In 1993 approximately 18 million tonnes of metals, in 2 100 to 2 500 plants, were galvanised worldwide after fabrication. In the same year, Japan's hot-dip galvanising amounted to nearly 1.9 million tonnes. In comparison with Japan, the German galvanising industry is of minor importance. Within the EU, however, Germany is by far the largest country in tonnes galvanised with more than 1.1 million tonnes. Italy ranks second with 729 000 tonnes, followed by France (602 000 tonnes) and the United Kingdom (together with Ireland constituting nearly 600 000 tonnes).

If the consumption of zinc is viewed separately, Germany retains its leading position within the EU with nearly 86 000 tonnes or 30 % of the total zinc consumption used for galvanising. The average percentage of zinc used per tonne of galvanised steel has decreased in all countries observed. Still, large differences exist among countries, especially in non-Member States where relatively larger amounts of zinc are used for hot-dip galvanising. Within the EU, the percentages range from 6.03 % in Spain to 7.90 % in the Netherlands.

whilst percentages exceed 13 % in Switzerland and come close to 10 % in some Scandinavian countries.

**Foreign trade**

During 1984 to 1991 extra-EU imports grew at a faster pace than extra-EU exports. Imports increased by an annual average rate of 11.8 %, whilst exports only grew by 5.8 %, annually. Consequently, the EU trade balance has been negatively affected by these developments. During this time, the trade surplus went from 255.2 million ECU in 1984 to 18.1 million in 1991. From 1991 on, however, the surplus has increased again as weakening EU demand has resulted in a stabilisation of imports. At the same time, weak domestic demand has forced EU manufacturers to increase their efforts to penetrate foreign non-EU markets. This latter development has resulted in a renewed increase of extra-EU exports of 7.7 % since 1991.

Source: DEBA

**Figure 5: Secondary transformation of metals  
International comparison of production in constant prices**

Source: DEBA

**Figure 6: Secondary transformation of metals  
Destination of EU exports**

Source: Eurostat

In 1993, the USA and Switzerland were the major suppliers of secondary transformed metals representing 21.2 % and 16.7 % of total extra-EU imports. Both countries have seen these shares decline though if compared with 1988. In contrast, Taiwan, Japan and Austria have recorded growing exports to the EU, increasing their market shares on the internal market.

Extra-EU exports for 1993 mainly found their destination in EFTA countries (Switzerland, Austria and Sweden) and the USA. If compared to 1988, however, a substantial decrease (10.7 % and 20.6 %, respectively) in both countries is observed.

## MARKET FORCES

### Demand

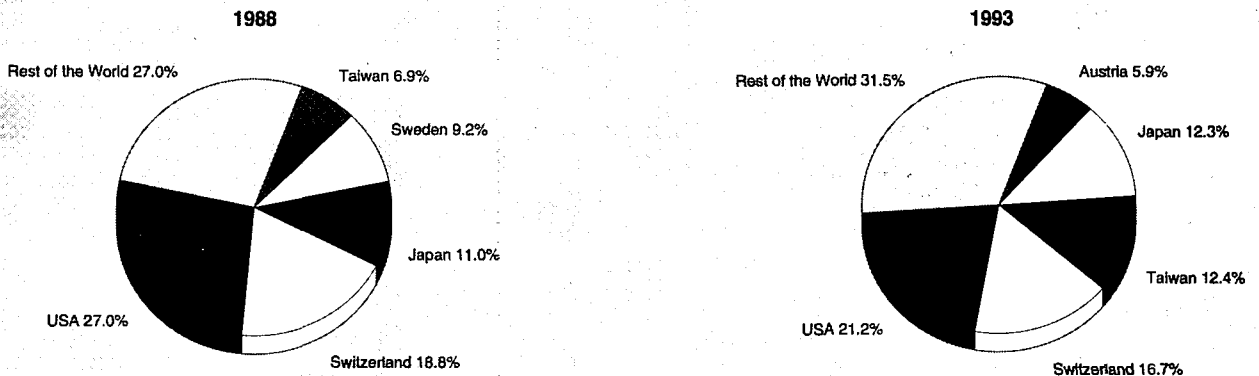

The primary client of the fastener industry is the automotive sector. Other important sectors are mechanical engineering, furniture, household appliances, construction and electronics. The EU galvanising industry serves more or less the same branches. Looking at demand for galvanised products, the construction industry appears to be the largest consumer, with 39 % of total sales. Street furniture follows at a distance with nearly 17 %, followed by the power industry (12 %), the

agricultural and horticultural industry (9 %), transport (5 %) and fastenings (5 %). A comparison of demand originating from these industries demonstrates rather stable shares. Overall bad performance of the galvanising sector is reflected in weak demand in all client industries.

In most EU countries the construction industry is the largest client industry. Only in Spain does the construction industry rank third after street furniture and power. In Germany, the leading galvaniser in the EU, the construction industry is by far the largest client industry constituting 48 % of total demand. In Belgium this industry is also of great importance to the sector with a 48 % share. Although, the relatively large share of the agricultural and horticultural client industry in France (19 %) is also worth noting. In France and the United Kingdom the construction sector is relatively less important with shares of only 31 % each. In both these countries street furniture scores above EU average percentages of market share with 21 % in France and 26 % in the UK and Ireland.

Technical and logistical developments in the client industries have a strong impact on the fastener industry. Technologically, the ongoing automation and robotisation of production processes has influenced demand for speciality and high quality fasteners, often in a negative way. Most of the standards for

**Figure 7: Secondary transformation of metals  
Origin of EU imports**

Source: Eurostat

screws, for example, are designed for manual fastening. These standards are widely used and producers can take advantage of economies of scale. Therefore, the price is relatively low. This has led to the use of these screws in automated production systems, even though in terms of quality of the end-product, the use of specially designed screws would be preferable.

### Supply and competition

Besides the fall in production, a major concern for the EU industry is the significant number of new plants which have been or are still being built following the successful expansion of the industry in the late 1980s. The exceptional growth during this period was mainly due to a boom in the non-residential construction sector and partly to an increase in the installation of street furniture. However, the sharp fall after 1989/1990 in construction across Europe, except for Germany, and a resulting modest production growth in galvanising in recent years has resulted in overcapacity in the new plants, which are also confronted with high costs due to increasing legislative requirements.

The market power of the main clients of the secondary transformation industry continues to increase. This is particularly true for the automotive industry, where Japanese competition requires more security, just-in-time delivery and increased quality from their subcontractors and suppliers. As an upstream market, the EU industry of secondary transformation of metals has to cope with developments in the automotive industry such as the growth of Japanese car production and the increasing use of single-sources by motor vehicle manufacturers. Japan's increasing production of cars within the EU will also force EU fastener manufacturers to cooperate with Japanese motor-vehicle producers, who have different design specifications than the European automobile industry. The increasing use of single-sources by motor vehicle manufacturers means less utilisation of subcontractors and fewer suppliers. Combined with the ongoing tendency towards concentration in the client industries, mutual dependency of the supplier and client industries is growing.

Due to weak demand in most downstream markets and the resulting overcapacity, prices have come under pressure. At the same time, competition from East European countries has intensified, where labour costs are relatively low.

With respect to the mass market of fasteners, strong competition from the Far East and Eastern Europe exists, especially

in standard screws, nuts and bolts. In this area, there is severe price competition and worldwide overcapacity. Both EU and non-EU fasteners seek high volume markets, such as Germany. Standard nuts and bolts from outside Europe are usually destined for the consumer market. The core of the competitive power of the EU industry, in contrast, is sophisticated, specially designed fasteners. The trend in trade is to export high value added products and to import low value added items.

The growing share of imports in total EU consumption reflects the growing supply of non-European fasteners. In 9 years time, the penetration ratio increased from 3.86 in 1984 to 4.9 in 1993. In contrast, the export to production ratio has only improved the last two years reaching 5.4 in 1993, almost back to the 1984 level of 5.6.

### Production process

In spite of the general economic slow-down, hot-dip galvanising capacity increased in the early 1990s. Between 1988 and 1992, average production increased by 5.8 % per year. The production process has also become more efficient. The average throughout Europe in 1993 was 13.6 tonnes of steel galvanised for every tonne of zinc consumed, while the average in 1970 was 11 tonnes of steel per tonne of zinc.

The galvanising industry is facing increasing costs due to higher wage increases than productivity growth. Unit labour costs have increased by 15 % from 1990 to 1993, whilst labour productivity has declined 3 %. This development has resulted in a drop in industry gross operating rates from 12.1 in 1990 to 5.7 in 1993. Cost increases not only stem from wage inflation but also from growing legislative requirements.

These cost increases give rise to a trend for mergers; larger minimum plant sizes are required to cope with the necessary investments. Environmental requirements also encourage specialisation; companies which formerly galvanised their products themselves now leave this to specialist hot-dip galvanising plants. By servicing a number of companies the unit cost can be reduced.

## INDUSTRY STRUCTURE

### Companies

The galvanising industry can roughly be subdivided in to three areas:

- small enterprises, using primarily hand-skilled labour;
- larger enterprises, operating more on a manufacturing scale, including in-house production of galvanised metal as part of the production process; and
- supply of zinc, machines, chemicals, etc., for the galvanising process.

The fastener industry follows a similar pattern, with many small and medium-sized enterprises. There are a few, however, that could be classified as medium to large enterprises, with sales over 100 million ECU. The largest companies and dealers are German, which is not surprising given the importance of the German machinery and motor vehicle industries in Europe. Italian, French and British manufacturers are not far behind, however. In the galvanising and electroplating sector, Metaleurop (D) had sales of approximately 140 million ECU in 1990, and in continuous galvanising of steel sheet, Galvanage (L) had annual sales of around 140 million ECU in 1989.

### Strategies

Rising costs and decreasing prices have forced producers to seek ways to lower production costs, especially through rationalisation. However, in certain segments of the mass market, price reductions would not restore competitiveness, as competitors can use cheap labour. In addition to rationalisation,

**Figure 8: Secondary transformation of metals  
Trade intensities**

Source: DEBA

therefore, a switch is made in the product-mix towards quality products. Further, measures have been taken to meet logistic requirements such as just-in-time delivery. All these factors lead to increased investment in new equipment.

In the subsector of speciality products, Computer Numerical Control (CNC) machines decrease the time and cost of change-overs. The trend toward orders for smaller lot sizes at more frequent intervals and with shorter lead times leads to increased change-overs for machinery. The use of CNC machinery partially alleviates the shortage of skilled labour as well.

The above factors have resulted in increased specialisation and product development in both fastener and galvanising sectors. Subcontracting of galvanising will also become more important, despite the preference of some client industries for single-sourcing. Forced by a need for more cost efficiency in the value chain and also by increasing legislative requirements, the need for close cooperation between galvanisers, zinc producers and the steel industry is growing.

### Impact of the Single Market

The impact of the Single Market on the industry of secondary transformation of metals has been positive, but limited. A reason for the limited impact is the low international trade intensity of the sector. Due to high transportation costs, most companies in the industry are regionally oriented. The sector is still characterised by many small and medium-sized enterprises, although due to environmental directives (e.g. environmental control measures; Integrated Producer Control (IPC) regulation, water purity) the minimum efficient plant size has been increasing. Among the remaining problems for the sector is the fact that some products, which can be used as secondary raw materials for the zinc oxide and zinc chemicals industry, are classified as "waste" by the EU, so that special regulations apply to its trade. A change of this classification and of the legislation concerned is considered a priority.

### REGIONAL DISTRIBUTION

Characteristic of the industry is its regional dimension. In general, enterprises in the secondary transformation of metals sector are located near major industrial centres of Europe. Because of the small scale of many of the firms, long distance transport is not usually viable. To decrease transportation costs, firms must be located near their clients. For instance, in Germany centres of the galvanising industry are in Nordrhein-Westfalen and in Baden-Württemberg.

### ENVIRONMENT

The electroplating industry is looking for ways to reduce the amount of waste created, in particular the metal content of the effluent. The metals concerned are copper, chromium, nickel and zinc. Efforts are underway to develop production processes which generate less effluent by regenerating it and by extending the dipping time. Also, the use of techniques, such as ultra filtration and electrolysis, have the advantage that they do not use additional chemicals. The cascade-washing technique, in combination with the recycling of metals, could reduce the metal concentration in the effluent from 300 g/l to 0.3 g/l.

Furthermore, recycling of metals out of galvanic waste disposal is an option, but only if the waste has a high enough metal content, preferably of a single metal. Currently, this is not very practical. Most of the small and medium-sized enterprises use third party firms for recycling metals. Also, the traditional technique of the galvanic bath is being replaced by showering the metal plates. The main waste products of hot-dip galvanising, zinc dross and zinc ash, are essential raw materials for the zinc chemicals industry.

### REGULATIONS

Standardisation is very important to fasteners. Standards specify dimensions and physical characteristics. German standards (DIN) are normally used.

The use on a voluntary basis of the ISO 9000 (EN 29000) quality management and quality assurance standards series should be encouraged.

In the galvanising industry the possibility of standardisation of hot-dip galvanising of fabricated products has been studied. A draft based on ISO 1461 has been made. After a period of comment this initiative will presumably lead to generally accepted standards. With respect to hot-dip galvanising, EU legislation is further directed towards the reduction of what is typified as 'waste products'. These so-called waste products, however, happen to be the secondary raw materials for zinc oxide and the zinc chemicals industry.

### OUTLOOK

Future development for the industry as a whole depends heavily on the evolution of the building and construction market and on developments in the automotive market and the mass market for fasteners. Most of these downstream markets have proven to possess a cyclical character. Therefore, resulting from the expected further economic recovery in the EU, production and consumption within the secondary transformation of metals industry are forecast to increase in the coming years. Although demand in some markets is close to saturation, the need for the products is expected to persist as galvanising after fabrication remains the most economical and effective way to protect steel from rusting. In the near future, growing demand is also expected from Eastern Europe.

# Constructional steelwork

## NACE 314.1

*With an annual production ranging between 6 and 7 million tonnes of steelwork, the European constructional steelwork industry is among the basic industrial activities within the European Union. Its output over 8 billion ECU per year and a direct employment of 200 000 people highlight the economic role the steelwork industry plays within the European economy.*

### INDUSTRY PROFILE

#### Description of the sector

The main activity fields for the steelwork industry are single-storey buildings and multi-storey buildings (both industrial and residential), masts towers and pylons, bridges and applications for agriculture.

The European steelwork industry is comparable (in volume terms) to that of the United States (with about 5 to 6 million tonnes per year) and of Japan (about 7 to 10 million tonnes per year).

In Europe, the United Kingdom had for a long time the largest tonnage with 1.3 million tonnes. Nowadays, the re-unified Germany is the largest producer in Europe with over 1.6 million tonnes.

The steelwork industry remains strongly cyclical. In most European countries, the growth rates of the steel construction industry peaked at the end of the eighties. In 1989, the tonnage was highest in the UK, Belgium, Sweden, Switzerland, Croatia and Norway. In 1990, Austria, Denmark, Finland, France, Italy and Spain all reached their peak. Finally, Western Germany and the Netherlands reached their highest production levels in 1992.

Since 1992, there has been a continuous decline in production except for Germany's Eastern Länder: in 1993, the fall in production in Europe reached on average 17 %, with a maximum fall of 39 % for the UK and a minimum of 10 % for Norway. A tonnage recovery has taken place for most European countries as of 1994.

The low inflation which should limit the rise in interest rates, the progressive absorption of the excess capacity in the building industry and the continuous technological progress made in the steelwork construction industry, such as widespread use of CAD/CAM, increased productivity and just-in-time delivery are all positive factors encouraging to see the future of that industry with a quite reasonable optimism.

#### Recent trends

##### Austria

In Austria, the market share for steelwork is low: 5 % of the market in multi-storey building, and 20 % in single-storey factories and warehouses. Building with steel is still very much influenced by public contracts. The new focal point, residential buildings, shows positive signs. Other positive prospects are for investment in infrastructure, especially bridges for the "New Railway" and for car parks.

Beside small electric power stations, a big Danube power plant is under construction in Vienna. Waste deposits are also increasing, as well as other components for environmental protection.

In the private sector, the decline of the commercial building sector is estimated to be over. The positive trend in refurbishment works is continuing as well as residential building demand in big township.

##### Croatia

Croatia became a sovereign state on May 30th 1991 following the break up of former Yugoslavia, but since then has suffered tremendous economic hardships because of war. The production of constructional steelwork has fallen down from 53 500 tonnes in 1989 to 29 600 tonnes in 1991. Reliable data from 1992 onwards are not available, but there is no doubt that they are still lower.

The basic prerequisite for normal development is the cessation of hostilities and the political stability, which would enable economic recovery based on foreign capital invested in accordance with international criteria and conditions.

The constructional steelwork industry will play a major role in the post-war reconstruction, a task which will be eased by the availability of cheap labour force.

##### Denmark

The recession of the Danish construction industry started in 1990, and the activity level has been falling for three consecutive years. The upturn in tonnage started at the turn of the year 1993/94, and in Spring 1994 the prices were somewhat better though still unprofitable.

All the market sectors have been depressed during recent years, but the Danish steel industry could smooth the negative effects by strongly increasing exports, which have grown from 11 000 tonnes in 1987 to 23 000 tonnes in 1994.

A good recovery of the market is foreseen in the industrial building sector and power stations from 30 000 tonnes in 1993 to 34 000 tonnes in 1994.

However, from 1994 onwards a decrease of the tonnage used in towers is foreseen, both because the high voltage system is complete and because in the future new sections will be built underground in order to meet environmental requirements. The tonnage for pylons and towers is estimated at 11 000 tonnes in 1994 (against 18 000 tonnes in 1989). The tonnage of steelwork for agriculture has been continuously decreasing since 1987 because of uncertainty about future government requirements for environmental protection and the level of subsidies.

##### Finland

In 1993, the volume of construction in Finland was about 50 % lower than the peak year of 1990, and the total steelwork output fell down from 150 000 tonnes in 1990 to 90 000 in 1993.

Exports have unfortunately followed and even amplified the decreasing trend, falling from 43 000 tonnes in 1990 to 30 000 tonnes in 1993, mainly because of the fall in imports from the Russian Federation and the Baltic countries and in spite of a strong increase in imports from the EU countries. In fact, Russia and the Baltic countries account nowadays for about 53 % of total Finnish exports of constructional steelwork, against about 36 % for the EU.

Exports remain of great importance to the Finnish structural steel industry, and the exported tonnage is estimated to have risen again in 1994 to 35 000 tonnes, close to 40 % of the total output.

Source: European Convention for Constructional Steelwork, 1993 Statistical Bulletin (Construction Forecasting and Research Ltd, 1993)

The market share of constructional steelwork in Finland is relatively high in 1993: 47 % in single storey industrial buildings, 23 % in agriculture and 15 % in multi-storey buildings.

The greatest progress has been made in multi-storey office buildings where the market share went from less than 5 % in 1988 up to 15 % in 1994.

### Germany

Compared to most European countries, in 1992 the German structural steel industry was still enjoying very favourable production conditions, mainly in Western Germany where the production peaked to nearly 1.4 million tonnes. Since then, the production has declined by 7 to 8 % in Western Germany, but it has increased by 18 % in former Eastern Germany. The estimate for 1994 is an additional fall by about 4 to 5 % in Western Germany and an additional increase by 8 to 10 % in the Eastern Länder.

The total 1994 production of 1.6 million tonnes can be compared with the other European countries' as the content of this production figure is similar to that of other countries. Indeed, the production figures provided by the Federal Statistical Office and by DSTV usually include about 0.8 to 1 million tonnes of steelwork used in building elements, which generally is not considered to be part of the structural steelwork sector.

From April 1994 onwards, the incoming orders are higher in volume and value than they were the year before. This should have a positive impact on the production not only in 1994 but also in 1995.

At present, the constructional steelwork sector in Germany is characterised by two contrasting trends:

- the production volume seems to stabilise, but prices are still too low because of the existence of an overcapacity estimated at between 15 to 20 %.
- in the Eastern Länder there is a progress in production, but in the Western part there is a sharp decrease in production except for bridges.

Concerning the employment in Western Germany - in Eastern Germany, no statistics are available - there has been a certain

stability after a continuous increase in employment since 1987: in 1993, the sector accounted for about 89 000 employees.

### France

Since 1991, the French economy has fallen into recession and the structural steel production which had peaked at 750 000 tonnes in 1990 has fallen in successive steps down to 545 000 tonnes in 1993. The year 1994 has at last put an end to that fall of production, and 1995 should show the first small increase. This more optimistic view of the future is based on three facts :

- The economy is growing again and the general feeling is that this movement should last until the end of 1995 at least.
- Even during the recession, the export of constructional steelwork could be kept at the high level of about 50 000 tonnes, compared with 35 000 tonnes five years before.
- The fall in production of constructional steelwork from 1991 on was largely due to the collapse of the market for industrial buildings which traditionally constitutes the main sector of activity for the structural industry. Today, it is precisely in that sector that a strong recovery is foreseen for the coming years, mainly due to strong activity in the car manufacturing and aircraft industry.

### Italy

In 1993, the construction industry faced its worst year since the end of the 1970s. The tonnage of about 800 000 tonnes is the result of a fall of about 13 % after two negative years (-7 % in 1991 and -18 % in 1992).

The reasons include a considerable worsening of prospects in the public works sector and a continued fall in private non-residential construction output, both for manufacturing and service sector. The measures to contain public spending as well as the investigations into bribe taking had a negative impact on the timing and the awarding of public sector contracts.

The specific situation of Italy is overlapping a general recessionary trend Europe-wide. The industrial production declined

**Table 2 : Constructional steelwork**

Source: European Convention for Constructional Steelwork, 1993 Statistical Bulletin (Construction Forecasting and Research Ltd, 1993)

in 1992 and also in 1993 despite the boost given to the export industries through devaluation.

If the production of 1993 is compared sector by sector with that of 1989, there is still a sharp fall in the industrial and public sectors like bridges, power stations and towers but there is a good, constant level in the non residential and non domestic sectors.

The consumption of constructional steelwork in the non-residential sector is very high compared with many other European countries. This may be explained by the very large demand in Italy for steel beams for refurbishment purposes. Italy has nearly half of all Europe's historic buildings. Italian building law forbids complete demolition of these buildings behind a retained facade and so, with steel beams replacing timber beams, the refurbishment is very steel intensive.

Concerning 1994, the table shows a level of production amounting to 790 000 tonnes similar to 1993. The estimated production in 1994 should represent the lowest point and also the starting point for recovery in 1995.

#### The Netherlands

The Netherlands have experienced a very favourable situation in the past years, as production of constructional steelwork has been continuously increasing until 1992 included. Whereas most countries experienced their peak point of production in 1990 or 1991, in the Netherlands the drop occurred only in 1993 with a fall of 14 % .i.e. from 583 000 to 503 000 tonnes.

The statistics are different from those given last year, since for practical reasons the greenhouses are no longer included. Indeed it was not possible to separate in weight the glass from the steel frame. The problem will however be analysed in the future as the agricultural sector represents a very important market for steel in the Netherlands.

The positive evolution of production and also of steelwork consumption until 1992 in the Netherlands has induced a continuous increase in employment in this sector, ranging from 13 481 in 1986 to 17 670 in 1992. In 1993, however, the employment had to be reduced to 17 000 units.

The Netherlands are also the country in Europe where the steelwork production per capita is the highest. The reason

for this is that besides very developed markets like agriculture, greenhouses, bridges and hydraulics, the steelwork has also a good market share in multi-storey building (26 %), and single storey factories and warehouses (80 %).

#### Norway

In Norway the production level of constructional steelwork has been relatively constant during the last years: 40 200 tonnes in 1991 against 40 000 tonnes in 1993 and an increase by 5 % estimated for 1994 which bring the production up to 42 000 tonnes. The decrease in the offshore activity in Norway has been more or less compensated by an increase in the building activity.

In Norway, the use of wooden structures is widespread (recent examples are the Lillehammer Olympic Arenas or the new Gardemoen Airport, where the roof of the main building will be made of a laminated wooden structure). In spite of that, the overall market share remains reasonably high: 20 % of the market in multi-storey buildings and 50 % of the market in single storey factories and warehouses.

#### Spain

The steelwork production in Spain is among the highest in Europe. In 1992 its total production was only exceeded by that of Germany.

The production peaked in 1990 with 1.27 million tonnes but fell by 30 % down to 860 000 tonnes in 1993. However, a production increase by 5 %, i.e. up to 900 000 tonnes was expected for 1994.

The market share for steel is quite high within Spain, except in agriculture and bridges amounting to 15 and 10 % respectively. For the other sub-sectors, the market share reaches 30 % for the multi-storey buildings, 85 % for single storey factories and warehouses, and 55 % for single storey non industrial buildings. Spain is also very active in exporting steelwork and is for many European countries a tough competitor.

#### Sweden

In Sweden, at the beginning 1994 it looked like the country had reached the bottom in 1993, but a turbulent situation

Source: European Convention for Constructional Steelwork, 1993 Statistical Bulletin (Construction Forecasting and Research Ltd, 1993)

with bullish interest rates in the 1994 Summer may have induced a further decline of the building industry.

In 1993, the steel industry tonnage declined for the fourth year. The production reached a peak of 96 000 tonnes in 1989, but continuously fell down to 64 000 tonnes in 1993. The 1993 and 1994 tonnage is expected to be the bottom line.

Only 15 % of the steelwork industry companies work at 100 % of their capacity. Despite the bad overall situation the steelwork industry could however produce some positive news:

- The general economic recession did not modify the steel market share, which was even consolidated to 50 % in multi-storey buildings, 80 % in single storey factories and warehouses and 40 % in bridges.
- The typically Swedish slim floor system, which allows a quick, cheap and safe building, is experiencing an increasing success inside and outside Sweden.

#### Switzerland

In Switzerland, a restrictive monetary policy succeeded in reducing inflation from 5.5 % by the end of 1991 to about 2 % by the end of 1993, coupled however with stagnating consumer demand and falling investment.

The construction output fell for the third successive year in 1993 and in all construction sectors orders were down. The consequence of the collapse of production is that the free capacity of the steelwork industry is increasing. For the fabricated and erected steelwork, sale prices have fallen severely but also the delivery delays. Constructional steelwork's market share should increase in the coming years all the more since the market share of steelwork in Switzerland is on the low side for multi-storey buildings (15 %) and on the very low side for single storey factories and warehouses (20 %), which is far below the European average.

#### United Kingdom

The production of constructional steelwork peaked in 1989 with 1.3 million tonnes, which was by far the highest in Europe, as the production statistics of Germany were still limited to those of Western Germany only. After that peak, the production has fallen for four years consecutively and the 1993 production level was about 40 % below the maximum of 1989.

However the GDP data for the second quarter of 1993 confirmed that the recession was over and that the UK economy had finally emerged from its longest recession since the 1930s. An upturn in retail sales and a rise in consumer credit have supported the view according to which the recovery is under way. However housing, whose confidence had been shaken by declines in house prices, remains depressed. The volatility of debt service costs and uncertain employment prospects have made consumers maintain a cautious stance in the short term.

Prospects for other construction sectors look less bright and 1993 has shown no recovery in steelwork production, the total tonnage levelling at 809 000 tonnes without exports and 871 000 tonnes exports included. It is worth highlighting the fact that during the recession, the exports could regularly be raised : from 49 000 tonnes in 1989 to 65 000 tonnes in 1993.

For the future, two elements allow to be more optimistic :

- During the recession, many companies went bankrupt and had to stop their activity. Many of the surviving companies have become more and more efficient and in the last five years have fully automated their production facilities. Most of the companies in this sector have now full CAD/CAM facilities and are moving to just-in-time production. This has led to a dramatic increase in productivity which has easily taken up the capacity lost when the bankrupt companies closed down. As a consequence, the time limits are

shortened, cost prices are lower and the time limits better respected.

- Despite the recession, the market share remained very high and has even increased in two basic sectors: - multi-storey buildings where the market share for steelwork is amounting to 62 % and single-storey factories with a market share of 90 to 95 %. For the other sectors, single-storey, agriculture and bridges, the market shares are also among the highest in Europe with 61 %, 85 % and 40 % respectively.
- An upturn at least for single-storey factories is already becoming evident during 1994 and the sector of multi-storey buildings looks far less critical than it was previously.

### **Impact of the Single Market**

So far, the Internal Market programme has not had much impact on the constructional steelwork sector. The achievement of free movement of goods added up to the already existing technical harmonisation to increase trade flows within the EU. More importantly, the opening up of procedures for awarding public works and supply contracts has enlarged market opportunities for EU firms.

Among the remaining internal barriers to trade, the industry feels that although public procurement procedures have become more transparent, the pre-qualification rules for bidding still differ widely from country to country: this obstacle should be removed by introducing appropriate harmonisation measures. Further harmonisation (without total assimilation) is also needed in the field of rules on workers' rights and social security, as well as safety and quality standards.

Another priority should be the achievement and application of the so-called Eurocodes, to replace existing national standards in the construction industry.

**Written by: ECCS**

The industry is represented at the EU level by: European Convention for Constructional Steelwork (ECCS). Address: Avenue des Ombrages 32/36, Bte 20, B-1200 Brussels; tel: (32 2) 762 0429; fax: (32 2) 762 0935.

# Boilers and metal containers

## NACE 315

Economic recession has resulted in weak intra-EU demand for boilers and metal containers. At the same time, the EU industry is experiencing increased competition from non-EU countries. In response, EU manufacturers have started to diversify into related segments and have increased their R&D efforts in order to meet increasing customer requirements for more efficient and environmentally friendly production processes. The focus on these elements is expected to lead to comparative advantages in the long run. In the short run, slight production increases are expected.

### INDUSTRY PROFILE

#### Description of the sector

The products of this industry can be divided into the following categories: steam generators and boilers; nuclear boiler construction; fitting for steam generators and boilers; flat and nuclear heat exchangers and condensers for nuclear reactors; water tanks, containers and cisterns; distillation; refining and similar equipment; pipework; and miscellaneous activities, including installation and maintenance.

EU production of boilers and metal containers is concentrated in Germany, France, the United Kingdom and Italy. These four countries together account for nearly 89 % of total EU production of boilers and metal containers.

Compared with other related industries, such as iron and steel and consumer electronics, the manufacture of boilers and metal containers is relatively small in terms of value added. The industry's size is compatible with the size of the manufacturing industry of machine tools.

#### Recent trends

Over the period 1984-1993 production in current prices increased at an annual average growth rate of 4.0 %, while apparent consumption recorded a marginally higher average of 4.3 %. Extra-EU exports, in contrast, remained relatively stable until 1991.

In real terms, the corresponding annual growth figures for production and consumption for the same period only reached 0.73 % and 0.99 %, respectively and extra-EU exports recorded a negative growth rate. Extra-EU imports, in contrast, demonstrated relatively high growth rates over the 1984-1993 period, with real average annual growth reaching 7.24 %.

In 1992 and 1993 the economic recession negatively affected consumption and production of boilers and metal containers. In two years time, consumption dropped by 6.2 %. Consequently, EU manufacturers started to look for other non-EU markets, increasing exports in order to obtain a reasonable capacity utilisation. As a result, the production decline was limited to a drop of 4 % from 1991 levels.

This production decline, in combination with a drive towards more efficient operations and cost savings, has resulted in a reduction of employment as well. From 1991 to 1993, employment has dropped by 15 100 people or 6.7 %.

#### International comparison

In 1993 the EU was the leading manufacturer of boilers and metal containers. With production totalling 19.8 billion ECU, the EU was far ahead of the USA and Japan with production figures of 7.2 and 4.9 billion ECU, respectively. If compared

Figure 1: Boilers and metal containers  
Value added in comparison with related industries, 1993

Source: DEBA

to 1984, the EU has recorded production growth of 41 % against a decline in US production of 12 % and a drastic increase in Japanese production of 385 %. However, growth figures for the USA and Japan are influenced by differences in exchange rates, although in volume terms production trends also point in the same directions.

In 1993, Germany was the largest single producing country in the world. With a production value of 7 375 million ECU, Germany was 159 million ECU ahead of the USA. Other major manufacturers are the EFTA countries of Austria and Switzerland. Recently, former COMECON countries, such as Poland and the Czech Republic have also become important suppliers of boilers and metal containers.

#### Foreign trade

With export rates in the range of 6 % to 9 % and import penetration of 1.2 % to 2.2 %, foreign trade is of relatively minor importance for boilers and metal containers. Trade is, however, gaining some importance as both export rates and

Source: DEBA

import penetration have been growing since 1991. Extra-EU exports, in absolute terms, increased by 74 % over the 1988-93 period.

The EU has always been a net exporter of boilers and metal containers. However, the declining export/import rate shows that imports grew significantly faster than exports until 1991. As a result of export-induced growth efforts by EU manufacturers and weak demand within the EU though, this ratio has started to increase again.

Major destinations of extra-EU exports are the USA, Austria and Switzerland. Other important destinations are leading developing countries in North Africa and South America and newly industrialised countries in the Far East. Although exports to EFTA countries have increased in absolute terms since 1988, their share in total extra-EU exports has declined from one-quarter to somewhat less than 19 %. The very modest share of exports to Japan increased too, while exports to the USA became relatively less important in 1993.

The industrialised world is still the major origin of extra-EU imports, although its share dropped from nearly 80 % in 1988 to just over 60 % in 1993. The share of the EFTA countries, by far the main origin of EU imports, declined from 51 % to 40 %. The decline in imports from the EFTA countries and the USA have been to the benefit of such countries as Poland and the Czech Republic, which together accounted for 23 % of total extra-EU imports in 1993.

## MARKET FORCES

### Demand

The boilermaking industry supplies equipment to many branches of other industries. It produces a variety of capital investment goods for the following purposes (in decreasing order of importance): the production of thermal and nuclear power; the oil and gas industry; the chemical, petrochemical and pharmaceutical industries; the food and drink industry; the construction industry; the iron and steel and metalworking

**Figure 4: Boilers and metal containers  
International comparison of production in current prices**

Source: Eurostat

industries; the paper industry; and various other industries including automobiles, textiles, mechanical engineering, cement, rubber and electronics.

The importance of customer industries varies by Member State. In France, the major downstream industries are energy (nuclear and classical), the chemical industry, the food and drink industry, building and construction, and oil and gas; accounting for 70 % of the sector's output. Major client industries in Germany are the chemical, automotive, engine construction and energy industries. In the United Kingdom primary outlets include oil, energy, harbour and shipping, and iron and steel, while in Italy, energy, automobile, harbour and shipping and ventilation industries are major clients.

The market has been subject to significant changes, including shifts in the relative importance of the main clients. Changes in demand, of most downstream industries, are heavily influenced by environmental developments. For instance, demand for the nuclear power industry collapsed due to sharp cutbacks in investments resulting from negative publicity about nuclear risks. As concern about global warming and future energy supplies intensify, some downstream industries are demanding more from fossil fuel-driven energy systems. This has resulted in growing attention for co-generation or the

simultaneous production of power and thermal energy (usually steam) from a common fuel source. Some major chemical companies see co-generation as an opportunity to save on investment in new boilers. Also, demand of power producers has changed, increasingly using combustion turbine techniques for the construction of combined cycle plants, instead of the more expensive boiler-fired steam plants of equal capacity.

Large cyclical and structural swings are significant features of the market for boilers and metal containers. Energy prices have a substantial impact on industry demand for boilers and in energy-saving equipment (heat exchangers), since they affect investment decisions. Relatively low oil prices since the end of 1985 have been an important determinant of recent demand trends. Another significant factor influencing demand is the industry's sensitivity to general economic developments. Postponement of investments in downstream industries affects the position of the boilermaking industry. Enterprises specialising in large boilers for heavy industry, such as power stations, are particularly vulnerable to these swings.

**Supply and competition**

Increased competition in export markets from emerging East Asian and East European boilermaking firms, together with declining investments in domestic markets and a slow down

**Figure 7: Boilers and metal containers**  
**Origin of EU imports**

Source: Eurostat

**Table 5: Boilers and metal containers**

of investments in developing and OPEC countries, affected the EU industry very badly. In most cases, manufacturers of boilers and metal containers also supply other investment goods. Most downstream markets of the manufacturers of this equipment and other investment goods have a high degree of capital asset utilisation. This is the major reason why these manufacturers are concentrated in countries with an emphasis on the production of investment goods: Germany, France, Italy and the United Kingdom. Except for the United Kingdom, these countries were able to increase production of boilers and metal containers throughout the 1980s, but have been suffering from weak downstream markets since 1991. Estimated profitability (non-labour income in value added) declined significantly and overcapacity emerged, urging manufacturers of boilers for heavy industry to reconsider their activities. Companies are trying to become less dependent on their traditional clients, such as the heavy industry by switching to new but related areas, for example civil engineering. Prospects in the short and medium term, however, seem to be more favourable.

The competitiveness of the EU industry can be further improved if increasing efforts are directed towards research and development (R&D) and towards complete tailor-made solutions. Induced by growing environmental concerns and ever increasing demand for higher efficiency by the downstream industries, manufacturers of boilers and metal containers are increasingly stimulated to direct more efforts to R&D. This

will lead to increasing technological know-how and to comparative advantages in the long run.

EU competitiveness not only depends on a high level of technological knowledge, but also on other product and service features such as high quality, product innovation, reliability and flexibility, which means adaptability to the needs of the market. Due to the high demands of European downstream industries, EU manufacturers have been stimulated to give high priority to these features. This has resulted in a technological lead throughout the world.

### Production process

Technical criteria are not the only decisive factors in international competition. Products must also be competitive from a cost perspective. Developments in labour productivity, unit labour costs and total labour costs indicate that the efficiency of the production processes has increased over the period 1984-89. Labour productivity, in current prices, increased at a faster rate than unit labour costs. Weak downstream markets, accompanied by lower capacity utilisation, have caused a stabilisation of labour productivity in the early 1990s. The resulting decline in employment, however, could not prevent an increase of unit labour costs. During 1990-93, these costs increased by 16.2 % against a stabilisation of the labour productivity index. As a result, the profitability of the industry has increasingly been put under pressure.

Looking at trade figures, the competitiveness of the EU industry does not seem to have been seriously affected by these developments. Although extra-EU imports are still of minor importance, in absolute terms, the penetration rate demonstrates an increasing trend. In contrast, fast growing extra-EU exports in 1992 and 1993 reflect improving competitiveness of the EU industry. However, the competitiveness of the industry can only be maintained if production costs are controlled.

### INDUSTRY STRUCTURE

#### Companies

In the boilermaking industry three types of firms can be distinguished: system integrators; product specialists; and activity specialists.

System integrators are the smallest, but most powerful group. They are usually medium-sized firms or divisions of large diversified industrial groups installing systems. They focus on three activities: design and engineering, manufacturing and on-site installation. The principal feature of system integrators is the high value added content of their activities. Raw material input represents about 20 % of turnover, whereas labour costs are about 45 % due to large design and engineering departments with highly-qualified technical staff. System integrators also offer a wide range of maintenance services, which are no longer lengthy and infrequent. The ageing of machines

**Figure 8: Boilers and metal containers**  
**Trade intensities**

Source: DEBA

and concern regarding the financial viability of the installations makes quick, frequent maintenance necessary. In areas which require a high level of skill, such as nuclear energy, firms are tending to broaden the scope of their services. System integrators further concentrate their activities on design, contracting and on-site installation. Much of the intermediate assembly work is contracted out to small local firms.

Product specialists supply equipment such as vessels, boilers and heat exchangers. Due to low unit costs of production, they have a good international competitive position for specific products. The enterprises, however, tend to be domestically oriented and are normally medium-sized. Raw material input represents over a third of total turnover and the value added content is less than that for system integrators.

Activity specialists are firms which manufacture particularly specialised items, mostly from client blueprints. This is the most common type of firm within the boilermaking industry. They are subcontractors of the system integrators and operate on a small scale. Their rather weak basis, due to specialisation, hinders export activity.

Enterprises in this sector have regional or national rather than an international orientation. The largest companies tend to be located in countries which dominate the Single market, although only one of the ten largest EU firms is located in Germany; Deutsche Babcock, the largest EU firm. Babcock is a special case, however, as many German enterprises are medium-sized. Other large firms involved in the industry include: CLN (I); Degremont (F); Sabroe Refrigeration (DK); Alstom (F); Industria Cantieri Metallurgici (I); Dexion International (UK), which is a subsidiary of Interlake (USA); Ponticelli (F); Aalborg (DK); Cockerill Sambre (B); and Stork (NL). Both US and Japanese firms have subsidiaries in the United Kingdom.

### Strategies

Successful firms in the boilers and metal containers industry are mostly demand oriented, rather than innovative. The relatively weak development of demand, as well as the changing roles of the diverse outlets of the industry and growing environmental concerns have forced enterprises to reconsider their key activities. Many companies are attempting to lessen their dependence on heavy industry as the main outlet and turn to related areas of work, such as mechanical engineering, electricity and civil engineering. Furthermore, the industry is increasing R&D efforts in order to offer complete tailor-made and environmentally friendly solutions. The changing economic environment of the boilermaking industry and the need to improve productivity, increases the need for more skilled labour. Consequently, personnel training is a major concern.

The opening up of markets in Eastern Europe and China will have a positive influence on EU manufacturers of boilers and metal containers. The enhancement of safety for nuclear power reactors in Eastern Europe means a high market potential for EU manufacturers. The cost of making safe or replacing Soviet designed nuclear power reactors is estimated between 10 and 30 billion ECU. In addition, strong demand for energy efficient technology and equipment for power plants and other heavy industries, not only in Eastern Europe but also to an increasing extent in China, will further stimulate EU production.

### Impact of the Single Market

Through the free movement for goods and capital, the liberalisation of services, and the harmonisation of technical standards, competition has become fairer, but more intense. Internal barriers, however, continue to exist as national testing bodies are still able to refuse machinery and equipment from other Member States which comply with EU standards but not with national standards. These barriers prevent fair competition. Another barrier relates to the lack of a single European currency instead of the different national currencies which can

lead to market imbalances and inefficiencies. The removal of all these barriers should have the highest priority. Another priority is the thrive towards more flexibility in labour, which could lead to cost

---

## ENVIRONMENT

---

The industry itself does not seriously threaten the environment. Environmental issues usually apply to downstream industries. Client industries, however, are becoming more aware of safety and environmental issues also induced by developments in the industry's regulatory environment. In an attempt to meet the needs of their clients, manufacturers of boilers and metal containers put efforts in to product innovations concerning both issues. For example, the industry is addressing the environmental problem concerning the danger of leakage of tanks for underground storage of chemicals and oil products. Much research has been done in the field of corrosion containment and substitute raw materials for tanks. In the USA, about 90 % of all new tanks for oil stocking are made of plastic. The discovery that metal tanks corrode not only from outside but from inside as well, stimulated the use of plastic tanks. Installation of underground plastic tanks is very different from metal tanks though, and demands a completely different organisation of the work. For instance, the use of a special glue allows only a limited amount of time to connect the pipework.

The market for environmental products, such as for cleaning industrial waste water or air pollution, is becoming increasingly important. This creates opportunities for the boilermaking industry. Enterprises are likely to have a competitive edge in countries where environmental regulation is already very strict (e.g. Germany and the Netherlands).

