers, and substitution forced the forging companies, early on, to develop strategies that would ensure the competitiveness of their products even in an enlarged market. These include, among other things: strengthening their export activities, while specialising and concentrating on particular segments of the market; reducing the multiplicity of products, combined with optimisation of the products using computerised methods (CAD/CAM/CAQ, FEM, etc.); increasing productivity by rationalising production with the aid of linked or automated plants; developing new materials with the aim of reducing the cost of the starting material or simplifying further processing operations (e.g. heat treatment, machinability); producing more precisely dimensioned workpieces in order to reduce the cost of finishing work; increasing the added value, e.g. by manufacturing completely finished workpieces or producing assemblies; and, improving and safeguarding the level of quality through the use of modern methods of quality assurance geared to the forging industry (FMEA, SPC, etc.).

Cooperative work plays an important part in the achievement of these aims. For the forging industry, which is predominantly structured around medium-sized companies, this is an essential measure to secure their continued existence. The financial strength of an individual company would not be sufficient to enable it to finance several fairly large projects at the same time on its own. Examples of such projects are CAD/CAM/CAE and quality assurance projects for the forging industry, as well as, numerous activities of an industrial administration nature.

With the increase in "just in time" deliveries, proximity to the customer is an important aspect when selecting a supplier. Consequently, the trend for forging companies to establish branches abroad or to enter into cooperation agreements will intensify.

**Figure 4: Forging Production by country (1)**

(1) NACE 312.11.  
(2) Including former East Germany from 1991.  
Source: Euroforge

Competition in the markets for forgings will also be affected by substitution. To a limited extent, cast products, sintered parts, composite materials and sheet metal constructions (or combinations of these) are offered as substitutes. Which product is ultimately used depends on a number of factors related to its purpose. Reliability, safety, weight, service life and environmental compatibility are all important criteria for decision making, as well as price.

### Impact of the Single Market

The impact of the Internal Market programme on the forging industry has been limited so far. Intra-EU trade has always been substantial in this industry. Therefore, any positive impact of the Single Market on trade is difficult to quantify. Still, the enlargement of both the European and the global market has led to strategies that ensure the competitiveness of forging products. One of these strategies is cooperation. Medium-sized enterprises in particular increasingly co-operate, notably concerning financing matters, to enable engagement in large projects.

Apart from the limited direct impact of European integration on the forging sector, more indirect and in most cases positive impacts derive from the effects of the Single Market on client industries (the motor vehicle, mechanical engineering and electrical industries).

---

### ENVIRONMENT

---

A substantial proportion of investments in the forging industry have been applied to environmental protection measures. The emphasis has been on measures to reduce noise, necessitated by legal constraints, to save energy, e.g. by equipping furnaces with recuperation apparatus, replacing the expensive compressed-air drives on power hammers with electro-hydraulic systems and using waste heat in the forging process. Expenditure on environmentally compatible waste disposal has also substantially increased.

An important advantage of forged products is the excellent opportunity for the recycling of forging materials. This is just one factor that has enabled substitution by plastics to be reduced, which was increasing markedly a few years ago.

---

### OUTLOOK

---

Despite the strategies that have been developed, dependence of forges on their main customers will continue unchanged. Unfortunately, the level of production achieved in the EU in the boom year of 1990 is unlikely to be reached again in the foreseeable future. But, the trend towards larger corporate units will continue and intensify. Measures taken by the forging industry to secure their competitiveness in the market will ensure that forgings will continue to make up an important proportion of industrial production in future years. Areas of opportunities for the industry are in: innovative product development; high quality standards; flexibility; and service.

As customers for forged components open production plants outside the EU, questions of location will have to be addressed. In addition, future risks for the forging industry include: dependence on the cyclical fortunes of the main customer industries and increased competition from Eastern Europe and non-member countries.

# Secondary transformation of metals

## NACE 313

After a period of high growth during the 1980s, accompanied by high investments in new plants, worldwide stagnation in demand has resulted in overcapacity and pressure on prices. In 1993, production output in the secondary transformation industry dropped back to 1989 levels, leading to a decline in total employment. In 1994, however, some signs of recovery can be observed. Prospects for the near future are favourable, although growth rates will not reach their averages of the 1980s.

### INDUSTRY PROFILE

#### Description of the sector

The products of this industry are highly diversified and can be divided into the following categories:

- manufacture of articles on turning machines or lathes, including the manufacture of turned screws (NACE 313.11);
- nuts, bolts, rivets, screws and related products (NACE 313.12);
- springs, except furniture and watch springs (NACE 313.2);
- sintering of metals (NACE 313.3);
- chains, except articulated link chains (NACE 313.4);
- treatment and coating of metals, including zinc coating, aluminising, anodising, enamelling etc. (NACE 313.5); and
- general mechanical engineering on a subcontract basis (NACE 313.6).

In general, the most important subsectors are the fasteners industry (the first two categories) and the treatment and coating industry (galvanising).

Fasteners can be further divided into two main categories: those which are used for construction purposes, and those which are used for assembly purposes. From a market point of view, fasteners can be divided into common fasteners and special fasteners. In the first category price is important, in the second, quality, marketing and delivery time are important.

The purpose of zinc coating is to improve the qualities of the metal. This can be done by several techniques, such as electrolysis. Galvanising, formally "hot-dip" galvanising, involves coating steel with zinc by immersion in molten zinc metal.

In terms of value added the secondary transformation of metals is a relatively small industry. In 1993, the industry's value added was 10 229 million ECU against a corresponding figure of 51 054 million ECU for the assembly of motor vehicles.

Within the EU, France and Germany together accounted for 62.5 % of total value added in the secondary transformation of metals industry. They are followed, at a distance, by Italy, Spain and the United Kingdom, who together constituted 32.5 % of total value added in 1993.

#### Recent trends

Over the period 1984-1991 the industry's production increased by an average rate of 9.2 % per annum. In the same period, apparent consumption of secondary transformed metals demonstrated a similar annual growth rate of 9.5 %. The steady

**Figure 1: Secondary transformation of metals**  
Value added in comparison with related industries, 1993

Source: DEBA

growth in production and consumption was accompanied by a 21 % increase in employment during the same period.

In 1991, the first signs of stagnating markets could be detected. These signs were followed by declines in both production and consumption in 1992 (4 % and 4.2 %, respectively) and 1993 (10.4 % and 10.7 %). In the EU, the strongest declines were seen in Belgium, Denmark and Italy. However, the market declined in other parts of the world as well. Production decreased in Japan by 3 %, in South Africa by nearly 7 % and in Australia by 14 % during 1993.

#### International comparison

The EU and Japan are of equal size if production value is measured in ECU. If compared with the situation in 1984 though, Japan's production has increased more rapidly than EU production. The USA, on the other hand, has suffered a decline in production since 1984. These figures are, however, strongly influenced by changes in exchange rates of the ECU against the Japanese yen and the US dollar.