---

## REGULATIONS

---

In 1995 the EU Directive 89/392 will attain a definite character. This Directive defines essential requirements concerning machine safety, health provisions for people and the environment. Provisions relate to the design, the materials used, the way in which machine operations should be illuminated, machine operation itself, safety against mechanical risks, the application of screens and other safeguarding components, maintenance and machine indications and identifications. Machines complying with the EU regulations will obtain the CE mark. Machine safety is of relevance to boilers. In anticipation of this EU Directive, but also in response to customer requirements for a safer working environment, the industry has already put much effort in R&D for the improvement of safety conditions of equipment. In new technology development, the industry also pays a lot of attention to environmental issues such as reduction of emissions.

The liberalisation of public procurement in the power plant markets is expected to generate significant changes in electrical power equipment supplier firms. More generally, EU energy policy will have a major impact on the upstream industries of the energy sector. But, harmonisation of the laws of Member States concerning pressure equipment is still required to establish an internal market for boilers and containers (vessels) subject to a pressure greater than 0.5 bar. A proposal for a directive on this subject has been made.

Another issue which deals with EU energy policy is the debate on the introduction of a carbon tax. Such a tax might affect total energy consumption leading to lower demand for boilers and metal containers in the long run. It might also lead to a growing demand for more efficient processing techniques in downstream markets. This last development is expected to have a positive influence for the manufacture of boilers and metal containers. The industry will not only benefit from an increase in demand for new innovative equipment, but will

Source: DEBA

also retain a comparative advantage against other countries resulting from know-how.

## OUTLOOK

The economic recession has resulted in weak intra-EU demand for boilers and metal containers. At the same time, EU industry is experiencing increased competition from non-EU countries. In response, EU manufacturers will continue to diversify and increase their R&D efforts in order to meet customer requirements for more efficient and environmentally friendly production processes. Growing environmental concerns are expected to lead to more EU legislation which will especially apply to downstream markets. The ability to meet present and future legal requirements is expected to lead to comparative advantages against other non-EU suppliers of all kinds of process equipment. In the short run, the recovery of EU demand and continued growth of extra-EU export, especially in Eastern Europe and the Far East, will stimulate EU production of boilers and metal containers. Growth rates, however, will be limited.

# Hand tools

## NACE 316.11

The general economic slowdown during 1991-1993 caused production to fall in the EU hand tool industry an average of 4.5 % per year in current prices. Due to increasing competition from outside the EU, demand was increasingly covered by imports, turning the EU in 1991 and 1992 from a net exporter into a net importer of hand tools. However, in 1993 a small trade surplus was recorded.

EU manufacturers try to cope with increased competition by rationalising their production process and by changing their product-mix towards the production of high-quality products. For the short term the outlook is cautiously optimistic; future prospects for the medium term are more positive.

### INDUSTRY PROFILE

#### Description of the sector

The hand tools industry comprises four principal segments: hand tools, tools for joinery, fixing tools for construction and metal saws. The sector manufactures such products as axes, screwdrivers, saws, files, rasps, pliers, shears, spanners, tools for drilling, taps and dies, hammers, planes, chisels, etc.

Although some hand tools perform the same function as power tools, they are increasingly being replaced by electrically driven tools, which are different products and produced by different manufacturers. Likewise, they are subject to different regulations. Some hand tools more related to the industry are also treated in the chapter on electrical equipment for industrial use (NACE 343.1).

#### Recent trends

EU demand for hand tools, in current prices, declined in 1993 by 14.4 % while production decreased by 6.7 %. However, extra-EU exports recorded a 3.4 % increase while extra-EU imports stagnated (-0.5 %) during 1993. International trade is playing an increasingly important role in the EU hand tool market. In 1993, approximately 48 % of production was exported, while 48 % of the consumption needs came from imports; in 1992 it was 44 % and 45 %, respectively.

Germany was by far the largest EU producer of hand tools in 1993 producing 44 % of total production, followed by the United Kingdom (21 %) and France (20 %). These countries are also the major consumer markets of hand tools (e.g. Germany's share is roughly 40 %).

With the exception of the United Kingdom, all Member States reported a decline in the production of hand tools for 1993 (data refer to six EU countries). For the second consecutive year Italy suffered the greatest production loss: with a 22.4 % decline (in 1992 they had a 13.2 % decrease). Spain's production declined by 15.2 % in 1993 while in Germany and France the reductions were 5.1 % and 6.8 %, respectively.

From 1984-1989 production in current prices grew at an average rate of 4.6 % per year for hand tools. In contrast, due to the general economic slowdown during 1990-93, the industry recorded an average drop in production of 4.5 % per year. However over the entire period from 1984 to 1993, the average growth rate for production was positive at 2.1 % per year. Consumption showed similar development patterns of growth from 1984 through 1991 and reductions in 1992 and 1993. But, the average annual growth rate for consumption from 1984 to 1993 was twice as high as that for production; namely, 4.0 % per annum. Since demand is increasingly being met by imports (48 % in 1993 versus 38 % in 1984), EU production is not fully benefiting from the rise in demand.

**Figure 1: Hand tools**  
Production in comparison with related industries, 1993

Source: DEBA, CEO

Practically all products in the hand tool market have to cope with weak demand, including screwdrivers, spanners (mostly used for home car repair) and wrenches which are the most important sectors of the do-it-yourself (DIY) hand tool market. The spanner sector was by far the most important sector until the mid 1980s. It has since suffered a decline due to a reduction in the sale of socket sets. Likewise, the screwdriver sector has been adversely affected by rising substitute sales of cordless drills, which double as cordless screwdrivers.

#### International comparison

The EU is the world leader in the production of hand tools. The rise of import rate and the increase in the export rate, however, reflect continued emergence of international competition but also considerable efforts made to penetrate extra-EU markets. In particular, China, other East Asian countries and the East European countries are becoming more productive. These countries are especially competitive through pricing.

## Foreign trade

With an import ratio and an export ratio of 48 % in 1993, it is obvious that extra-EU trade plays a major part in the EU hand tool market. Between 1984 and 1993 the average annual growth rate for imports was substantially higher than that for exports: 9.6 % versus 1.6 %, ultimately creating a negative trade balance in 1991 and in 1992. However, in 1993 the trade balance became slightly positive, due to a growth rate of 3.4 % for extra-EU exports, while extra-EU imports fell by 0.5 %.

In 1993 roughly 12 % of EU exports of hand tools were destined for the USA, which are the most important single destination for hand tools exports since the accession of most EFTA countries. The developing countries account for more than half of extra-EU exports of hand tools.

The countries of origin of extra-EU imports of hand tools have changed considerably during the 1993 period. In 1993, Taiwan and China accounted together for about 40 % of EU imports, against 15 % in 1988. Since the accession of the new Member States, Taiwan has become by far the largest exporter of hand tools to Europe; the share of the USA has grown moderately over the 1988-93 period, while the Japanese share has actually decreased.

## MARKET FORCES

### Demand

Hand tool manufacturers operate in both the industrial and private markets. Although there are differences between Member States and according to the type of tool, industrial demand is more important than private demand. Demand for hand tools for industrial use depends on the propensity to invest in the downstream industries. In the case of saws and tools for joinery machines and metal saws, demand depends almost entirely on investments made by industries such as furniture manufacturers, sawmills, and mechanical engineering firms. For the building and construction industry anchor bolts, masonry drills and power tools are most relevant. The propensity to invest depends on the activity level and strength of the downstream industries, which largely depends on the general economic climate.

Private demand for hand tools is also determined by the general economic situation. Tools for private use, in general, have a long economic life. These tools have a high price elasticity. As a result, when the economy is strong and disposable income is growing, there is greater demand for the more expensive high-quality tools at the top of the product range. However, declining disposable income is a strong factor in pushing demand towards the cheaper end of the product range. Private demand is especially important to the DIY sector. With rising home ownership levels the DIY sector boomed in the 1980s. As people became more confident about tackling DIY jobs, they tended to buy higher quality tools. Manufacturers have introduced more advanced products, such as hardpoint saws, to the DIY market in response to this change in demand.

Poor economic conditions in the EU during 1990-1993 largely explain the declining consumption of hand tools both for industrial and private use.

### Supply and competition

Depending on the size and maturity of the market, the EU countries can be categorised into three market types: 'leaders', 'developing' and 'small'. The leading countries include France, Germany, Italy and the United Kingdom. Although imports are important, these countries are major producers of hand tools, accounting for some 70 % of the EU market. Several extensively used distribution channels also exist in these countries and they have a long tradition of tooling and DIY activities.

The second market type consists of Greece, Ireland, Portugal and Spain and accounts for an estimated 15 % of the market. Greece has the least developed market and is almost entirely dependent on imports for its supply of hand tools. Besides some simple, mostly agricultural hand tools no hand tools are manufactured in Greece. The remaining countries also rely overwhelmingly on imports, as their production covers only a restricted number of segments of the hand tool market. This applies particularly to Ireland and Portugal. Further, modern distribution networks from the leader countries are establishing themselves in the 'developing' countries.

The small EU countries of Belgium, Denmark, Luxembourg and the Netherlands comprise the remaining 15 % of the market. They have distribution channels comparable to those in the leading countries, but, like the 'developing' countries, they rely largely on imports as the size of their markets does not justify a complete domestic product range.

In the leading countries some 50-60 % of sales of hand tools are accounted for by DIY superstores/multiples. These stores are characterised by wide product ranges, accessible presentation and competitive offers. Another 15 % or so of sales go through independent DIY stores, while speciality hardware stores account for a further 18 %. Tools for joinery machines and metal saws are partly distributed by retailers and partly sold directly to manufacturers of plant and machinery. However, in the last few years a stagnation in the DIY market has led to alterations in the distribution system. Due to the stagnation and a continuous flow of low priced products from East Asia and East Europe competition has become particularly fierce in this market segment, putting prices under continuing pressure. As a result, retail prices for the main hand tools in the United Kingdom decreased by 1 % in the multiples last year.

### Production process

During the period 1985-1993 labour costs increased at an average rate of 5 % per annum. By Member State this rate varied from 2.5 % in the Netherlands to over 7 % in Italy and the United Kingdom. The continuous rise in costs, together with a recessive market at the beginning of the 1990s, has encouraged manufacturers to rationalise their production processes. At the same time, growing supplies of cheap hand tools

**Figure 3: Hand tools  
Destination of EU exports**

from East Asia and East Europe has caused EU producers to change their product-mix, and to switch to the manufacturing of products with a higher value added content.

The rationalisation process in the sector has been continuing in 1994, as a result of continued pressure originated by cheap imports.

## INDUSTRY STRUCTURE

### Companies

In the EU the bulk of the companies engaged in the production of hand tools are small. About two-thirds of the firms have less than 20 employees. In individual Member States this share varies from 45 % in France and Spain to 70 % in Germany. The principal reasons for the abundance of small-sized companies are the low value added nature of the products, the wide diversity of the products and the small production runs per item. Moreover, many companies are family-owned, which can limit the acquisition of capital.

The few medium to large, sometimes internationally operating, firms account for the largest portion of production. These

include Sandvik AB (S) and Bahco (S), Stanley (UK/F), FA-COM (F), Rotherberger (D) and Hilti (CH). The Swedish manufacturers Sandvik and Bahco have several production facilities in the EU. This applies also to the US-based Stanley Works, which in the United Kingdom is known as Stanley Tools. In the leading countries, major manufacturers often have a large market share. For instance, 50 % of the UK DIY market for screwdrivers is supplied by Stanley and Draper (an importer/packager), while 75 % of the DIY market for hand drills is covered by Stanley, Draper and Record Ridgeway, which is part of Record Holdings.

### Strategies

Fierce price competition, due to the increasing volumes of cheaper imports, has forced many manufacturers to improve their productivity and to reconsider their product-mix. Lowering production costs and making a switch to quality products are prerequisites for remaining competitive. Further, the saturation of a number of EU markets particularly in the 'leading' and 'small' countries is causing manufacturers to look for new markets and new production opportunities.

**Figure 4: Hand tools  
Origin of EU imports**

Source: Eurostat

Rationalisation of production processes and the establishment of production capacity in countries with lower levels of (labour) cost will enable manufacturers to lower production costs. At the same time, these countries usually have underdeveloped markets allowing for market extensions. Such new markets are possibly to be found in Eastern Europe, provided the worst economic developments can be overcome in those countries, and in the 'developing' markets within the EU. As an example, Stanley Works (USA) has set up a joint venture with the Polish Fabryka Narzedzi Kuznia near Krakow. This deal works in two ways. The new company takes over Kuznia's hand tools manufacturing capacity and makes further investments in new equipment and facilities later on. And, in return, Stanley is allowed to manufacture Stanley branded products cheaply and sell them throughout Europe. Another example is Sandvik AB (S), which produces files and rasps in Portugal through its subsidiary Sandvik Obergue.

With the upgrading of the product-mix, after-sales services will become increasingly important. Quality improvements and after-sales service are particularly important in the high-income West European countries. However, these factors are of greater importance in a booming economy because in a recession the customers tend to concentrate on price.

Growth among market leaders in these largely satiated markets will be through the acquisition of smaller rivals rather than through greenfield investments.

### Impact of the Single Market

The overall impact of the Single Market on the hand tools sector is considered to have been positive. The enlargement of the market has stimulated trade and has resulted in an

intensifying competition. The intensifying competition, however, has also resulted in a declining number of companies (through mergers and acquisitions) and has not necessarily led to a fairer competition. In order to achieve fair competition, EU regulations should be unified in all Member States and clarified to third countries outside the EU. Further harmonisation of technical and safety standards at world level should be a next priority. A level playing field in terms of social legislation, both within the EU and with respect to non-EU countries, should also be a future priority.

### REGIONAL DISTRIBUTION

The sector has local, regional and global aspects. Manufacturers who are operating on a small scale, and who depend on the demand from downstream industries like mechanical engineering, tend to be located in the area where these industries are concentrated. For instance, in Germany and Spain manufacturers are concentrated geographically. At the same time however, the big firms in the industry and those engaged in the production of DIY products have a global orientation.

### OUTLOOK

Demand for hand tools is closely linked to the general level of economic activity. Due to the economic slowdown the industry faced declining production and consumption levels during 1991-1993. One of the main downstream industries, the building and construction sector, was severely hit by the recession, as well as the mechanical engineering and private household sectors. Although one can argue that poor economic conditions encourage demand for DIY products, as people tend to renovate and repair themselves, declining disposable income also pushes demand for DIY products towards the cheaper end of the product range. Thus, this negative impact of the recession on demand outweighed the positive one as seen by the overall decline on retail sales.

Besides cyclical factors, structural influences played a role in the deterioration of the market for hand tools. Fierce competition from outside the EU was relevant in this regard as the drop in sales was partly due to the increase in imports of cheap tools from the Far Eastern and East European countries. In order to enable the sector to maintain its position in the future, structural changes are required. More rationalisation to reduce costs is expected to take place, probably by way

Source: NEI

of take-overs, mergers and other forms of alliances. At the same time, a switch to quality products is occurring.

Recently, signs of recovery in the hand tool market have been observed. In the United Kingdom, where economic conditions improved first, the hand tool market is heading for recovery, which is reflected by the stabilisation of the production level in 1993. In addition, the sale of hand tools in DIY outlets increased some 20 % between February 1993 and February 1994. There is also some evidence of trading up on the part of the consumer. These developments are considered to be indicative for the EU as a whole, with the recovery encouraging demand for hand tools from private households and from the industrial sector. Hence, the developments in the United Kingdom justify some cautious optimism for the short term. However, adverse structural factors, in particular fierce competition from outside the EU will continue.

The economic outlook for the medium term is better. Regarding the industrial market, a recovery in the downstream industries is expected. At the same time, structural measures (rationalisation and quality improvement) will have a favourable impact on demand. In the private market the economic recovery will bring about a rise in demand, particularly for quality products.

# Light metal packaging

NACE 316.42

The light metal packaging industry has enjoyed slow but regular growth over the last few years. Substantial production cost savings and significant productivity increases have been achieved, principally due to technological advances. The sector, as a whole, is characterised by a high degree of competitiveness, due to a broad range of alternative processing and packaging options currently in existence or under development. The impacts of environmental regulations and recycling are particularly important in this sector.

## INDUSTRY PROFILE

### Description of the sector

The term "light metal packaging" is applied to all metal packaging less than 0.49 mm thick, with a capacity below 40 litres. By contrast, the term "heavy metal packaging" applies to packaging manufactured from cold-rolled sheet steel with a surface thickness equal to or greater than 0.5 mm and used in the fabrication of casks, cans and drums, with a capacity of 30 to 220 litres.

The distinction between "light" and "heavy" metal packaging is by no means arbitrary. Not only does it reflect the use of different raw materials, as well as, different manufacturing technologies, it also relates to entirely distinct consumer markets.

Within light metal packaging, further distinctions apply to specific product groups:

- packaging for foodstuffs, particularly cans for food and beverages;
- various types of light multi-purpose packaging (called general line cans), notably removable-lid cans for paints and varnishes, oil cans, cans for cleaning agents, non-sealed cans for foodstuffs, decorative cans, aluminium dishes, and metal containers for specific industrial applications (e.g. electric battery cases);

- aerosol cans for use as containers for a mixture of gas and liquid, used primarily in the cosmetics, pharmaceutical and cleaning agents subsectors; and
- lids and caps, including crown corks and other types of metal closures (especially for glass bottles), and screw-on caps and lids.

### Recent trends

In 1993, the light metal packaging sector produced 6.8 billion ECU worth of packaging, a drop of 4.3 % compared with 1992. Net exports totalled 349 million ECU (an increase of 3 %) in 1993, while apparent consumption fell by 4.7 % to 6.5 billion ECU.

Current estimates suggest that light metal packaging accounts for around 16 % of the European packaging market, as a whole, ranking it third in terms of packaging industry materials. By way of comparison, paper and board account for 30 % of the packaging industry's current requirements, with plastic packaging accounting for a further 30 %. The percentages for glass, heavy metal and wood are: 7 %, 4 % and 4 %, respectively.

A combination of sectoral restructuring and productivity-boosting measures have, since 1981, resulted in a steady fall in employment, which dropped below 50 000 for a second consecutive year. Over the same period, productivity increased from 70 000 ECU per employee in 1980 (at constant 1985 values) to about 140 000 ECU in 1993. The sector counts some 300 companies.

### Foreign trade

The metal packaging sector is not traditionally characterised by major long-distance international trade for technical and economical reasons. Although the EU is a net exporter in this sector, imports continue to grow faster than exports. In 1993, extra-EU imports grew by 7.1 %. The EFTA countries continue to represent the largest share of EU imports, accounting for 66.5 % in 1993. This clearly reflects an increased interest by these countries to boost sales into the EU.

At present, although imports only represent 3 % of market demand, they have grown significantly over the last few years. Intra-EU trade is also increasing substantially, and amounted to more than 1 billion ECU in 1993.

## MARKET FORCES

### Demand

Although originally developed for food products, light metal packaging has developed an increasingly important role in everyday life thanks to its unique properties compared with other forms of packaging. Food conditioned in metal packaging can be stored for long periods without any loss in nutritional value or any risk of corrosion or contamination. The primary advantage of this longevity is that products can be more readily transported and stored.

Efforts are being stepped up to enhance the quality of printing and design (stackability, easy open ends) aimed at upgrading the image of metal packaging. This should positively influence demand. Up to now, metal packaging has quite successfully withstood the pressures arising from packaging waste issues.

In recent years, economic growth within the sector has been relatively modest, ranging from 2 to 3 % per year on average. However, 1993 was a bad year for the sector, with apparent consumption and productivity both dropping by more than 4 %. While consumption for most products fell, this was not the case for drinks and aerosol cans.

Currency devaluation in the third quarter of 1993, in some countries, tended to distort figures expressed in ECU, for the UK, Spain and Italy. Most of these countries managed to record a higher output expressed in their own local currency. Production by country, in 1993, evolved as follows: UK -5.2 %, Germany +1.4 %, France +6.7 % and Italy -20.1 %. Sales in Greece showed a substantial jump, due to improved data collection, which now covers a major part of the industry. Some European countries saw their export sales fall substantially (UK -23 %), while others increased (France +12 %, Italy +16 %).

Besides overall poor demand, the industry was also faced with serious overcapacity in some product lines. The combination of these elements naturally had a negative impact upon prices, and consequently, returns to companies. It seems likely that most of the structural growth in the metal packaging sector is attributable to developments in the canned foods industry and the emergence of new market segments in canned beverages and aerosols.

As far as industrial packaging is concerned, however, the industry's position is distinctly less positive. This is due to a difficult economic situation in certain consumer sectors (among them the construction industry) and to growing com-

petition from the plastic packaging sector, in terms of specific applications, notably motor oils and cleaning agents.

Overall, developments in the light metal packaging sector are strongly influenced by a number of external factors, including:

- changes in consumer preferences and patterns (including a trend towards individual portion packaging in the food industry and more sophisticated methods of preservation), which have prompted an increase in demand for packaging of sophisticated canned food, pre-cooked dishes and aerosols;
- stiffer competition from new types of packaging (such as compound plastics on impregnated board, ultra-lightweight glass and flexible packaging) and new preservation technology (e.g. deep-freezing or freeze-drying);
- psychological aversion to certain types of packaging and product presentation, particularly where long-life foodstuffs or beverages are concerned; and
- environmental legislation and the unpredictable reaction of the conditioning industry to packaging materials, which they will favour in the future.

### Production process

At present, light metal packaging production can be broken down as follows: 60 % food packaging (of which 83 % is accounted for by foodstuffs and 17 % by beverages), 30 % multi-purpose packaging and 10 % metal closures and accessories.

Tinplate, blackplate and aluminium are the three principal raw materials used in the manufacture of light metal packaging. Tinplate is cold-rolled steel sheets less than 0.5 mm thick and coated on both sides with a thin (3g/m<sup>2</sup>) film of tin. It is used principally in light metal packaging. Some 95 % of annual tinplate production (which is to say, approximately 11 million tonnes world-wide) is used by this sector. Among the various properties which make it especially useful for the light metal packaging industry are: high mechanical strength, susceptibility to decoration (it accepts print readily), and the fact that a vast range of products can be packaged using this material; notably food, chemical and pharmaceutical products.

Blackplate, usually referred to as tin-free steel, is a steel substrate coated with a chrome oxide compound. Although the technical properties of blackplate are inferior to those of tinplate, it has been widely used in recent years to manufacture products to less exacting specifications. Typical examples include: can bases and lids, bottle caps, and so on. The principal

factor in its favour is that it is approximately 10 % cheaper than tinplate.

Aluminium is the third most popular base material for light metal packaging. Currently, around 10 % of world aluminium production is earmarked for the packaging sector. Major uses include: dishes, small food cans for fish and meat, flexible tubing, can lids and beverage cans. However, use of aluminium for light metal packaging varies significantly by region. Aluminium accounts for 95 % of can packaging for drinks in the USA market (with tinplate accounting for a modest 5 %), about 40 % in the United Kingdom, but only 15 % in Germany.

Consumption of tinplate accounts for 51 % in the conditioning of food and drinks, while blackplate and aluminium account for 40 % and 9 %, respectively. Overall, some 18 % of packaging needs are accounted for by aluminium. In 1993, consumption of tinplate and blackplate totalled 3.4 million tonnes and 500 000 tonnes for aluminium.

Changes in the relative cost of tinplate and aluminium largely dictate the use of these two materials in the metal packaging sector. Although the price ratio between tinplate and aluminium may have evolved, in favour of the former during the past decade, some unsettling movements in tinplate prices over the past year, if they persist, could well change this balance. At the same time, aluminium has not escaped the overall increase of raw material prices either, which have set in since the third quarter of 1993. Over the long term, however, one can observe a slight move towards increased use of aluminium for some types of cans. This is highlighted by a 40 % jump in aluminium consumption in 1993.

Packaging manufacturers, particularly in the food sector, rarely limit themselves to a single technology or a single type of packaging material. For example, the leading world-wide groups each use a broad range of materials. Hence, they are an important factor in the development of materials they will use in the future.

## INDUSTRY STRUCTURE

### Companies

All EU Member States are involved in the light metal packaging sector in varying degrees. The four largest producers are the United Kingdom, Germany, France and Italy, together accounting for 74 % of total EU output, which currently equals two-thirds of US output.

The light metal packaging sector is relatively concentrated within the EU. Its structure is based on large groups that manufacture predominantly standardised products and small to medium-sized firms that specialise in customised products. Standardised products (those mass-produced on highly-automated production lines) are manufactured by a small number of large companies in each country. This is particularly true with respect to standard-size food and beverage cans, caps, and so on.

Several factors impact on concentration within the sector, not least of which is the capital investment implicit in large-scale production. For example, a modern beverage can production line requires an initial outlay of up to 40 million ECU. There is also the problem of access to advanced technologies. The trend towards mergers at the level of major industry clients, such as food processing groups and brewers, has also affected the structure of the light metal packaging sector. Finally, economies of scale, implicit in mass-production, are a factor in increased concentration.

Merger and acquisition activity, joint ventures and cooperation agreements between firms are becoming increasingly common. As a result, beverage can production is now largely concentrated in the hands of five European manufacturers. These manufacturers, which are also the five major industrial groups dominating the light metal packaging sector in the EU are: Pechiney (F); Carnaud-Metalbox (F-UK); VIAG, Continental Can Europe (D); Crown Cork Cy (USA); and PLM (S). However, the fact that CMB, the market leader, only has 6 % of the market (according to Marketline, a market research bureau) clearly indicates how much the European market is still fragmented.

Customised products are manufactured in smaller quantities and for more limited markets. Customisation frequently relates to the shape of the packaging (conical or irregular shapes), non-standard sizes (outsize or mini-capacity packages), or product-specific decorative effects. Typically, such customised packaging is produced by small or medium-sized firms employing 20 to 200 people. General-line cans, where product variety and limited volume require optimal production flexibility, are manufactured principally by companies in this category.

### Impact of the Single Market

The Internal Market programme, and especially the environmental policies of the EU, have had an impact on the industry: the free movement of goods and the enlargement of the market have facilitated trade and stimulated competition within the

sector, whereas the environmental and recycling policies have impacted competition between different packaging materials. The EU Directive on packaging is thus highly relevant to the sector. In the different Member States, however, national regulations remain which complicate trade and in some cases constitute new internal barriers. The removal of these barriers should have the highest priority.

### REGIONAL DISTRIBUTION

The geographical spread of companies in the sector is largely determined by the nature of the products they manufacture.

Metal packaging offers the benefits of a comparatively low unit value (the sale price of a standard food or beverage can is currently around 0.1 ECU) combined with large volume. As packaging requires significant space in transporting for small unit values, large-scale exporting or long-distance delivery is not very profitable. In practical terms, the maximum sales radius, within which a firm can deliver its products on a competitive basis (taking account of transportation costs), is approximately 300 kilometres. It is for this reason that firms are so widely dispersed throughout every region of the EU. It is also for this reason that food can manufacturers are typically located in predominantly farming regions and general line can manufacturers in industrial areas. However, large multinational groups of manufacturers achieve wider market networks by buying up local producers and rationalising their respective product ranges.

### ENVIRONMENT

In volume terms, packaging accounts for nearly one-third of the 100 million tonnes of waste generated by EU households. However, metal packaging waste represents only a small part. By weight, all metal containers account for less than 2 % of household waste, with drink cans accounting for less than 0.5 %. Nevertheless, environmental problems, together with increasing pressure from certain substitute materials, are major challenges for the sector.

In recent years, the EU and most national governments have set up environmental policies which focus on packaging waste. These policies have two aims: to increase the proportion of recyclable packaging by discouraging the sale of large quantities of non-returnable packaging; and, to promote new forms of environment-friendly recycling. These priorities have been supported by a series of rules and regulations, including a Directive on the packaging of food liquids dated June 27, 1985.

A proposed new Directive, covering the packaging industry as a whole, was approved by the European Commission on 15 July 1992, and was formally voted on by the European Parliament on 16 November 1994. This new Directive aims at promoting substantial reductions in the total volume of packaging on the market and stepping up requirements relating to the re-use and recycling of all types of packaging. As several countries are stepping up efforts to develop their own solutions for limiting the packaging waste stream, the European Commission and its Member States recognise an increased need to stop the proliferation of national initiatives, which risk having a negative impact upon the environment and trade. Member States and the industry, therefore, welcomed the passing of this Directive. In the long term, 90 % of all packaging used in the EU marketplace will be required to be re-usable and/or recyclable.

The recovery rate of metal packaging waste in EU Member States is already relatively high, around 20-30 % on average, but it should increase substantially as the new Directive takes effect.

In this respect, the metal packaging industry is well placed to comply with future EU legislative requirements because it represents a packaging process which is ecologically sound and capable of reducing waste to a minimum. Advantages of the Directive for the light metal packaging industry include:

- the raw materials used are in plentiful supply and will remain so for the foreseeable future;
- in the case of tinplate in particular, process, recycling and transport-related energy consumption is modest by comparison with other materials; and
- elimination of downstream consumer waste is relatively simple to achieve, given that the packaging material can be selectively recovered and recycled without difficulty.

Steel substrate-based packaging has a salient advantage in that it can be separated and recovered by magnetic means. This also means steel packaging materials can be recovered even from non-separated domestic waste or after incineration.

As a non-magnetic material, aluminium does not offer this advantage. On the other hand, its high residual value constitutes a major incentive to selective recovery and recycling, an operation that requires only one-twentieth of the energy required for primary smelting. After recovery, both aluminium and steel are readily reprocessed by raw materials producers to derive new products, which exhibit no quality loss.

As mentioned earlier, several EU Member States, such as Denmark, Belgium and Germany intend to or have already introduced relatively stringent regulations. For example, in

Denmark, refillable bottles are mandatory for domestic production of carbonated soft drinks, implying an absolute ban on beverage cans. In Germany, the Töpfer Packaging Ordinance makes distributors responsible for re-use and recycling of packaging outside the public waste disposal system. These obligations are waived, however, for manufacturers and distributors taking part in a "Dual System" organisation, which collects, sorts and passes on used sales packaging free of charge for recycling. All collection and sorting costs are financed through the use of an onpack "Green Spot" symbol. Metal packaging manufacturers also participate in this scheme. The Ordinance also fixed some collection targets (e.g. 40 % of tinplate and 30 % of aluminium from January 1993, and 80 % of all materials from July 1995) and recycling rate targets (e.g. 65 % for tinplate in 1993 and 90 % in 1995).

In 1993, a voluntary agreement was signed in France requiring manufacturers and importers to take responsibility for the recovery of packaging waste from households. As a result, service organisations such as Eco Emballage, ADELPHÉ (Wines and spirits packaging) and CYCLAMED (pharmaceutical packaging) have been set up to carry out the disposal obligations on behalf of the manufacturers and importers. In July 1994, a new decree on industrial and commercial packaging was adopted. Metal packaging will have to comply with this regulation from July 1995 onwards. Likewise, the Dutch industry and public authorities concluded a voluntary agreement known as the "Covenant."

In Belgium, the national government introduced the Eco-tax law imposing environmental taxation on beverage containers. The three regional authorities intend to conclude an inter-regional cooperation agreement, in anticipation of which, the service organisation Fost Plus was founded.

There are also grounds for optimism when one considers the situation in certain non-EU countries. In the USA, for example, more than 60 % of beverage cans are now recovered and recycled. In order to improve the present recycling rates in the EU, 22 international mass-market manufacturing and user firms, including several producers of light metal packaging, have decided to pool their efforts within the framework of an umbrella group known as the European Recovery and Recycling Association (ERRA) to develop and promote ecologically-sound and commercially cost-effective solutions to the problem of waste processing.

## OUTLOOK

A diverging pattern of demand in various user sectors combined with increased competitive pressures exerted by plastic packaging across a broad spectrum of applications will act as a brake on output over the coming years in the light metal packaging sector. Output in 1994 is likely to improve as the economic climate improves and a pick-up in consumer spending is realised. For 1995 and 1996, output could increase again by 2-3 % each year, provided, the overall economic situation continues to recover in Europe. Yet, as new plants are being set up in some central European countries, it is not excluded that output growth in the EU could be hampered to some degree.

Certain market subsectors will outperform others. The food can industry seems poised on the threshold of a growth period and there is no indication that conventional food cans will be substituted by another type of packaging in the medium term. The pet food sector is currently expanding at 6 % to 10 % per year and exhibits solid prospects for the years ahead. The total market for all beverage cans is projected to increase by close to 20 % between 1991 and 1995, with metal cans predicted to increase substantially their current 15 % share of this market. Nevertheless, certain EU manufacturers have over-reacted to this potential demand and committed substantial investment into the industry, which could lead to an excess of production capacity in certain regions of the EU. Packaging for miscellaneous applications (such as paints and detergents) should, at best, maintain its current position.

In addition to these specific market developments, there will be significant progress, in the next few years, in terms of product quality and production line yields. These forecasts are based on a variety of factors, including: the development of new materials; the progressive ability to reduce the thickness and quantity of metal substrate, as the quality of protective coatings improves; the use of laser welds; the rationalisation of production through the application of stricter standards; the introduction of more sophisticated printing techniques, which enable packaging to play a more effective role in product promotion; and, steady increases in productivity.

Overall, the tendency towards increased concentration, both within the EU and world-wide, seems set to continue in the years ahead.

# Steel drums

## NACE 316.41

The steel drum has been around for a long time and in that time both the container and those who use it have had to adjust to meet prevailing circumstances. The concept of the steel drum might be a hundred years old, but the technology to achieve its current high performance has to be "state-of-the-art".

During its evolution and particularly during recent years, the steel drum has had to adapt to changes in legislation, covering both its performance and its suitability for re-use and recycling.

### INDUSTRY PROFILE

#### Description of the sector

The term "heavy metal packaging" as listed under NACE 316.41 is unclear and may cause confusion if the words are inverted during translation into different languages such as English or German.

This designation was probably adopted by the authors of NACE by analogy with "light metal packaging", but as an easy solution it would have been more correct to describe the products in this sector as industrial metal packaging.

In fact they are simply steel drums which are officially defined at European and world level by the competent authorities of the European Union (Combined Nomenclature), the UN, the European Committee for Standardisation and ISO as follows: "drums, casks, barrels and cans having a capacity not exceeding 300 litres, manufactured from cold sheet steel having a thickness equal to or greater than 0.5 mm".

The industry within this sector produces steel drums having a capacity of 18-250 litres, and the determining factor which separates it from the light metal packaging sector is the 0.5 mm thickness of the steel sheet used for their manufacture.

The commonest packaging units in this sector are steel drums of a capacity of 210 or 216.5 litres (55 USG) which are covered by the European Standards laid down by the European Committee for Standardisation. They are supplied with either full aperture (with lid) or partial aperture (with bung) for the packaging of dangerous or non-dangerous solids or liquids.

#### Recent trends

Turnover in the European steel drum sector is thought to be about 750 million ECU, and the annual consumption of cold-rolled laminated steel is approximately 850 000 tonnes. Most of this raw material is used for the production of 40-42 million steel drums with a capacity of 18-250 litres.

After a drop in demand in 1992 and 1993, partly as the result of the general recession and partly because of competition from other types of packaging, the most recent data indicate an upward trend which began in the first half of 1994.

This encouraging development has been confirmed by the incomplete data already available for the second half of 1994: in comparison with 1993, production in 1994 appears to have gone up by 5 % to 6 %, with a larger increase for full aperture steel drums.

### MARKET FORCES

#### Demand

Steel drums are used principally for the transport of chemical and petrochemical products (mineral oils, lubricants, paints

Figure 1: Steel drums  
Development of production

Source: SEFA

and varnishes etc.) and agri-foodstuffs. Recently, following the evolution of demand, the industry has also started the production of higher value added products (such as stainless drums for beer).

Because of their volume, large empty steel drums are hardly ever supplied for filling at distances in excess of 300 or 400 kilometres. It follows that they are manufactured at a large number of production plants located throughout Europe.

After filling, steel drums are used to carry products throughout Europe and the rest of the world. They meet the requirements of transport regulations and are approved in accordance with a large number of certification systems, which means they can be used on all continents.

It has been estimated that, every year, some 40 million tonnes of products are transported in this way by air, land and sea.

#### Impact of the Single Market

The sector has been particularly affected by environmental legislation. The proposed measures inevitably lead to industry-wide technical improvements which, in conjunction with rationalisation efforts imposed by business trends, resulted in productivity gains and leaner corporate structures.

Due to freight rates, empty steel drums usually do not travel distances over 300-400 kilometres. They are manufactured in strategically located production units throughout Europe. The creation of the Single European market did not, therefore, have major consequences on this regional oriented industry, the more so since the most common packaging units in this sector are standardised to a large extent in Europe and at world level. In addition, packaging produced by the sector is submitted to stringent performance tests imposed by the United Nations, so that the role of the EU is of minor importance in this field.

On the other hand, however, exchange rate fluctuations and the distortion of competition originating in countries with lower labour costs are of concern to the sector, which favours stable currencies for its international contracts and harmonised social legislation to eliminate unfair competition.

### ENVIRONMENT

Steel is a 100 % recoverable material which complies with the requirements relating to economy and usage of natural resources. The strength of steel and the existence of an in-

dustrial reconditioning infrastructure also mean that steel drums can be reused.

Millions of steel drums are reconditioned, restored or recycled in Europe every year and the necessary arrangements have either already been made or are in the process of investigation to improve systems for collection, reconditioning and recycling.

The European sector has established contacts with the steel drum industry in the USA and Japan with a view to manufacturing to universal standards, which will permit the reconditioning and reuse of steel drums throughout the world.

---

## OUTLOOK

---

Even though it is a traditional type of packaging, the steel drum is continually being developed to meet technical and ecological demands. Efforts made to this end require a high level of investment and greater cooperation among all those involved in the life cycle of packaging in this sector.

## Overview NACE 32

The mechanical engineering sector supplies almost exclusively capital goods and their components. Consequently, its performance is strongly dependent on cyclical fluctuations in the propensity to invest. Currently, the sector is receiving momentum from the diffusion of computer-aided machinery, the growing demand for environmental technology and an increasing service content in the products offered. As a supplier of advanced production technology, mechanical engineering holds a key position within the manufacturing sector of the European Union. The performance of its products determine the potential of productivity growth and quality enhancement in all manufacturing sectors. Mechanical engineering is therefore at the base of industrial competitiveness in the European Union. The mechanical engineering industry in the European Union has so far been able to maintain its leading international position. However, in the field of standardised machines and components it is facing severe price competition from East European and Asian producers.

### INDUSTRY PROFILE

#### Description of the sector

The mechanical engineering industry fulfils an essential role in the economy as supplier of capital goods. It supplies production equipment to all sectors of the economy. Its product range extends from miniaturised precision components to complete production plants. These products all embody highvalue technology, although, with a few exceptions, they are not considered to belong to the so-called leading-edge technologies. The sector is nevertheless very innovative in the integration of micro-electronics, optics and sensor technology in mechanical applications.

The standalone machine has lost its position at the centre of the product range to integrated machinery systems incorporating state-of-the-art information technology. To operate these systems customers increasingly need services such as advice, training, maintenance and special software. Most machinery manufacturers therefore also supply product-related services, which already make up more than one tenth of total turnover in the sector.

Many client firms demand customised solutions. To serve these demands manufacturers are forced to abandon the mass-production of standardised items and to adopt a high degree of specialisation. This promotes the international division of labour and offers good opportunities to small and medium-sized enterprises.

Mechanical engineering is one of the leading manufacturing sectors in the EU, contributing 8 % of total industrial output. The industry is concentrated in Germany, which accounts for 49 % of the net product of the mechanical engineering sector in the EU in 1993. The other important producers are the United Kingdom (with a share of 15 % of EU production), Italy (13 %) and France (10 %). Behind them comes a group of countries with shares of between 2 and 3 %, including Spain, the Netherlands, Denmark and Belgium. The entry of Finland, Austria and Sweden has added almost 10 % to machinery production in the EU.

Figure 1: Mechanical engineering Value added in comparison with related industries, 1993

Source: DEBA

#### Recent trends

The mechanical engineering industry experiences much wider cyclical fluctuations than most other industries. This is a consequence of its strong dependence on investment activity, which is highly sensitive to overall economic conditions. This applies in particular to industrial investment in equipment, which is the outlet, directly or indirectly, of most mechanical engineering products. This relation underlies the evolution of the mechanical engineering sector in recent years.

The large investment wave between 1988 and 1990 caused machinery manufacture in the EU to surge. In contrast, the subsequent three years 1991-1993 were marked by a sharp reduction of investment activity, and the demand for machinery fell drastically. Production was cut back and the growth achieved during the preceding boom was largely lost. The

Source: DEBA

segments supplying standard components were particularly hurt, because downward adjustments of the stocks of components reinforced the impact of the decline of equipment demand. The machine tool industry also experienced an excessively sharp drop in demand, not only because it supplies equipment to the capital goods industry, which itself suffered from the decline of equipment demand by the industry at large, but also because it was affected by the worldwide decline in armaments production. The sharp drop of production and thus revenues forced manufacturers to reduce the workforce drastically. Between 1990 and 1993 about 320 000 mechanical engineering jobs in the EU disappeared. This figure does not include job losses in East Germany, where structural changes were accompanied by the loss of another 350 000 jobs in the same period.

Investment activity outside Europe recovered in 1993, giving machinery manufacturers in the EU the opportunity to increase sales to nonEU countries. However, extra-EU exports only partly compensated for lost sales within the EU. The protracted

economic downturn in Western Europe finally ended in early 1994, with the result that the volume of orders received by machinery manufacturers started to increase. In the first phase, the recovery of demand was mainly fuelled by rebuilding of stocks, and benefited component suppliers. Soon afterwards investment in equipment also picked up. In the course of 1994 the recovery of the mechanical engineering sector accelerated and exceeded predictions from earlier in the year. Job losses, however, did not show any slow-down until the end of the year. In 1994 another 130 000 jobs disappeared.

The strong growth of orders in early 1994 was followed by production only after an unusually long delay. This observation applies in particular to Germany. Two reasons can be cited. Firstly, a very high proportion of the orders related to large-scale plants, which require long lead times. Secondly, as demand recovered in the course of 1994 the drastic workforce reduction in the preceding recession created bottlenecks, particularly with suppliers, which prevented prompt completion of orders. These problems are temporary, related to the transition from recession to recovery. Production and employment are therefore expected to follow soon the growth in orders.

**Figure 4: Mechanical engineering  
International comparison of production in current prices**

Source: DEBA

**International comparison**

The EU, the USA and Japan are the world's three largest machinery markets. In 1993 the market volume was about equal in the three regions. In 1994 machinery demand in the USA, where economic recovery had already started in 1992 and investment activity was strong, pulled ahead of that in the EU and Japan, where the recession had barely ended. These divergent demand evolutions caused a further deterioration of the persistent US trade deficit in machinery, whilst the EU and, in particular, Japan, were able to increase their export surplus.

Machinery production mimics the evolution of demand. The US machinery industry emerged earlier from the recession than its counterparts in the EU and Japan. The recession in the USA was also smaller. Whereas US production fell by 7 % in 1990 and 1991, production in the EU dropped by 15 % between 1991 and 1993, and in Japan by 17 % between 1992 and 1994. Not until Japan had as last pulled out of recession in early 1995 did the production of machinery increase in all three Triad regions, and this for the first time since 1989.

**Figure 5: Mechanical engineering  
International comparison of production in constant prices**

### Foreign trade

Divergent economic conditions between Western Europe and the rest of the world have determined the trade performance of the EU in machinery. Whilst exports to nonEU countries showed a strong growth in the period 1992-1994, extra-EU imports shrank in 1992 and 1993. They recovered in 1994, but their growth remained far behind that of extra-EU exports. As a result the EU trade surplus in machinery increased, after having stagnated since the mid-eighties. Exports represented almost 36 % of EU machinery production in 1993, and in 1994 the export intensity has probably increased still further. This ratio is much higher than the corresponding figures for Japan and the USA, which in 1993 were respectively 25 % and 16 %.

The loss of sales in the EU by nonEU countries does not indicate a deterioration of their competitive position, but is the result of the low investment activity within the EU. NonEU countries have maintained their share of machinery sales in the EU. In 1993 extra-EU imports reached more than 18 % of sales, compared to under 14 % in 1984. EFTA countries hold the strongest position, with a market share of 7 % in

1993, ahead of the USA with about 6 % and Japan with 3 %. Machinery trade between Member States has also intensified in the last decade. Between 1984 and 1992 the share of intra-EU imports in machinery sales in the EU went up from 27 % to 33 %. There are indications that this trend has continued in 1993 and 1994, although accurate data are not yet available.

Divergent economic trends in the various regions of the world have also affected EU machinery exports to nonEU destinations. The Europe-wide recession hit the EFTA countries simultaneously with the EU, and produced a similar slump of investment activity. As a result the EFTA was overtaken by the USA as the biggest export market for the EU mechanical engineering sector. Japan, where imports account for only some 5 % of the supply of machinery, has never been an important export market. Its importance has declined even further in recent years due to the recession. However, other countries in the Far East have gained importance. These include China, South Korea, Hong Kong, Taiwan and Singapore, which together already accounted for 9 % of extra-EU exports in 1993. Markets in the Far East continue to be dominated by Japanese machinery manufacturers, but the enormous appreciation of the yen has seriously hurt their ability to compete. EU machinery exporters have benefited and in recent years have consistently improved their position in Far East machinery markets, which are the world's fastest growing. Finally, EU exports to Latin America have also increased, without, however, attaining the level of the early eighties.

### MARKET FORCES

#### Demand

Well over half the output manufactured by the mechanical engineering industry consists of finished capital goods. The remainder predominantly consists of unfinished goods to be built into capital goods. This includes not only components such as drive units, but also turbines for ships, or even entire industrial furnaces to be installed in a cement works. Only a few of these unfinished goods are built into consumer durables, e.g. roller bearings in domestic washing machines. Finished consumer goods are an exception in product range of the mechanical engineering industry, e.g. domestic sewing machines.

Attempts to provide a more detailed description of the segments of the mechanical engineering sector than the one presented above encounters problems of insufficient statistical data. A breakdown of domestic sales by customer sector of

**Figure 6: Mechanical engineering  
Destination of EU exports**

**Figure 7: Mechanical engineering  
Origin of EU imports**

Source: Eurostat

the German mechanical engineering industry can be made using the inputoutput tables constructed by the Statistisches Bundesamt (Federal Office of Statistics) and the investment calculations of the IfoInstitut. 70 % of the production of the mechanical engineering sector is delivered to the manufacturing industry, 4 % to energy and water utilities, 4 % to agriculture and forestry, and 4 % to the construction industry. The service sector has substantially increased its consumption of mechanical engineering products in recent years and now takes up 14 % of production. Within the manufacturing industry, mechanical engineering is its own biggest customer because of the large share of unfinished goods in the product range, followed by vehicle manufacturing and electrical engineering. Within the service sector, commerce is the biggest customer, as logistics requires much equipment.

The high degree of dependence on investment activity implies that the demand for mechanical engineering products is characterised by strong cyclical fluctuations. Investment decisions are influenced by changes in past or anticipated capacity utilisation, evolution of earnings, cost of borrowing and overall business conditions. These factors exhibit similar evolutions

in broad areas of the economy, causing peaks and troughs in the economy as a whole and in overall investment activity. The mechanical engineering industry is therefore forced to follow the booms and recessions of the economy.

Between 1991 and 1993 investment activity and the demand for machinery were very low in the EU. Expansion investment almost disappeared, and even replacement investment was postponed. The latter created a substantial pentup demand for machinery, which fuelled the recovery of early 1994. In addition, demand receives momentum from the diffusion of computer-aided systems. As the recovery progresses, capacity expansion investments will also pick up. Demand prospects are equally favourable in the new Member States, Finland, Austria and Sweden, and also in the rest of Western Europe.

Sales opportunities in Eastern Europe have also improved. Successful restructuring efforts have created companies capable of financing the modernisation of their production apparatus. Such a modernisation is necessary if the company desires to export to Western markets, since only modern equipment can achieve products of the required quality levels. In addition the demand is fuelled by the increasing amount of direct investment by Western companies in Eastern Europe.

Outside Europe the demand for machinery recorded steady growth in 1993 and 1994, which is continuing in 1995. The highest rates of growth were achieved in North America and the emerging countries of the Far East. As Japan too has now emerged from the recession, demand will this year increase in all large machinery markets of the world.

### Supply and competition

The slump in the production of the mechanical engineering industry in the EU between 1991 and 1993 was unusually deep. The industry responded by deep cuts in capacity and workforce. The contraction was strongest among component suppliers, where downward stock adjustments reinforced the impact of the declining demand, and in the machine tool industry, where low investment activity in the automotive industry and by machinery manufacturers coincided with an almost complete absence of orders from the armaments industry. In these segments the unexpectedly brisk recovery of demand has already caused bottlenecks, which normally only occur in peak years. In addition, many machinery manufacturers complained in early 1995 of difficulties in the supply of special steels, castings and electronic components. These bottlenecks are the after-effects of a particularly deep recession, after which many companies are unable to raise production levels quickly. These initial problems will probably

100 or more employees	4 437	3.7	62.3	64.0

(1) Estimates.  
Source: Eurostat "Enterprises in Europe"

be overcome in the course of 1995. The sector plans to increase the workforce by at least 2 % and investment by more than 10 %.

The sharp fluctuations in the production of the mechanical engineering industry are also visible in the evolution of labour productivity and unit labour cost. A declining rate of capacity utilisation, as experienced from 1991 to 1993, reduces labour productivity and increases the weight of labour costs. Presently, in a period of growth, the opposite situation occurs. The combined effects of the increasing capacity utilisation and the cost-cutting measures implemented in the recession have contributed to substantial productivity gains in 1994. In 1994 the mechanical engineering sector in the EU achieved a marked reduction in unit labour costs, and despite the expansion of output manpower costs increased only moderately. This trend will continue in 1995 and will provide the basis for lasting improvements in profits, despite increasing materials prices.

The mechanical engineering industry in the EU continues to hold a strong competitive position at the global level. Its comparatively modest growth performance in the early 1990s does not reflect a deterioration of its competitiveness, but the unfavourable demand evolution in its main markets. The competitiveness of the EU mechanical engineering industry is built on advanced technology, high quality and the ability to offer specialised solutions to the specific production problems of customers. EU producers face a continuous pressure on prices, until recently from Japanese competitors, but increasingly from producers in the emerging countries of the Far East and Eastern Europe. However, EU producers benefit from the fact that the ability of equipment to solve a production problem is a more important decision criterion than price. This is borne out by the fact that the demand for machine equipment is far less price-sensitive than for most other industrial products.

The competitiveness of the EU mechanical engineering sector depends crucially on its success in maintaining a superior level of technological expertise. Patent statistics provided by the Ifo-Institut suggest that EU machinery producers are indeed successful in this area. Of the patents for mechanical engineering products applied for in at least two countries between 1989 and 1991, EU manufacturers accounted for 43 %, the USA for 23 % and Japan for 21 %. By restricting attention to patents applied for in at least two countries, only the inventions which the applicant considers so important that he does not limit their registration to his own country are taken into account. No other major EU industry group performs so well on this measure as mechanical engineering.

The mechanical engineering industry manufactures products that combine high-quality engineering with applications from new technologies such as microelectronics, information processing, optics, sensor, laser and advanced materials. The incorporation of new technologies fuels an ongoing process of innovation, which offers machinery manufacturers frequent opportunities to gain an advantage over their competitors. In addition, established techniques are continuously improved

and made more efficient. A very important recent trend in this respect is the shift from standalone machines towards integrated machinery systems. The incorporation of high-technology applications and the spread of system solutions has increased purchaser needs for consulting advice, training, software and maintenance. Most machinery manufacturers provide these services themselves, because they regard this as an area in which they can enhance their standing and gain a competitive edge. The provision of these services requires specially-qualified personnel. The availability of a highly skilled and qualified workforce is one of the main strengths of EU companies, which distinguishes them from competitors in most nonEU countries.

The internationalisation of manufacturing constitutes a new challenge to the mechanical engineering industry in the EU. Relocation opportunities have become more numerous, principally for manufacturing processes that can be carried out at a location separate from research and development activities. In the mechanical engineering sector this is the case for standard products which are manufactured in large volumes. In contrast, in customer-oriented mechanical engineering, where practical experience in production situations is fed back to research and development, the separation and relocation of manufacturing is much more difficult. EU producers enjoy a considerable locational advantage because of the availability of a highly qualified workforce. However, the decline of transport costs increasingly allows standard components and supplies to be obtained and shipped in from lowest cost locations. Outsourcing is an important strategy to reduce the extremely high value added component in mechanical engineering as compared with other industries.

The opportunities for machinery producers in the EU to relocate their manufacturing operations have substantially expanded with the opening up of Eastern Europe, which has made lowest cost manufacturing locations available at a very short distance. Moreover, some East European countries, especially the Czech Republic, have a long tradition in mechanical engineering. In practice, however, the cost advantage of these countries has turned out to be much smaller than suggested by the huge discrepancy in labour cost. A much lower level of productivity combined with a high cost of communication and quality control severely constrain cost savings. The development of manufacturing in Eastern Europe and emerging economies elsewhere in the world will on the whole have a positive effect on the performance of the mechanical engineering industry in the EU. Although the producers in these countries are a source of additional pressure on prices, they also create a growing demand for modern production equipment which they are unable to manufacture themselves in the required diversity and quality. This demand represents a substantial market potential for machinery exports from the EU.

### Production process

Most machinery is produced in very small volumes, often a volume of only one. The very small batch sizes are necessary to meet the multiplicity of specific customer requirements.

**Table 6: Mechanical engineering

Source: DABLE

Mechanical engineering products are usually highly complex, manufactured with precision and very expensive. To be able to supply these products manufacturers employ a high proportion of engineers and a skilled labour force. The mechanical engineering sector is a very labour intensive industry. Employee costs represent about 30 % of the production value.

Unfinished goods and components represent 60 % of production value and are largely obtained from within the sector itself. The electrical engineering sector is the second largest source of supplies. Its importance is growing because of the increasing application of microelectronics. The most important raw material for the construction of machinery is steel. However, a large fraction of steel is purchased in partly processed form, for example as castings, forgings or structural steel work.

The sector makes efficient use of computerisation in all phases of the production process, ranging from design and work preparation to manufacturing and management of stocks. Flexible manufacturing systems prevail. They have allowed to reduce the overall lead time for an order, to provide more flexible responses to individual customer requirements, and to implement ongoing quality control. Finally, information and communication technologies are also used for marketing and invoicing.

## INDUSTRY STRUCTURE

### Companies

In 1990 almost 120 000 mechanical engineering companies were active within the EU. Of this number almost 99 000 firms had fewer than 20 employees. They were primarily involved in repairs or the production of parts. Only 21 000 therefore had more than 20 employees, which is considered as the lower limit for the industrial production of complex products. However, even in this category large firms were a small minority. Only 4 400 companies employed more than 100 employees, and only 800 more than 500 employees. The total number of firms has probably declined in the recession years between 1991 and 1993, when the number of bankruptcies increased and new company registrations went down. Nevertheless, the size structure has probably remained virtually unchanged.

The distribution of firm sizes shows that the mechanical engineering industry in the EU is characterised by small and medium-sized companies. The structure of the sector results from the characteristics of the manufacturing process. Machinery equipment is, as a rule, not suitable for volume manufacturing. Consequently, there is no incentive to establish large units to achieve economies of scale. On the contrary, the high degree of specialisation required by the market often is pro-

vided better by small companies. The few large mechanical engineering companies are generally active either in standard equipment production, where economies of scale can be achieved, or in the construction of complete plants, which requires substantial human and financial resources.

Experience has shown that small and medium-sized engineering companies can respond more flexibly than large firms to the large cyclical fluctuations of demand that characterise this sector. They have lower capabilities, however, in finance, research and marketing, the latter particularly in distant markets. These disadvantages can generally be overcome through cooperation. A clear trend towards closer cooperation has emerged in the past few years, although many medium-sized companies are still reluctant to engage in such ventures.

Many of the largest companies are included in the mechanical engineering sector because of the nature of their main activity. In addition, they are engaged in other areas of industry, ranging from steelmaking to electrical engineering. The share of these companies in the total turnover of the industry is hence not entirely representative. Nevertheless, all surveys of industry concentration have shown mechanical engineering to be one of the least concentrated sectors.

### Strategies

During the recession, many machinery producers implemented cost reduction programmes. The programmes affected every part of the production organisation: slimming down of administration, development of less expensive products, rationalisation of the flow of materials, and promotion of team work. The restructuring efforts have not yet been completed, but they have already accomplished a sizeable reduction in costs.

Merger and acquisition activity increased during the recession. Some deals were part of rationalisation programmes, and combined firms whose performance had become dismal due to the recession. It remains to be seen whether the new entities will prove viable. In other cases, successful companies took the opportunity to take over struggling competitors. Overall, however, merger activity is still negligible in the mechanical engineering industry, and hence can not be interpreted as a move towards greater concentration.

During the recession the European market had lost all appeal to mechanical engineering companies due to the protracted situation of low investment activity. Instead, EU producers explored the rapidly growing machinery markets in the Far East, where their presence had formerly been negligible. The recovery in Western Europe has shifted attention back to the home market. The EU market is also gaining attractiveness owing to the expansion of the EU and the further harmonisation of technical guidelines for machinery.

## Impact of the Single Market

The mechanical engineering sector has welcomed the New Approach to technical harmonisation and standards which was a key element of the Internal Market programme. Under the New Approach, directives only lay down the essential safety or other requirements with which products put on the market must conform. The development of harmonised standards which, if adhered to, ensure compliance with the essential requirements established by the directives, is entrusted to standardisation bodies. If products are manufactured in accordance with harmonised standards, or if manufacturers can prove in any other way that the products conform to the requirements established by the relevant directives, these products enjoy free movement throughout the EU. The New Approach therefore constitutes a powerful tool to remove technical barriers and implement the Single Market. The necessary legislation to implement a unified internal market in machines is already in place. Since 1 January 1995, the Machinery Directive, the most relevant New Approach Directive for the sector, is fully in force. Nevertheless, important barriers to the movement of machines within the EU remain. These are mainly the result of problems and delays in the transposition and implementation of the New Approach Directives. The most important problem is that the national transpositions of the Machinery Directive often contain requirements differing from those in the Directive itself, and also differing across Member States. In case no harmonised standards have yet been developed, manufacturers must prove conformity with the requirements of the national transpositions. If these requirements differ, the free movement of a product throughout the EU is constrained. The mechanical engineering sector therefore considers as priorities for future action the checking by the Commission of future transpositions, and the continued development of harmonised standards.

## REGIONAL DISTRIBUTION

In all Member States the mechanical engineering industry is concentrated in particular regions. These generally coincide with historical centres of industrial activity, because machinery producers were traditionally located near their main customers. Cooperation and close contacts with industrial customers were necessary to develop machinery that met customer requirements. In Germany centres of machinery production are situated in Baden-Wuerttemberg, Bavaria, Hessen, Low Saxony and Nordrhein-Westfalen, in Italy in Lombardy and Emilia-Romagna, in the United Kingdom in the South East and the Midlands, in France in the Ile de France and the Paris Basin, and in Spain in Catalonia and the Basque Country. Modern transport and communication facilities and the international dimension of most important machinery manufacturers have eliminated the reasons for regional concentrations, but they remain as the legacy of historical development.

## ENVIRONMENT

The production of machinery usually does not cause serious environmental pollution. The noise generated by metalworking was a problem in the past, but it has been greatly reduced by modern machine tools. Cooling lubricants can be disposed of without creating pollution. Surface treatment processes such as galvanising did create pollution. Now, however, these processes are generally carried out by specialists outside the mechanical engineering sector, who operate under strict regulations to safeguard the environment. Many machinery producers have installed an environmental management system and will have their operations verified by an "EU Eco-audit. On the whole the costs of environmental protection are low in the mechanical engineering sector.

On the other hand, the mechanical engineering sector is one of the main suppliers of environmental technology. It provides

**Table 7: Mechanical engineering

Source: DEBA

the techniques for the safeguarding of soil, air and water. Furthermore, it incorporates environmental requirements in the design of its products to prevent pollution associated with their operation. Growing environmental awareness and the implementation of EU regulations will increase the demand for environmental technology, creating new development challenges for the mechanical engineering industry.

## REGULATIONS

The EU Machine Directive requires that machines placed on the EU market comply with essential health and safety requirements. This Directive applies to almost all machines and engines for commercial, industrial and private use. The manufacturer certifies his compliance with the directive by affixing the CE mark to his product. The European Commission has also appointed the European standards organisations to devise standards that, when followed, ensure compliance with the Machine Directive.

To export to nonEU countries producers must be able to deal with a large variety of special technical requirements. As the mechanical engineering sector is already geared towards meeting specific customer needs, such requirements do not normally pose significant problems. Machinery producers experience more difficulties with export controls that prevent the supply to certain countries of advanced technology or equipment that could be used in the manufacture of arms. The EU harmonisation in 1994 has brought an improvement, because it was much more straightforward than the preceding national regulations.

Except for Portugal and Greece all Member States have a substantial surplus in mechanical engineering trade with nonEU countries. For many specialists even the internal market is too small to support an adequate production volume. These facts demonstrate that EU machinery producers benefit from free world trade, and therefore do not favour restrictions on imports from other countries.

## OUTLOOK

The production of the mechanical engineering industry in the EU is expected to record a substantial increase in 1995. Investment activity has picked up throughout Western Europe and the sector can expect a growing demand for machinery in all markets. The recession has forced manufacturers to lower costs and explore new concepts, resulting in a strong level of competitiveness. They are therefore in an excellent

position to benefit from the worldwide surge in demand for machinery equipment. The recovery of the mechanical engineering industry in the EU, which began in 1994, will accelerate in 1995. The strong economic conditions will allow manufacturers to address the aftereffects of the recession. The most serious problem is the low level of profitability, which constrains investment and innovation efforts. Furthermore, in the early phase of the recovery, many small and medium-sized mechanical engineering companies encountered difficulties in obtaining bank funds to finance the orders they had received. Finally, the drastic cuts in production has created capacity bottlenecks, although new investment and hiring should soon resolve these.

The cyclical recovery of the mechanical engineering industry will continue beyond 1995, but might lose momentum after 1996. Over the long term, ignoring seasonal fluctuations, the mechanical engineering industry in the EU will remain a growth sector. EU producers benefit from unique locational advantages, which will safeguard its international competitiveness. The most important is the availability of a highly qualified workforce, which is essential in the provision of customer-oriented, tailor-made engineering solutions. The increasing internationalisation of manufacturing and the emergence of new industrial nations offer EU machinery producers more opportunities than risks.

# Agricultural machinery

## NACE 321

1993 will be remembered in the annals of European agriculture as a hinge-year: implementation of the reform of the Common Agricultural Policy (CAP) and conclusion of the Uruguay Round of the GATT negotiations in December.

Such drastic changes in the philosophy of the European Union could only have adverse effects on farm machinery markets: the average decrease reached 9.2 % a year in real terms between 1989 and 1993. In other words, this industry sector shrunk by 38 % in volume during the period under consideration.

As the disinvestment of the European agriculture could not continue much longer without damaging its competitiveness, 1994 put a stop to the deterioration, even showing a noticeable recovery in certain sectors of activity and/or in some countries of the EU.

1995 should evidence a continuation of this tendency, albeit at a slower rate. European agriculture might again enter a zone of major turbulence as 1996 draws near due to the fact that the pluriannual commitments agreed upon within the framework of the reform in May 1992 will have to be re-negotiated.

In addition, it may be then that the first constraints resulting from the implementation of the multilateral GATT agreement of December 1993 will become apparent.

In this context it is to be reckoned that the agricultural machinery production sector as well as its markets will take a fresh downward turn at the end of 1995.

### INDUSTRY PROFILE

#### Description of the sector

The diversity of animal and vegetable farm products as well as the different stages of processing ranging from simple cleaning to the preparation of marketable products in the vicinity of production sites have led the manufacturers of the farm machinery sector to cover a wide range of equipment totalling around 450 different types of machines manufactured in Europe alone. The main machines produced are: agricultural and forestry tractors; motor cultivators, motor hoes and motor mowers; machines and implements for soil preparation and soil working; machines and implements for sowing, planting and distributing fertilizers; machines and implements for crop and root harvesting; machines and implements for crop protection or irrigation; machines and implements for cleaning, grading or treating farm products; dairy and cattle-breeding equipment; forestry machinery; transport equipment; storage equipment; lawnmowers; other agricultural and horticultural machines and implements.

The extreme diversity of the equipment offered enables a large number of small and medium-sized companies, which are often specialised in the manufacture of a single type of machine or a range of agricultural machines used in a specific agricultural area of production, to exist side by side with a small number of large multinational or international companies which essentially manufacture tractors and self-propelled harvesting machines.

The sector of agricultural and horticultural machinery and tractors is one of the most important of the European mechanical engineering industry, representing 5 % of the total production.

Germany, with 35 % of the total added value, is the largest producer of agricultural machinery in the EU, followed by France (18 %), Italy (16 %) and the United Kingdom (9 %).

**Figure 1: Agricultural machinery**  
Value added in comparison with related industries, 1993

Source: DEBA

The other countries represent approximately 21 % of the total EU added value.

#### Recent trends

The situation of the sector, which had substantially deteriorated between 1989 and 1993, not only in terms of production (-32 % in volume) but also in terms of market size (-38 % in volume) recovered in 1994.

The European production of agricultural machinery appears to have risen by 9.5 % in volume against 1993, whilst at the same time the EU market showed a 10.3 % increase in real terms.

#### International comparison

In 1993, production of agricultural machinery reached practically identical levels in the USA and the EU (i.e. 11 billion ECU). Compared to 1984, there has been a decline in production both in the EU and the USA: from 1990 onwards,

1994 are DEBA estimates.  
Source: DEBA

this decline has been more marked in the EU (see Figure 5), while the USA enjoyed a mild recovery since 1991.

In 1993, Japanese production of agricultural machinery was lower than in the other two members of the Triad, at about 9.7 billion ECU. Production in real terms in Japan has been slightly but steadily declining since 1990.

In order to take full advantage of the weakness of the American dollar, guaranteeing a satisfactory protection of the domestic market and providing exports incentives, the two major American producers have recently introduced redeployment schemes and resorted to temporary shutdowns with the result that production sites have been relocated in the United States.

The positive effect of these measures start to become apparent as, after the depression observed in the years 1991 and 1992, American production increased by 6 % in real terms in 1993 and should register still better results in 1994.

On the other hand, Japan is still confronted with problems connected with a heavily subsidised agriculture and the high level of the Yen. Even though the rapidly declining rate of the agricultural population vs. that of civilian workers tends to put Japan on a level with the European average, the fact remains that the average useful agricultural area of Japanese holdings (1.5 ha) presents a noticeable handicap in terms of mechanisation.

In real terms, Japanese production of agricultural machinery continues to decrease annually by 1.2 % over the period 1984-1993.

**Foreign trade**

In 1993, the companies belonging to this industry's sector have exported 25.5 % of their production outside the EU. Total exports, including intra-EU trade, exceed 50 % of the total production. Extra-EU exports, which had dropped significantly in 1991 (-5 %) and 1992 (-11.5 %), recovered in

**Figure 4: Agricultural machinery

1993 (+6.5 %). This trend should continue until 1995, where-upon a reversal should be witnessed in the following years. The main markets are the United States (22.5 %) and EFTA countries (18.3 %). The market share of Japan in extra-EU exports reached 5.4 % in 1993. It is also to be noted that Russia is now absorbing 4 % of the total exports of the industry sector.

Extra-EU imports have been steadily increasing for several years. However, it would appear that there has been a slowing down over the recent period. The EU however remains a net exporter of agricultural machinery, as exports were 2.25 times higher than imports in 1993. Nevertheless, the fact remains that extra-EU imports, which represented only 6 % of the total Community apparent consumption in 1985, now make up for almost 14 % of the agricultural machinery market of the EU. The United States remain the main supplier, with 47 % of the total extra-EU imports in 1993, followed by EFTA countries (26 %) and Japan (12.6 %).

## MARKET FORCES

### Demand

Since 1989 and up to 1993 European demand for agricultural machinery has steadily and substantially dropped by 9.2 % annually in real terms.

This deep trough in sales of agricultural machinery within the EU is the direct result of the confusion experienced by European farmers at the announcement of the CAP reform. The signature of the GATT agreements at the end of 1993 has rekindled their disarray.

However, the trend which is taking form now - mastering production volumes thanks to the variation of set-asides and narrowing the gap between world and European prices - begins to appear as potentially beneficial to the farming community. This is the reason why a recovery in demand for agricultural machinery has been witnessed in 1994, which led to sales increases in the order of 10 % in real terms.

**Figure 7: Agricultural machinery  
Origin of EU imports**

Source: Eurostat

## Supply and competition

The EU which represents a market of 245 million consumers with a high standard of living - i.e. 6.5 % of the world population - and a little less of 5 % of the total arable land, is the most important market of agricultural products in the world.

Advances in genetics and the implementation of new techniques made it possible - with the help of the CAP - to increase the Community agricultural production.

The European agricultural machinery industry sector has been associated with these developments over the years until it ranked first in the world.

It is also worthwhile noting that branches of the main North-American companies, some of which have been re-deployed as early as under the Marshall Plan, count among the largest producers in the Community.

In direct proportion with the drop in demand, productivity is shrinking every year (-13.4 % between 1989 and 1993). As a result, the sector is faced with an excess output capacity which necessarily burdens its profits. Few factors speak in favour of a change in the trend in the coming years.

## Production process

For many years the European companies belonging to this industry's sector have been investing in robotics and in machining centres in order to optimise their production techniques and facilitate work. Most of them have already implemented the principles of the "just in time" and "stockless" production.

Computer-aided design (CAD) has been introduced in the largest firms, whereby the software is taking charge of the design of tools, forging bolsters and of programmes necessary to the manufacture of the different components of a machine.

In direct proportion with the above-mentioned, a rapid increase in internal investments in the order of 8 % per annum has been observed in the recent period.

Up to now however all these endeavours have only resulted in a 14 % decrease in per capita value added between 1989 and 1993 whereas unit labour costs increased by 37.5 % over the same period.

Nevertheless the conditions for obtaining productivity gains do exist, as soon as a recovery occurs, which was the case in 1994 which registered a 10.5 % increase in the added value over 1993.

## INDUSTRY STRUCTURE

### Companies

As the companies belonging to the Industry's sector produce a wide range of machines it is difficult to give an overall picture of the European farm machinery industry, which is divided into two segments of similar size: tractors on one side and other agricultural and horticultural machines and implements on the other.

A large number of small and medium-sized specialist companies (around 4 000) are present beside a few large multinational or international companies.

Most of these large companies produce tractors and self-propelled harvesting machines. The main European manufacturers of this type of machines are FIAT-Geotech (Italy) which in 1991 has taken over Ford-New Holland, a company established in Belgium and in the United Kingdom. SAME (Italy), Renault Agriculture (France), KHD and Fendt (Germany) and the German firm Claas producing combine harvesters and balers.

The large American companies are also established in Europe: Case International Harvester, John Deere and Massey Ferguson. The activity of the large companies generate around 60 % of the turnover in the profession.

Year after year the world agricultural machinery market is contracting. In addition, hundreds of thousands of European farm holdings are bound to disappear in the coming years. In order to fight the unavoidable fall of the markets the companies - and more specifically the large ones - have been led to conclude cooperation or manufacturing agreements with some of their competitors on the world scene such as John Deere with Zetor-Brno or Massey Ferguson with AGCO, Landini, Steyr and Valmet.

In 1994 new cards have been dealt out in the agricultural machinery industry more rapidly:

Whilst the Tenneco Group launched a public offering of 35 % of the Case capital, Varsity announced the transfer of all their Massey Ferguson shares to AGCO, another American Group which already owned Hesston, Allis, Gleaner and White.

At the same time Massey Ferguson concluded a mutual supply agreement with Iseki, the Japanese specialist of small compact tractors, which also provided for the creation of a joint subsidiary to distribute Massey Ferguson and Iseki products in Australia and Japan. Iseki for its part became a partner in Landini, which specialises in the production of narrow tractors, together with Massey Ferguson.

Finally, in the same period, Massey Ferguson concluded an industrial and technical partnership agreement with Renault Agriculture which led to the creation of GIMA (International Group of Agricultural Engineering) - a subsidiary held on a fifty-fifty basis by Massey Ferguson and Renault Agriculture - in order to design and produce gears.

Renault Agriculture also concluded a mutual agreement with John Deere, according to which John Deere would supply Renault Agriculture with diesel engines whilst John Deere would take care of the marketing of Renault Agriculture tractors equipped with John Deere engines.

The year 1995 seems to start under similar auspices: the German Group Klöckner-Humboldt-Deutz (KHD) has just signed a letter of intent with the object of selling the agricultural machinery side of its business to the Italian firm SAME. SAME already owned the Italian mark Lamborghini and the Swiss Hürlimann.

### Strategies

A strategic study on the development of the European agricultural machinery industry prepared for the industry and the European Commission was delivered in November 1994. It

**Table 5: Agricultural machinery  
Production specialisation (1)**

(ratio)	1984	1993

Source: DEBA

concludes that agricultural machinery companies within the EU need to make the most of the new possibilities offered by the harmonised internal market, step up research and training efforts and industrial alliances. They should capitalise on the market opportunities emerging in the countries of Central and Eastern Europe, in the short term by building up direct exports, in the medium term by complementing this approach with industrial cooperation. In view of the risk of chronic decline and stagnation in the domestic market for traditional agricultural machinery, it will become increasingly important to focus the innovation effort on the expected growth areas of agricultural non-food production and landscape management activities.

### Impact of the Single Market

The impact of the Single Market on the agricultural machinery industry is linked to the Common Agricultural Policy (CAP) and its effects on agricultural activity and the number of farmers. Due to the change in policy from price fixing to the reduction of capacity (with compensation payments), demand and thus sales of agricultural machinery have been positively influenced. A remaining barrier is the failure of a mentality among farmers and farmer's associations to think European instead of thinking nationalistic. Another problem is that at this moment new barriers (labelling) are created or continue to exist on national levels, which cannot be prevented by the EU.

In terms of the trade impact, the industry is internationally oriented, being the number one in the world. As this position is not really threatened, the industry has approved the double zero taxation of the GATT agreements. However, EU SMEs are often not able to benefit from the European Programmes for SME's, as the procedures are perceived to be too complex and there is often a language problem. The removal of the remaining barriers to intra-EU trade should have a high priority.

### REGIONAL DISTRIBUTION

In 1994 the largest producer of agricultural machinery in the EU was Germany with 34 % of the total European production, followed by Italy (20 %), France (19 %) and the United Kingdom (11 %).

Germany is also the most important extra-EU exporting country with 36 % of the total exports, followed by the United Kingdom (23 %), Italy (18 %) and France (9 %).

In terms of intra-EU trade Germany's share represents 28.5 %, followed by Italy (24 %), France (14 %) and the United Kingdom (12 %).

### REGULATIONS

The importance of standardisation in the agricultural machinery industry is always increasing. The implications at commercial level and therefore in the conception and design phases are becoming very real. This is to say that the time when standardisation was considered a side-issue belongs to the past.

This new orientation results from several factors:

- Liaisons (mechanical, hydraulic, electric, electronic couplings) between the tractor which remains the mostly used energy source and the machine are becoming more sophisticated. Their standardised characteristics must be observed if one wants to make the best of the tractor-machine combination.
- Farmers always require more data on the performances of their machines. These performances must be determined in clearly defined terms, i.e. in standards. It is considered that agriculture is polluting the environment owing to the animals' production of organic dejections and the use of chemicals in treatments and fertilising. Construction standards which will enable farmers to measure precisely what they distribute are under current study and will be implemented in practice.
- Due to the "New Approach" principle which has been introduced in Europe to implement EU Directives, standards are becoming particularly important. The importance of this issue has resulted in the abandonment of a strictly national standardisation in favour of a European or international standardisation.

The activity in this field can only increase in the coming years.

All categories of agricultural machines fall under Directive 89/392/EEC (amended by Directive 91/368/EEC among others) which has come into force on 1st January 1995 and specifies safety and health aspects to be complied with.

Agricultural tractors either fall under Directive 74/150/EEC (applicable to four-wheel tractors with a limited maximum speed) or are dealt with by the different national provisions as the Directive is optional.

### OUTLOOK

The EU agricultural machinery sector supplies approximately 87 % of its own market. The impact of the confidence crisis experienced by the European agriculture in relation to its future has already been analysed at length. The recovery observed in 1994-95 can be considered as a purely technical phenomenon.

1996 will be the year of the intergovernmental conference, where the fifteen governments of the European Union may

**Table 6: Agricultural machinery  
Expected real annual growth rates**

(%)	1994-95	1995-97

Production	5.9	-1.8
Extra-EU exports	2.5	-2.0

Source: CEMA

discuss about the future of an enlarged Europe extended to Central and East European Countries and review the adjustments to be made to the amended CAP.

The first constraints resulting from the implementation of the GATT agreement may also appear at that time. So many changes occurring over such a short period of time are not likely to restore durably the confidence of the farmers who need stable rules. This is why forecasts for the years 1996 and 1997 are downward-oriented, as much in terms of production (- 2.5 % per annum in real terms) as in terms of apparent consumption (- 2.7 % per annum in real terms). At the same time extra-EU exports should drop by 3 % per annum in volume.

**Written by: CEMA**

# Machine tools

## NACE 322

The EU industry has got a strong technological position in markets for special machinery and systems, but R&D in areas of new technologies is not sufficient. In volume markets Japanese competitors are in the lead.

The current broad economic recovery provides the environment for the implementation of future oriented measures. Among them must be the expansion of basic and applied research, the improvement of price competitiveness and the restructuring of some companies to evolve to full European and even global players.

### INDUSTRY PROFILE

#### Description of the sector

The machine-tool industry provides machines for the processing of metal. The product programme can be divided into two broad groups, cutting and forming machine tools. The first group lost shares on total industry's output. In the mid-1980s, it accounted for about 75 % of production volume, whereas in 1993 it only accounted for 63 %.

The major product groups among cutting machinery are lathes, milling machines, grinding machines, gear cutting machinery and machining centres. The second group, forming machines, comprises among its main products presses, bending and shearing machines.

Beside mechanical manufacturing processes there are non-mechanical processes, such as laser cutting, electrical discharge manufacturing (EDM) and electrical chemical manufacturing (ECM). Since the mid-1980s the demand for this kind of machinery has grown much stronger than for the whole industry on average.

The supply of the industry does not only comprise standalone machines. The industry also provides complete manufacturing systems. Besides transfer lines, especially for the automotive industry, flexible manufacturing systems and cells (FMS/FMC) are supplied.

Due to the growing importance of systems, machine-tool companies have expanded their product programme by supplying equipment and software not only for the production but also for related areas, as for production planning systems (PPS) and computer aided design (CAD). Thus, the industry is more and more involved in engineering services.

As a whole, the machine-tool industry provides goods and services for production purposes and is, therefore, of major importance for the efficiency of a broad range of manufacturing industries.

#### Recent trends

The machine-tool industry is greatly affected by business cycles, and demand is more volatile than for most other goods (see Figure 3).

An overall economic slowdown began in 1990. The manufacturing industries throughout the EU were hit hard. Shrinking profits and over-capacities induced a slump in manufacturing industries' investment activities. The EU machine-tool manufacturers suffered the most severe recession after World War II. In 1990, production had peaked and then declined for four subsequent years. In 1994 the real output only reached 50 % of the former record volume.

In 1994 the European economy - preceded by the United Kingdom - recovered progressively, and the investment climate

**Figure 1: Machine tools**  
Value added in comparison with related industries, 1993

(1) Estimate; including former East Germany.  
Source: CECIMO, DEBA, Vieweg

improved. The framework conditions for the machine-tool industry changed for the better. For most of the important EU Member States new order bookings expanded by more than 10 % in comparison with the preceding year. But there is always a lag between orders and deliveries because of the nature of production of specialised machine tools which explains why the output remains largely behind the orders.

The production of the British machine-tool industry, as well as the Spanish one, grew by a double digit rate in 1994. The overall EU output was nearly stable in 1994 compared to 1993 thanks to an upward reverse of the trend in mid-1994.

Due to the broad recovery of the world economy most forecasts indicate that there will be no major set back. Medium-term prospects for the manufacturing industries are bright, and investment activities will grow.

However, the continued price pressure and the low margins do not allow the manufacturers to take full profit of the growth.

 1994 are DEBA and Vieweg estimates.  
 Source: CECIMO, Eurostat, Vieweg

Taking into account the forecasts for the development in the capital goods markets and business cycle indicators, the EU machine-tool production will probably grow by about 15 % in 1995 and by 10 % in 1996.

The dismissal of employees came to an end in late-1994. A further reduction of capacities is not required, and the companies have achieved "leaner" organisations with an improved efficiency. Currently the demand push induces companies to hire new staff, above all blue collar workers, and demand for white collar workers is set to take off later on.

Nevertheless the losses during the recession will not be balanced in the upturn phase. In spite of the recovery, in 1997 the number of employees will be around 25 % below the past peak.

**International comparison**

The importance of the EU machine-tool industry is shown by its weight on worldwide production. Its contribution accounted for 35 % of the output in 1980 as well as in 1993.

Currently, about 60 % of the deliveries are dedicated for the domestic market and about 40 % are exported to third countries. In 1984 the export ratio reached 42 %, but meanwhile some Asian competitors (mainly Taiwan and Korea) have grown significantly. The EU imports reached a share of the apparent consumption of around 25 % in 1993. In comparison with 1984 it has increased slightly.

The EU share of exports of production shows a strong dependency on foreign markets and can be regarded as a result of the international competitiveness of the EU machine-tool industry. With respect to the size of the internal market the high share is noteworthy.

Japan, the other important nation in the machine-tool market expanded its share of worldwide production from 14 % in 1980 up to 25 % in 1993. The foreign trade is marked by an enormous surplus induced by a low import ratio, with less than 10 % of the domestic demand provided by foreign suppliers. On the other hand the share of exports of production is even higher than for the EU. In 1984 it accounted for only 39 % and in 1993 it reached 51 %.

Source: CECIMO, American Machinist, Vieweg

The third important supplying nation in machine tools is the USA, although the contribution to the worldwide output declined from 18 % in 1980 to just 11 % in 1993. In principle the US companies' dependency on foreign markets is low. The share of exports of production accounted for only 17 % in 1984. But the share grew and reached 30 % in 1993. This development is partly due to investment in anticipation of the entry into force of the NAFTA and related exports, especially to Mexico, but also due to Japanese transplants in the US market which started exporting to third countries.

The time series of the Triad members' production show dependency on the high cyclical business. Between 1990 and 1993 the Japan and the EU machine-tool industries suffered a major setback due to the recession with a reduction of production by 51 % and 41 %, respectively, in real terms (the strong appreciation of the yen is a major factor behind this trend). The US machine-tool industry enjoyed a better development, because the economic situation in the domestic and neighbouring market was brighter.

### Foreign trade

The EU industry is not only the largest supplier of machine tools, but also an important player in the international trade. With their extra EU exports the European players command a share of around 30 % of the worldwide trade. The analyses of time series suggest that this indicator of competitiveness has been stable.

The dynamic countries in the Far East have been heavily investing in manufacturing industries, and the demand for machine tools is growing strongly. During the early 1990s EU deliveries to Far Eastern markets as a share of total EU exports increased from 15 % in 1990 up to 25 % in 1993.

This expansion was above all caused by the People's Republic of China that has become the most important single client country beside the USA. China is the only Asian country which EU companies have a better access to than their Japanese competitors. The EU share of Chinese imports stays at a level of around 35 % 1990 and 1993. It must be mentioned that Japanese companies are expanding their efforts in this market and competition will be tougher.

There is a challenge for EU companies to improve the access to other Asian markets too, to benefit from the growth potential. This is also true for the large Japanese machine-tool market to which only 2.7 % of EU exports were delivered in 1993.

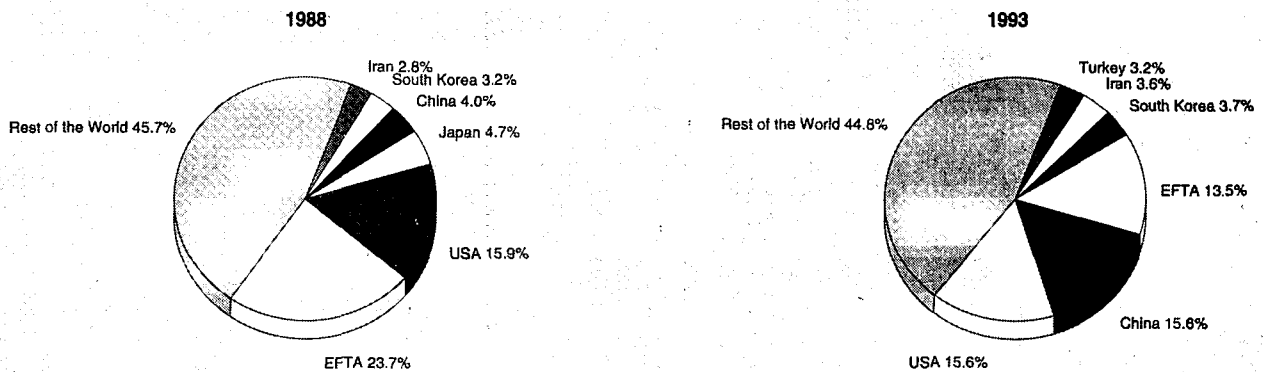

In spite of the cyclical upswing in the USA the EU machine-tool exports to the United States only grew slightly between 1990 and 1993. The EU share of US machine-tool imports declined from one third in 1990 to one fourth in 1993. It was only in 1994 that EU companies enjoyed growing exports into this market, a trend which is likely to continue.

The dissolution of the COMECON and the breakdown of the centrally-planned economies induced a slump in the demand for machine tools. The exports to the CIS countries shrunk by more than one third between 1990 and 1993. Although exports to CIS countries grew in 1994, further prospects are rather poor.

The Central Eastern European countries overcame major difficulties of the transition period. Due to an improved economic framework and foreign inward investment in manufacturing industries the demand for machine tools is growing. But up to now the share for this region of EU exports is low, even lower than that of the CIS.

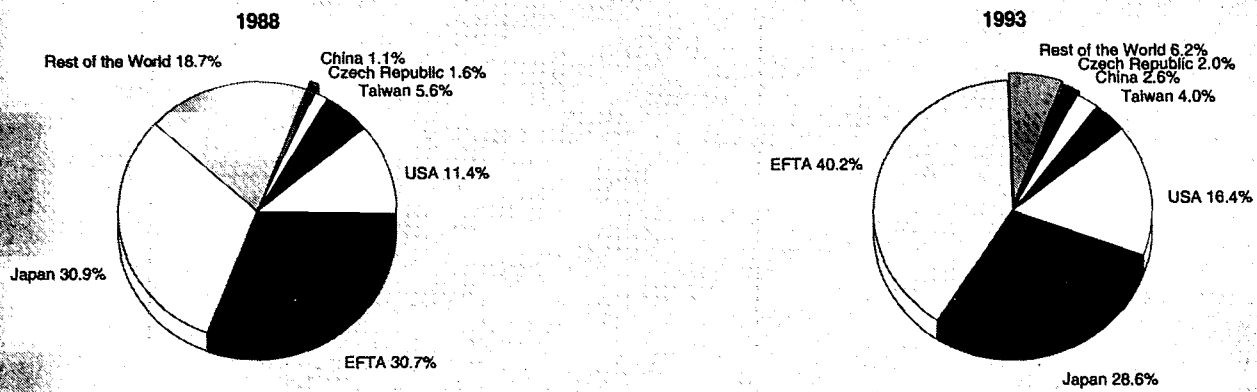

Total EU machine tool exports grew at an average yearly rate of 2.0 % between 1984 and 1993; simultaneously the imports grew at an average rate of 4.1 % per year. This de-

**Figure 6 : Machine tools**  
Destination of EU exports (1)

Origin of EU Imports (1)**

(1) Including former East Germany.  
Source: CECIMO, Vieweg

development indicates that the EU position in international trade has been worsening, although indicators for the performance in the international trade, such as the trade balance and X/M (exports/imports ratio) have not changed very much.

The foreign supply of machine tools in the EU is dominated by EFTA companies; most important are Swiss firms. Although their deliveries shrank by 42 % since 1990 they could maintain their share on EU imports which declined to the same extent during the recession.

Since 1987 the share of Japanese deliveries to the European market for machine tools is roughly stable, but this country remains, with about 30 % of EU machine-tool imports, by far the most important single supplying nation. Other Asian countries that were successful in European markets during the late-1980s are up to now only of minor importance. Some of their deliveries originate from Japanese transplants that could expand due to exchange rate alterations.

The US companies' exports to the EU shrank by less than 20 % during the recession, but in comparison with other for-

eign suppliers they were successful. Their share of EU imports grew up to 16.4 % in 1993. The driving forces behind this development are an improved price competitiveness by the devaluation of the USD, but also technological progress and presumably deliveries of Japanese transplants.

## MARKET FORCES

### Demand

The machine tool industry supplies capital goods above all for the manufacturing industries, most important is the mechanical engineering industry with a share of one third of total EU-demand. Second in this ranking is the automotive industry and third the electrical products industry with a share of one quarter and one tenth respectively. The aeroplane and space industry is of less importance by volume. But its demand for highly sophisticated technology is stimulating innovations.

The manufacturing industries were hit hard during the latest recession and investment budgets were cut. This development not only affected investment in advanced machinery and new capacities. In the latter half of the 1980s manufacturing companies had basically renewed their capital stock and, therefore, even the necessity for replacement investment was low.

Due to this development the EU share of the worldwide demand for machine tools slumped from 37 % in 1992 to 29 % in 1993. This development was not only due to the shrinkage of the EU market, but also induced by enormous growth rates for other important markets, such as the USA, Canada and China by 40 %, 23 % and 44 %, respectively. Furthermore, during the recession period a sustained demand for second-hand or refurbished machines reduced the demand for new machines.

### Supply and competition

The description of the machine-tool market requires a distinction between two segments. One comprises standardised machinery, which have high shares in turning, milling, drilling and machining centres. The other segment comprises specialised and customised machinery. Specialised machinery comprises machining operations that require a specific know how, such as gear finishing, the machining of gears or extremely big parts and special presses. Customised machinery comprises machines and systems that must be adapted to a client's requirements.

Most markets for standardised machinery have evolved to volume markets, in which global players are of major im-

**Figure 8: Machine tools  
Trade intensities (1)**

 Source: CECIMO, Ifo Institut, Vieweg

portance. In many of these markets Japanese companies have taken the lead, and European companies face strategic disadvantages. Their production capacities are too low, to enjoy economies-of-scale similar to their Japanese competitors, especially in the standardised metal cutting area.

During the latest recession the market for standardised machinery suffered a greater set back than the market for specialised and customised machines. The slump in demand provoked heavy losses, capacities were reduced and production sites were closed.

This poor development not only affected European suppliers. Japanese production fell even more. But the effects on the structure of the supply side in standardised machinery were more severe in Europe. Some strategic investment of the late-1980s, to catch up the Japanese lead, were withdrawn. The predominant Japanese suppliers were able to maintain their position and new competitors from Taiwan, Korea etc. emerged. Thus European machine-tool suppliers in volume markets face an even bigger challenge than before the recession.

In markets for special machinery, customised machinery and manufacturing systems, European companies have got a good position in international markets. Engineering know-how is of major importance for the production of high performance machinery. On the contrary, Japanese companies have a deficit in adequate qualified engineers. The same is true for some emerging competitors from newly industrialising countries (NICs).

The technological lead of European companies in this market segment reduces price pressure in comparison with volume markets. Nevertheless the EU firms must take into account that new competitors could try to penetrate the market if they perceive opportunities for sufficient profits. Therefore, cost cutting must be a strategic task even for technological leaders.

There is some doubt that the specialisation of the Japanese machine-tool industry on standardised products, and European suppliers on special machinery and systems, will result in an equilibrium in the world market. Indeed under pressure from some emerging countries and the higher salary costs in Japan, Japanese machine-tool manufacturers could be forced to penetrate the special machinery segment or to relocate an even more significant part of the production. In addition European specialised manufacturers benefit from the volumes which component suppliers are able to generate for volume machine business. A further reduction of such component production in Europe would increase the costs of these components for everyone.

Most important changes in price competitiveness during the past five years were induced by exchange rate alterations.

Production sites in Japan lost their competitiveness through several appreciations of the Yen against all other European currencies. For Japanese companies this development is a threat as far as their domestic plants are concerned. But many Japanese machine-tool manufacturers have become global players during the past 10 to 15 years and have launched production sites in their most important foreign markets. The dependency on the domestic currency has shrunk.

In contrast, US companies enjoy a strong depreciation of the USD against most other currencies. Additionally there are some signs that the US machine-tool industry enjoys a technological recovery that is partly stimulated by former secret R&D for defence projects. Some of the results have become available for market-oriented innovations.

During the 1980s the competition in the machine tool market could be characterised by the Japanese challenge. During the late 1990s there will be competition among all Triad members to be on the leading edge in advanced production technologies.

The challenge for the European industry in this environment is to compete with Japanese and US firms in some new technologies that are of importance for machine tools. This concerns the areas of new materials, highly integrated electronic components, high speed processing and micro machining.

### Production process

Usually machine tool manufacturers procure drives, controls and other electrical as well as electronic components from companies specialising in this area. These preliminary products are of key importance for the design of high performance machines.

European machine-tool manufacturers prefer to combine different components or modules to build new types of machines, but this requires enormous R&D efforts for the mutual adaptation. Up to now these tasks were time consuming because of lacking compatibility.

Current developments show that suppliers of electrical and electronic components try to overcome these problems by creating products designed as modules that are easy to combine with other units. By the introduction of a so-called open architecture for CNC systems the adaptation of different programme packages becomes easier. These developments provide the European machine-tool industry with a cost reduction potential in an area in which they experienced a major disadvantage in international competition.

In spite of this technological progress within Europe it must kept in mind that Japanese suppliers remain in the lead in R&D on advanced highly integrated controls. This is mainly due to the world's leader in numerical controls (NC) Fanuc (JPN). Japanese manufacturers are convinced that Fanuc con-

tributed a lot to the leading position of Japan in standard machine tools.

During the late-1980s advanced production technologies were widely introduced in the industry. Multi-purpose machines, flexible manufacturing systems (FMS) and -cells (FMC) were installed. Sometimes it was difficult to hire adequate educated operators to run these complex systems.

The advantages of investment in such automated production technology come into effect only if the utilisation of capacities is high. Otherwise pay back periods are too long. The cyclical demand for machine tools capital intensive production - with phases of under-utilisation - requires at least a flexible adaptation of running hours to become profitable. Relative rigidities in working practices in certain Member States

---

## INDUSTRY STRUCTURE

---

### Companies

The EU machine-tool industry consisted of 1 212 companies in 1993. The industry consists of predominately medium-sized firms with an average turnover of 6 to 7 million ECU and 100 to 110 employees. The industry's structure differs widely between the Member States: the average German firm employs 215, whereas the average Italian firm, which works with more subcontracting operations, only employs 67. Firms in the Netherlands and Portugal are even smaller.

The European industry is not dominated by large companies. The top five enterprises accounted for about 20 % of the EU machine tool production in 1993. The concentration of the Japanese and above all the US machine tool industry is much higher with the biggest five firms commanding 40 % and 55 % of the nations machine tool output, respectively.

### Strategies

The years of recession and current recovery have been marked by a major reshuffle of the industry, to create long term competitive companies, after some important suppliers have been dismantled. Mergers and acquisitions took place in the industry to create competitive units.

There is one major difficulty hampering the restructuring of the industry: to raise sufficient money for the implementation of strategies by adequate investment in production sites or in foreign subsidiaries or in distribution channels. Currently banks and other financial institutions are hesitating to grant the necessary credits.

Due to this problem the evolution towards a pan European industry has slowed down, because cross border investment is left undone. Additionally, companies that decided to remain in the volume market have to invest in adequate production sites and distribution channels to meet the challenge of the global players in the market.

European suppliers in particular in volume market are strongly dependant on the economic policy framework. Important fields are non-wage labour costs in some countries, high interest rates, qualification and flexibility of the labour force, R&D and trade policy. There are some initiatives of the EU that could contribute to overcome the difficulties of the industry, contained in the third and fourth Framework Programmes. In October 1994, the Commission adopted a communication on the competitiveness of the machinery construction industry. This proposes a coherent package of horizontal industrial policy measures to be taken by industry, Member States and the EU in the fields of investment promotion, the business environment, industrial cooperation, technical harmonisation, research and innovation, vocational training, regional policy, foreign trade and environmental protection, with a special attention to SMEs which form the bulk of this industry.

Many machine-tool companies have problems in getting access to EU schemes. This is true for the small companies and for the firms that are not classified as medium sized by the European Commission, because they have got more than 250 employees. These medium-sized companies with less than 500 employees have problems to meet all requirements in application forms for R&D schemes etc. that were designed for large companies.

---

## REGIONAL DISTRIBUTION

---

In 1993 three quarters of the EU machine tool industry's value added was produced in Germany and Italy. Next in this ranking are the United Kingdom and France with 12 % and 7 %, respectively. Spanish firms have caught up and currently command 4 % of the EU value added. Traditionally their competitive edge is the price, but they have caught up in the technological performance.

Analysing the countries' specialisation on machine-tools indicates Italy to be in the lead. The Italian's machine-tool industry's share of total output of the Italian manufacturing industries comes to 0.54 % in 1993. This share is higher than in 1984, indicating that the industry performed well during this period. For most other EU member countries this specialisation indicator shrank over time. This is also true for Germany, the country that was more specialised in machine tools than any other Member State. But it must be mentioned that due to German unification the comparison might be disturbed.

German production of machine tools is concentrated in Baden-Württemberg and in Nordrheinwestfalen. The unified Germany has got another important region, Saxony, situated in the South of the new Länder. In Italy most of the industry is located in the North, in Piemonte, Lombardia, Emilia-Romagna and Veneto. French suppliers are concentrated around the Ile-de-France and Rhône-Alpes. In the United Kingdom the machine-tool industry is located in the traditional industrialised region of the Midlands, in Yorkshire/Humberside and in the South-East. Spanish companies are centring in Euskadi, Catalunya and Madrid. In Portugal the industry is concentrated around Oporto. Denmark, Belgium and the Netherlands do not have particular areas of concentration.

---

## ENVIRONMENT

---

The machine tool industry's production consists predominantly of mechanical processes such as turning, milling, boring, drilling, grinding, forming, bending and assembling. Most of the preliminary products are of metal, and the input of energy is of minor interest. Therefore, the major threat for the environment lies in the use of cooling and lubricating liquids. The application of improved dressing equipment expands the life span of liquids and reduces the amount of liquids to be disposed.

Currently new kinds of cooling liquids are being developed, posing a reduced threat to the environment and the health of the employees.

Another opportunity for the protection of the environment is provided by the development of dry manufacturing processes. This kind of machining is an innovation that is used within the machine-tool industry but also supplied to customers. It must be admitted that dry manufacturing is restricted to specific materials and processes.

Hardening and galvanising are used to increase the durability and rigidity of materials and special surfaces such as slides. As hardening by heat treatment is not sufficient, chemical processes are necessary. Most of the machine-tool companies do not have their own capacities for these processes and employ specialised subcontractors.

**Table 6: Machine tools  
Production specialisation (1)**

(ratio)	1984	1993
Belgique/België	0.43	0.50
Danmark	0.60	0.25
BR Deutschland	1.83	1.63
Hellas	0.00	0.00
España	0.60	0.59
France	0.46	0.34
Italia	1.23	1.69
Nederland	0.14	0.16
Portugal	0.29	0.19
United Kingdom	0.74	0.63

(1) Ratio of production in the sector compared to manufacturing industry for each country, divided by the same ratio for the EU. Estimates.  
Source: CECIMO, Eurostat, Ifo Institut, Vieweg

Because of technological progress advanced machine tools are equipped with controls, motors etc.; new materials are used, such as composites and compounds. These machines are not as easy to scrap as their predecessors. The recycling of components will only be possible if machines are adequately designed. Companies are beginning to comply with such requirements.

## REGULATIONS

The Machine Directive allows machine tools which comply with essential safety requirements, and whose compliance has been attested in accordance with set procedures, to circulate freely within the European Economic Area. Intra-EU trade has become easier, but exports to third countries furthermore require the compliance with specific safety regulations.

Some groups of machine tools are so-called dual-use (i.e. they could be used for military purposes) machines and require a special permission for exports in third countries. Up to now each EU Member State had its own regulation. In late 1994 the EU Council of Ministers adopted a regulation and a decision setting out a harmonised approval procedure on exports of dual-use machines. This will provide more transparency for EU machine-tool companies and simultaneously fully liberalise intra-EU trade.

Regulations, such as the electromagnetic compatibility directive and agreements on interfaces between data processing facilities set standards that ease the combination of products of different EU countries. These regulations are prerequisites for the Single Market and very important for the setting up of automated manufacturing processes.

## OUTLOOK

The Western European economies are enjoying a broad cyclical upswing, and the accession of Austria, Sweden and Finland improves the framework conditions. Thus confidence of companies in the future development stimulates the investment climate and medium-term prospects for capital goods' demand are bright.

Some threats endanger this overall dynamic development. Most likely are disturbances in the financial markets and the exchange rate mechanism. It is not presumed that such an incidence would trigger a recession, but that only a short break in the upward trend would take place.

In this environment the demand for machine tools will strongly expand, especially during the early years of the upswing. The first challenge for the companies is to meet booming demand; the second challenge is to develop long-term strategies that enable them to stay in an extremely volatile market environment. Especially in volume markets, companies have to reconsider their strategies.

# Textile machinery

## NACE 323

In recent years, the EU textile machinery sector has experienced extremely low intra-EU demand, forcing European manufacturers to concentrate on foreign export markets. Through considerable increases in extra-EU exports, manufacturers have been able to compensate for weak domestic markets. Competition on the world market, however, is strong and intensifying as Japan and other countries want to take advantage of the growing and promising textile markets in the Far East.

### INDUSTRY PROFILE

#### Description of the sector

NACE 323 covers the manufacture of textile machinery, accessories of textile machinery (NACE 323.1) and sewing machines (NACE 323.2). This monograph mainly focuses on NACE 323.1 which can be further subdivided into: spinning machinery; weaving machinery; knitting and hosiery machinery; dyeing and finishing machines; and parts, accessories and other machines, such as man-made filament and fibre processing machinery, and preparatory machines. These machines spin (natural and synthetic) fibres into yarn; weave or knit the yarn into fabric; dye, print and finish the resulting fabric; and produce garments or other fabric products.

Production of textile machinery in the EU (in current prices) accounts for approximately 4 % of total production of the mechanical engineering industries in the EU. Compared to other related industries the textile machinery industry is relatively small.

Within the EU, Germany is the largest producer in the industry, accounting for 61 % of total value added, followed by Italy with 16 %. As a result, Germany accounts for more than 50 % of employment in the EU textile manufacturing industry and Italy accounts for about 18 %.

#### Recent trends

The general world recession of recent years did not spare the textile sector. According to the annual report of the International Textile Manufacturers Federation (ITMF), the world textile machinery market is still in a recession. The world market for staple spindles and looms for weaving dropped by approximately 20 % in the course of 1993. Textile machinery manufacturers have to meet changing needs of textile industries in both the developing and developed countries of the world and, perhaps more importantly, have to meet the growing needs of the vastly expanding textile regions of the Asia/Pacific, in which China is now the predominant producer of textiles.

After a 2 % decrease in EU production in 1993, there are signs of recovery, induced by an increase of extra-EU exports. Production in almost all EU countries declined in 1993, with the exception of Germany. German production rose by 4 % in 1993. For 1994, however, production increases are expected in Italy and the United Kingdom as well. Apparent consumption of EU textile machinery declined dramatically (26.8 %) in 1993 and no recovery is expected for 1994.

Employment in the EU textile machinery industry has been declining since 1990. In five years time, the number of employees fell from 107 300 in 1989 to 83 800 in 1993, a 22 % reduction. In Japan, employment has dropped as well. Only the USA has demonstrated a small rise in the total number of employees since 1992.

Figure 1: Textile machinery  
Value added in comparison with related industries, 1993

Source: DEBA

#### International comparison

The traditional predominant position of the EU as the world's largest producer of textile machinery has been affected by rapid production growth in Japan, which has become the largest single producing country. Besides Japan, Switzerland is also an important producing country of textile machinery and supplier on the world market. In 1984, EU production of textile machinery was 26.6 % higher than Japanese production; while in 1993 the difference was only 6.7 %. In 1994, however, production in Japan dropped, whilst production in Europe is expected to increase slightly. The main reason for the drop in Japanese production is a stagnation of exports, especially caused by the appreciation of the Japanese yen. US production is relatively small compared to production of Japan and the EU. Since 1991, however, US production has been increasing by 5 % per year.

**Foreign trade**

The textile machinery sector can be characterised as highly export-oriented. In 1993, the EU export rate was nearly 74 %, compared with a rate of 61 % in 1992. Import penetration is much lower, but the import/consumption ratio increased in 1993 due to a lower decline of extra-EU imports than the drop of intra-EU demand. Total imports increased until 1990 and have declined since then. Total exports declined in 1990 and 1991 but recovered in 1992 due to an increase in extra-EU exports. These foreign trade flows have resulted in a growing trade surplus between 1984 and 1993 with the export/import ratio almost doubling.

In terms of size and output, the German textile machinery industry dominates the world export market with a share of more than one-third of total world exports. The most important export destinations for German textile machinery in 1993 were the USA (16 %), China (11 %), Turkey (8 %) and CIS (7 %).

Current market trends show Asia and the USA as the most active areas, while India is becoming increasingly important.

Italy is responsible for 20 % of total EU textile machinery exports. Asian countries are the most important buyers of Italian exports taking about 42 %, followed by EU countries (18 %), other Western European countries (11 %), North America (13 %), South America (7 %), East European countries (5 %) and Africa (4 %). Italian exports increased in 1993 with export sales improving in several areas, particularly the Far East and Middle East.

French machinery firms produce about 8 % of total EU textile machinery exports and focus on Taiwan and Korea.

In 1992, British textile machinery exports amounted to 6-7 % of total EU exports. There are indications of rising British export sales during 1994, especially to the USA, which is in a re-equipment cycle that is expected to continue in the fore-

Source: Eurostat

seable future, and to the newly developing and developed countries in the Asia/Pacific region.

Extra-EU imports mainly originate from the two most important countries in the world textile machinery market: Switzerland and Japan. Both countries together accounted for 58 % of total EU imports in 1993. The share of the USA was 12 % in 1993, up from 9 % in 1988.

## MARKET FORCES

### Demand

Demand for textile machinery depends on demand for clothing and textiles. The world market for textiles and clothing is expected to reach 56 million tonnes by the year 2000 compared with 38 million tonnes in 1992. By the year 2002 the populations of China, Latin America, AND developing Asia and Africa are expected to consume some 21 million tonnes of textiles compared with 15.7 million tonnes in 1992, a rise of 34 % over the ten-year period.

North America, Western Europe and Japan are becoming markets of the past as textile manufacturers seek to establish operations in developing areas of the world, especially in the Middle and Far East. These operations will require the most

modern and innovative equipment in order to produce the highest quality products with the greatest flexibility.

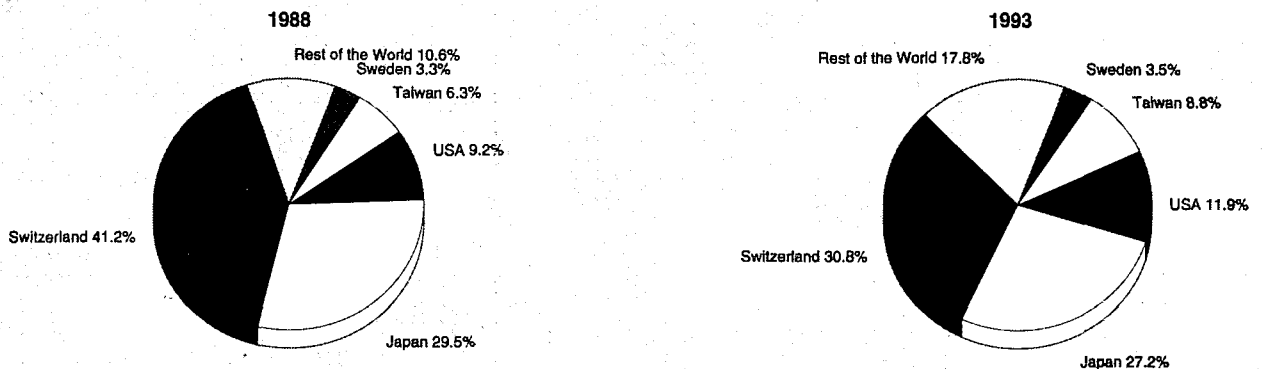

Some of the growth markets of the 1980s, such as Korea and Taiwan, are reaching a point of stagnation and investments will increasingly be placed elsewhere. South-East Asia, China, India and the Near and Middle East offer the best prospects for the next decade.

Further development in the former COMECON market is very difficult, but restructuring of the textile industries in Poland, Hungary, the Czech Republic and Slovakia is nearly finished and prospects are promising. A lack of hard currency is the main problem with regard to demand in Russia. For example, Stentex, a former GDR enterprise, based business on credits granted by the German government to the Russian state, which proved very unsatisfactory. As a result, a joint venture (Stentex-Kostroma GmbH) was established in April 1994 to activate the market.

### Supply and competition

International competition is growing rapidly. Japan has become the major competitor of the EU in the world market. The Japanese produce standard and highly advanced machinery and they have a strong position in the Asian markets. The

**Figure 7: Textile machinery  
Origin of EU imports**

Source: Eurostat

importance of Japanese products on the EU market is not increasing however.

Local companies in newly industrialising countries in the Far East and South-East Asia produce standard machinery at low prices and have become important competitors in the low-end markets.

Labour productivity in the EU textile machinery industry has been rising since a drop in 1991. Due to rationalisation of production and a reduction of the labour force, unit labour costs and total unit costs declined in 1993, causing a rise in the gross operating rate for the industry.

Global production of sewing machines is mainly concentrated in Germany and Japan. Other production facilities within Europe are located in Sweden, Switzerland, Italy and Spain. The rest of the global production takes place in the USA and Asia. Newly industrialised countries in Asia copy Japanese technology and sell their machinery at lower prices.

### Production process

During the 1980s new mechanical technologies provoked a renewal of capital stock, especially in the textile industries of the industrialised countries. Currently, machine manufacturers do not expect innovations that incorporate the potential to push labour productivity to new heights. Investment activities of developing countries in textile machinery are now focusing more on the latest technologies in order to attain cost reductions and higher quality levels through a more efficient and technologically advanced production process.

In contrast to mechanical technologies, the introduction of information and communication technologies (ICT) provide opportunities to increase efficiency. Most machinery provides opportunities for computer added manufacturing (CAM). In spinning and weaving, an integrated data exchange with a production planning system (PPS) is state of the art. The integration of several production steps with an automated flexible manufacturing system (FMS) has been reached, but fully automated production lines are still an exception. In-house integrated data processing connecting R&D, stocks and other logistic functions with the PPS are found in the textile manufacturing industry, but the level of penetration is low.

## INDUSTRY STRUCTURE

### Companies

The EU textile machinery industry consists of mainly small or medium-sized enterprises. There are about 160 German enterprises with roughly 39 % of them comprised of up to 99 employees. Only 24 % of German enterprises employ 500 people or more. The Italian textile machinery industry is more fragmented consisting of 400 enterprises with most companies being small or medium-sized. Among the 20 leading textile machinery manufacturers in Europe there are only two Italian companies.

One reason for the flexibility and innovative potential of the German textile machinery industry is the fact that many companies fall into the medium-sized category. High levels of expenditures on R&D also typify the German machinery sector. Important companies in the German textile machinery sector are: Schlafhorst, now part of the Saurer Group; Lindauer Dornier; Trützschler; and, Monforts and Fleissner GmbH & Co.

The 12 leading French textile machinery makers are: N. Schlumberger & Cie; Asselin; Houget Duesberg Bosson; Thi-beau; I.C.B.T.; Laroche; Staubli-Verdol; Comeureg; S.M.T.I.; Ameliorair; Caemard; and, Superba.

Belgium has a specialisation in the yarn and fabric making processes and the Netherlands has one in the finishing end of the business. Three Belgian companies are: Picanol (weaving machinery), Van de Wiele (carpet equipment) and Gilbos (winding systems). While Stork, Brugman and EFT are internationally operating Dutch companies.

### Strategies

The annual report of the ITMF states that as a result of the recession various textile machinery groups have been subject to reorganisation. The industry has been confronted with internationalisation and increasing competition. The resulting rationalisation of production has led to a number of acquisitions, mergers and other forms of cooperation within Europe and at the international level. The aim of specialised individual textile machinery manufacturers is to become a complete supplier to meet the growing demand of newly industrialised and industrialised countries for fully equipped, highly automated production plants.

Further standardisation is another strategy. Machinery of accepted standard technology will mainly be sold in developing countries. Another strategy is producing special high-quality and flexible machinery. A relatively small size allows maximum specialisation and close customer relationships. Advanced machinery is especially destined for industrialised countries. Internationalisation also involves import substitution policies, e.g. companies in developing countries that manufacture under licenses of EU manufacturers.

Japanese textile producers are now attempting to reform themselves without being bound by traditional philosophies in areas such as the attitude of textile producing districts, change in generations, distribution structure, creation, manpower development and globalisation.

### Impact of the Single Market

The impact of the creation of the Single Market on the textile machinery industry has been very limited. One reason for this is the already highly international character of the industry. As the largest share of production is sold outside the EU, measures concerning the creation of the Single Market have not affected the major trade flows in the textile machinery industry. The removal of external barriers is considered to be much more relevant for this internationally oriented industry, as are all the measures aimed at diminishing the disadvantages of the small and medium-sized enterprises (SMEs) created by the Single Market.

Source: DEBA

## ENVIRONMENT

In new technology development the industry pays a lot of attention to environmental issues such as a reduction of the production of noise (a maximum of 85 decibels being allowed for unprotected workers) and other emissions. Stricter laws on noise levels will raise the prices of machines. However, the trend in noise levels differs according to the kind of machinery. In general, the level will be affected by two factors: the replacement of the noise-making parts with more quiet parts, and by the actual running speed of the machines, which has been increasing.

## REGULATIONS

The Machine Directive (89/392/EEC) will attain its definite character in 1995. This Directive defines essential requirements concerning machine safety, health provisions for people and the environment. Provisions relate to the design, the materials used, the way in which machine operations should be illuminated, machine operation itself, safety against mechanical risks, the application of screens and other safeguarding components, maintenance and machine indications and identifications. Manufacturers that comply with the provisions of the Directive may affix the CE-mark on their products. In anticipation of the EU Directive for a safer working environment, European manufacturers have already put much effort in to R&D for the improvement of safety conditions of their machinery.

Products labelled with a CE-mark will have free access to the markets of all EEA States. The CE-mark can also become beneficial for EU manufacturers with respect to extra-EU export markets. While technology and know-how are becoming increasingly important to survive, strict EU regulations are inspiring manufacturers to innovate. Maybe not in developing countries, but certainly in Western economies, the CE mark will stand for safe and environmentally friendly machinery and equipment.

In 1992 the Directive for Electromagnetic compatibility (89/336) came into force. The transition period will last until January 1, 1996. The Directive applies to all electric and electronic equipment, systems and installations which can cause electromagnetic disturbances, or which can be influenced by such disturbances. The Directive tries to prevent the electromagnetic susceptibility of machinery and to stimulate the electromagnetic immunity of machinery. Manufacturing of machinery following this Directive implies the incorporation of the relevant measures in the development stage.

## OUTLOOK

Increases in production in Italy, the United Kingdom and some smaller EU countries were responsible for an anticipated overall increase in total EU production of textile machinery in 1994. Production increases are expected to continue in the medium term.

Demand in the EU for textile machinery will not rise in the near future. It will probably only rise in the long run as some replacement investment within the EU and a growing demand for technologically advanced machinery are expected. Technologically advanced machinery, including the application of modern technology, sophisticated automation, electronics and computer-to-computer communications, will generally find its destination in industrialised countries.

Developments outside the EU are particularly relevant for the highly export oriented EU textile machinery industry. Despite intensifying Japanese competition, in particular Asian markets, and a growing tendency towards local production of machinery in current export markets, extra-EU exports are expected to double over the 1987-97 period.

Written by: Netherlands Economic Institute  
The industry is represented at the EU level by: Comité Européen des Constructeurs de Matériel Textile (CEMATEX).

# Chemical machinery

## NACE 324.12

Total production in the EU chemical machinery industry is estimated at 6.5 to 7 billion ECU. The chemical machinery industry is largely dependant on the chemical processing industry. Remarkably, despite a decrease of investments in the chemical industry in 1993 and the prevailing recession, production increased in both Germany and the United Kingdom. This increase was particularly due to rising exports. With respect to demand for chemical machinery, quality control and environmental concerns are playing an increasingly important role. From 1994 onwards, the prevailing adverse economic conditions are expected to gradually improve.

### INDUSTRY PROFILE

#### Description of the sector

The products of the chemical machinery industry can be divided into the following categories:

- producer-gas or water-gas generators;
- centrifuges and dryers; and
- filtration and purifying machinery for liquids and gases.

Important products include: pressure vessels, heat exchangers, process towers and reactors, dryers (rotary, belt, adsorption), piping, filtering engineering, mixers, structural steel engineering, valves and fittings, heavy walled tubulars, air conditioning and jacketpiles.

As several products are not specific to the chemical industry, they have been classified differently within the EU. For instance, the production of water purification equipment is usually, but not always, classified under the heading of chemical plant equipment. Other equipment, which may or may not be considered chemical machinery in national statistics, includes furnaces, heat exchangers and pressure vessels. Comparing statistical evidence by Member State should thus be done with care.

#### Recent trends

Production in the six EU countries considered is estimated at around 6 billion ECU, while estimated total EU production was 6.5 to 7 billion ECU (the countries considered are assumed

to represent 85 % to 90 % of total production). With a trade surplus of 0.6 billion ECU in 1991, demand for chemical machinery was in the range of 5.9 to 6.4 billion ECU. On the basis of the above information, the export rate in 1991 can be estimated to be in the region of 20-22 % and import penetration in the region of 12-13 %.

Germany is still the largest producer of chemical machinery. In 1991 it accounted for a share in the region of 40 % of total production, while Italy and the United Kingdom followed with roughly 15 % each. France probably accounted for about 10 % of total production in 1991. Due to differences in the statistical classification systems, these figures give only an order of magnitude.

From 1988 to 1991 production in current prices grew at an average rate of 8.3 % per year. However, this rate varied significantly by Member State from 1.5 % in the Netherlands and 2.5 % in Belgium to 21.2 % in France. Two of the major producing countries, the United Kingdom and Italy, recorded average annual growth rates during the period of 6.3 % and 11.5 %, respectively. Available statistical evidence further reveals declining production in the Netherlands for 1992. Conversely, production in Germany and the United Kingdom continued to increase after 1991; although at lower rates than before. Ironically, investments in the chemical industry dropped in 1993 both in Germany (8 %) and in the United Kingdom (14 %) from their 1992 levels. The possible adverse impact of these declining investments on the chemical machinery industry has been compensated for by an increase of extra-EU exports of 16 %. Investments in the chemical industry also dropped in other Member States from 7 % in France to over 20 % in Belgium. Italy and the Netherlands from 1992 to 1993.

#### Foreign trade

Traditionally a sizeable net exporter of chemical machinery, EU saw its export-import ratio decline year by year from 3.4 in 1983 to a low of 1.8 in 1991-92, although the rate of decline slowed after 1986. Remarkably, the rates for 1988 and 1993 were virtually identical (2.22 versus 2.19), indicating that extra-EU imports and exports grew on average at about the same rate per year, namely by 9.7 % and 9.2 %, respectively. However, in 1993 extra-EU imports declined by 3 % and extra-EU exports increased by 16 %, resulting in an increase of the trade surplus of almost 40 %.

The USA, EFTA countries and Japan are the major non-EU suppliers of chemical machinery. In 1993 these countries accounted for 76 % of total extra EU-imports. However, in 1988

Source: National statistics, ANIMA

this share was 92 %, indicating a loss of market share to other countries. In this respect, mention should be made of South Africa, which increased its share from virtually nothing to 8.6 % in 1993. Eastern Europe also recorded a larger share, although they represented less than 3 % of extra-EU imports in 1993. Poland and the Czech Republic are likewise main suppliers.

The main non-EU export markets for EU chemical machinery manufacturers are the EFTA countries. In 1993 they accounted for one-fifth of extra-EU exports. However, this is a decrease from their one-quarter share in 1988. In contrast, the relative importance of the United States, Eastern Europe and the Far East markets has increased. In 1993 they each accounted for 13-14 % of extra-EU exports for chemical machinery. With respect to Eastern Europe, exports to Poland, Hungary and the Czech Republic increased during the period. Also, export growth to South Korea, Thailand, Taiwan and the Philippines is worth mentioning.

## MARKET FORCES

### Demand

The chemical plant equipment industry has a variety of client industries, all of which are processing industries. Among the customers are: the chemical industry, the petrochemical industry, the pharmaceutical industry, the biochemical industry, the food processing industry, water purification utilities, oil and gas exploration and production companies, refineries, power generation plants, environmental application companies, engineering contracting companies and government institutions. Most client industries follow cyclical business patterns.

Although other processing industries are also important clients, the chemical machinery sector relies most heavily on investments in the chemical industry. During the course of 1989 demand for chemicals started to decline. In 1991, the Gulf war, the recession in some major export markets, the depreciation of the US dollar and the Japanese Yen all added to the adverse development in the chemical industry. The recent recession also resulted in a decline of investments of 13 % in 1993 in the main client industry; however, preliminary figures suggest that this tendency has been partially reversed in 1994. Remarkably, available data suggests that the recent fall in investments did not result in a corresponding drop in EU production of chemical machinery. Production in major producing countries, such as Germany and Italy, even increased in 1993 stimulated by a substantial increase of exports. For the EU as a whole export growth was 16 % in 1993.

EU production of chemical machinery is several times higher than Japanese production (no figures are available for the USA due to differences in industry classification). Capital

investment in the chemical industry of Western Europe is by far the largest in the world, compared with the USA and Japan. Investments in Japan, however, grew faster than in Europe during the 1980s, while investments declined in the EU by 13 % in 1993.

Fierce competition in the downstream industries, and increasing regulatory requirements imposed on them (in particular with regard to safety and environmental issues) continue to be the main factors influencing demand for chemical machinery. Their need to improve energy efficiency, stemming both from the competitive situation and the regulatory context, also remains important. Hence, capital spending by the client industries is increasingly directed towards de-bottlenecking, energy-efficiency, environmental issues and safety.

### Supply and competition

Chemical machinery manufacturers operate on the world market. This applies not only to large firms, but also to small companies. Reasons behind this are the highly internationalised downstream industries, as well as, the existence of large petrochemical multinationals. Since most of the machinery is designed for single-piece work, chemical machinery manufacturers from all over the world can bid for the specialised product needs of a multinational client. The competitiveness generated by this practice keeps prices low, and slow to respond to a booming market. On the other hand, in a recessive market prices tumble quickly.

The USD exchange rate is an important determinant of demand for EU chemical machinery. The prevailing cheap USD not only affects EU exports to the USA, in a more indirect way, it also affects competition with foreign companies in the EU market. Hence, the relatively high-valued EU currencies and the volatility of the USD adversely affects the competitive position of the EU chemical machinery industry. However, in 1993 Italy was an exception to this situation because the lira devaluated by 22 % as compared to the USD.

In order to meet the demand for increasingly sophisticated machinery and to meet clients' requirements with regard to flexibility, the environment and safety, the chemical machinery industry focuses on product innovation to upgrade the quality of their supplies. Areas of particular interest are:

- improvement of 'traditional' chemical process technology, such as, the cogeneration of heat and power, and more efficient and less polluting burner and combustion systems.
- microtechnology, to provide reliable sensors for process control and environmental monitoring.
- environmental technology and biotechnology, which often overlap. For example, biotechnology forms the basis for various promising approaches to soil decontamination. Fur-

**Figure 2: Chemical machinery  
Destination of EU exports**

Source: Eurostat

ther, bioreactors for groundwater treatment achieve purification levels of nearly 100 % for chlorobenzenes.

- 'green chemistry' or 'green technology', which seeks to incorporate environmental consciousness and the notion of sustainability into chemical research and development. This is an effort to shift the balance from an exclusive focus on yield to one that places economic value on minimising or eliminating wasteful by-products.

### Production process

Quality control is a major concern for the chemical industry, which has extended to machinery suppliers. Certification under the ISO 9000 series of quality-assurance standards is increasingly a prerequisite imposed by downstream industries on companies wishing to supply them with machinery. When implemented, these standards often complement industry-specific product standards in assuring customers that the processes and systems used by a supplier are indeed consistent with contractual requirements for quality. To the extent that such purchaser requirements are spread internationally, quality certification will be a tool of competitiveness for the European chemical machinery industry.

CAD/CAM systems are used to design and manufacture machines. Computerisation and application of advanced electronics have become a basic feature in the manufacture of new machinery, not only to improve the efficiency of the machine itself, but also for machine safety, pollution control, precision in operations and the like.

The increasing complexity of the machines, as well as, the higher quality standards with which they must comply, make it necessary to have more and better skilled labour. It is in this area that shortages are common. Spending on in-house training may need to increase.

## INDUSTRY STRUCTURE

### Companies

In the chemical machinery industry there are no large multinational enterprises, although most of the companies engage in exports. Two types of firms can be distinguished: product specialists and jobbers or activity specialists.

Product specialists are firms which design and develop equipment by themselves and can successfully export specific products due to low unit cost. These enterprises are normally medium-sized and export more than half of their production. In addition, they usually have a specific technical knowledge of the process in which the machinery will be involved after production.

Jobbers, or activity specialists are firms which manufacture items from the client's blueprint. This is the most common type of firm in the industry. However, they are less export oriented than the product specialists with exports normally accounting for less than 50 % of production. These firms' knowledge of the processes in which the machinery will be involved is less crucial than for the product specialists.

### Strategies

The strong dependency on its main client industry makes the chemical machinery industry vulnerable in a structural sense and to cyclical swings. One-sidedness can lead to a product-oriented attitude which can be detrimental in a market where competition is growing.

Knowledge of chemical processes can be profitable for an enterprise, because it allows them to discuss with the customer not only the apparatus, but also the whole process in which it is a part. This is important because optimisation of the

**Table 2: Chemical machinery

Source: NEI

process cannot be achieved through optimisation of the individual units alone; an overall plan must be made.

Companies are seeking to reduce the negative effects of such over-dependency in two main ways. One way is by engaging in other markets. Given the process oriented products, logical markets are the food, pharmaceutical, power and environmental industries. Other companies are applying knowledge of the main client industry to develop new products for that industry. These companies tend to become niche players. While there are not many real niches in the world market, the companies that find one are much less affected by cyclical downswings.

### Impact of the Single Market

The impact of the creation of the Single Market on the sector has been neutral. The chemical industry is undergoing a restructuring worldwide, which is attributed to the globalization trend in the major downstream markets and not to the single market. The lack of one single European currency is considered an important internal barrier, and should be addressed in priority. Red-tape is another barrier for intra-EU, but also for extra EU operations and trade. Amongst the external barriers to trade which should be addressed are the import duties raised by other world countries, in particular some Far Eastern countries.

### ENVIRONMENT

Unlike the chemical industry, manufacture chemical machinery does not seriously threaten the environment. Moreover, by increasingly applying new production techniques, such as CAD/CAM, energy consumption and waste are reduced as much as possible. New production techniques also have a favourable impact on the ergonomic condition, for example through noise reduction. Finally, technological progress has also induced changes in the products themselves. Advanced chemical machinery is equipped with controlling equipment, and new materials, which can be recycled, are used as composites and components of the machinery.

### REGULATIONS

Three EU Directives are of particular interest to the chemical machinery industry: the Machinery Directive, the Directive on pressure vessels and the Electromagnetic Compatibility Directive for electrical equipment. Manufacturers whose products comply with the relevant provisions of these Directives and who have demonstrated this conformity by following the applicable procedures set out in the Directives may affix the CE-mark. This allows free movement of the products throughout the European Economic Area.

The Machinery Directive sets out safety requirements for all machinery. Concerning its application to most chemical machinery, the transitional period for the Machinery Directive expired on 1 January 1995: it is therefore now mandatory.

The Directive on pressure vessels addresses simple compressed gases vessels; especially for oxygen and nitrogen. Pressure vessels have to fulfil certain requirements regarding safety.

**Figure 3: Chemical machinery  
Capital investment in the chemical industry by Member State, 1993**

Source: CEFIC

The Directive does not, however, apply to pressure vessels for nuclear installations, to pressure vessels for the propulsion of ships and aeroplanes or to fire extinguishers.

The Electromagnetic Compatibility Directive lays down mandatory essential requirements concerning emissions of electro-magnetic disturbances and immunity from such disturbances for electrical apparatus, equipment, systems and installations. The transitional period will end on 31 December 1996, until which time manufacturers may choose to comply instead with any relevant national legislation.

### OUTLOOK

The recession in the EU caused an adverse situation in the sector's main client industries, as both output and investments declined. A significant feature was the fall in investments in key countries such as Germany and the United Kingdom. Remarkably, due to increased exports to non-EU destinations, production of chemical machinery increased in these countries. However, during the latter part of 1993 and in 1994, the signs of recovery for the industry have been numerous, and are to be confirmed in 1995.

The current focus from client industries on quality, flexibility, environment, health and safety will encourage technological developments in areas such as the improvement of 'traditional' chemical process technology, environmental technology, biotechnology and 'green chemistry' or 'green technology'. These developments will create opportunities for the EU chemical equipment industry. This applies also to the creation of new export markets, for example in Eastern Europe, although the slow economic restructuring process and the shortage of foreign exchange will restrict short-term demand from these countries.

Short-term growth of the chemical plant industry is expected to be slow. In the medium-term, however, when more of the opportunities can be seized growth will accelerate, but it is still expected to be modest.

The industry is represented at the EU level by: European Committee of Chemical Plant Manufacturers (EUCHEMAP). Address: c/o FME, Bredewater 20, Postbus 190, NL-2700 AD Zoetermeer; tel: (31 79) 531 1256; fax: (31 79) 531 1365.

# Packaging machinery

## NACE 324.2

The EU is the world's largest manufacturer of packaging machinery. Germany and Italy are the major producing Member States. In 1993 EU demand declined by 10 %. As exports grew by 13 %, production declined by 1.5 %. New opportunities in areas such as Eastern Europe, Central and South America and the Far East have caused major shifts in export patterns.

EU competitiveness will increasingly depend on an enhanced quality of engineering that meets the demand for more versatile and 'environmentally friendly' products. This requires a large R&D effort and a highly qualified labour force.

The new EU Packaging Waste Directive will encourage the use of new packaging materials, which will be a challenge for the manufacturers of packaging machinery.

There are signs of economic recovery. The EU packaging machinery industry is expected to emerge gradually from the recession. Growth will pick up, but without attaining the high pre-1992 levels.

### INDUSTRY PROFILE

#### Description of the sector

The machinery classified under NACE 324.2 varies widely in use. The industry includes: form, fill and seal machines; combined filling and closing machines, group packaging and filling; accessories, parts and spares. These four groups account for around 60 % of total production of packaging machinery; 'other machinery' is accounting for another 40 %. These products are used in a few main downstream industries.

#### Recent trends

In 1993 EU production of packaging machinery totalled an estimated 5.8 billion ECU. Germany and Italy are the most important producing countries; their joint share was 75 % in 1993. Some two thirds of EU production is exported, of which over 65 % has a non-EU destination. With export shares of 74 % and 79 % respectively, Germany and Italy have an even stronger export orientation than the EU on average. These countries also have the lowest import penetration: about one third. This makes Germany and Italy both net exporters; all the remaining Member States recorded trade deficits in 1993.

Total employment in the EU packaging machinery industry is estimated at about 58 000 employees (United Kingdom excluded).

The packaging machinery industry has benefited from a favourable development in recent years. However, the situation deteriorated in 1992. The downswing of the trade cycle in the major industrial countries had an adverse impact on domestic and foreign demand. Furthermore, the reunification boom in Germany came to an end in 1992. These adverse developments caused a drop in growth rates e.g. in Germany the 1992 growth rate was 5 % as against 13 % to 15 % per year from 1989 to 1991. In 1993 the ongoing depression brought about a drop in EU demand for packaging machinery by over 10 %. However, production declined only by 1.5 %, because exports increased by 13 %. This sharp upturn is attributed to the Italian manufacturers, who took advantage of the devalued Lira by pushing their products into industrialised Europe, and to the seizing of opportunities in areas such as East Europe, Central and South America and the Far East.

#### International comparison

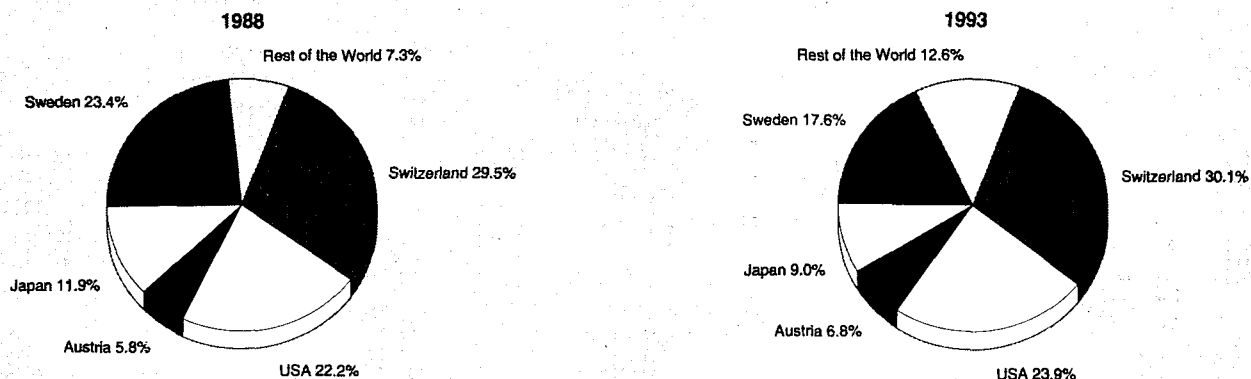

The Triad's total production was 11.8 billion ECU in 1993. The EU held about half of this figure; Japan accounted for 27 % and the USA for 23 %. While Japanese and American firms benefit from large domestic markets European firms have turned to exports markets. Germany and Italy account together for two thirds (intra-EU exports included) of the Triad's exports. Germany is the world's largest exporter. For Japan foreign trade is rather insignificant: only 7 % of production is exported, and only 4 % of Japanese demand is covered by supplies from abroad. For the USA these rates are 19 % and 23 %. The EU is a net exporter of packaging machinery and so is Japan, despite its low export orientation; the USA recorded a trade deficit in 1993.

#### Foreign trade

Throughout 1985-1993 the EU recorded a trade surplus. From 1985 to 1989 this surplus fluctuated from 1.2 billion ECU to 1.3 billion ECU. Then it increased at an average rate of 12.3 % per year, mainly because of growth in exports. Imports remained stable after 1990. Wrapping machines for candy, tobacco products, filling machines for the beverage industry and sundries were the main EU export products.

Three (blocks of) countries account for almost the entire extra-EU imports of packaging machinery: the EFTA countries, the United States and Japan with a collective share of 95 % in 1988 and 92 % in 1993. The EFTA countries were the

Source: COPAMA, NEI

larger trade partner: in 1993 they accounted for 59 % of the extra-EU imports. However, given the relatively small size of extra-EU imports, they met only some 15 % of the EU needs. Although still small, both East European and Far East countries have increased their share in extra-EU imports: from virtually nothing to 2 %, and from 1 % to 2 % respectively.

The share of the developed countries in extra-EU exports has declined from 54 % in 1988 to 36 % in 1993, implying that these countries have become relatively less important for the extra-EU sales of packaging machinery. This is particularly true for the EFTA countries and the USA. The share of these destinations declined from 22 % to around 14 %. Conversely the exports destined for less developed countries, including East Europe and NICs recorded an increase in their joint share from 46 % to 64 %. Export growth to the Far East, including China, and East Europe was the main factor in this development. In 1988 these destinations accounted for respectively 10 % to 11 % of the extra-EU exports; in 1993 this was 17 % and 15 %. The lack of a Japanese export orientation, thus far, has created market opportunities for EU manufacturers in Far East countries. In this group the main countries of destination were China and South Korea. Exports to East Europe were mainly directed at Poland, Hungary and Rumania. The share of Mexico in extra-EU exports has increased remarkably, namely from 1 % in 1988 to 4.5 % in 1993.

The entry of Austria, Finland and Sweden in the EU will sensibly increase the weight of intra-EU trade in the sector.

## MARKET FORCES

### Demand

Demand for packaging machinery comes mainly from the food, beverage and tobacco industry. These industries account for an estimated 60-70 % of total demand. They are followed by the pharmaceutical, chemical and related industries. These downstream industries each have their own specific needs. The fact that these industries meet essential consumer needs causes demand for packaging machinery to be less cyclical than demand for other machinery and equipment.

Quality rather than price is increasingly determining demand for packaging machinery. Future trends in demand will continue to focus on automation, efficiency and flexibility. Ergonomics also has become important. More efficient, reliable, flexible and versatile machinery will enable the manufacturers to respond to the further diversification of consumer demand. This will cause product life cycles to shorten. More flexible and versatile machinery is needed to enable quick change-overs for packaging different products, package sizes and variable quantity production runs. In order to cope with the ongoing de-skilling process in the client industries the operation of the machinery should be made more simple. Furthermore environmental considerations will affect the packaging machin-

ery industry. They imply a gradual movement from plastic packaging to cartons. For instance blister packs are being replaced by hanging carton.

### Supply and competition

Many European, e.g. Italian manufacturers have invested heavily in research and development, and in production equipment in recent years. The resulting improvement of the quality of engineering has made their products more in compliance with current market requirements, which stress flexibility, production speeds and fast change-over times.

The minor Japanese share on the world market and its low export ratio can be explained by the fact that the packaging machinery industry is characterised by small businesses producing custom-tailored products that require extensive after-delivery service. For this reason the Japanese have been focusing on the nearby and large domestic market. Once the industrial trend is moving towards more standardised machinery and equipment, Japan will be able to develop similar advantages as they have in the automotive and other industries. However, as long as the market stresses engineering and tailor-made solutions, no large threat should be expected from the Japanese. For example, the export share of Japan in extra-EU imports declined between 1988 and 1993 from around 12 % to 9 %.

In contrast with other US machinery manufacturing industries, the packaging machinery industry seems to have been able to benefit from the lower dollar exchange rate. USA exports increased by 4 % in 1991, and by nearly 10 % in 1992. However, in 1993 they remained virtually stable. Compared to Italy and Germany, the USA export share is rather low (around a quarter). The USA packaging machinery is noted for its robust construction and sophisticated electronics.

The high degree of concentration in downstream industries such as in the food industry, might result in price cuts and lower margins in the long run. The packaging machinery industry, however, is itself also moving towards more concentration and a further internationalisation.

### Production process

Like in other mechanical engineering industries - especially where custom-tailored products are being produced - the labour force is an important asset. As a consequence, the quality of the labour force and thus the quality of the training programs is a major factor influencing the success of EU industry in the long run. Therefore, the quantity and quality of education and training should be maintained, if the technological ad-

vantage of the industry is not to fall behind. Furthermore, when demand for well-trained employees exceeds the supply of labour, productivity losses are likely to occur.

Keeping the quality of the labour force, however, should not lead to excessive wage increases. Sharp rises in input prices of materials and labour wages - as happened during the last couple of years - will have a negative impact on the industry's profitability and will cause reduction in investments weakening the competitiveness of EU firms.

The extent to which a manufacturer of packaging machinery is able to meet customer requirements is also determined by the quality and precision of its production equipment. The increasing demand for versatile machinery for instance requires advanced production equipment together with high labour skills and large investments in R&D.

## INDUSTRY STRUCTURE

### Companies

The total number of enterprises in the EU belonging to NACE 324.2 is estimated at some 1 050 in 1993. With an average of 60 to 65 employees and an average turnover of some 5.5 million ECU, these companies are mostly medium-sized, although figures vary by Member State. Average employment ranges from less than 20-25 employees in France and Spain to 90-100 in Germany and the Netherlands; average turnover varies from 2.0-3.0 million ECU in Spain and the United Kingdom to 8.0-10.0 million ECU in Germany, Italy and the Netherlands.

### Strategies

In general the enterprises focus on one market segment (e.g. mostly one machine function for a specific client industry). This also applies to larger firms, like for example Krones which focuses only on the beverage industry. Firms such as Bosch (D) and SIG (CH), which offer a whole range of products for several downstream industries, are still rare. A trend towards vertical integration might have been set by the two Swedish multinational companies Tetra Pak (milk and juice packaging group) and Alfa-Laval (manufacturer of food and other industrial equipment). Tetra Pak took over Alfa-Laval, thereby creating the possibility of 'one-stop shopping' as packaging and processing machinery can be bought from the same group.

Company strategies have been reviewed in response to the general market expansion caused by the Single Market, the

Source: NEI

German unification and the political changes in the former East bloc countries, and also to developments in specific markets. The general trend towards higher concentration through mergers or cooperation follows from these developments. Cooperation enables companies to offer tailor-made machinery and equipment to meet customer needs. A further explanation for the concentration of activities can be the threat of increasing market power of the large multinationals that dominate the downstream markets. This might lead to lower margins for the manufacturers of packaging machinery.

On the other hand, the expansion of the same multinationals in the former East bloc countries also offers market opportunities for EU manufacturers of packaging machinery. A further internationalisation will increase the strength of current market positions, and enhance opportunities to benefit from the European unification.

### Impact of the Single Market

The larger market and the harmonisation of regulations are considered to have been the main two (positive) effects of the single market on the packaging machinery sector. These have nevertheless not translated into a notable increase in production or trade, as harmonisation facilitates but does not really stimulate trade. An important remaining internal barrier concerns the differing regulations of the individual Member States with respect to safety and other related issues for the packaging machinery. The removal of these barriers should be the next priority.

### ENVIRONMENT

The growing consciousness among consumers regarding environmental issues together with the growing influence of downstream industries and retail channels on packaging decisions is affecting the packaging machinery industry.

Ever more restrictive legislation is determining the nature of packaging and packaging material, particularly in the West and North European countries. This has caused a growing demand for recyclable packaging material and 'environmentally friendly' packaging. For example, the Dutch government, the food industry and retailers in the Netherlands have concluded an agreement to switch to the recyclable glass bottles and discontinue the use of PVC packaging.

In the near future a growing demand is expected for form, fill and seal machinery, resulting from the rising demand for snacks and food in thermoform-packages. Other growing segments are combined filling and closing machinery and for group packaging.

### REGULATIONS

Packaging machinery manufacturers are preparing for the Machinery Directive, which is coming into force on January 1st, 1995. This Directive sets out safety requirements for all machinery, and hygiene requirements for machinery used to make or package food. Compliance with the provisions set in the Machinery Directive entitles manufacturers to affix on their machines the CE mark (Conformité Européenne). The com-

mercial value of the CE mark is that it will bring about free trade among the Member States. Currently Member States apply different technical and quality standards with respect to safety and hygiene, implying an obstacle to free intra-EU trade. Once carrying the CE mark a product is entitled to enter the EEA (European Economic Area) market, and individual States cannot refuse the product to their markets.

The CENTEC 146 EC safety standards also apply to the packaging machinery. In each member country, the packaging machinery manufacturers are cooperating with their national standards organisation to develop European standards.

The industry will also be affected by the Packaging and Packaging Waste Directive. This Directive must prevent the occurrence of differing national regulations, which would violate the Single Market principle. For example, the German Packaging Ordinance is said to constitute a barrier to free trade within the Community. Within the framework of the Packaging and Packaging Waste Directive, the EU Council of Ministers has agreed upon the upper and lower limits for recovery and recycling waste, and has developed a hierarchy of waste management options. This hierarchy places a high emphasis on waste reduction at the source and re-use of materials in the production of packaging. Despite the common position reached by the Council of Ministers the Directive is facing an uncertain future; Germany, the Netherlands and Denmark opposed, because of the watering down of the Directive; both the recovery and recycling targets were considered to be too low. Later Belgium and Luxembourg joined the opponents. Their refusal upset the delicate balance of votes within the Council, which requires that a qualified majority of the Member States support an initiative. In the meantime national legislation will prevail.

Changing requirements regarding packaging and packaging waste, such as the prohibition of excessive packaging and the substitution of certain raw materials by less polluting materials (e.g. a shift from plastic to board) might affect the machinery industry too. Enforcement of the development and production of new packaging materials could encourage the demand for new and innovative machinery.

Finally, the Electromagnetic Compatibility Directive for electrical equipment is relevant to the (packaging) machinery industry. This Directive comes into force on January 1, 1996.

### OUTLOOK

In 1989-1991 the EU packaging industry recorded double digit growth rates of 13 % to 15 % per year. However, since the autumn of 1992 manufacturers continued to feel the effects of the ongoing economic slump in major markets, which together with the ending of the reunification boom in Germany led to a much lower growth rate (5 %) than in the preceding years. In 1993 the ongoing recession caused a drop in the sales of packaging machinery of 1.5 %. This decline was much smaller than the drop in EU demand which was 10 %, as increase of 13 % in sales outside the EU compensated largely for this decline; the EU industry benefited from the recovery in the United States and from the growth of new markets in the Far East and Eastern Europe.

It is expected that from 1994 onward, the EU industry will gradually emerge from the recession, but growth rates as before 1992 are not envisaged. In 1994 production is expected to stabilise. After 1994, production growth will gradually pick up.

The EU industry already has strong footholds on the world market. However, in order to retain its competitiveness substantial effort and resources must be allocated to research and development and training of the labour force. This will allow the industry to respond effectively to the shift in demand to more versatile machinery.

New legislation such as the Packaging and Packaging Waste Directive, may give rise to a change in raw material requirements for packaging, and could create a stimulus for the manufacturers of packaging machinery. However, at the same time this legislation may increase cost in the client industries, thereby putting their profit margins under pressure, and lowering investment incentives.

# Plastics and rubber machinery

NACE 324.3

*Rapid growth of the plastics and rubber machinery sector in the European Union has been interrupted in the last few years by the downturn in the global economy. The UK economy is already beginning to improve and it is expected that this will spread. Former environmental threats are now perceived to present new opportunities for technical innovation and new products. The Far East and Eastern Germany are emerging as the big markets for the future, but tough competition is to be expected from the Japanese. Nevertheless, the sector is in good shape to take full advantage of the return to growth.*

## INDUSTRY PROFILE

### Description of the sector

The plastics and rubber machinery manufacturing industry in Europe has a turnover of around 7 billion ECU, comprises about 600 companies and employs about 60 000 people. The industry manufactures a wide range of equipment for use by trade converters and in-house manufacturers of consumer and industrial products. The range of machinery includes: extruders, injection moulding and blow moulding machines, compression presses, foam converting and thermoforming machines. It also manufactures other equipment not separately classified, such as granulators, calenders, mills and a variety of spare parts and ancillaries.

Recently, specialised equipment has been developed for recycling materials and products into secondary applications in support of the general trend towards care for the environment. Most of this type of machinery can be adapted to suit particular requirements for processing plastics or rubbers. The machinery ranges in size from small bench-top machines for making small precision components to giant plants for making large storage tanks. Products made on such machinery range from: light weight burger cartons to large building insulation slabs in expanded polystyrene; medical catheter tubing to large diameter sewer pipes; and, miniature high precision computer components to full size truck cabs.

The wide range of plastics and rubber materials in use requires machinery specifications to be adaptable to suit their particular processing characteristics. Specialised machinery, such as tyre forming, vulcanisation and associated equipment and compounding mills are particular to rubber processing.

The world's leading producers of plastics and rubber processing machinery are based within the EU and include: Germany, Italy, France, UK, Austria, Netherlands, Spain and Luxembourg. Germany and Italy are the principal producers having shares of a half and one-third, respectively. The other countries together account for just one-fifth of the total.

An analysis of the production and consumption figures by machinery type shows the leading role that injection moulding and extrusion machines play in the processing sector.

### Recent trends

Apparent consumption, using total trade data in the four principal EU Member States, rose by an annual average of 20 % between 1984 and 1988, making this sector one of the fastest growing in the EU during the last decade. However, between 1988 and 1993 this average (excluding intra trade) was -4.0 % due to an average annual decrease in consumption of 27.7 % between 1991 and 1993.

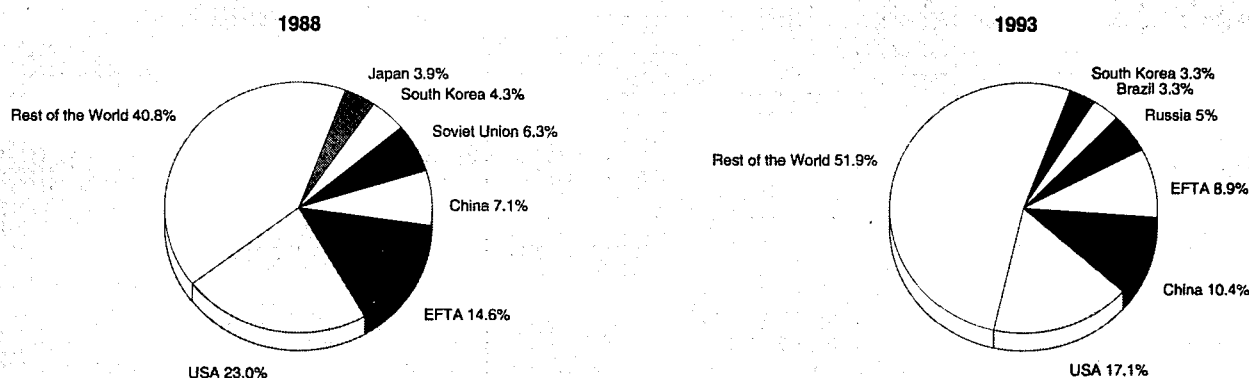

Production of machinery in these countries in 1993 totalled around 4.5 billion ECU, a decrease of about 5 % compared with the previous year. This decline is, however, less than that experienced in the previous year and is regarded as a temporary interruption in the continuing growth of the sector.

Total exports during this period showed growth of 8.5 % from 3.64 to over 3.95 billion ECU. This gives the industry confidence that its competitive strengths will enable it to take advantage of the upturn in investment by the plastics processing sector, which is already starting to happen as demand in world markets begins to grow.

### International comparison

European manufacturers are continuing to build upon their long established technological leadership in this sector and have established a commanding position with over three quarters of the world market. Competition from the USA, Canada and Japan continues to intensify, but prospects remain good for European manufacturers whose knowledge and experience give them an overall advantage. The growing ASEAN countries are being targeted as an area of great opportunity for the near future.

### Foreign trade

Germany still ranks first in world exports of plastics and rubber machinery in 1993, with 29 % of the total. Japan is now in second place with about 18 % and Italy third with 13 % of the total. Overall, European manufacturers secured 61 % of world exports in 1993. A 5 % recovery in the growth rate of European exports was seen over the last year reversing the trend of the previous three years. Most trade during this period was within the EU, with the UK and France being main destinations.

The single European market already exists in the plastics and rubber machinery sector. As for potential markets in Eastern Europe, they have yet to show signs of anticipated growth.

Growing internationalisation of the major consumer product manufacturers is leading to internationalisation of their key suppliers and of manufacturing standards.

### MARKET FORCES

#### Production process

Computerisation of control systems continues to be a prime feature of machinery specifications. It has become an essential requirement for the integration of processing machinery into modern production lines to meet ever increasing quality standards and productivity levels. European protocols have now been established for these computerised control systems and for links to ancillary equipment and central computers. Automation and robotics are also now well established features

**Table 6: Plastics and rubber machinery  
Production and consumption by Member State, 1993**

(million ECU)	Apparent consumption (1)	(%)	Production	(%)

Source: BPF/Euromap

of modern plastics and rubber processing machinery and equipment.

Environmental pressures have led to big improvements in machinery designs aimed at reducing product weight, collecting and recycling process waste, and optimising energy consumption. For example, new machinery has been developed to efficiently reprocess and recycle used products collected from the domestic and industrial waste streams to reduce their impact on the environment and, ultimately, to recover the residual energy content of end-of-life components.

New plastics materials, products and applications continue to challenge machinery manufacturers ingenuity. However, European manufacturers are still at the leading edge of innovation in machinery design and development.

---

## INDUSTRY STRUCTURE

---

### Companies

The leading machinery manufacturing companies in the EU include: Krupp (D); Battenfeld (D); Klockner (D); Mannesmann (D) (including DEMAG and Krauss-Maffei); Sandretto (I); Reifenhauser (D); Engel (A); Stork (NL); Billion (F); Negri Bossi (I); Francis Shaw (UK); Netstal (CH); Bucher Guyer (CH); and Windmüller and Hölcher (D).

In the face of growing competition from Eastern Asia, the progressive trend of mergers and acquisitions continues as resources are rationalised and expertise is consolidated.

### Impact of the Single Market

The creation of the single market is considered positive from a general point of view. Due to the already existing international character of the industry, however, the impact of the Internal Market programme on the sector has been limited. A current obstacle for a further facilitation of trade concerns the regulations of the individual Member States with respect to safety and other related issues for the plastics and rubber machinery. Removal of this barrier should have a high priority. Another priority is related to external barriers which still exist with respect to exports to third countries. The EU should encourage mutual recognition of regulations on a global scale.

---

## ENVIRONMENT

---

Environmental considerations continue to grow as public opinion and legislation focus increasingly on energy conservation and pollution. Policies, codes of practice and legislation are impacting upon products and machinery specification and design.

The EU Machinery sector, through its trade associations, has been at the forefront of developments in design and technology to facilitate the exploitation of opportunities for improving products and processes. Modern machinery enables the minimisation of product weight and process waste, has low process emissions and maximises energy efficiency. Special machinery has been developed for the efficient collection, conveying, size reduction and reprocessing of domestic and industrial waste. The sector also collaborates closely with other pan European organisations in relevant promotional and educational activities.

---

## REGULATIONS

---

Implementation of the new Machinery Directive has had a major impact upon the sector during the year. Consequently, manufacturers and users have focused a great deal of time and effort into ensuring compliance, which is consistent with remaining competitive in the international marketplace.

---

## OUTLOOK

---

The UK economy started to improve in 1993 and is expected to continue over the next few years. Other principal European countries in the plastics and rubber machinery industry are also beginning to see signs of improvement. The sector has undergone some painful restructuring in order to survive in the interim and to sharpen up to compete in the future.

Winning potential new markets in the ASEAN region will provide a formidable challenge. Also, the market in Eastern Germany has yet to develop. This will present a considerable challenge in the face of growing competition.

Environmental threats will provide opportunities for EU machinery makers to exploit their leading technological expertise.

Growing markets for plastics and rubber products include: packaging; building and construction; transport; and, electrical/electronic goods. These markets are becoming increasingly international in their structure and more demanding in their product standards. The EU Machinery sector is fit and ready to take advantage of these opportunities as the international economic climate begins to improve.

Written by: British Plastics Federation

The industry is represented at the EU level by: European Committee of Machinery Manufacturers for the Plastics and Rubber Industries (EUROMAP). Address: c/o VDMA Postfach 710864, D-60498 Frankfurt; tel: (49 69) 660 3840; fax: (49 69) 660 3831.

# Machinery for lifting and handling

## NACE 325.5

*The manufacturers of lifting and handling equipment basically produce investment goods. Therefore, demand is largely dependent on investment decisions in downstream industries. Manufacturing industries (consumer and capital goods), construction, transport and warehousing are major client industries.*

*R&D and highly qualified labour are essential for the industry. Customisation as well as environmental, ergonomic and safety considerations have increasingly become the driving forces behind technological and product development in the industry. Most companies are specialised in certain kinds of machinery and focus on specific market segments.*

*After years of continuous growth during the 1980s production fell in the early 1990s due to the economic recession. Although market demand is still not satisfying, there are signs of economic recovery. In 1993, the UK production of machinery for lifting and handling started to increase, a trend which is also expected for other Member States in the short term.*

### INDUSTRY PROFILE

#### Description of the sector

Lifting and handling equipment guarantees the physical flow of goods in all production processes and throughout the whole value chain. The industry covers the following products: conveyers, cranes, pneumatic handling equipment, hoists (electric and pneumatic), elevating work platforms, storage/warehousing and retrieval machinery, and industrial trucks. The industrial trucks industry includes any wheeled vehicle, not running on rails, which is designed to carry, tow, push, or lift any kind of load. Besides these industrial applications, the sector also produces lifting and transport machinery to convey people, such as lifts, escalators, passenger conveyors, ropeways, cablecars and ski-lifts.

Continuous handling equipment (conveying and loading equipment for bulk and unit loads) is the largest segment in Europe with a 26 % market share. Fork-lift trucks, lifts/escalators for passengers and storage/warehousing machinery follow with market shares of about 17 % each, cranes account for approximately 11 % and serial lifting comes in at 7 % of the total. These figures are, however, estimates as they do not fully account for warehousing equipment and does not handle person lifts.

Warehousing equipment includes high-lift trucks/stackers, reach trucks, narrow aisle trucks, medium and high-lift order pickers, pallet trucks and other vehicles.

#### Recent trends

According to FEM, in 1993 EU production of lifting and handling equipment accounted for 15.4 billion ECU and consumption totalled 14.2 billion ECU. Germany, France and the United Kingdom were the primary producing countries with Germany accounting for 47 % of total EU production, France and the United Kingdom each representing 21 % and Italy following at 9 % of total production.

After years of continuous growth in the 1980s, production (in current prices) dropped during the period 1991-93 by 2.3 billion ECU or 13.3 % due to the world-wide economic recession. All Member States recorded production declines over the period; however, the declines were highest in Italy (-41 %) and the Netherlands (-30 %) and relatively low in the 3 major

producing countries of Germany (-3 %), France (-10 %) and the United Kingdom (-9 %).

Due to the economic recession and resulting over-capacity, employment in the industry also decreased over the 1991-1993 period. Labour markets for machinery for lifting and handling in Italy and Germany were hit extremely hard by the recession evidenced by employment drops of 34 % and 23 % respectively. In the Netherlands employment decreased by 14 %. Remarkably, France recorded a 4 % rise in employment.

#### International comparison

The EU is the world's major producer of lifting and handling equipment. In 1992 EU production amounted to nearly 16.5 billion ECU, while production levels in North America and Japan reached 13 billion ECU and 8.3 billion ECU, respectively. With an export share of 35 % (including intra-EU trade), European manufacturers depend heavily on foreign markets, compared to a 29 % share for Japanese exports and 18 % in North-America. In 1992, 16 % of the total EU production was sold in non-Member States. With respect to imports, 30 % of the EU domestic demand was covered by foreign suppliers (including intra-EU imports), as compared to 15 % in North-America and a meagre 5 % in Japan.

#### Foreign trade

Most of the foreign trade for individual Member States involves intra-EU trade. In 1992, 58 % of total EU exports found their destination in other Member States, while 70 % of EU imports had their origin in other Member States.

In current prices extra-EU trade in lifting and handling equipment has grown by 41 % between 1988 and 1993. Extra-EU exports increased by an average annual rate of 5.1 % and extra-EU imports rose by an average annual rate of 4.4 %. As a consequence, the export/import ratio increased from 2.0 in 1988 to 2.2 1993. Imports actually grew faster than exports between 1988 and 1991, but have since been declining.

Throughout the 1988-1993 period, the EU has been a net exporter of machinery for lifting and handling equipment. Until 1993, the trade surplus ranged from 1.1 to 1.2 billion ECU, but due to a substantial drop in extra-EU imports in 1993 it has grown to 1.5 billion ECU. Germany alone accounted for 47 % of the total EU trade surplus, followed by Italy (19.5 %) and the United Kingdom (16.3 %). In the same

Source: FEM

year only Belgium/Luxembourg. Greece and Portugal recorded negative trade balances with non-Member States.

In 1993 the former EFTA countries and the USA together accounted for almost 32 % of EU exports of machinery for lifting and handling. However, the relative importance of these export markets has declined since 1988. The USA's share has dropped from 15 % in 1988 to 11 % in 1993. In contrast, China, other Far Eastern countries and countries in the Middle East have become increasingly important as export markets for EU equipment. Their joint share in EU exports increased from around 16.5 % in 1988 to 28.5 % in 1993.

Excluding the former EFTA countries, Japan and the USA are the major non-EU suppliers of machinery for lifting and handling, together accounting for 32 % of EU imports. Although this share remained fairly stable between 1988 and 1993, some shifts among the individual countries' shares can be observed. Whereas Japan saw its share decrease from over 24 % in 1988 to 16 % in 1993, the share of the USA remained at a rather stable level of 14 % to 15 %.

However, although it is true that direct official imports from Japan have decreased, "grey" imports of lifting and handling vehicles of Japanese origin increased alarmingly during the same period. In 1994, "grey" imports dwindled thanks to Commission monitoring.

## MARKET FORCES

### Demand

The products of this sector are basically capital goods. Thus, demand is highly dependent on investment decisions of downstream industries. The client industries differ by type of machinery with each having their own unique characteristics. Manufacturing industries (consumer and capital goods), construction, transport and warehousing are all of particular interest to the manufacturers of lifting and handling equipment.

Traditionally, the role of warehousing within the manufacturing industry has been to achieve the three objectives of: storing products manufactured at an optimum production rate against perceived customer demand; setting up stocks against production shortfalls; and anticipating seasonal demand patterns. Nowadays however, the importance of these factors is diminishing as more flexible production planning is developed, better information on customer demand is available and more open relationships between manufacturer and customer are established.

As materials handling and logistics are the most effective ways to gain flexibility, this sector is less affected from investment cutbacks in the client industries. Demand, therefore, is expected to increase in the anticipated climate of economic recovery in the immediate future.

### Supply and competition

The EU industry for lifting and handling equipment is highly diversified. Despite the cyclical character, profit rates have remained fairly stable and even improved at the end of the 1980s, reflecting the fairly limited role of price competition. In contrast, competition concentrates on quality (assurance) and customised production, enabled by automated, highly flexible production processes. Customers are willing to pay more for high quality products when efficiency improvements by these products offer higher returns on investment.

Technological progress has also resulted in economic, flexible and highly automated cranes, which play a major role in logistics. Remote control systems permit crane and load operations to form a better and more ergonomic working environment. Such ergonomic and safety aspects will also continue to be the driving force in innovation for serial lifting equipment, used in workstations to reduce body strain and to improve the flow of work.

For storage equipment, racks, shelves and warehousing the trend towards future storage systems is relevant. This trend is aimed at maximising space utilisation, minimising use of manpower (particularly in hostile environments such as cold stores), easy location and retrieval of stock, as well as accuracy and order assembly. Finally, in the market for lifts and escalators up-to-date technology is directed towards user-friendly, safe and efficient lifts.

As a whole, there are numerous specialised companies operating in the market for lifting and handling machinery. Competition intensity varies between market segments though. World-wide competition is probably strongest in the market for forklift trucks, which is dominated by a few international companies offering standard products in all shapes and sizes

for any conceivable application. The world-wide market for lifts and escalators is also dominated by a few large companies, two of which are the European companies - Schindler and Kone - together accounting for more than 50 % of the world market. In storage equipment, racks, shelves and warehousing a number of companies are active and there are some 100 manufacturers of mobile and loader cranes in Europe.

European manufacturers are leading in the world market for electrically operated trucks, although the USA is the market leader in the sub-market for narrow aisle trucks. Japan is the incontestable leader in the market for combustion powered units; whereas EU market share is 'only' 21 %, due to the strong environmental considerations prevailing in Europe.

### Production process

CAD/CAM systems are used to design and manufacture machines. Automation and application of advanced electronics have become basic features in new machinery, not only to improve the efficiency of the machine itself, but also for machine safety, pollution control, precision in operations, etc. Hence, innovation has become top priority in maintaining competitive advantages.

The industry requires highly qualified employees, which have knowledge about modern technologies in machinery and equipment. Some companies have education facilities for their employees to keep them up to date with these technologies.

Enabled by a modular production process which uses standardised parts and components, the lifting and handling equipment sector has become customised rather than standardised. By combining different modules, customisation has become possible. The required increase in production flexibility has been obtained by applying modern technology in the produc-

**Figure 2: Machinery for lifting and handling  
Destination of EU exports**

Source: Eurostat

tion process. Technological development is also proceeding in lifting and handling material itself. For example, as a result of factory automation and automated warehousing, industrial trucks have to be equipped with electronic devices for advanced handling systems. An example of a modern industrial truck is the automated straddle carrier which is able to locate and move containers without human interference.

## INDUSTRY STRUCTURE

### Companies

The lifting and handling sector consists of many small companies and a few large groups. The total number of companies is estimated at 1 500 with total employment at 160 000. The average number of employees per company varies between 100 to 110. Large multinationals dominate the industrial truck market. European suppliers like Linde/Fiat (D), with 30 % of the fork-lift market, Lansing (UK), Jungheinrich (D), Lancer-Boss (UK), and Manitou (F) compete with leading suppliers from Japan, such as Toyota, Komatsu, and Mitsubishi-Caterpillar (JPN/USA) and from the USA, such as Hyster and Clark. An important new EU supplier is Valmet (Scandinavia), which accounts for 60 % of the world market for straddle carriers.

In the warehousing equipment sector, the largest EU supplier is Jungheinrich (D), with slightly more than 30 % of the market, Linde/Fiat (D) with around 30 %, followed by BT (S) with 15 %, and at some distance by Crown, Nissan, Toyota and Vestergaard.

### Strategies

In order to anticipate and cope with the opportunities and threats following from the creation of the Single Market, EU companies have been, and still are, restructuring their operations. This has resulted in a flow of mergers, acquisitions and strategic alliances with other companies. Also, non-EU companies are trying to maintain or improve their positions in the EU by concentrating supply.

Japanese manufacturers have responded to the establishment of the Internal Market by building production facilities in EU Member States. For example, Nissan set up a production line for industrial trucks in Spain in 1989 and Toyota, Komatsu and Mitsubishi have signed cooperative agreements with EU companies. JCB (UK) has linked with Sumitomo; and Fiat (I), Hitachi (J) and John Deere (USA) have considered a joint venture. Moreover, Krupp (D) concluded an agreement with

Komatsu for selling Krupp's mobile cranes in Japan. US manufacturers have also expanded their activities in Europe: Clark and Caterpillar relocated production facilities to Europe in 1986. Additionally, other important examples of industrial co-operation are the Mitsubishi/Caterpillar joint venture, Manitou's manufacturing of trucks for Toyota and the cooperation agreement between Komatsu and Lancer Boss.

Most of the manufacturers of lifting and handling machinery tend to be highly specialised because, with the exception of the few big companies, they are too small to cover all the market segments. Specialisation permits manufacturers to: remain up to date with respect to trends in technology and customer needs; respond in a quick and adequate way to the ever changing technology and consumer focus; and, direct research and development towards envisaged future developments.

### Impact of the Single Market

The impact of the creation of the Single Market has been limited so far. An EU Directive of particular relevance to the manufacturers of machinery for lifting and handling is the Directive on Machine Safety, which came into effect on January 1, 1995. Four issues are of extreme relevance to this industry: the free movement of goods, the freedom to provide services and the right of establishment, the community trade mark, and policies concerning small and medium-sized enterprises (SMEs). The industry fears that some internal barriers will remain due to wrong interpretation and implementation of the directives by the Member States, thereby hindering harmonisation. The first priority at this moment should be the enforcement of EU legislation at the Member States level, and a period without amendments in the EU legislation to enable SMEs, the majority of the companies in this industry, to adapt to new legislation.

## ENVIRONMENT

Customisation as well as environmental, ergonomic and safety considerations have increasingly become the driving forces behind technological and product development in the sector. For industrial trucks, technological progress has enabled the sector to cope with the widely varying and fast changing needs of its varied client base. At the same time, because industrial trucks are basically mature products, environmental issues such as noise, vibration, emissions and energy consumption are important potential areas for further improvements.

**Figure 3: Machinery for lifting and handling  
Origin of EU imports**

Source: Eurostat

Demand from the client industries for energy efficient and less polluting machinery and equipment is increasing. The client industries want their production processes to be as clean as possible, not only as a result of consumer demands, but also to anticipate restrictive national and European regulations. Consequently, R&D is focusing to an increasing extent on these environmental issues.

For fuel-powered equipment, such as industrial trucks for outdoor use, restrictions on pollution from exhaust fumes have become increasingly important. As a result, industries are trying to improve on energy efficiency and exhaust pollutants. For electrically operated trucks, new concepts such as fuel cells and high energy content batteries will provide a technological push and a reduction of combustion-powered units. European companies currently spend as much as 5 % of their turnover on research in this field. Other environmental areas of concern are noise and vibrations.

---

## REGULATIONS

---

The EU Directive on machine safety is of particular relevance to the manufacturers of machinery for lifting and handling, as it is to the other mechanical engineering industries. This Directive, adopted in 1989, envisages the application of safety standards for EU produced machinery by January 1, 1993. In 1991 the coverage of the Directive was extended to apply to lifting equipment for goods and mobile machines, and in 1993 to person lifts. Since January 1, 1995 the Directive is in total application, except for equipment for lifting persons for which manufacturers can choose until December 31, 1996 to comply either with the Member States' regulations in force on June 14, 1993 or with the Directive. Machinery and equipment complying with the new Directive will, however, obtain the CE mark. Products labelled with a CE-mark will have free access to the markets of all EU-countries.

Although the validity of this mark is limited to the EU-market, it can also become beneficial for EU-manufacturers with respect to their extra-EU export markets. While technology and know-how are becoming increasingly important for survival, strict EU-regulations will inspire manufacturers to innovate. In Western economies the CE-mark will stand for safe and environmentally friendly machinery and equipment.

---

## OUTLOOK

---

Investments in handling and storage equipment are becoming increasingly important. Materials handling plays a crucial role in all modern production processes where goods are to be moved and stored in order to optimise logistics, to save on operating expenses, to reduce inventories and to add to the much needed flexibility. Investments in handling and storage equipment, therefore, are decisive determinants of profitability for the manufacturing and processing industries.

Due to the ongoing downswing of the business cycle, 1993 demand for lifting and handling equipment remained depressed both within and outside the EU. Furthermore, the positive impact of German unification on demand has virtually disappeared. However, preliminary figures for 1994 showed a turnaround which is to be confirmed in 1995. Whereas the United Kingdom and the Scandinavian countries already recovered in 1993, other countries are showing an increase in export orders, fuelled by the strong demand from Asia and recovery in the United States. However, these gains are too small to offset the slow business in Europe.

The domestic situation in Germany, France and Italy is still unsatisfactory. Although obviously the downward trend has been stopped, unemployment rates are still high and huge deficits in the public domain exist. Hence, though demand is expected to pick up, a further economic recovery is not expected until after 1994.

Written by: Netherlands Economic Institute

The industry is represented at the EU level by: European Federation of Handling Industries (FEM). Address: Case Postale 179, Kirchenweg 4, CH-8032 Zurich; tel: (41 1) 384 4844; fax: (41 1) 384 4848.

# Transmission equipment

## NACE 326.1 and 326.2

Despite the structural and growing need for transmission equipment, the industry has proved to possess a strong cyclical character. The economic recession in 1992 and 1993 had a negative impact on EU internal demand. In 1994, however, some signs of economic recovery can be seen which will positively influence demand for transmission equipment in the short and medium term. In the long run, a higher degree of mechanisation in most downstream industries is the basis for growing use of transmission equipment. Mechanisation will be steadily raised for technical and cost reasons. EU competitiveness will increasingly depend on a high level of technological knowledge in combination with product and service features, such as high quality, product innovation, reliability, and flexibility which means adaptability to the needs of the market. On this account, importance should be attached to research and development (R&D) and the training and education of employees.

### INDUSTRY PROFILE

#### Description of the sector

This industry encompasses the manufacture of transmission equipment for motive power (NACE 326.1); and manufacture of ball, roller and similar bearings (NACE 326.2).

The manufacture of transmission equipment includes the manufacture of gears, gear assemblies (gear-boxes, variable speed gears, industrial gear-boxes, high-speed gears and differentials), transmission chains (including bicycle chains) and other transmission equipment. Not included are transmission equipment manufactured for the automotive industry nor hydraulic or pneumatic transmission equipment. Some companies in the industry deliver to both the automotive industry and other manufacturing industries, or offer a wide product range, thereby covering other products than transmission equipment, gears and bearings.

In comparison with related industries, the transmission equipment industry is of considerable size with value added for the EU (excluding Portugal, Ireland and Luxembourg) equaling nearly 5.2 billion ECU. Germany alone accounts for 51.5 % of this total value added, followed by Italy (16 %) and France (12 %).

#### Recent trends

From 1984 to 1990 the industry recorded production growth of 58 % in current prices, or 8.1 % on average per annum. Since 1990, however, production of transmission equipment has declined putting production back to 1988 levels of less than 11 billion ECU. This drop in production has mainly been caused by weak domestic demand in most Member States, which could not be completely compensated for by export-induced production growth. Consequently, there has also been a loss in employment. Since 1990, the number of people employed in the industry has decreased from 178 300 to 140 600; a drop of 21 %. Employment was expected to drop further, to 129 800 in 1994.

Compared with the total manufacturing industry the sector has clearly been underperforming. Where the total manufacturing industry recorded a drop of 3.1 % in production (in constant prices) from 1990 to 1993, production of transmission equipment declined by 20.6 %. Also, losses of employment

Figure 1: Transmission equipment  
Value added in comparison with related industries, 1993

Source: DEBA

were more drastic in the latter industry than in the manufacturing industry as a whole.

#### International comparison

Since 1984, Japanese production of transmission equipment (measured in ECU) has grown by 71.7 %, resulting in a leading position on the world market. In contrast, the USA has lost its market leadership and now ranks third after the EU. These production shifts, however, are influenced by changes in exchange rates. EU production dropped by more than 5 % in 1993, but the Japanese production figure is influenced by the appreciation (by more than 20 %) of the yen in 1993. As a result, Japanese production increased from 9 billion ECU in 1992 to more than 12.5 billion ECU. Nevertheless, Japan recorded growth in its own currency, while European production dropped in ECU.

The Japanese transmission equipment industry also constitutes 24.6 % of total extra-EU imports. Production growth in this country, however, mainly stems from economic developments

in the Far East. The drop in US production of transmission equipment is also reflected in the share of extra-EU imports. While the USA accounted for 27.7 % of total imports in 1988, in 1993 this share dropped to 23.2 %.

**Foreign trade**

The EU is a net exporter of transmission equipment. The trade surplus increased on average by 6.9 % per year between 1984 and 1993. The export and import penetration rates changed little between 1984 and 1992, although a slightly increasing tendency can be observed. The export rate was 25 % to 26 %, and the penetration rate was 16 % to 18 %. These rates reflect the international character of the sector. The international character is further emphasised if it is considered that export figures do not include indirect exports; transmission units incorporated in machinery products, which are in turn exported.

In 1993, the trade surplus increased by 26.6 % thanks to weak domestic demand within the EU. This increase was a

result of a 4.5 % decrease in imports and a simultaneous increase of 7.3 % in extra-EU exports caused by EU manufacturers efforts to penetrate foreign markets of transmission equipment. The growing importance of exports is reflected in the 1993 higher export rate of 29.5 % against 26.0 % in 1992. In current prices, the trade surplus in 1993 increased by 303 million ECU reaching a value of 1 441 million ECU. As a consequence, the exports/imports-ratio increased from 1.61 in 1992 to 1.81 in 1993.

As regards exports, EFTA countries are the EU's principal trade partner followed by the USA. In 1993, these two trade partners accounted for 50 % of total EU exports. In 1988, however, this share was slightly higher at 53.7 %. Japan is only of marginal importance for EU exports of transmission equipment.

EFTA countries, Japan and the USA play a major role in EU imports of transmission equipment, together accounting for 77.9 % of total EU imports in 1993 against 84.6 % in 1988.

**Figure 4: Transmission equipment

The decline is due to decreases from both the USA and EFTA countries. As a consequence, the USA lost its second position to Japan.

## MARKET FORCES

### Demand

The transmission equipment industry is decidedly a supplier industry with a variety of client industries. Demand for transmission equipment depends, to a large extent, on investments in capital goods made by downstream industries. The economic downturn which emerged in the early 1990s resulted in disappointing growth rates for global downstream markets and declining profits. This situation, together with high capital costs, did not encourage investments in capital goods. The downturn came after a period of booming investments in the second half of the 1980s by most client industries. For 1994, however, prospects are again positive. Production of transmission equipment is expected to grow as domestic demand in most Member States is recovering.

Customers of the industry are chiefly involved in mechanical and electrical engineering. The variety of products is a reflection of the broad range of applications. Wherever some-

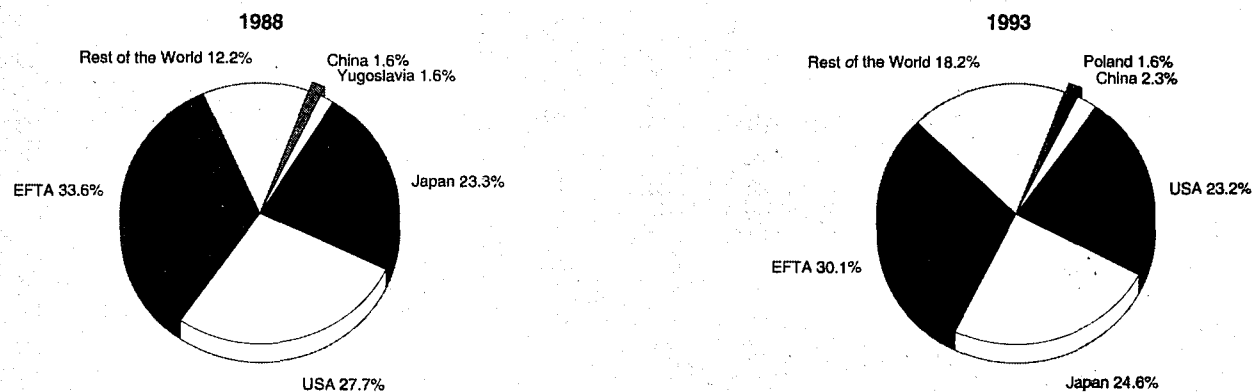

thing turns or moves, transmission equipment is at work. The product range of the industry comprises rather classical machine elements, such as bearings, cranks and chains.

Increased electronics content and greater use of miniaturisation in the products of downstream industries could directly reduce demand for mechanical transmissions, since in some cases they may be less suited to meeting the new customer needs which result. The extent to which demand for mechanical transmissions is displaced will depend on the extent to which these needs are better met by equipment using other (electrical, hydraulic or pneumatic) means of transmission. The changing nature of the equipment itself, which increasingly combines different transmission techniques, makes it difficult to predict the effect of this changing demand on producers.

### Supply and competition

Enterprises in the industry offer a wide range of products. In most cases, manufacturers of transmission equipment also supply other investment goods. Most downstream markets have a high degree of capital asset utilisation. This is the major reason why manufacturers are concentrated in countries with an emphasis on the production of investment goods: Germany, France, Italy and the United Kingdom. All these

**Figure 7: Transmission equipment  
Origin of EU imports**

Source: Eurostat

countries recorded production growth in 1993 after a period of declining output since 1990.

Weak downstream markets in the early 1990s caused lower labour productivity due to lower capacity utilisation. The resulting decline in employment, however, could not prevent an increase of unit labour costs. From 1990 to 1993 these costs increased by 15 %. Fortunately, the competitiveness of the EU industry does not seem to have been seriously affected by these developments. Although the import penetration rate demonstrates a slightly increasing figure during this period, faster growing extra-EU exports reflect improving competitiveness of the EU industry.

EU competitiveness depends on a high level of technological knowledge and other product and service features, such as high quality, product innovation, reliability and flexibility; which means adaptability to the needs of the market. Due to the high demands of European downstream industries, European manufacturers have been stimulated to give priority to these features, resulting in a technological lead throughout the world.

### Production process

Of particular importance for the efficiency of the industry is the quality of the technical solutions that it offers. On this account, great importance is attached to research and development (R&D). In Germany, besides the R&D efforts of individual firms, joint research projects have been established. As a result of these joint research projects, technological developments have been obtained in the fields of: materials (properties, application and heat treatment); stress and durability of components; safer designs; and production process (more geometrical shaping of components thereby achieving higher utilisation of materials). The application of this research to transmission equipment results in better performing, more environmentally friendly, less noisy, energy-saving products. These developments help to secure market and technological leadership.

Technical criteria are not the only decisive factors in international competition though, products must also be competitive from a cost angle. Developments in labour productivity, unit labour costs and total labour costs indicate that efficiency of production processes increased over the period 1984-1989. Labour productivity, in current prices, increased at a faster

rate than unit labour costs. Since 1990, however, the labour productivity index demonstrates zero growth, while the unit labour costs index has increased by 15 %, despite the reduction in employment. This has caused a drop in the industry's gross operating rate. Competitiveness of the industry can only be maintained if production costs are controlled.

## INDUSTRY STRUCTURE

### Companies

Apart from a few large companies, the industry's structure is mainly characterised by small and medium-sized enterprises. In Germany, for instance, about 80 % of the firms employ less than 500 people. The product spectrum has a wide range but is well diversified. In addition to some specialised companies with a narrow product range, there are companies which offer multi-products and which are broadly diversified.

Enterprises often do not operate plants in other countries. Only a few EU enterprises are present in several Member States. German companies, such as FAG Kugelfischer and ZF Friedrichshafen, are two large companies active in several Member States. In the market for speed changers, industrial high speed drives and gears, A.F. Flender AG is an important manufacturer.

The Swedish enterprise SKF already has a strong foothold in the EU with production facilities in major EU countries. Like its main competitor FAG Kugelfischer, SKF has also invested in former East Germany. In contrast, Japanese production is still concentrated in Japan and other Asian countries. Within the EU, only a few production plants are Japanese owned. Japanese exports, however, account for a growing share in EU demand.

### Strategies

In order to remain competitive, most manufacturers have chosen the strategy of constantly improving the adaptation of specific problem solutions to the respective applications, while paying attention to quality, reliability and flexibility, and simultaneously reducing design and production costs. This leads to the incorporation of electronics in product application, design and construction. This means consistent expenditure on R&D and constant adaptation to customer requirements in domestic markets and foreign markets.

The importance of R&D also highlights the importance of the present and future supply of highly qualified engineers and employees. In Germany, great efforts are made to secure the supply of engineers. Organisation of practice-related seminars at universities and institutes of higher education, as well as the initiation of industry-related diploma theses, practical studies, and the provision of trainee places, are all examples of this.

### Impact of the Single Market

The overall impact of the Single Market on the sector is positive, albeit small. The freedom of movement of goods and harmonisation, indeed, have a larger effect on the companies which used to operate nationally or regionally (mostly SME's and manufacturers of transmission equipment). Most bearings manufacturers operate internationally and are large-sized and are therefore less dependent on the effects of the single market.

Many of the expected effects of the Internal Market programme, such as harmonisation of technical standards etc., only have a potential effect. The EU should first enforce its regulations to the Member States and prevent discriminatory exceptions per country. A legal regulatory framework at an European level which would stimulate competition is considered highly relevant, especially for the SME's.

Source: DEBA

## ENVIRONMENT

The industry does not seriously threaten the environment. The hardening and galvanising stages of the production process could cause serious harm to the environment, but measures have already been taken to prevent this. Client industries, however, are becoming more aware of safety and environmental issues induced by developments in the industry's regulatory environment. In an attempt to meet customers' requirements, manufacturers of transmission equipment put high efforts in to product innovations concerning both issues. As far as products in mechanical power transmission are concerned, noise might be a problem. However, noise levels have been largely reduced as a result of improvements in production techniques.

## REGULATIONS

The Machinery Directive (89/392/EEC) sets out safety requirements for all machinery. As regards its application to transmission equipment itself, and to many types of machines which incorporate it, the transitional period expired on January 1, 1995. It is therefore now mandatory.

In anticipation of this EU Directive and in response to customer requirements for a safer working environment, the industry has already put much effort in to R&D for the improvement of safety conditions of equipment. In new technology development, the industry pays a lot of attention to environmental issues, such as reduction of the production of noise and other emissions.

Another Directive of relevance for certain transmission equipment is the Low Voltage Directive (73/23/EEC). This sets out the principal elements of the safety objectives with which equipment designed for use with a voltage rating between 50 and 1000 V alternating current and between 75 and 1500 V direct current must comply in order to be legally placed on the EU market. The Electromagnetic Compatibility Directive (89/336/EEC) lays down mandatory essential requirements concerning emissions of electromagnetic disturbances for electrical apparatus, equipment, systems and installations.

Manufacturers whose products comply with the relevant provisions of these Directives and who have demonstrated this conformity by allowing the applicable procedures set out in the Directives may affix the CE-mark. This allows free movement of the products throughout the European Economic Area.

## OUTLOOK

A high degree of mechanisation is the basis for the use of transmission equipment. Mechanisation will be steadily raised in most client industries not only for technical reasons but increasingly from a cost angle. In all plant and machinery there are machine elements and components that serve to transmit or support power. Demand for mechanical power transmission elements will therefore increase structurally with general technical progress world-wide. New materials and their treatment, electronics, new findings in tribology and a more advanced measuring technology will bring about further technological progress.

Despite the structural and growing need for transmission equipment, the industry has proved to possess a strong cyclical character. The economic recession in 1992 and 1993 had a negative impact on EU internal demand. However, as the economy is recovering, prospects in the short run are improving. 1994 saw a sharp increase in demand, marking the definite end of the long recession. The outlook for 1995 is for this upturn to be maintained. For the years ahead, production increases are expected, resulting from further growth of exports and an increase in domestic demand.

# Woodworking machinery

## NACE 327.1

The sector has recovered in 1994 from the recession suffered in 1992 and 1993. EU demand is rising but foreign competition is intensifying. The European know-how has proved to be an important comparative advantage in maintaining a leading position on the world market. Not only the competitive threat from the Far East, but also European legislation forces the European industry to put much effort in innovation and in R&D as safety and environmental regulations are becoming stricter.

In 1995, an increase of production is expected, especially borne by a recovery of the export markets and domestic demand in most Member States.

### INDUSTRY PROFILE

#### Description of the sector

The manufacture of woodworking machinery is part of NACE 327. NACE 327 includes the manufacture of machinery and equipment for use in specific branches of industry. Under this chapter the following industries are categorised:

- manufacture of machinery for working wood and similar materials (NACE 327.1);
- manufacture of paper, paper goods making, printing and bookbinding machinery (NACE 327.2);
- manufacture of laundry and dry cleaning machinery (NACE 327.3);
- manufacture of plant for the leather industry, including boot and shoe machinery (NACE 327.4).

The worldwide production of woodworking machinery attained an estimated value of 5.8 billion ECU in 1993. Production in the sector is relatively small if compared to the wood processing industry with a production value of more than 36 billion ECU in the EU.

Germany is the world market leader, its production totalling 1.8 billion ECU or 31 % of total worldwide production. Italy

is the second largest manufacturer of woodworking machinery at world level, with a production value of 1 billion ECU in 1993.

Germany and Italy together account for an estimated 49 % of world production (excluding China and the former USSR) of woodworking machinery. Other major manufacturing countries of this machinery are Austria, Finland, France, Japan, Sweden, Taiwan and the USA.

#### Recent trends

During the 1980s, strong production growth was achieved thanks to rapidly growing intra-EU trade. The economic downturn in 1992 and 1993 resulted in a drop of demand, especially in Italy and Germany. During 1993 and in the first half of 1994 improving export markets seem to have become the driving force behind the recovery of the EU woodworking sector.

#### Foreign trade

Most European countries are characterised by high export intensity, as more than 50 % of production is destined to foreign markets. More than 45 % of total EU trade finds its destination in other Member States. Major client countries outside the EU are the EFTA countries with a share of 18.8 % of total extra-EU exports in 1993 and the USA (14.8 %).

Figure 1 shows a major shift in demand. In 1988, the Western economies accounted for nearly 50 % of total EU exports. In 1993, this share had dropped to only 36 %. Especially Eastern Europe and the Far East have increased their demand, along with South Africa and Latin American countries.

Overall, extra-EU imports have been rising during the 1988-93 period, although with some ups and downs. Austria remains the largest supplier of woodworking machinery to the EU, with a share of 41.2 % in 1993, followed by Switzerland with 17 %.

### MARKET FORCES

#### Demand

The industry is strongly cyclical, following the ups and downs of major client industries such as the sawmilling and furniture industry. As a result, the economic recession in 1992 and 1993 has affected EU demand for woodworking machinery. In 1993, domestic Italian demand dropped by 22.5 %, while a weak domestic German demand could only be partly com-

**Figure 1: Woodworking machinery  
Destination of EU exports**

**Table 1: Woodworking machinery**  
**External trade in current prices**

(million ECU)	1988	1989	1990	1991	1992	1993
Extra-EU exports	695	932	942	827	760	892
Extra-EU imports	133	159	185	215	188	179
Trade balance	563	773	757	612	572	713
Ratio exports / imports	5.2	5.9	5.1	3.9	4.0	5.0
Terms of trade index (1)	96.5	97.6	100.0	94.2	94.8	96.5

(1) NACE 327  
 Source: Eurostat

compensated by increased demand from the former East Germany. In the first quarter of 1994, German domestic demand has dropped again (13%). This drop, however, has been fully compensated by a considerable increase of exports in the same period (+60%). By contrast, domestic Italian demand has recently showed a mild recovery, as Italian domestic sales increased by 11% (calculated in local currency) in the first three months of 1994. Throughout the rest of the EU, 1994 has generally been a recovery year, with demand driven up by exports and a mild improvement of internal demand.

In the woodworking machinery industry, there is a visible trend towards further automation in order to save on the use of raw materials, to cut energy cost and to increase productivity and competitiveness. Market demand is strong for specialty machinery and custom-made solutions, as well as for standardised machinery.

Among small and medium-sized client firms, there is growing demand for small, fast and quickly convertible machinery and equipment for the secondary transformation of massive wood.

The economic recession and the resulting overcapacity has directed the attention of manufacturers towards efficiency improvement in assemblage, construction and intra factory transportation. With respect to intra factory transportation, demand for integrated machinery is increasing at the expense of simple conveyor belts and loading platforms. This also improves the safety conditions.

Developments in the whole value chain, from raw material production to client industries and to consumer markets, will influence the market for woodworking machinery. The trend,

for instance, towards "cocooning" in the house furniture market together with the demographic trend towards more but smaller households will imply a real stimulus for demand for furniture and for house decoration products. The manufacturers of woodworking machinery will benefit from the developments in these important client industries.

In geographical terms, the opening up of Eastern Europe have already led and will further lead to stronger demand. The industry can benefit especially from new investments in construction and housing as it did in former East Germany.

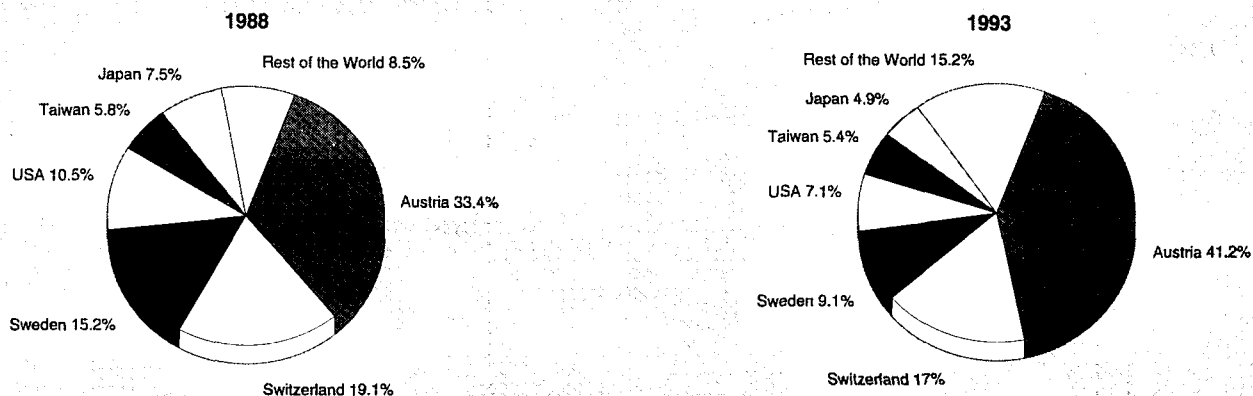

### Supply and competition

Germany and Italy are the main competitors on the world market. The strong position of German manufacturers is a result of the high quality products, increasing attention for after-sale service and technological advantages. The German know how is reflected in the number of patents held by German companies (31% of total at world level), against 3% by Italian manufacturers.

To an increasing extent, Italian manufacturers are becoming competitors in know-how. Italy already dominates some high-tech segments of the furniture industry. Still, as far as the Italian machinery is concerned price plays the most important role, helped by the recent devaluation of the lira.

Custom-made solutions require know-how, high product flexibility and service quality. In these areas, the EU woodworking machinery industry is still ahead of the competition from Japan and Taiwan. With respect to standardised machinery, however, the price is still the most important factor. This means that low wage countries in Eastern Europe and the Far East have a comparative advantage.

**Figure 1: Woodworking machinery**  
**Origin of EU imports**

Source: Eurostat

The EU furniture industry, one of the major purchasers of woodworking machinery, is increasingly being threatened as foreign companies enter the EU market. As competition intensifies, the EU furniture industry is increasingly transferring labour-intensive activities to low-wage countries. This trend, which applies to the wood sector as a whole, might have serious consequences for the European manufacturers of woodworking machinery. Although most of the EU manufacturers are already internationally oriented, the transfer of these activities will require increased marketing efforts and a better knowledge of foreign market developments. The concentration of the manufacture of furniture in the Far East will ease the path for the regional production of woodworking machinery and will lead to a loss of EU market share in low tech segments of the furniture industry. In the high-tech segments, the European industry will only be able to retain its market position if innovation and marketing efforts will be maintained at a high level.

## INDUSTRY STRUCTURE

### Companies

In 1993, some 923 companies employed 47 396 people in the manufacture for woodworking machinery. The German and Italian industry encompassed around 540 companies in 1993, employing 34 000 people. The average size of the Italian companies used to be much smaller than other European manufacturers: through several mergers and acquisitions in recent years, the sector has become more concentrated.

### Strategies

The European woodworking machinery sector is composed by a large number of relatively small companies, along with some large companies such as Mannesmann (D), BTR (UK) and BICC (UK). In recent years, in Germany company growth has been achieved mainly through acquisitions. In their search for concentration and expansion of sales networks, a few larger groups have been created, such as the Homag group, encompassing twelve affiliates: the IMA group with five partners and the Wehrmann group, including, besides traders, six producing companies.

Supply in Italy used to be highly fragmented. As a consequence of the recent economic recession and weak domestic demand, Italian manufacturers have been forced to concentrate operations. A series of mergers and acquisitions have resulted in the creation of industrial groups such as SCM, Biesse, Delmac, Costa and Omga. Along with these groups, there is still a high number of specialised manufacturers in Italy.

Also in Germany the tendency is towards more concentration. The German company Michael Wenig AG (the world market leader on the market for massive woodworking machinery) acquired Dimter GmbH, a manufacturer of equipment for the improvement of wood quality. As wood prices rise, demand for such equipment will increase.

As technology is becoming increasingly important for European manufacturers to survive, further concentration is expected to finance rising R&D costs. High efforts in R&D and marketing are necessary in order to maintain strong market positions within the EU, but also on major export markets such as the USA.

### Impact of the Single Market

The creation of the Single Market has resulted in a fairer competition throughout the EU, and in this respect the impact is positive. Some internal barriers still exist with respect to woodworking machinery, in that the Machine Directive is not enforced enough. In certain Member States, own labels and standards continue to exist or have been created which imply barriers to operate in these countries. The European manufacturing industry of woodworking machinery has always been

and still is number one in the world. In this respect competition from non-EU suppliers is relatively limited but exists. Mutual recognition of regulations is still a barrier to overcome.

Within the EU, the highest priority for the future is a better enforcement of the Machinery Directive. As the industry consists of many SME's, another priority deals with policies concerning these firms. Especially the access to these programmes for SME's should be eased, and measures should be taken to facilitate the creation of new companies. At this moment companies disappear but no new ones enter the market, which is a worrisome development.

## REGULATIONS

Machine safety is of particular relevance to woodworking machinery. In this respect, it is important to note that in 1995 the EU Directive 89/392 has attained a definite character. This directive defines essential requirements concerning machine safety and health provisions for workers and the environment. Provisions relate to the design, the materials used, machine operations, safety against mechanical risks, maintenance and machine indications and identifications. Most woodworking machines fall under Annex IV of the Directive and therefore have to be submitted to type approval by notified bodies.

In anticipation of this EU Directive for a safer working environment, the European manufacturers have already put much effort into R&D for the improvement of safety conditions of their machinery in recent years. In the manufacture of woodworking machinery, the trend towards more automation also implies less dangerous working conditions. In new technology development the industry pays a lot of attention to environmental issues such as a reduction of the production of dust, noise and other emissions.

In 1992 the directive for electromagnetic compatibility (89/336) came into force. The transition period will last until January 1, 1996. The directive applies to all electric and electronic equipment, systems and installations which can cause electromagnetic disturbances, or which can be influenced by such disturbances.

Products being labelled with a CE mark will have free access to the markets of all EEA countries. Although the validity of this mark is limited to the EEA market, it can also become beneficial for EU manufacturers with respect to their export markets. While technology and know how is becoming increasingly important to survive, the strict EU regulations inspire the manufacturers to innovate.

## OUTLOOK

The industry is characterised by a strong cyclical character. The economic recession in 1992 and 1993 has resulted in a drop of EU demand. However, as the economy is recovering and as the figures for the first quarter of 1994 are rather positive for the German and Italian industry, prospects in the short run are improving. Hence, for 1994 and 1995 a production increase is expected, especially borne by a recovery of the export markets and domestic demand in some Member States. In 1995, also German domestic demand will recover and further support growth. Until 1998 the European manufacturers are expected to enjoy positive growth rates, but their position on the world market will be increasingly threatened by Far East countries.

Written by: Netherlands Economic Institute

The industry is represented at the EU level by: European Committee of Woodworking Machinery Manufacturers (EUMABOIS). Address: Defense 1, Cedex 72, F 92038 Paris La Defense; tel (33 1) 47 17 67 17; fax: (33 1) 47 17 67 25.

# Liquid pumps

## NACE 328.3

In recent years, reduced demand on the Internal EU market, due to the cyclical downswing, and increased non-EU competition accounted for a fall in production. In 1993, however, production recorded growth of 2.1 % resulting from improving extra-EU export markets. Above-average export growth was recorded to Asia. As further recovery of the economy is expected, prospects in the short run are favourable. For 1994 and 1995, slight production increases are expected, resulting from export growth and a recovery of demand in most Member States. In 1995, German domestic demand will also recover and support further growth.

### INDUSTRY PROFILE

#### Description of the sector

This NACE includes the manufacture of compressors, pumps and equipment for operating machinery by hydraulic or pneumatic means. Besides liquid pumps, the sector also covers compressors and vacuum pumps. However, for these latter product groups little statistical information is available. Consequently, the description of the sector will mainly cover liquid pumps.

Liquid pumps can be divided into six classes: hand pumps; reciprocating pumps; rotary displacement pumps; centrifugal pumps; other pumps (not elsewhere specified); and parts for pumps. Liquid pumps are mainly used in the fields of: sewage and industrial waste-water disposal; drainage and the prevention of water pollution; chemical and petrochemical industries; energy and offshore technology; industry generally; processing techniques; shipbuilding; mining; water conservation; and construction.

#### Recent trends

Until 1992 the world market for liquid pumps grew for many years by an average of 6 % per annum. From 1988 to 1993 EU production (in current prices) increased at a slightly higher annual rate than demand: 6.8 % versus 6.4 %. Due to the economic recession, both production and consumption dropped in 1992. In the same year, excess demand resulting from German unification and high German export quotes, the leading manufacturer of liquid pumps world-wide, somewhat compensated for weak EU demand. In 1993, however, a further drop in demand of 2.2 % for liquid pumps and parts could be observed. EU production, however, recorded growth of 2.1 % resulting from improving extra-EU export markets, stimulated by an appreciation of the US dollar and the Japanese yen against the ECU.

In 1993, German production increased by 8.3 %, recording above-average export growth to Asia. The Netherlands, Belgium and Denmark also recorded strong production growth in 1993, varying from 7.8 % to 18.8 %, while production in Italy declined by 8.2 %.

#### International comparison

The EU is the world's largest producer of liquid pumps. Within the EU, Germany was the world's second largest producer in 1993 at 2.2 billion ECU after the USA (2.9 billion ECU) and ahead of Japan (1.8 billion ECU). In the world export market, Germany is even the largest exporter holding a 23 % share, followed by the USA with 16 % and Japan with 13 %. Other European exports are accounted for by Italy, the United Kingdom and France with respective market shares in the world export market of 10 %, 8 % and 7.5 %.

#### Foreign trade

Throughout 1988-1993 the EU was a net exporter of liquid pumps. Extra-EU imports grew faster than demand, demonstrating the growing importance of foreign suppliers on the EU market. The penetration rate increased from 15.4 % in 1988 to 16.6 % in 1993. In 1993, however, extra-EU imports remained fairly stable only increasing by 0.9 %.

In 1992 net exports amounted to 891 million ECU, while in 1993 net exports increased by 18.4 %, reaching a value of 1 055 million ECU. Against the background of stabilising imports, growth in extra-EU exports caused the export/import-ratio to increase from 2.4 in 1992 to 2.6 in 1993.

Germany accounts for the highest share in total extra-EU exports with 48.4 %, followed by the United Kingdom with a 23.5 % share. The most important German export markets outside the EU are the EFTA countries and the USA. Within Europe, France and Italy are the most important export markets for Germany.

## MARKET FORCES

### Demand

Liquid pumps are often compared to the human heart because they discharge, with precision and reliability, the most varied tasks in the transport of liquids vital for a modern economy. Market demand can be divided into two categories of liquid pumps: standardised pumps and engineered pumps. Both groups encompass a wide range of products and applications. Major markets for standardised pumps are the chemical industry, process industry, construction industry, food industry, shipping, horticulture, civil engineering, and the original equipment manufacture (OEM) sectors. Special, highly engineered pumps are used in the petrochemical and chemical industries, power stations, and irrigation and water supply. Both markets require custom solutions for which efficient production is needed.

The diversity of technical demands made on pumps have led to a high degree of specialisation in the pump-manufacturing industry. This requires know-how and R&D efforts which not only lead to comparative advantage but also to new ingenious applications that promote the safety and profitability of industrial processes, as well as the conservation of global resources and protection of the environment.

Sales of pumps to the chemical industry have been negatively influenced by reduced investment programs. The only area of expansion world-wide, with reasonable expectations, is petrochemicals. The water supply sector suffered its first losses in 1993. In recent years, demand from this segment was stimulated by German reunification, but these effects are petering out. In contrast, the power engineering sector has drawn some short-term profits from a number of large orders for power station retrofits in former East Germany.

**Table 3: Liquid pumps**

Source: Europump

The civil engineering and construction industries have demonstrated stagnation in demand for liquid pumps in 1993. In addition, pump sales for environmental protection measures showed a far poorer picture in comparison with 1992.

During 1988-1993 the production of centrifugal pumps, the largest item of original equipment, showed growth rates similar to those for original equipment as a whole. In 1993, the fastest growth rate in this market in the EU was recorded in Belgium. However, rotary pumps have been a significantly growing component of total production in several countries.

In geographical terms, major sales markets for EU production are found in Western Europe. Of growing importance though are the Americas and Asia. More than a quarter of German exports flow to Asia and North and South America.

As the quality of liquid pumps is crucial for the EU industry, manufacturers are increasingly meeting the tailor-made requirements of their customers to remain competitive. Customer advice and support through highly-qualified specialists are the base for a lasting customer-supplier relationship.

### Supply and competition

As competition is intensifying, given the growing import penetration of non-EU manufacturers and that customers are becoming more demanding, the industry's attention is drawn to R&D for new product development, innovations, and improvement of the quality of liquid pumps. This has not only strengthened European competitiveness, but has also opened up promising new areas of business.

One example of improved product quality is new pump-diagnosis systems, which serve to enhance operational functions, alleviate work and cut costs. Another example deals with the trend towards customer-oriented solutions effected through complete pump systems. Given the complexity of such systems the supply of special intelligent software is also growing.

In recent years, R&D efforts and innovations have resulted in: the cutting of operating expenditures; the reduction of energy consumption; the lengthening of serviceable product life; and the reduction of noise generation. The importance of R&D also highlights the importance of the present and future supply of highly qualified engineers and employees. In Germany, efforts are made to secure the supply of engineers. Organisation of practice-related seminars at universities and institutes of higher education, as well as the initiation of industry-related diploma theses, practical studies, and the provision of trainee places, are all examples of this.

The increase in extra-EU exports, in contrast, with stabilising extra-EU imports is an indication of the improved competitiveness of the EU industry. This is partly due to favourable exchange rates, but it can also be attributed to a comparative advantage resulting from high quality products, a problem-solving attitude and high service levels.

## INDUSTRY STRUCTURE

### Companies

Apart from some large enterprises with production facilities in many parts of the world, small and medium-sized firms are typical for the industry. In recent years, R&D efforts have brought about improvements in energy saving, guaranteed function, production, operation and maintenance, and also recycling potential.

### Strategies

European manufacturers of liquid pumps are increasingly trying to meet customer requirements. These customers or client industries are aware that the safety and full working order of their industrial plants often depends on the reliability and serviceability of pumps that are employed, and that the quality of their products is decisively influenced by such factors.

In order to compete more aggressively on the EU Internal Market, the industry is trying to internationalise. This will bring changes to the structure of the pump sector. In recent years, a number of mergers and acquisitions have resulted in some big pan-European companies, such as KSB (D); SIHI (D); Wilo Salmson (D); Grundfos (DK); GEC Alsthom Bergeron (F); and, Weir (UK). In addition, a number of non-EU companies have production facilities in the EU, such as ABS (S); Ingersoll-Dresser Pumps (USA); Sulzer (CH); and, ITT Flygt (S/USA). For the majority of the enterprises, specialised in smaller market niches, joint ventures with similar companies in other EU Member States should be a better means to benefit from the advantages of the European unification process.

Source: Europump

Weak markets have already forced many companies to reduce capacity and costs to remain competitive. Wide deployment of CAD/CAM/CIM (computer-aided design, computer-aided manufacturing, computer-integrated manufacturing) has resulted in productivity improvements and, consequently, to labour cost savings. This trend is likely to continue.

In the standardised pump sector, widespread and efficient distribution networks on key markets are becoming increasingly important. Most specialised companies will have to put more effort in to product innovation and product modifications to retain a competitive advantage and to comply with the trend towards products which offer better environmental protection. The latter trend provides the industry with extra demand for pumps for water purification, for example. On the other hand, the same trend has induced the industry to produce less polluting pumps (i.e. without leakages).

#### Impact of the Single Market

The Internal Market programme is perceived to have had a positive, but limited effect so far. Some strategic investments have been made by customer industries due to the increased European integration. At this moment, tangible positive results can, however, not be assessed for the industry itself. On the one hand there may have been positive effects on the larger companies (benefits of economies of scale), and on SMEs through measures such as the stimulus and development of R&D efforts on an European level (CRAFT programme), collective actions concerning the export promotion of this EU industry, common fair participation support, and the normalisation as a result of the Machine Directive. On the other hand, there may have been small negative impacts of some EU policies on the sector, in particular of regional support policy.

#### ENVIRONMENT

Customers are now aware of two important issues: safety and the environment. In an attempt to meet customer requirements, manufacturers of liquid pumps put strong efforts in to product innovations concerning both issues. Each market segment requires pumps designed for specific applications that meet certain quality and safety standards. For instance, in the chemicals/petrochemicals industry, pumps are used that guarantee protection from unwanted toxic emissions and make production operations safe where dangerous liquids are involved.

For many years, EU countries have passed environmental laws on their own initiative. Nowadays, the EU is building up its own environmental policy, to ensure that regulations are applied at European scale. However, the industry fears unfair competition if these regulations are not applied on a European scale. Manufacturers of liquid pumps, however, are not expected to suffer from growing environmental pressures. Demand has risen for waste water pumps, partly due to the guideline of March 1991 addressing the management and processing of urban waste water.

Noise pollution has been considered a major problem for the industry, but thanks to steady improvements in production techniques and processes, noise has been and will be further reduced. Furthermore, due to growing environmental pressures, reflected in demand, the industry has been induced to manufacture less polluting pumps with less leakage. Technologically developed manufacturers could take advantage of these environmental pressures if their products can meet the environmental requirements.

#### REGULATIONS

In 1995 EU Directive 89/392 will enter fully into force. This Directive defines essential requirements concerning machine safety. Provisions relate to design, the materials used, the way in which machine operations should be documented, machine operation itself, safety against mechanical risks, the application of screens and other safeguarding components, maintenance, and machine indications and identifications. The manufacturer is entitled to affix the CE mark on machines complying with EU regulations. Machine safety is of particular relevance to liquid pumps.

In anticipation of this EU Directive for a safer working environment, European manufacturers have already put efforts in to R&D for the improvement of safety conditions of their machinery. The trend towards more automation also implies less dangerous working conditions. In new technology development, the industry pays attention to environmental issues, such as reduction of the production of noise and other emissions.

Another Directive which applies to liquid pumps is the Low Voltage Directive, which will be amended on January 1, 1995. It states that machines complying with the requirements of the Directive are obliged to wear the CE mark. In 1992 the Directive for Electromagnetic Compatibility (89/336) came into force. The transition period will last until January 1, 1996.

Products labelled with a CE mark will have free access to the markets of all EEA countries. Although the validity of this mark is limited to the EU market, it can also become beneficial for EU manufacturers with respect to extra-EU export markets. While technology and know-how are becoming increasingly important to survive, strict EU regulations inspire manufacturers to innovate. In Western economies, the CE mark will stand for safe and environmentally friendly machinery and equipment.

#### OUTLOOK

The industry has proved to possess a strong cyclical character. The economic recession in 1992 and 1993 had a negative impact on EU internal demand. However, as the economy is recovering, and figures for the first quarter of 1994 are rather positive for the German and Italian industries, prospects in the short run are improving. The year 1994 should see stabilisation, if not recovery, in pump production by Germany

and France, and continuing recovery in other European countries. Hence, for 1994 and 1995 slight production increases are expected, resulting from recovery of the export markets and domestic demand in some Member States. In 1995, German domestic demand will also recover and further support growth. Until 1998, European manufacturers are expected to record relatively high growth rates.

Written by: Netherlands Economic Institute

The industry is represented at the EU level by: European Committee of Pump Manufacturers (Europump). Address: c/o Fabrimetal, Rue des Drapiers 21, B-1050 Brussels; tel: (32 2) 510 2517; fax: (32 2) 510 2301.

## Overview NACE 34

With a production volume of nearly 260 billion ECU and a workforce of 2.3 million, electrical and electronic engineering was one of the largest industrial sectors in Europe in 1994. The sector thrives on the strong growth in high-tech producer and consumer goods, of which the electrical and electronic engineering industry itself is one of the major buyers. The companies within the sector, with their innovative technologies and products, contribute to enriching the European market for electrical and electronic engineering applications for other industrial sectors, and to fostering overall technological development.

### INDUSTRY PROFILE

#### Description of the sector

The electrical and electronic engineering industry accounts for approximately 10 % of total manufacturing output and 12 % of the correspondent workforce in the EU. Given the importance of microelectronics as a driving force of technological progress, industry competitiveness, and the competitiveness of entire economies, depend on the electrical and electronic engineering sector, which is one of the main providers of infrastructure (power supply, telecommunications etc.).

The electrical and electronic engineering industry (NACE 34) comprises the following sectors:

- insulated wires and cables (NACE 341);
- electrical machinery including electric motors, generators, transformers and switch gear etc. (NACE 342);
- electrical equipment for industrial use, batteries and accumulators (NACE 343);
- telecommunications equipment, electrical and electronic measuring and recording equipment and electro-medical equipment (NACE 344);
- radio and television sets, sound producing and recording equipment (NACE 345);
- electric domestic appliances (NACE 346);
- electric lamps and other electric lighting equipment (NACE 347);
- assembly and installation of electrical equipment (NACE 348).

This statistical classification does not always describe the industry's actual market activities which are very broad. In some cases, precise information is hard to come by since the different sectors include a wide variety of product groups. For this reason, only the most important aspects of each sector are covered in this overview.

The electronics sector, i.e. telecommunications, electro-medical devices, equipment for measurement, control and automation, motor vehicle electronics, consumer electronics, and electronic components, has registered strong growth in recent years. Other products also increasingly include electronic components. This "electronification" is accompanied by a vigorous growth in industrial services which are profoundly changing the structure of services offered, which include project planning and engineering, as well as the development of software.

**Figure 1: Electrical and electronic engineering Value added in comparison with related industries, 1993**

Source: DEBA

Together they have reached nearly one quarter of the industry's total output. In some sectors, e.g. telecommunications, services account for as much as 50 % of the turnover. It should be noted that existing statistics, which only cover hardware production, substantially underestimate the sector turnover by excluding such services.

#### Recent trends

In the period 1984-93, production in current prices rose from 160 billion to 252 billion ECU. This represents a nominal average growth rate of 5.2 % per year. In real terms, the average annual growth rate was 4 %, significantly above that of other EU manufacturing industry which on average grew by 1.9 %. In terms of net output, as measured by value added, Germany had a 47 % share of the total EU market, France accounted for 16 %, the UK and Italy for 14 % each.

**Figure 3: Electrical and electronic engineering  
Production and employment compared to EU total manufacturing industry**

1994 are Eurostat estimates.  
Source: DEBA

The world-wide slump in 1992 and 1993 affected both production and apparent consumption volumes in the sector. From 1991 to 1993, in line with the decline in production, employment dropped by over 240 000 people, a fall of 9 %. Expected recovery in infrastructure investments should have a positive impact on the industry's production which was forecast to grow by 3 % in 1994.

**International comparison**

The EU, Japan and the USA dominate electrical and electronic engineering and together account for 75 % of the world market (not including Eastern Europe and the former Soviet Union). In 1984, production in the EU, Japan and the USA amounted to some 630 billion ECU. By 1993, it had increased by 40 % to just below 900 billion ECU.

EU production, with a world market share of 28 %, equalled 94 % of US production and 87 % of Japanese. Japan's electrical and electronic engineering industry experienced a deep

recession in 1992 and 1993, whereas the US industry resumed growth in the same period.

In 1993, the EU electrical and electronic engineering market amounted to 256 billion ECU. With a production value of 252 billion ECU compared to extra-EU exports of 50 billion ECU and imports of 54 billion ECU, the trade balance was in the negative at a deficit of 4 billion ECU. Hence, 79 % of the EU's demand for electrical and electronic engineering products was met by EU production, whereas 21 % originated from extra-EU countries. The United States led the league with a market share of 5 %, followed by Japan at 4 % and the EFTA countries with 3.8 %.

**Foreign trade**

Electrical and electronic engineering has always been an export-intensive sector. The period 1984-93 witnessed a strong expansion in world exports. The three largest exporters, Japan, the USA and Germany, together accounted for around 60 %

**Figure 4: Electrical and electronic engineering  
International comparison of production in current prices**

Source: DEBA

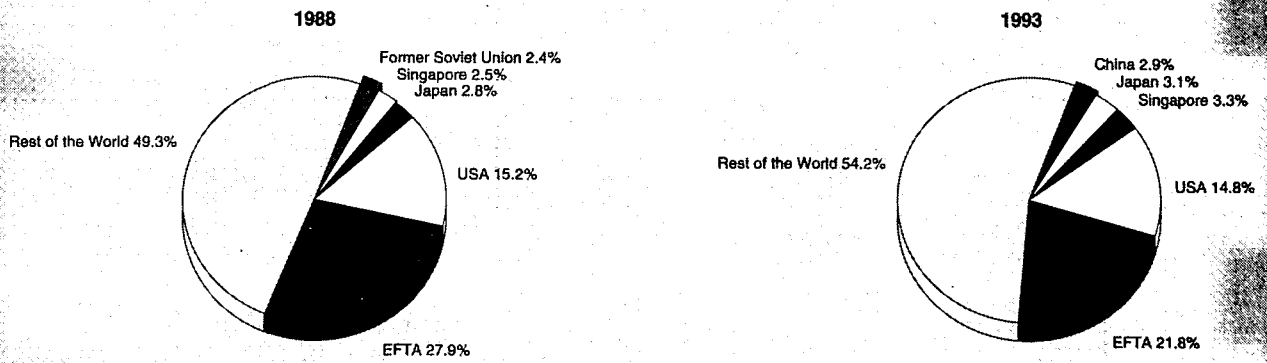

**Figure 5: Electrical and electronic engineering  
International comparison of production in constant prices**

Source: DEBA

**Figure 6: Electrical and electronic engineering  
Destination of EU exports**

Source: Eurostat

of all electrical and electronic engineering exports. Other major exporters are the UK, France, Italy and the Netherlands.

In the 1980s, exports of electronic components grew faster than the electrical and electronic engineering sector average, whereas in other segments, such as electronic measurement and control, power engineering, telecommunications and consumer electronics, growth was below average. Producer goods make up nearly two thirds of electrical and electronic engineering exports, whereas consumer goods and primary materials account for less than one fifth each. Export levels vary with individual product groups.

The dependence on external markets is decidedly higher than indicated by the exports to production ratio. If indirect exports were taken into account, i.e. including intermediate products used in other products that in turn are exported, the ratio would be higher. Apart from automotive manufacturing, indirect exports are primarily found in mechanical engineering.

The main end markets for extra-EU exports of electrical and electronic engineering equipment are the EFTA countries (22 % of the total in 1993, down 6 percentage points since 1988) and the USA (stable at around 15 %). The main buyers in the rest of the world category (54 % of extra-EU exports

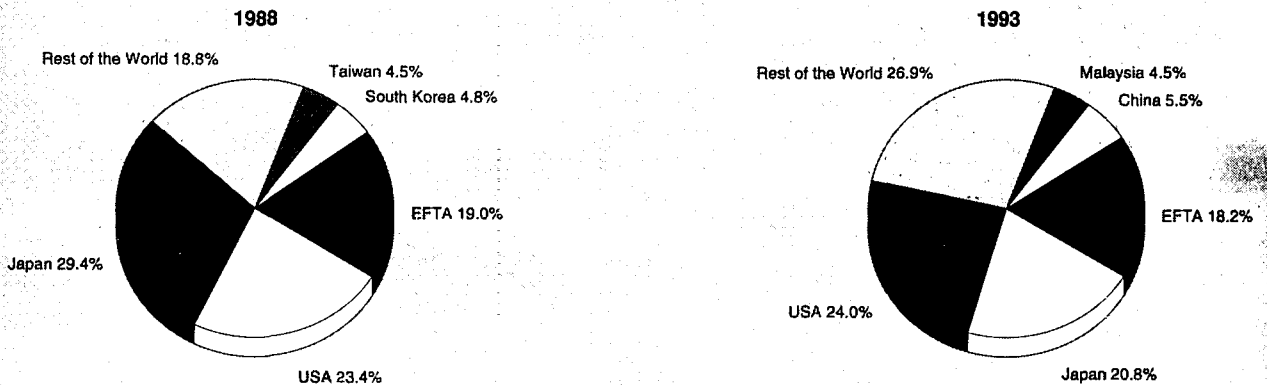

in 1993) are the developing countries, although growth in their imports has levelled off in the last few years.

The convergence of international markets, leading to stiffer competition, has not been without effect on trade in the sector. In the 1970s, imports were already growing faster than exports. This trend continued between 1984 and 1993. With a nominal average growth rate that amounted to nearly 9 % per year, imports from extra-EU countries doubled over the period, whereas exports grew by 6 % per year in the same period. Main suppliers to the EU in 1993 were the USA (24 %), Japan (21 %) and the EFTA countries (18 %). Japan lost almost 9 % market share in imports from 1988 to 1993, to the benefit of other countries, whilst the USA and the EFTA countries managed to retain their shares.

As in the case of exports, producer goods also dominate imports and make up more than 60 % of the EU total. Consumer goods and primary materials represent the remaining 40 %.

The imports to consumption ratio rose steadily in the period, from 16 % in 1984 to 21 % in 1993. The trade balance has been negative since 1988, although the situation improved in 1993 with an exports to imports ratio that rose to 0.93.

Source: DEBA, Eurostat

The marked growth in external trade in the 1980s in all areas of electrical and electronic engineering reflects the widening international division of labour. The balance of trade for electrical and electronic engineering goods, however, has significantly deteriorated. Whereas in 1988, the surplus totalled 4 billion ECU, the surplus turned into a deficit as imports rose much faster than exports. In 1991, the deficit had reached nearly 9 billion ECU but has since then improved to below 4 billion ECU in 1993.

Intra-EU imports exceeded imports from extra-EU countries over the entire 1984-93 period. Nearly 60 billion ECU of total EU exports, which in 1993 amounted to 108 billion ECU, went to other Member States. One third of these came from Germany, 16 % from France, 12 % from Italy and 12 % from the UK. With more than 22 %, Germany is also the largest buyer in the EU, followed by France (19 %), Italy (13 %) and the UK (12 %). In intra-EU trade, only Germany achieved a trade surplus (6 billion ECU).

## MARKET FORCES

### Demand

Around one third of total production is made up of intermediate products, i.e. supplies for further processing or integration into in other products, in the sector itself or in other industries. Most products are sold within the industry. Other important

buyers of intermediate products are the mechanical engineering, services and automotive sectors.

With producer goods taken separately, the services sector is the most important buyer. Within this sector, transport and communication services (including telecommunications) rank first, before public administration.

### Supply and competition

The electrical and electronic engineering industry is a diversified sector with a product spectrum ranging from micro-components to nuclear power plants. For this reason, the overall growth rate reveals little about the different developments among the individual product groups. It appears that the rise in production value has been particularly high in electronic components, telecommunication equipment, and measurement, control and automation systems. Slow growth has been registered in the areas of electricity supply and distribution, domestic electrical appliances and in consumer electronics.

Production growth is influenced by technological change, the complex processes involved in production - ranging from large-scale mechanical engineering to miniaturisation in precision mechanics - and by the developments in costs and prices.

Different growth rates in the individual product groups has led to changes in the production structure. Power engineering, domestic electrical appliances and consumer electronics have declined. By contrast, non-consumer electronics and electronic components have grown.

On account of the very broad spectrum of electro-technical and electronic products, close interdependencies have developed, both on the supply and on the demand side, between electrical and electronic engineering and other industry sectors. Intermediate supplies involve other sectors of the economy. Among these, intra-company supplies constitute nearly 50 %. Intermediate products that are sold outside the sector particularly go to the services sector, with trade and transport and communication services (including telecommunications) in the top of the list.

The most important suppliers in the manufacturing industry are the plastics and non-ferrous metal industries. Similar to the iron and steel industry, they primarily supply raw materials and semi-finished products, whereas primary and intermediate products come from various other sectors (plastics processing, iron, sheet and metal working industries, mechanical engineering, paper and glass industry, etc.).

The share of the services sector in intermediate supplies has risen steeply, whereas primary and producer goods industries have become less important. This is mostly due to the reduction in the quantity of material used in the production process which has been achieved through improved utilisation of e.g.

raw materials, and smaller product dimensions. The share of imports in intermediate supplies has stabilised at around 15 %.

Among the sectors which supply the electrical and electronic engineering industry with producer goods, mechanical engineering is the most important. The second largest supplier is the electrical and electronic engineering industry itself, followed by the construction industry.

### Production process

Among manufacturing industries, the electrical and electronic engineering industry is the largest employer, along with mechanical engineering. Employment in the sector remained more or less stable until 1991, at 2.7 million. In 1992, 129 000 jobs disappeared, followed by another 113 000 in 1993 and an estimated 24 000 in 1994. This translates into a 12.5 % drop since 1991.

Employment levels have developed differently for the individual sectors and product groups. Areas with an above-average growth in production (e.g. measurement, control and automation) also reported above-average employment figures. As expected, employment decreased in areas with below-average growth (e.g. consumer electronics) as the result of rationalisation measures or relocation of production.

The electrical and electronic engineering industry is one of the most research-intensive manufacturing industries. At between 8 and 10 per cent of the industry's turnover spent annually on research, it is in the top in terms of research-intensity (not including the aircraft and spacecraft industry).

## INDUSTRY STRUCTURE

### Companies

In the EU, concentration in the electrical and electronic engineering industry is very high. Approximately 4 % of all firms employ nearly 80 % of the sector's total workforce and

account for around 80 % of the total turnover. It is noteworthy that this pattern is very similar in all Member States (as in other industrialised countries): a number of very large manufacturers cover nearly all product segments and operate on a world-wide basis, followed by a host of small and medium-sized businesses.

In 1993, the three largest EU firms in the sector were: Siemens (D), Philips (NL) and Alcatel-Alsthom (F). The strong presence of ex-EFTA firms among the top twelve is noteworthy, the most important of which are Asea Brown Boveri (CH/S), Electrolux (S) and Ericsson (S).

### Strategies

Apart from expanding exports, the electrical and electronic engineering industry remains distinctly oriented towards foreign investment (establishment of production units and marketing facilities). These investments serve the purpose of developing existing markets or opening up new ones. Attention is focused primarily on the public procurement markets which are subject to the EU utilities directive, and on Southeast Asia which is currently the strongest growth market for electronics. High growth is also expected in the longer term in Eastern Europe.

### Impact of the Single Market

The impact of the Single Market on the Electrical Engineering industry has been on the whole positive; nevertheless, some distinctions have to be made. First of all, the effects might have been greater if Member States had completed implementation of relevant Directives (e.g. "Packaging Directive"). Further, the incomplete adoption of EU legislation has caused problems and delays in Member States' full acknowledgement of the European standards regulation. In this sense, the implementation of the Internal Market program did not spark off any important improvement. In fact, the industry is still confronted with the same obstacles that were indicated by the 1985 White Paper. In the developed world and among

Source: DEBA

Newly Industrialised Countries, NTBs and trade barriers are major competitive problems. The industry feels that, in addition to complete implementation, simplification of legislation (Molitor group) and elimination of "hidden" NTBs should be the next priorities.

## REGULATIONS

Public procurement plays a decisive role in the development of the internal market for the electrical and electronic engineering industry. In the EU, contracts awarded by governments and state-owned companies, such as public railways, post and telecommunications, and electricity distribution companies, account for a high proportion of the GNP. The liberalisation of public procurement is necessary in order to take advantage of the benefits of enhanced competition offered by a unified market, in the areas covered by the Utilities Directive. Here, care must be taken to ensure that EU regulations are implemented and that markets are opened up as a result. Development of European technical standards is also an essential prerequisite for the expansion of trade.

## ENVIRONMENT

Normally, the production of electro-technical equipment is not harmful to the environment. However, increasing consumption creates the problem of disposal of equipment and appliances no longer used by commercial and private consumers (e.g. refrigerators, TVs, measuring instruments etc.). The electrical and electronic engineering industry, especially in Germany, at an early stage took initiatives to solve the problems of waste disposal and recycling. Design and construction of appliances have been modified in order to achieve significant energy savings. Apart from such activities, the electrical and electronic engineering industry, with a variety of equipment, such as measuring and control instruments, is providing equipment necessary for environmental monitoring and improvement.

## OUTLOOK

The structural environment of the electrical and electronic engineering industry will continue to be marked by the liberalisation and harmonisation of the EU markets, and by continued technological progress. Following the 2 % decline in production in 1993, a 3 % growth was forecast for 1994 which is likely to be followed by continued growth in the following years. However, this growth is unlikely to compensate for the employment cutbacks in 1993 and 1994.

According to estimates, the world market for electro-technical products will have nearly doubled its volume by the year 2000, compared to 1990. In this context, the future-oriented research and product development work of the companies, as well as their investment activity play, a decisive role.

# Insulated wires and cables

## NACE 341

Demand for insulated wires and cables is influenced by two fundamental factors: development of the infrastructure for electricity and telecommunications and the general health of the economy. The economic downturn that hit the European Union in 1993 impacted negatively on activity in the insulated wires and cables sector. Production in the EU declined for the third year in a row. The outlook for the EU cables sector calls for a slight improvement of market conditions as the sector's main client industries emerge from the doldrums. This relative recovery will particularly be driven by the development of the information technology market and by strong demand for data and control cables. The sector will also take advantage of the liberalisation and privatisation of the telecommunications and energy industries.

### INDUSTRY PROFILE

#### Description of the sector

The markets for insulated wires and cables are extremely diverse with applications in virtually all areas of modern life, from winding wire in the electrical shaver to optical fibre, which provides the basis for the telephone call, to energy cables, which are used in the basic infrastructure of energy generation, transmission and distribution.

Electrical energy cables are fundamental to domestic life and all industrial and commercial activities of the Community. Wires and cables supply energy from the electricity generation centres to the individual points of utilisation, and differ according to the voltage range.

Information cables have two important areas of application: telecommunications and electronic data control and broadcasting. Recent demand for telecommunications cables has been strong, reflecting the massive surge in demand for new telephones associated with the increasing use of fax machines, as well as, demand associated with investment in the telecommunications infrastructure; particularly in Member States which are modernising and extending the optical fibre network. Demand for information cables is also strong in the multi-faceted area of electronic data/control applications and broadcasting. For all the developments in information technology, communications cables, ranging from simple wires to coaxial cables, armoured cables and glass fibres are an important element.

Winding wires are used in all forms of electrical equipment where a magnet is required. Thus, every electric motor, transformer, generator, dynamo, etc. requires a magnet or winding wire that is enamelled or otherwise insulated.

#### Recent trends

The fastest growing segment of the insulated wires and cables industry is that of information cables. Between 1986 and 1993, the share of information cables in total production rose from 23 % to 35 % (although it actually declined from 37 % in 1992), while the share of energy cables declined from 70 % to 56 %. This trend is in line with the recent surge in the demand for telecommunications infrastructure and equipment, coinciding with relatively slower demand growth in the more mature segment of energy cables.

The insulated wires and cables sector in the EU has suffered a year of muted demand, resulting from the sharp downturn in activity experienced by its major client industries. In 1993,

Figure 1: Insulated wires and cables  
Production in comparison with other industries, 1993

Source: Europacable, DEBA

EU's demand for insulated wires and cables, as measured by apparent consumption, was down for the third year in a row.

In line with poor market conditions, production was also down in 1993, in spite of the encouragement the sector received from its export markets, which posted a 12 % growth in value.

Employment has also been on the decline, falling from 107 000 in 1991 to 71 200 in 1993. However, the decline has been muted in 1993 (-7 000 units) with respect to 1992 (-20 000 units), indicating that the declining trend is not linear. This evolution obviously reflects the recent cyclical downturn in activity. But, it also reveals recent restructuring, productivity gains, the adoption of more capital-intensive production techniques, and less labour-oriented production lines. In particular, the shift away from copper to optical fibre in the production of telecommunications cables has induced changes in the production process, which in turn translated into changes in the profile and level of employment in the sector.

### International comparison

The EU remains the largest producer of insulated wires and cables in the world. Proximity to the market is very important, particularly for heavy industrial cable. Investment in Europe's infrastructure has been a strong source of demand for EU producers.

The USA and Japan are also sizeable producers. Contrary to the EU market for insulated wires and cables, where both supply and demand sides are still fragmented, the USA and Japanese industries have benefited from an early implementation of deregulation and liberalisation of their telecom and energy markets. Quick implementation in the EU of this process will enable EU producers, along with foreign competitors, to increase significantly their geographical market coverage.

### MARKET FORCES

#### Demand

The three main categories of insulated wires and cables (winding wires, information cables and energy cables) are subject to very different forces of demand.

Demand for energy cables is not only dependent on increases in electricity consumption, but also on demand for new generation and transmission facilities, as well as replacement demand. As a result, the demand for wires and cables can be considerably affected by energy policy. In the long-term, demand for energy cables will keep pace with the growth of GDP and the associated growth in electricity consumption. The energy cable industry addresses demand from power utility companies, which in many cases are publicly owned, and from the construction sector.

Demand for information cables is linked to the development of a country's telecommunications market and the level of advancement of its telecommunications infrastructure. The overwhelming portion of the market is accounted for by the public telephone network operators. The strongest growth is in trunk (long-distance) traffic, where technological developments have substantially reduced cable-costs. Demand for electronic data control cables is expected to continue its steady rise.

Demand for winding wires is naturally linked to trends in end markets such as automotive and electro-domestic devices.

#### Supply and competition

Production capacity of the EU cable and wire industry has traditionally exceeded demand. Technological improvements, an increase in capital intensity, which has changed production techniques, and shrinking home demand are key forces which have combined to change the environment in which manufacturers operate.

The EU cable and wire industry has achieved a world lead in numerous technologies which are important for cable production. These include: non-ferrous metallurgy, insulation physics, rubber chemistry, high-tech materials, superconduc-

tivity, electrical engineering for power cables and optical-fibre technology for telecommunications cables. The industry's investment in R&D has also translated into new capital intensive production techniques which have generated higher turnover, and a steady decrease in employment, and a steady increase in productivity, but which have also contributed the declining employment levels in the sector.

The EU wire and cable industry has a strong presence on world markets, and in particular in the USA through local investment. However, the EU wire and cable industry is faced with stiff competition on world markets, not only from its traditional competitors (USA and Japan), but also, increasingly, from emerging producers. As indicated earlier, many former principal export markets have established their own production facilities. In particular, Korea and Taiwan have become sizeable producers of insulated wires and cables, and are emerging as formidable competitors on international markets. China is also emerging as an important world producer, though its production base is still in the hands of western manufacturers. These countries enjoy unit labour costs largely below western levels, thus enhancing their competitiveness on international markets.

#### Production process

Two raw materials are of particular importance to insulated wires and cables production: copper and aluminium. In the EU cable and wire industry, more than 1.4 million tons of copper and about 196 000 tonnes of aluminium were used in 1992. The use of these two main inputs, however, varies according to their price, which fluctuates widely, taking into account the fact that about twice as much aluminium is needed in electrical applications (copper is a better conductor of electricity than aluminium). Thus, while copper is generally preferred to aluminium because of its intrinsic qualities (durability, conductivity), the choice between the two metals is influenced on other factors such as cost, availability and technical suitability for some specific applications.

The trend in copper prices provides an example of the degree of price variability. The price per tonne of copper doubled from 1 592 ECU per tonne in January 1986 to 2 986 ECU in January 1989. The average price per tonne of copper in 1991 was 1 772 ECU. Given these wide price fluctuations, not to mention currency fluctuations, the trends in consumption, production and foreign trade in insulated wires and cables, which appear in this report, must also be viewed in light of the price trends of its main raw materials.

During the last ten years, optical fibre has become another strategic input in the production of telecommunications cables. Optical fibre cables are particularly designed for transmitting data and sound impulses and signals by light generated by laser. Perfect substitutes for copper cables in these types of applications, optical fibre cables also provide higher transmission capacity and are much cheaper than metal cables. The industry performed a major substitution from copper to optical fibre in the production of telecommunication cables. Although there are similarities between the manufacturing and production technologies applied, the production of optical fibre cables requires a clean, laboratory-type atmosphere. In con-

**Table 2: Insulated wires and cables  
Breakdown by sector**

Informations cables	4 026	3 398
Winding wires	877	825

Source: Europacable

trast, the production of copper cables basically remains a metallurgical process. As a result, cable manufacturers tended to construct new plants dedicated to the manufacture of optical fibre cables instead of converting copper cable production facilities towards optical fibre processing. Today, as it is experiencing plummeting demand for copper cable, the EU industry faces a gross over capacity, and is actually operating close to break-even. In addition, the shift from copper to optical fibres has accelerated in the last five years. This acceleration, coinciding with a severe downturn in demand, which followed the boom of the 1980s, led to a dramatic overcapacity in optical fibre.

Thus, restructuring remains on the agenda, even after rationalisation of production facilities, which led to a dramatic fall in employment levels.

---

## INDUSTRY STRUCTURE

---

### Companies

There are more than 100 firms that produce cables and insulated wires in the EU with 250 production facilities and about 71 000 employees. Production sites are located in all Member States, with the exception of Luxembourg. The major manufacturers of insulated wires and cables are: Alcatel (F), BICC (UK), Pirelli (I), Siemens (D), Nokia (FIN/F) and draka (NL). If all of Europe is considered, ABB (S/CH) should be added to the list. These large companies produce both energy and telecommunications cables, as well as, winding wires. Small enterprises tend to specialise in one product, often in energy cables, although this varies according to country. In the smaller countries, small companies often manufacture the whole spectrum of products. In France, Germany and Italy, however, apart from four of the top five large producers, there are many small specialist producers. As a matter of fact, about 10 % of production volume is accounted for by small and medium-sized companies in the EU.

The increasing share of glass fibre cables in telecommunication cables has led to the fusion of small and medium-sized firms, in order to provide the necessary capital inputs for the technologically advanced production processes. There are now only about a dozen manufacturers of optical fibre cable in the EU.

The EU insulated wires and cables industry is also characterised by its complete independence from its downstream industries, in spite of the close commercial links they have developed in terms of supply. The industry's activities do not evidence any downstream vertical integration in Europe. The only example of such integration can be found in the USA, with the leading telecommunications firm AT&T operating in cable and telecommunications equipment, as well as being a network operator.

### Strategies

To meet the challenges of increased competition, there are three main strategies: investment; research and development; and, cooperation and concentration. The main motive for investment is an increase in productivity and reduction in costs, especially labour costs, in the medium and long term. In the years when the cable business was booming, expansion was an additional objective.

Innovation in new products or new processes and production methods are other strategies for keeping up with the competitors.

Mergers, acquisitions, alliances and joint ventures are organisational methods for increasing, or at least maintaining, competitiveness on the international market. Several large cable manufacturers have made cross-border investments within the EU, either for reasons of cost or for closer proximity to markets. Investments outside of the EU have been made, above all,

by French, Italian, British and German cable producers. These have been primarily in North America (USA, Canada), Latin America (Mexico, Argentina, Brazil and Peru) and Africa (Lebanon, Kenya, Morocco, Nigeria and South Africa). They also have a strong presence in Saudi Arabia, Bahrain, and in Asia (Australasia, Singapore, Malaysia, Indonesia, China and India). As companies have experienced difficulties in 1993, there have not been any significant moves since 1992 by majors in Europe. 1993 and 1994 have been years of consolidation rather than expansion. The recession has not prevented, however, some EU cable producers from preparing the groundwork for further expansion moves. In particular, EU majors and medium-sized companies are active in the emerging economies of China and eastern Europe, where they are setting up joint ventures or greenfield starts. Such investments, outside of the EU, have been primarily made in order to benefit from growing markets, and also aimed at diversifying into new markets to reduce companies' vulnerability to business cycles and over dependence on mature and declining markets.

### Impact of the Single Market

There are two major factors behind the limited impact of the Internal Market programme on the insulated wires and cables industry. First, there has always been substantial cross border trade in this sector, largely facilitated by the establishment of one of the earliest European agreements on mutual recognition of standards (HAR) in 1973. Secondly, two of the sector's main customers (telecoms and energy utilities) are usually best supplied by nearby suppliers of products which are often bulky and for which the existence of skilled installation capabilities and effective after-sales service are important prerequisites.

Over the last five years, the most relevant impacts of the Single Market programme on this sector have been through the progressive liberalisation and deregulation of the telecoms and energy utilities markets. This has greatly increased competition between suppliers in these markets, particularly where this deregulation has been accompanied by the privatisation of the customer industry.

Another set of measures which has a potentially important impact on the cables sector is the opening of procedures for awarding public work and supply contracts. In this area, there is, however, still progress to be made to effectively implement these rules. Although there remain historical examples of different national systems requiring specific national products, cable suppliers are usually capable to supply any technical requirement.

---

## REGIONAL DISTRIBUTION

---

EU insulated wires and cables production is dominated by Germany, which accounted for 33 % of total EU production in 1993. France, Italy and the United Kingdom are also large producing countries. A glance at the regional distribution gives evidence of the gravitation of production of insulated wires and cables towards the industrial heartlands. Relatively limited by high transportation costs, particularly for heavy industrial cable, producers have tended to locate near their main customers. Central and western regions of the EU accounted for about three quarters of total EU production and of EU employment in the sector in 1993.

The enlargement of the EU in 1995 will somewhat move the hub of EU insulated wires and cable production towards central and northern Europe. In effect, the entry of Sweden, Finland and Austria into the EU in 1995 will expand significantly the base of insulated wires and cables production. In 1993, these three countries represented 7.4 % of the EU-15 output and 7.7 % of current employment levels in the sector.

---

## ENVIRONMENT

---

Generally speaking, cable manufacturing is not a burden on the environment. The manufacturing process is clean and the materials used are normally non-toxic; those posing potential risks are strictly regulated. The cable industry has been very responsive to environmental concerns. In 1993, the manufacturers actually expressed this environmental consciousness by producing a voluntary code of practice.

The industry puts particular attention on its use of raw materials and its design of products, minimising the potential hazards of their installation and use. Specially designed cables, with reduced flammability, are available and there are already acceptable alternatives to PVC and other compounds in areas with fire risks. Cable makers no longer use materials containing dioxin and are investigating the possibilities of substituting materials containing halogens. Cable insulation without halogens emits little in the way of toxic fumes. This is particularly important in public areas, transport and warehouses, as well as any place frequented by people or housing combustible goods.

---

## REGULATIONS

---

Regulations that relate to technical standards, the use of dangerous preparations and health and safety all have implications for cable makers, although there are no specific directives which are directed to the industry. The directive (89/336/EEC), for example, lays down mandatory essential requirements concerning emissions of electro-magnetic disturbances and immunity from such disturbances for electrical apparatus, equipment, systems and installations. In so far as cables in systems or installations may produce or transport such disturbances, adequate measures, such as shielding, may be required.

On another front are the public procurement directives which liberalise the awarding of public contracts. A large part of the market for insulated wires and cables has been dominated in the past by the public utilities (both in energy and telecommunications), which often favour national suppliers. With the liberalisation of the tender procedure and procurement, competition within the EU will intensify. Harmonised standards will also allow EU manufacturers and their foreign competitors to penetrate markets other than their own, once the utilities have themselves harmonised their systems.

---

## OUTLOOK

---

The short term outlook for the EU insulated wires and cables sector is diverse across the three main categories, which are subject to different forces of demand. The market for energy cables remains fairly limited as the energy infrastructure is virtually complete in the Union. Demand therefore consists to a large extent of replacement, maintenance and upgrading of existing infrastructure. Energy cables will, nevertheless, benefit from increased deregulation. Sales possibilities in less developed economies are unlikely to increase significantly. In spite of important needs, improvement in the energy infrastructure is making very slow progress due to limited financial leeway.

The market for telecommunications cables has been stagnating in recent years. In the years to come, this market segment should witness significant improvement, driven by developments in the information technology market and the growth in personal communications, particularly, mobile telecommunications. Privatisation and liberalisation of public procurement in the telecommunications sector should also positively impact on the sector's prospects.

The demand for winding wires will lead the short term outlook, as its main client industries, in particular, the automotive and electro-domestic sector, emerge from a deep crisis. Demand for data and control cables will remain buoyant, based on a dynamic market for office and data processing equipment. However, the EU sector will remain in a fragile competitive position in this market segment, as it faces stiff competition from the world leading computer producers, the USA and Japan.

In the long term, the energy cable segment will benefit from the growth in GDP and the associated increase in electricity consumption. Telecommunications cables will continue to be a fast growing segment, and will benefit from the buoyancy of the information technology market. At last, encouraging prospects for construction and the manufacturing industry will positively impact on the demand for all cables.

On the employment front, the outlook remains rather grim. As the industry is bound to complete rationalisation and is confronted by important overcapacity on both metallic and optical fibre cables, employment will drop further in the next few years.

# Electrical machinery

## NACE 342

Whereas demand for electrical machinery products boomed during the second half of the 1980s, growth has slowed down over the last few years. Overcapacity in the electricity-generating sector and the decline in investment activity are partly responsible for the fall in demand growth.

During the course of the 1990s, demand for the industry's products is expected to grow, mainly boosted by demand from developing countries (South East Asia, China and Eastern Europe). Domestic demand is expected to increase at a slower pace, due to market saturation.

Extra-EU competition has increased, particularly in the segment of mass-produced, standardised equipment. Technical harmonisation in the EU is eliminating barriers between Member States, thereby allowing producers to achieve greater economies of scale. In view of the focus of Japan and the newly industrialised Asian countries on mass-produced standardised equipment, EU firms will need to increase cooperation efforts and intra-EU sales, streamline production and improve cost competitiveness to face up to a further intensification from both within and outside the EU.

### INDUSTRY PROFILE

#### Description of the sector

The electrical machinery sector comprises two main subsectors: the manufacture of machines, equipment and instruments for the production and conversion of electricity, which includes electrical motors, electricity generators and rotary converters, transformers, current rectifiers, electromagnets and electromagnetic apparatus; and the manufacture of equipment for the distribution of electric power, including equipment for closing, opening, and protecting electric circuits of 1 KV or more (high-voltage switchgear), installation equipment up to 1 KV (low-voltage switchgear), and fixed and variable resistors, including potentiometers

Germany is the most important producer in the EU, with an estimated share of 43 % of total EU production, followed by France (29 %), the UK (13 %) and Italy (13 %). Among manufacturing industries, the electrical machinery sector carries significant economic weight. In 1992, value added in the sector was around 30 % higher than that of consumer electronics.

Figure 1: Electrical machinery  
Value added by Member State, 1993

Source: DEBA

#### Recent trends

Production volume on average increased by 2.5 % per year from 1984 to 1993, slightly above the average growth rate of the manufacturing industry (+1.9 %). Demand grew at a faster rate, around 3 % per year in real terms. In the last few years, however, the sector has been confronted with strong competition from outside the EU. On average, extra-EU imports grew by nearly 12 % per year in current prices from 1984, to reach some 9.5 billion ECU in 1993 (equalling approximately 25 % of apparent consumption). After slow growth from 1983 to 1988, extra EU exports grew at an average rate of 7 % per year from 1984 to 1993.

The industry is highly-export oriented, with extra-EU exports accounting for 31 % of production in 1993. The trade balance has been positive throughout the last decade.

#### International comparison

The EU is the most important producer of electrical machinery within the Triad. In 1992, Japanese production was the equivalent of 82 % of EU production, whilst US production equalled about 68 %. Japanese production increased the fastest, by roughly 41 % from 1987 to 1991, representing an annual average growth rate of nearly 9 % in real terms. EU production

Origin of EU imports**

Source: Eurostat

grew more moderately, at roughly 2.6 % per year from 1984 to 1993. US production has been declining since 1989.

### Foreign trade

The most important feature of trade in the last decade has been the rapid growth in imports, which grew by more than 12 % per year in current prices from 1984 to 1993. The EFTA countries remain the most important origin of imports to the EU, providing around 27 % of total extra-EU imports. Switzerland, in particular, is an important competitor for EU producers. The USA and Japan each hold EU market shares of roughly 20 %. Over the last years, however, all the traditional competitors (with the exception of Japan), have been losing market share in the EU, mainly to the benefit of developing and industrialising countries, the market shares of which increased from 20 % in 1987 to 30 % in 1993 (Taiwan and South Korea held 4 % and 6 %, respectively).

In current prices, extra-EU exports grew by 7 % per year from 1984 to 1993. The most important market for EU producers is the group of developing and industrialising countries (including the East Asian NICs) which accounted for around 63 % of total extra-EU exports in 1993. The EFTA countries represented approximately 23 % and the USA slightly below 14 %. The EU trade balance has remained positive (at 3.6 billion ECU in 1993), with extra-EU exports about 1.5 times the size of imports.

Trade within the EU grew fast, by some 13 % per year, over the period 1983 to 1992. The share of intra-EU trade out of total EU imports remained more or less constant over the same period. The most important intra-EU exporter in the EU is Germany, with about 42 % of the total, followed by France (19 %), the UK (10 %) and Italy (9 %).

## MARKET FORCES

### Demand

Overall demand for electrical machinery has increased significantly over the last 10 years (with growth at 3 % per year) although there have been important variations in the different segments.

Demand for products closely related to manufacturing processes benefited the most from the investment boom of the second half of the 1980s. The EU manufacturing sector made efforts to expand production capacity and improve efficiency in anticipation of the Single Market. This led to strong demand for electric motors, electromagnetic equipment, low-voltage

switchgear, installation equipment and fixed and variable resistors. Product innovation also had a positive effect on demand. One example is the switch from DC converters to three phase converters. In the last few years, however, following the decline in investments, demand has grown more moderately.

Subsectors more closely related to the production and conversion of electricity went through a quite different pattern of development over the last decade. Rapidly growing demand for electrical power in the late 1980s resulted in the expansion of electrical energy supply, as well as of distribution networks. This had a positive effect on the producers of equipment such as electricity generators, transformers and high-voltage switchgear.

In the last few years, however, the picture has changed. With the slowdown in electricity demand growth, due to saturated markets, a fall in fossil fuel prices, and energy-saving measures, demand for products related to the generation and distribution of electricity has declined. Electricity distribution companies have now completed substantial investments in most EU countries, with the result that the industry now has significant excess capacity. For several years to come, investments in these areas will therefore be oriented towards replacement, rather than capacity increases.

In addition, the recent downturn in general economic activity has affected demand for the industry's products, as decisions to invest in power stations are closely tied to expected GDP growth. In view of depressed demand on the domestic market, EU producers have sought to increase their presence on other markets. In some cases, however, this has been hindered by protectionist measures designed to maintain national control over electricity production, which is often viewed as a "strategic" industry.

### Supply and competition

As demand has increased over the last decade, EU production of electrical machinery has grown steadily (at approximately 3 % per year between 1984 and 1993). In many areas of the sector, EU producers may be considered to be market leaders with significant market shares. In 1990, EU manufacturers held a 35 % share of the world market for high-voltage switchgear, followed by the USA with 28 % and Japan with 26 %. In low-voltage switchgear, EU producers held a similar share, compared to the USA at 24 % and Japan at 20 %.

**Table 5: Power transformers**  
**External trade in current prices**

(million ECU)	1984	1985	1986	1987	1988	1989	1990	1991	1992	1993
Extra-EU exports	488.7	439.1	421.3	376.4	412.4	483.6	510.3	567.7	621.1	682.7
Extra-EU imports	137.0	145.7	157.6	158.9	220.4	271.3	259.0	280.0	303.6	335.5

Ratio exports / imports	3.6	3.0	2.7	2.4	1.9	1.8	2.0	2.0	2.0	2.0

Source: Eurostat

Technical harmonisation in the EU is eliminating barriers between Member States. In order to face increasing internal and external competition (from Japanese and other Asian producers in the mass market), EU producers will have to increase cooperation and improve their cost competitiveness. This increasing competition is having significant repercussions on several market segments. For example, the exports to imports ratio for transformers fell from 6 in 1982 to 2 in 1993. In low-voltage switchgear, competition from Japan and East Asian NICs reinforced imports from this part of the world. All in all, the imports to consumption ratio rose from 10 % in 1983 to 25 % in 1993, a figure that now seems to have stabilised.

## INDUSTRY STRUCTURE

### Companies

The number of companies manufacturing electrical equipment in the EU has been declining over the last 20 years. However, the concentration has created powerful and competitive manufacturers.

Hence, the sector is dominated by a few very large pan-European manufacturers which operate in a wide range of electrical engineering activities. The most important is ABB (CH/S), which is active in the major electrical machinery segments (turbo-alternators, high-voltage and low-voltage switchgear and motor control equipment), followed by Siemens (D), also active in the main market segments. GEC (UK) is mainly specialised in turbo-alternators and high-voltage switchgear and the joint-venture GEC-Alsthom (UK/F) is present in the main segments of the sector. AEG (D) is a leading firm in low-voltage switchgear and motor control equipment; other major players are Schneider (F) and Jaeger (F).

Precise employment figures for the sector are not available and total employment was estimated at 350 000 in 1993. Approximately 35 000 people were employed in the high-voltage switchgear sector in the EU, and in Germany alone there are 48 000 people employed in the low-voltage switchgear sector.

By promoting intra-EU trade and agreements between European manufacturers, the Single Market has consolidated the EU electrical machinery market. US and Japanese manufacturers, fearing a possible "Fortress Europe", have undertaken huge restructuring of their production and are looking for co-operation agreements with the largest European manufacturers. Both US and Japanese companies are nevertheless powerful on the world market for electrical machinery. They supply an estimated 40 % of world-wide demand.

### Strategies

The largest EU producers have been focusing upon emerging markets for a long time. The relative saturation of many domestic markets has forced them to expand their horizon. China and other Asian countries, as well as South American ones, represent huge potential markets for the largest manufacturers.

However, most internationally active players are attracted to these markets and the battle for market share is fierce. Success

on these new markets is generally dependent on several factors, such as political relations between countries, local presence in the country, previous experiences of foreign markets and ability to sub-contract to local industry.

Today, EU producers have a relatively strong position on their own market but the potential in foreign markets is much higher, and in the medium term domestic market shares will certainly evolve with the ability of companies to tap these emerging markets. At the same time, EU producers continue to restructure the industry. On the one hand, R&D and quality control expenditures are increased to compete on product quality and know-how. On the other, cost reduction and production line modernisation continue, in order for companies to remain competitive vis-à-vis East Asian low-cost manufacturers.

However, such restructuring is often insufficient to stay competitive on the global level and many companies are continuously looking for partnerships and other commercial agreements with local manufacturers to ensure physical presence in certain countries or to take advantage of local opportunities. One recent deal is noteworthy: ABB owns the majority of a joint venture in Vietnam with CTBT, a local transformer manufacturer (according to ABB, the joint venture was the largest in the electro-technical industry to be set up in Vietnam by a foreign company). In general, EU firms are increasingly present in various emerging markets (such as South East Asia, China and Central Europe), through cooperation with local partners (e.g. ABB has set up joint ventures in switchgear in the Czech Republic).

EU producers currently follow three main lines of strategy: to develop sales on emerging markets (mainly China and certain South American countries); to restructure production lines in order to improve quality and reduce costs; and to set up co-operation agreements with local manufacturers or to grow externally through mergers and acquisitions.

### Impact of the Single Market

Demand for electrical machinery has grown over the past few years. This was due not only to general economic recovery and increased demand from developing countries, but also to EU technical harmonisation which has reduced barriers to entry into the market and has resulted in an increased concentration of European firms. Nevertheless, trade is still hampered by other internal and external barriers, such as enlarged testing requirements and certification activities and high protectionist barriers.

The sector, in view of the realisation of the Single Market, has made important production capacity and efficiency improvements which, in due time, will assist the recent boost in demand. Harmonisation of EU legislation has also helped to reduce SMEs' financial burdens and encourage their investments. Finally, an overall assessment of the impact of the internal market on the electrical machinery industry would certainly call for a positive evaluation of its effects on the global business environment.

---

## ENVIRONMENT

---

Production of electrical machinery does not present particularly relevant environmental issues. In the past, the use of PCB (polychlorinated bi-phenyls) to insulate the wires in the bodies of transformers did represent an a threat to the environment, but their use has since been discontinued.

It is likely that the industry will benefit indirectly from increased concerns regarding emissions from fossil fuels. Coal power plants, for example, may have to be replaced by cleaner methods of electricity generation.

---

## REGULATIONS

---

Important directives for the sector are the Low Voltage Directive (73/23/EEC), the Electromagnetic Compatibility Directive (EMC; 89/339/EEC) and the Machinery Directive 89/392. Manufacturers whose products comply with the relevant provisions of these Directives and who have demonstrated this conformity by following the applicable procedures set out in the Directives may affix the CE-mark. This allows free movement of the products throughout the European Economic Area.

---

## OUTLOOK

---

In discussing future demand, the market for electrical machinery may be divided into three categories: developed markets, emerging markets and the replacement market.

Developed markets will continue to grow at a very slow pace and some segments may even decline. Even in the case of a strong economic recovery, many markets cannot expect a growth rate higher than 2 % per year due to the relative saturation of the market. Moreover, the trend towards increasing energy efficiency has a direct impact on the sector.

Demand on certain emerging markets is expected to play a major role in the future for the sector's performance. In the medium term, certain countries in Asia (such as China) and Latin America may represent huge markets and provide rewards for those producers able to get a foothold in these countries. It is difficult to estimate potential market growth, however, even if we know that GDP growth currently is between 6 % and 18 % per year in these countries.

The third driver of demand will be the replacement market, a market highly dependent on economic recovery. In this field,

demand is likely to be stable, with expected growth in Southern Europe and Ireland.

On the supply side, the short-term situation should remain the same. However, it may be affected by the increasing competition from East Asian manufacturers which are very well positioned to play an important part in supplying electrical machinery to our part of the world.

The European electrical machinery sector is likely to grow at a very slow pace over the next five years, although growth may be stimulated by the more buoyant developing markets.

# Electrical equipment for industrial use

## NACE 343.1

*Synchronisation in economic growth in the G-7 economies during the fourth quarter of 1994, emphasised by a sharp pick-up in economic activity in Germany, has led to a strong rebound in demand for electrical equipment for industrial use. Structural modification in demand, mainly due to dramatic changes in Eastern Europe, will also support demand through the second half of the 1990's. The inclusion of three new Member States, namely Austria, Sweden and Finland will have an important effect on structural aspects of the industry. For instance, the world leader in the welding equipment sector, namely ESAB of Sweden, will have easier access to other EU markets where major client companies are located. Although major European producers still enjoy a comfortable market position, low cost producers constitute a potential threat. Furthermore, US, Japanese and South Korean multinationals, holding world brands, reacted more positively than EU producers to the globalisation of markets.*

### INDUSTRY PROFILE

#### Description of the sector

The electrical equipment for industrial use sector comprises a number of relatively unrelated subsectors:

- electrical equipment related to internal combustion engines, motor vehicles and other means of transport, and to traffic;
- electrical industrial and laboratory furnaces, ovens and other types of heating equipment;
- equipment, machinery and materials for electric welding and cutting of metals;
- portable electrical tools; and
- other electrical apparatus, appliances and equipment for industrial use.

Due to the number of products covered by this industry, activity is distributed among a large number of competitors who are either highly specialised in a specific product segment or diversified in a number of industries (e.g. Robert Bosch (D), Peugeot (F) or Fiat (I)). However, none of the analysed companies offer a product range covering all segments of the industry.

Two segments dominate the electrical equipment for industrial use sector: power tools and welding equipment. Together, they account for over 50 % of total sales within the EU. Figures for production are not as important due to manufacturing delocalisation.

The power tools industry produces equipment such as drills, planers, circular saws and other tools, which are generally portable. Main consumer segments are professional (e.g. construction, metal-working and wood-working sectors), accounting for 40 % of 1993 revenues, and domestic DIY - Do It Yourself, accounting for the remaining 60 %.

#### Recent trends

Sales of power tools in the EU and EFTA countries reached over 2 500 million ECU in 1993, with drills accounting for 34 % of the total. Germany is the largest consumer, accounting for close to 40 % of total consumption, followed by France, Italy and the UK, all under 15 %.

Total consumption of welding equipment in EU markets for 1993 exceeded 1 300 million ECU including robots and working environment equipment. Arc welding equipment accounted for nearly one third of this figure, while resistance welding equipment represented 30 %, and other types of equipment such as working environment equipment, laser and electron beam machines represented the remaining part. Within the EU, Germany was the largest consumer with over 45 % of the total, followed by France with over 20 % and Italy with 15 %. The main consumer market for welding equipment is by far the automotive industry, followed by the DIY sector.

The 1989-1993 compound annual growth rate (CAGR) of total extra-EU exports of the industry was 3 %, but with inequalities on a year by year basis. CAGR of total extra-EU imports increased twofold, reaching 6 % during the same period. Consequently the trade surplus, as much as 500 million ECU in 1989, fell dramatically to reach 100 million ECU in 1993. Trade among EU Member States has been growing at a CAGR of around 7 % for both exports and imports. Therefore, the share of intra-EU exports out of total EU exports has been growing over the last five years. For 1993, export and import activity in internal EU trade was at least 40 % higher than external EU trade.

In the last four years, power tools imports have grown three times faster than exports, mainly due to a slowdown in the growth of exports outside of the EU. In contrast, extra-EU exports of welding equipment have grown at 1 % CAGR, while extra-EU imports have declined at an average annual rate of 4 %. However, external exports have decreased in nominal terms over the period.

#### International comparison

In the electrical equipment for industrial use sector, China is still a minor producer although it should be seen as the most threatening. While exports to this country represented 3 % of total EU exports in 1993, imports of Chinese equipment were close to 5 %. Also, while 1988-1993 CAGR in exports grew by "only" 15 %, imports grew from 9 million ECU in 1988 to over 260 million in 1993, in nominal value, or a CAGR of 97 %.

EFTA countries are the EU's major destination countries corresponding to 22 % of total exports. For total imports, the EFTA countries share is lower at 18 %. However, imports are increasing at a faster rate than exports. In 1993, 61 % of the welding equipment imported by the EU came from EFTA countries, mainly Switzerland and Sweden (host of the world's leading producer).

In 1993, EU's trade balance was negative both with the USA and Japan: 12 % of EU exports were destined to the USA, while 20 % of EU imports came from that country, with a five year CAGR of 6 %; Japan absorbed only 2 % of EU exports, while it represented over 22 % of EU imports, with a five year CAGR of 8 %. It is in the power tools segment that these countries are particularly strong competitors for EU producers. For instance, Japanese power tools account for 17 % of EU imports, while exports to Japan only account for 2 %. However, Japan has lost market share between 1988 and 1993 in EU imports to the benefit of emerging and low cost producing countries such as China or Hungary.

#### Foreign trade

The trend towards increasing import penetration of electrical equipment for industrial use as a whole is demonstrated by the fact that 1984-1993 CAGR of extra-EU imports grew by 9 %, while extra-EU exports only grew at 4 % CAGR. In 1992, the nominal value of imports was slightly higher than that of exports, leading to a negative trade balance of 51 million ECU.

In power tools, the EU trade balance has suffered a sharp decline since 1988. From 1989-1993, extra-EU imports grew

three times faster than exports, with Switzerland (host of a large number of Bosch facilities, the EU's leading producer) Japan and China representing a combined share of 71 %. It is also important to note that German imports grew by 15 % per year in the last five years, while exports only grew by 4 %, evidence of an increase in competitiveness of other countries, particularly outside the EU. France, Italy and the UK are also large importers.

Apart from the US and EFTA countries, major clients for EU producers of welding equipment are countries such as China, the former Eastern block, Turkey and ASEAN countries. In 1992, the most important intra and extra-EU exporter was Germany (40 % of intra-EU and 42 % of extra-EU exports) followed by Italy (16 % and 20 %, respectively) and France (13 % and 11 %). With regard to imports, Germany was also the largest importer in 1993 accounting for 34 % of total EU imports, with two-thirds originating from outside the EU, followed by the UK, Italy, the Netherlands (which holds a negative trade balance in this subsector) and France.

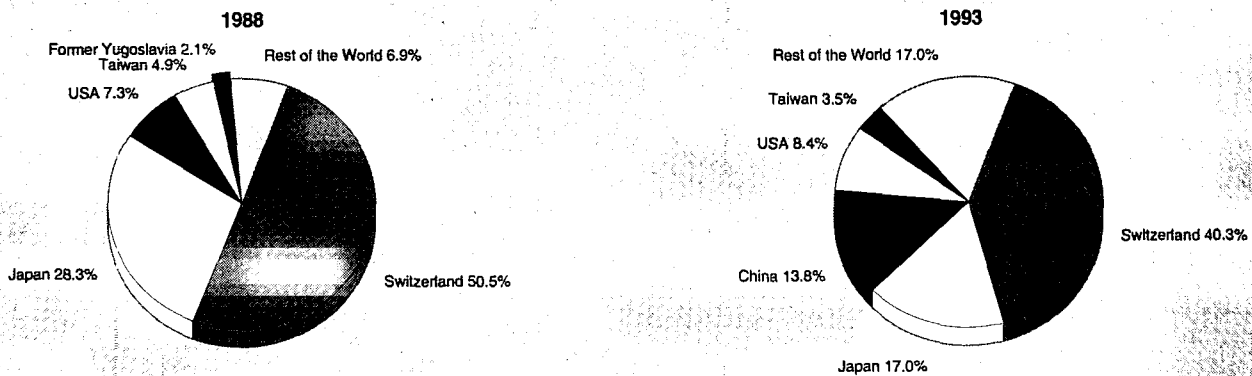

## MARKET FORCES

### Demand

Notwithstanding power tools, whose demand is determined to a large extent by private household expenditure, products from this industry are either intermediate or investment goods. For welding equipment, consumables (filler materials) are not consumed as such, but are used in connection with the production of durable investment or consumer goods, such as cars or ships. Demand for electrical equipment for industrial use is therefore determined mainly by the evolution of production in a large number of client sectors. Investment goods can be classified as:

- electrical equipment related to internal combustion engines, motor vehicles and other means of transport, and traffic, where demand is determined by the level of production of transport equipment, and by replacement needs;
- furnaces and ovens, where demand depends mostly on construction activities or replacement in manufacturing plants, as well as, R&D activity;

**Figure 2: Power tools  
Origin of EU imports**

Source: Eurostat

**Figure 3: Welding equipment  
Destination of EU exports**

Source: Eurostat

- welding equipment and materials, where demand depends mainly on activities in the processing industry, power generation and transport industry (which includes the construction of cars, ships and aircraft), but also on a wide range of other activities, such as the production of cans, cross-wire products, steel constructions or pipelines; and
- electrical power tools, where demand is mainly driven by construction, metal- working, wood-working, craftsmanship, small scale manufacturing, maintenance and DIY activities.

Most products of this industry are highly sensitive to variations in general levels of economic activity. As a result, recession was the main cause of the 1990-1993 market slowdown. Major drops in the welding equipment industry were caused by the fall in orders by client industries, which postponed capital investments. In contrast, the power tools market downturn (which was less than 2 % in 1990 and 1991) was relatively unaffected by its high dependency over consumer goods markets. These markets, mainly the DIY sector, are defensive sectors in a recession.

As many EU countries slowly emerge from recession, demand in 1994 is expected to post a small growth in revenues, and growth rates are expected to pick up from 1995 onwards. Main factors affecting future demand will be: a strong contribution of the massive German market, particularly from the former East German region where most companies and consumers will need to invest in equipment goods and where extremely intensive construction, metal- and wood-working activities are expected to occur. Other contributors will be Italy and the Iberian Peninsula, where construction is a major sector of the economy.

Furthermore, power tools sales growth is anticipated in markets where DIY is still relatively underdeveloped and where market shares of the superstore distribution segment are predicted to escalate.

**Supply and competition**

Major companies in this market are based in the EU, the USA or Japan. In the power tools segment, competition in European markets is fierce between these three geographical blocks, mostly because of high product standardisation and easy access to distribution channels. In other segments, EU

producers are less threatened by outside competitors. Most firms active in these segments supply relatively custom-made products and services to their client industries, creating barriers to these markets for non-EU producers. Barriers to entry also exist because strong cooperation and joint research between supplier and customer are more important than pricing.

In welding equipment, particularly the car assembly lines equipment segment, regional producers, or at least EU-based producers, have an edge over suppliers from other countries. "Transplant" production facilities are generally a threat to EU suppliers as they constitute a market penetration opportunity to non-EU companies: transplants are generally equipped by original suppliers from the mother-company. For example, Japanese car transplants in the UK receive most of their equipment from Japan.

In the power tools segment, although EU companies have an intrinsic advantage because they are dealing on home territory and control distribution, Black & Decker (USA) has an entrenched network that places it above most competitors. It is also likely that major distribution expansion will be achieved by Japanese companies, which combine wide product ranges, quality and innovation (particularly in the cordless segment). However, some European manufacturers are at an advantage versus German and Japanese competitors because of currency weakness, allowing them to maintain a price-competitive edge (i.e. Italy).

### Production process

For most of the sector's products, raw materials and energy represent a small portion of production costs. R&D is a very important input as products must adjust to changes in the production process in client industries. A major part of the labour force is skilled. Technological change is rapid, but evolutionary rather than revolutionary. It is interesting to note that the adoption of major innovations in the welding segment, such as laser cutting/welding technologies or electron-beam welding, may be held back by reluctance from client industries to master new, untested products. This also happens when problems such as the high cost of the certification process come forward (e.g. introduction of new technologies in the aerospace industry). In power tools, upcoming major innovations are electronic upgrades, both for professional and DIY segments, and the improvement of cordless and battery-recharging technologies.

## INDUSTRY STRUCTURE

### Companies

The industry is undergoing a concentration process with smaller firms being absorbed by large groups, both within

their countries and across borders, particularly in the welding equipment industry. Activity is distributed among a large number of competitors who are either small companies, highly specialised in a specific product segment, or large corporations, active in a number of businesses (e.g. Robert Bosch (D), Fiat (I) or Atlas Copco (S)).

With regard to the welding equipment sector, there are at least two distinguish fields: arc welding and resistance welding. In the arc welding segment, machines are of relatively small value, but consumption of filler-materials represents a large part of welding cost. Sales are usually made through a network of distributors. Leading competitors have appeared as the result of a consolidation process carried out over the last decade. ESAB (S) is the world's leading supplier of welding equipment and consumables with a total group turnover of over 750 million ECU in 1993, of which 400 million ECU was in West Europe. ESAB was formerly controlled by Incentive (S) of the Wallenberg family and acquired by Charter, the UK industrial group, in 1994. Messer-Griesheim/Norweld/Lincoln (D/I/USA), SAF/Oerlikon (F/CH) Migatronic (DK), Kemppi (FIN) and Hobart & Miller (USA) are also major producers in the European market.

The resistance welding segment is more fragmented. However, some companies have grown out of this activity to become major automation companies and are now mainly involved in the production of transfer lines used for the assembly of automobiles. Major producers are: Sciaky (F) the major independent firm in Europe which offers the widest range of resistance welding equipment, as well as, conveyors and mechanical handling equipment; Renault Automation (F); Kuka (D); Comau (I) a subsidiary of the Fiat (I) group; Lamb-Technikon (UK); and Stadco (UK). Smaller companies (under 150 employees) active in this segment manufacture more standard welding machinery, such as classic spot or projection seam welders. Among others, the following can be mentioned: British Federal (UK); Ideal (D) which produces butt welders and transformers; Elrex (D) which produces transformers; Dalex (D); and PRD (F). Most of the firms in the industry operate in a number of EU countries, if not world-wide.

The power tools industry is less fragmented. The sector is dominated by a reduced number of international producers who are challenged locally by small producers specialising in professional and industrial tools, often custom made. Here, companies can be divided into three categories: multinational; national; and regional.

Multinationals, for which this activity is often only a fraction of total revenues, are geared towards offering a broad range of products to all end-use sectors in all geographic regions. They function by means of manufacturing sites in different international locations, with each site producing a specific range of tools. Distribution is controlled either through direct subsidiaries a joint venture. Examples are Robert Bosch (D), the market leader with portable power tools sales reaching 1 000 million ECU in 1989 and a declared 20 % world market share; Black & Decker (USA), for which power tools contributed to over 25 % of total revenues in 1992; or Rioby (JPN), with sales of over 300 million ECU in 1992. National producers also offer a broad product range, but tend to serve one end-user group in particular or a single geographic area. Production sites can be numerous, but are located in only one or two countries from where products are distributed via subsidiaries for main markets or agents in lesser markets. Examples are AEG Elektrowerkzeuge (D), a former AEG division taken over by Atlas Copco (S), which owns other power tool manufacturing companies; Wickes (UK), more a retailer than a producer with more than 60 stores in the UK and 30 others in France and the Benelux area; and Peugeot (F). Regional producers are generally niche producers with narrow product ranges, often custom made, which satisfy a need too specific for the broadly-based large companies.

## Strategies

Demand for electrical equipment for industrial use is, and will remain, subject to EU and world economic cycles. However, firms in the sector must be able to respond fast to fluctuations in demand. This can be achieved through high levels of automation, component out-sourcing and flexibility in employment. Successful strategies leading to a sustainable competitive edge should combine a mixture of four factors: identification of end-user needs, geographic shifting of production, innovation and product differentiation.

R&D, particularly joint R&D, is also an important factor in maintaining a competitive edge, as well as, close cooperation with client sectors. These strategies allow firms to adapt products to client needs and build up customer loyalty.

On the mergers and acquisitions side, apart from the acquisition of welding equipment world leader ESAB by Charter, Black and Decker divested some non-core business activities such as Dynapert (USA), Corbin & Russwin (USA) and Minicraft (UK) in 1994 for an estimated total of over 300 million ECU. They also announced plans to discontinue manufacturing operations at their Limburg (D) facility in favour of the Spennymoor (UK) site.

## Impact of the Single Market

The impact of the Internal Market on the various areas of legislation of direct relevance to the electrical equipment for industrial use sector is, with important exceptions, fairly weak. Exceptions arise in the free flow of goods. In particular, technical harmonisation has had a positive effect on the sector because product standardisation has stimulated competition amongst pan-European players. Also, full implementation of the Internal Market measures will prevent new barriers from being created. Another important Single Market issue stems from consumer protection; in fact, since some third country products are of poor quality, misleading advertising and producer liability legislation could be used as effective international trade tools. Finally, the Single Market program is bound to have a decisive effect on small and medium sized enterprises, as administrative and financial burdens will be minimised, thus encouraging investment related activities.

## REGIONAL DISTRIBUTION

It is foreseeable that a shifting of production facilities from high-cost to lower-cost regions will increase in the coming years. This is true not only within the EU, but also on a global level.

## ENVIRONMENT

Ecological issues are of small concern to the production processes in electrical equipment for industrial uses as energy consumption is low and emission of noxious fumes or other pollutants is negligible.

Recycling for the industry is rarely a problem because the industry produces relatively low volume and high value added products, with a large share of recyclable metals in the composition of materials. For the arc welding industry, fumes represent a problem at the user's end due to the special composition of the different types of electrodes used in the welding process. Here, the danger is not for the environment in the usual sense but for the workers' health. This is dealt with by the use of aeration systems, filters, and masks, with Nederman (S), member in the ESAB group, as world leading supplier of such equipment.

## REGULATIONS

Major regulations affecting the industry are norms and their homogenisation across the EU. However, only standard components such as transformers, electrodes' sizes, cables, etc. are affected. Most of the equipment produced by the industry is highly specialised and built to suit specific requirements. Thus, there is little scope for exogenously imposed normalisation. However, some types of equipment do produce electromagnetic radiation and the European Commission is working on a regulation to reduce its possible negative effects on workers and the near-by environment. The power tools industry has to comply, in most cases, with general safety regulations.

Key directives affecting the electrical equipment for industrial use sector are: the machines directive (89/392/EEC), the low voltage directive (73/23/EEC), the electromagnetic compatibility directive (EMC; 89/336/EEC) and the March 1994 directive on protection equipment and systems to be used in potential explosive atmospheres (94/9/CE).

## OUTLOOK

The outlook for the industry of electrical equipment for industrial use is closely related to general variations of GDP. Although the present global economic recovery appears to be well on course, and given that final demand from client industries will most likely increase in the next three years, unqualified optimism is still not justified.

With regard to the car industry, global car sales in 1993 fell to their lowest level in six years, but demand has recovered. Global car sales could rise by nearly 6 % in the next three years. This will foster growth in the sectors related to the automotive industry (e.g. electrical components for motor vehicles) and benefit the welding industry. Demand for transport and traffic related equipment has remained strong in a number of EU countries, mainly Germany, France and Spain thanks to important railroad development projects. The development of transport, Trans-European Networks (TEN), promoted by the EC is expected to extend this positive trend to all Member States and boost activity in the EU. For other types of equipment in this industry, demand will benefit from EU and world economic recovery.

Growth rates for the total Western European market are expected to rise from less than 1 % in 1993 to over 2 % in 1994. Growth rates are also projected to experience strong acceleration during 1995-1998. The CAGR for the 1995-1998 period is projected at close to 5 % with production expected to grow at similar rates. Extra-EU imports and exports should follow similar growth paths as demand. In the long run, export growth should outstrip import growth, thanks to the development of demand in Central and Eastern Europe.

# Batteries and accumulators

NACE 343.2

*Concentration of the industry is well under way. In 1994, US manufacturers dramatically consolidated their position in the EU and are now close to controlling the important starter batteries market. Demand for consumer batteries is being boosted by the greater use of remote controlled and battery operated appliances. Starter batteries for the automotive industry suffered from general economic recession, but recovery in global car sales should boost sales in this segment over the next three years.*

*Recent technological improvements have generated a series of dilemmas for the leading companies of the industry. For example, longer lasting batteries have a negative effect on sales volumes; rechargeable batteries affect sales of non-rechargeable batteries; and efforts to develop environment-friendly batteries might, in the short term, affect EU manufacturers price competitiveness.*

## INDUSTRY PROFILE

### Description of the sector

The batteries and accumulators industry can be divided into two main subsectors: the production of primary batteries, which are not rechargeable, and that of rechargeable batteries, i.e. accumulators.

There are six types of primary batteries: zinc carbon batteries (the first type of dry batteries); longer life alkaline manganese batteries; mercuric oxide batteries; silver oxide batteries; zinc air batteries; and lithium batteries.

Accumulators are of two main types: lead acid batteries and nickel cadmium batteries.

Depending on their use, batteries can be further divided into: drive batteries, stationary batteries and starter batteries. Drive batteries are employed to operate electric motors to propel vehicles, in particular handling equipment, but also electric cars. Stationary batteries are used mainly for the operation of emergency devices such as alarms, control systems and back-up units (i.e. Uninterruptible Power Supplies). Starter batteries are utilised in motor vehicles to provide electric power until the internal combustion motor has been started.

The automotive sector is the major client of the batteries and accumulators industry accounting for over 40 % of sales.

In the EU, the most important producers of batteries and accumulators are Germany, France, Italy, the United Kingdom,

the Netherlands and Spain. Important producers are also located in Sweden and Finland.

### Recent trends

Demand for starter batteries from the automotive industry increased at a compound annual growth rate (CAGR) of 1.6 % in volume terms between 1983 and 1992. However, sales in the last five years were hit by the drop in car orders and the slow down of batteries replacement. Demand from other client industries grew at a slower pace (1.2 % CAGR) over the same period, but showed an encouraging 2 % CAGR during the 1988-93 period.

In terms of units, imports of starter batteries from outside Western Europe grew twice as fast as domestic sales, reaching a CAGR of 3.2 % during 1984-93 and stabilising at 28 % of total Western European sales in the last five years.

### International comparison

US and Japanese companies have been extremely aggressive in recent years. Both countries constitute a potential threat to EU firms which seem to have difficulty in adapting to the ever increasing need for global products. Reaching a critical size is apparently considered a key success factor by US competitors, particularly in the automotive batteries and consumer batteries markets. The 1994 acquisition campaign of Exide Corp., one of the largest batteries manufacturers in the US, is a clear indicator of this trend.

The major outside competitor for EU producers is Japan, with just under 35 % of total extra-EU imports. The US and EFTA countries come next with a market share of 20 % each. Developing countries have emerged in the last five years by increasing their share of extra-EU imports from some 15 % to over 20 %.

The EU's balance of trade is positive with EFTA countries, but shows a very strong deficit with the US and Japan. Strong extra-EU exports to less developed countries demonstrate that EU products are currently less competitive than US and Japanese productions.

### Foreign trade

Over the last ten years, the EU batteries and accumulators' industry has been facing stiffening competition from countries outside the EU. The first half of the 1990s were painful for EU producers with extra-EU imports increasing at a 13.7 % CAGR. However, between 1984 and 1993, imports grew at a CAGR of 24 %. In 1993 imports exceeding exports by only 31 % compared to 42 % in 1992. As a result, the trade balance deficit has been improving over the last two years.

The most important exporter to countries outside the EU is Germany, accounting for 37 % of total extra-EU exports in 1993 (a 7 % increase from 1992), while France follows with about 20 %. With regard to imports, the most important EU destination is Germany, with roughly 31 % of extra-EU im-

ports, followed by the United Kingdom, with 20 %. France and Belgium were the only Member States to maintain a positive trade balance in 1993.

Competition between EU producers continues to grow (8 % CAGR in the 1988-92 period), but is less intense than a decade ago (15 % CAGR in the 1984-92 period). However, given the fact that extra-EU imports grew at a faster pace, the share of intra-EU imports out of total imports declined from 72 % in 1984 to 60 % in 1992.

## MARKET FORCES

### Demand

Demand for batteries and accumulators increased considerably during the last decade. In the field of non-rechargeable (primary) batteries, market growth was roughly 2 % per year in volume. Primary or consumer batteries are used in high-fidelity equipment (50 %), games (20 %), lighting (11 %), watches and alarms (11 %) and photo equipment (8 %). Consequently, demand for this product largely depends on private consumer expenditure. Increasing use of battery operated appliances and remote controlled devices, spurred by product innovation, are the main factors for this favourable development of demand. The short-living zinc-carbon battery is gradually being replaced by the longer-lasting alkaline battery; whose life is nearly three times longer. At present, the latter accounts for roughly 40 % of the market in the EU (up to 73 % in France and 57 % in the UK). Newer developments in this context are zinc-air and lithium batteries, which contain no mercury.

Within this relatively optimistic demand context, two issues are of concern to major players. First, while technology is improving the life span of consumer batteries, this affects sales in volume terms. Second, the increasing number of retailer own-brands is affecting prices for both consumer and starter batteries.

Demand for rechargeable batteries (accumulators) has been booming in recent years due to increased usage in portable office equipment and wireless mobile communications; particularly since 1985, when nickel-cadmium rechargeable batteries became available to final consumers. The CAGR of

rechargeable batteries from 1989 to 1993 is estimated to be as high as 15 % to 20 %. Accumulators using the nickel-cadmium technology are not only lighter but also last longer (5-10 years) than conventional accumulators. However, this new technology affects sales in volume terms.

Among accumulators, the most important segment is starter batteries (mainly used for motor vehicles, construction machinery, agricultural machinery and aircraft), which accounts for about 55 % of total production of rechargeable batteries. Drive batteries follow with 25 % of the total and stationary batteries represent nearly 10 %. The market for starter batteries in Western Europe represented some 48 million units in 1992 with about one-third going into new motor vehicles, and the remaining two-thirds representing replacement demand for used vehicles. Replacement demand is rather stable since motor vehicles fleets are not subject to short term variations. In contrast, demand for new starter batteries is highly cyclical, following the fluctuations in motor vehicles' production. As the size of the motor vehicles fleet keeps increasing, replacement demand keeps steadily increasing as well.

### Supply and competition

Increased competition from outside the EU is mainly concentrated on accumulators. The largest producers of primary cell batteries have production facilities in the EU and, therefore, do not need to import these products. Nevertheless, dry batteries producers are faced with a rapid decline in prices: a consequence of over capacities built up on the basis of overestimates of the market's growth potential.

The increased competition for EU producers is coming primarily from Japanese, South Korean and Indonesian firms. As contended by EU producers, the price competitiveness of these products is due not only to lower production costs, but also to subsidies on raw materials and export-dumping policies. Despite the producers' contention, no anti-dumping duties are currently levied on imports of batteries and accumulators into the EU.

In the face of increasing competition from outside the EU and over-capacities within the EU, the market suffers from strong negative pressures on prices.

**Table 3: Batteries and accumulators**  
External trade by Member State

Destination of EU exports**

Source: Eurostat

**Production process**

In 1990, the subsector of primary batteries employed about 15 000 people in Western Europe in about 10 factories. In the accumulator industry, about 40 000 people were employed in some 80 factories. As a result of the need to reduce over-capacity and to improve productivity, employment levels are expected to continue falling over the next few years. Redundancies are brought about by the relatively low level of sophistication of the production process and by the possibility of increasing automation.

With regard to technological progress, increasing governmental pressures in favour of zero-emissions vehicles push companies to develop "super batteries" and test assembly lines for future production. Germany's AEG, a subsidiary of Daimler-Benz (D), claims it is the first company in the world to start series manufacture of high-performance sodium/nickel chloride batteries for electric cars. The battery should deliver up to 4 times more power than the conventional lead-acid units.

**INDUSTRY STRUCTURE**

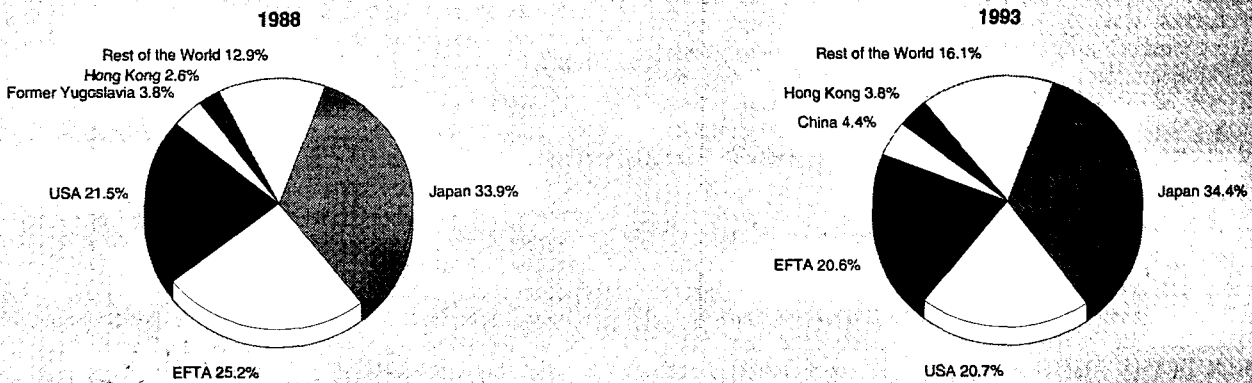

**Companies**

The Western European primary batteries industry is highly concentrated on the supply side, with about 80 % of the market being covered by the four largest manufacturers: the US based Duracell (UK), Varta (D), Philips (NL) and the US based Ralston Energy Systems (CH). Other important players in this field are Kodak of the US, and Sanyo and Matsushita of Japan.

In the accumulators sector, there are about 25 manufacturers in the EU. Major players are: Varta (D), Bosch (D), Saft (F), CEAC controlled by Fiat (I) and Alcatel Alsthom (F) (which has a minority stake), Tudor (E), Fiamm (I) and Hawker (UK). The two leading US firms Exide and GNB also have a strong presence in this segment in the EU.

The largest EU producer is Varta, which is active in both primary batteries and accumulators. Varta has 35 subsidiaries spread around the world, although its traditional markets are Germany and the EU. The group makes roughly 40 % of its turnover in portable batteries, 27 % in starter batteries and nearly 23 % in storage batteries for industry.

**Figure 2: Batteries and accumulators  
Origin of EU imports**

Source: Eurostat

Regarding starter batteries, the number of manufacturers declined from 18 Western European producers in 1988 to 10 in 1991. As a result of increasing concentration, rationalisation and globalisation of their main customers, virtually all EU producers are operating on the European market and most of them are operating globally as well.

### Strategies

In 1994, Exide, the largest battery maker in the US, launched an aggressive acquisition campaign with take-overs in the first half of the year of Gemala and B.I.G. Batteries, two UK starter batteries manufacturers, followed by a successful tender offer for Spain's Sociedad Española del Acumulador Tudor. Tudor is Europe's third-largest battery maker with a 20 % market share in the starter market and 15 % in the industrial market. Tudor operates plants in Spain, Portugal, Germany and Scandinavia (where it controls 30 % of the market as the company is the sole supplier to Volvo). Finally, there was the acquisition from Fiat (I) of CEAC, the largest European industrial and starter battery manufacturer with a strong presence in Italy, Germany, France and Turkey. CEAC owns 17 plants producing starter batteries (11 million units in 1993) and industrial batteries with a total turnover of 580 million ECU in 1993.

In one year, Exide has become the clear leader of the EU battery market, particularly in the starter segment. Other US battery companies have also made recent acquisitions in the EU. The strategic rationale can be summarised as follows: on top of giving access to specific technologies, the acquisitions offer wider market distribution, geographical proximity to clients requiring advanced services (an increasing need), European R&D and production facilities, and future access to R&D programmes funded by the EU.

In August 1994, Autosil, a family-owned Portuguese battery manufacturer, in which George Soros (US) has an indirect minority stake, took a 75 % stake of CFEC (F). The company will control 20 % of the French starter battery market since it is to supply Renault, Citroen and Fiat.

The concentration process is illustrated by the fact that the three companies Varta/Bosch, CEAC, and Tudor together hold a market share of roughly 60 % in the starter market in Western Europe.

The batteries and accumulators' industry in the EU is characterised by surplus in production capacity, and by strong and growing competition from outside the Union. The combination of these factors will probably lead to increasing pressure on prices.

To combat the constraint on margins and to reduce costs, EU companies have rationalised their production process. In particular, efforts are oriented towards a greater concentration of supply in order to gain economies of scale.

Companies are also investing to penetrate new, expanding markets. For example, Japan's Matsushita and Philips (NL) formed a joint venture to build and operate an alkaline battery plant in Poland. Varta, is establishing subsidiaries in countries as diverse as Finland, Argentina, Mexico, Brazil and Singapore. Saft launched a similar strategy in Korea and Finland, from where it will co-ordinate the penetration of South East Asia and Central and Eastern Europe.

### Impact of the Single Market

The prevailing opinion on how the Single Market has hit the batteries and accumulators industry is on the whole neutral. In fact, even though recovery looks set for a new start, this has had more to do with general economic conditions than with the Internal Market measures. The programme has not exerted much pressure on the sector also because it is dependant on main trends of other businesses (e.g. car industry for accumulators).

An important aspect of internal market legislation has been the harmonisation of environmental standards, but the relevant Directives did not have a fundamental impact on the market because, on one hand, Member States started to diverge about interpretation, and on the other, third country competitors did not have to face the same requirements. The effects of the achievement of the Internal Market might have been greater if legislation had been adopted with stricter rules for implementation and enforcement.

---

### REGIONAL DISTRIBUTION

---

As mentioned above, concentration of the industry is well under way. However, small and medium companies still have an impact on the competitiveness of certain sensitive EU regions (Autosil in Portugal, ASB in Bourges, Central France, or B.I.G. in Wales). These companies are either privately owned or controlled by a large group.

Private SMEs, which survived industry concentration, will soon face increasing difficulties in financing R&D projects. As a consequence, they will lose their technological edge. Therefore, it is essential to foster cooperation in the development of new products and provide easy access to public programmes.

Local factories controlled by large corporations do not face financing problems, but it is key for regional authorities to maintain attractive and competitive business conditions in the area. If not, large corporations might switch production to more attractive areas of the world, provoking additional unemployment and subsequent impoverishment of EU regions.

---

### ENVIRONMENT

---

Some of the most important product innovations in the industry over the last few years are related to concerns over the environment.

Most important is the reduction of the heavy metals content for non-rechargeable batteries; namely mercury, which has traditionally been used in both saline and alkaline batteries. Two directives of the European Commission in 1982 and 1984 require the reduction of mercury waste. Since 1985, the primary batteries industry in the EU has cut the amount of mercury discharged from batteries into the environment by half, and has undertaken to reduce this by a further 84 %.

Other environmental concerns are oriented towards recycling batteries. Some Member States have already introduced separate waste collection for primary batteries containing mercury. In 1991, the Commission adopted a Directive forcing producers to take back used batteries, in order to collect and recycle harmful substances. In the Nordic countries, a cooperation agreement was signed in 1994 on the collection and recycling of used lead-acid batteries. Each country is to establish a national funding system for the collection and recycling of used batteries, based on the principle of producer responsibility.

With regard to regulations, the problem is that the required low energy and low emissions recycling techniques are not fully controlled at the moment; except for lead recycling. In the field of lead-acid accumulators, the recycling ratio is already close to 100 %, while in nickel-cadmium batteries it is about 60 %. Besides the technological aspects of the problem, the use of recycled materials is likely to increase production costs. In addition, the cost of collecting the products is very high. In July 1994, the Swedish government raised the environment fee for nickel-cadmium batteries by 45 % because previous fees did not cover the cost for handling the collected batteries. Another factor liable to increase costs to customers is the proposal from the EU to impose a deposit on batteries, as an incentive to return them to the seller.

Presently, a debate is being held on the basis that, if international competition is not forced to face the same requirements as EU producers, then EU producers could lose price competitiveness. However, EU producers might gain strong competitive and technological advantages in the long term stimulated by strict regulations.

---

## OUTLOOK

---

Demand for consumer batteries is being boosted by the greater use of remote controlled and battery operated appliances. This is true both for non-rechargeable and rechargeable consumer batteries. The client industries to which these products are associated are expected to continue their long term growth phase. The "mobility concept" is growing strong in telephoning and computing, as well as, in all electronic devices and high-fidelity equipment. Security is another strong growth area with Uninterruptible Power Supplies (UPS) increasing by over 15 % per year. On the other hand, the decline in the quantity of energy needed in portable devices and longer lasting batteries may dampen demand to a certain extent.

Technology is moving fast. Growth and high margins will only be captured by those companies able to face today's challenges by offering longer life, lighter, smaller, environment-friendly and compatible batteries. Lithium batteries, which last about seven times longer than ordinary batteries, are 30 % lighter and which contain neither mercury nor cadmium will constitute a strong growth segment.

Starter batteries suffer from the general economic recession which has affected most of its client industries (motor vehicles, construction machinery, agricultural machinery and aircraft) since 1989. However, global car sales could rise by nearly 6 % in the next three years, the construction sector is expected to grow around 2 % per year in the next four years and orders for aircraft have shown signs of recovery in the second half of 1994.

In addition, a considerable demand for high energy drive batteries could possibly be created by the development of electrically driven motor vehicles. The first clear indicator is California's adoption of legislation requiring 2 % of new car sales in 1998 to be on non-polluting "zero-emission vehicles" (or approximately 20 000 cars), rising to 10 % by the year 2003.

The sector is represented at the EU level by: European Portable Battery Association (EPBA); Association of European Accumulator Manufacturers (EUROBAT). Address: P.O. Box 5032, CH-3001 Bern; tel: (41 31) 382 2222; fax: (41 31) 382 0311.

# Domestic electrical appliances

NACE 346

The domestic electrical appliances industry in the EU has been faced with changing demand patterns over the last few years. High penetration rates in EU households have dampened demand growth in particular segments, although the effects of the recent economic downturn have been partly offset by a positive trade balance. Another important feature is the concentration process that has taken place in the industry.

Short and medium term prospects for the European domestic electrical appliances industry are relatively positive. Expected recovery in both consumer expenditure and residential construction should boost industry output. Product innovation, pushed by environmental concerns, should help to sustain the upward trend.

Competitive pressures are expected to grow further during the 1990s and EU producers will have to reduce their production costs. Rationalisation efforts are likely to result in new mergers and acquisitions.

## INDUSTRY PROFILE

### Description of the sector

The domestic electrical appliances sector comprises the following products for domestic use: electrical refrigerators and freezers; electrical washing-machines and equipment; electrical dishwashers (including parts); other equipment with electrical motors (including vacuum cleaners, floor polishers, grinders and electrical apparatus for treatment of hair and skin); stoves, cookers and similar electrical heating appliances; other electrical heating appliances (including hair dryers, electrical ironing appliances).

Compared to other manufacturing sectors, domestic electrical appliances are of relatively minor importance, as the sector output is about 65 % of that of consumer electronics, measured in terms of value added in 1993. Germany, with 40 % of the total value added in 1993, is the dominating EU producer. Italy follows at 20 %, France at roughly 12 % and the UK at around 9 %.

### Recent trends

The sector experienced favourable growth during the last decade, above the average in manufacturing industry as a whole. Whereas production in the manufacturing sector on average increased by 1.9 % per year in constant prices from 1984 to 1993, production of domestic appliances grew by 3.5 % per year over the same period. Production was expected to reach some 25 460 million ECU in 1994 (up 5 % from 1993 but only slightly above the 1992 figure).

Demand for domestic electrical appliances, as measured by apparent consumption, increased by 3.6 % per year in real terms over the period 1984-93. In recent years, however, the EU market has lost some of its momentum. The slowdown in consumption growth in the 1989-93 period (+2.4 % per year) also led to a lower production growth (+2.6 %), despite the substantial rise in exports to countries outside the EU (+5.0 % per year in volume).

In the first half of the 1984-93 period, the industry was faced with rapidly growing imports from outside the EU (+12 % per year in real terms), particularly in small appliances and microwave ovens, causing the trade surplus to fall by 41 % in current prices between 1985 and 1988. From 1989 and

Figure 1: Domestic electrical appliances Value added in comparison with related industries, 1993

Source: DEBA

onwards, however, lower demand growth led to a decline in the growth of imports, resulting in an improvement in the EU trade balance, from 3.4 % of production in 1989 to 4.7 % in 1993.

Provisional figures for 1994 indicate that the domestic electrical appliances sector in the EU has witnessed the start of a recovery of consumption.

### International comparison

Japan is the most important producer of domestic electrical appliances within the Triad (i.e. the EU, the USA and Japan). Japanese production was 58 % higher than that of the EU in 1993, and nearly three times as important as that of the USA. In current prices, the order was the same in 1984. From 1984 to 1993, production in the EU on average increased by 3.5 % per year in real terms, whereas that of Japan rose by an annual 2.4 % and that of the USA by 2.3 % per year. In Japan, production increased at a faster rate (at 5.3 % per year) from 1984 to 1992. In 1992 and 1993, however, Japanese production

 Source: DEBA

fell steeply (-15 %), mainly due to a significant drop in domestic demand.

**Foreign trade**

The development of trade with countries outside the EU has been dynamic over the last few years. Trade among EU Member States has also increased, at an average annual rate of 12 % from 1984 to 1992, to reach approximately 7.8 billion ECU in 1992.

From 1984 to 1993, extra-EU exports increased by nearly 8 % per year in current prices. Important markets for EU producers were the EFTA countries and the "rest of the world" group, including developing countries and the East Asian NICs, with more than 48 % of extra-EU exports. In 1993, the USA and Japan were markets of relatively minor importance for EU producers, with stable 9 % and 4 % shares, respectively. The main characteristic of EU exports over the last few years has been the decline in importance of the traditional EFTA markets. Whereas approximately 48 % of total extra-EU ex-

ports went to these countries in 1988, that share had decreased to 33 % in 1993.

The most important exporting countries within the EU are Italy (32 % of total intra-EU exports), Germany (30 %) and France (14 %). Germany, with 22 % of intra-EU imports, has become the largest importer of white goods, mainly due to German reunification.

Competition from outside the EU has increased rapidly over the last few years. Extra-EU imports grew on average by more than 10 % per year from 1984 to 1993 in current prices. The EFTA countries are important suppliers to the EU, with a stable share of 29 % of extra-EU imports. Remarkably, Japan's market share has been declining over the last few years: in 1987, nearly 22 % of imports from outside the EU came from Japanese suppliers, whereas in 1993, their share had fallen to around 5 %. A decline in competitiveness vis-à-vis other fast-growing economies, and increasing efforts of Japanese producers to set up production facilities in the EU are

**Figure 4: Domestic electrical appliances**

**Figure 6: Domestic electrical appliances  
Destination of EU exports**

Source: Eurostat

the main explanations. South Korea followed the same trend with a market share of 7 % in 1993, down from 13 % in 1988. Conversely, China has made an impressive breakthrough to capture 20 % of extra-EU imports in 1993, up from a mere 2 % in 1988.

During the 1984-93 period, total German imports increased at a rate of 10 % per year in current prices, to reach 2.3 billion ECU. This was to the benefit of other EU Member States (which represent 58 % of German imports) which increased their exports to Germany by 9 % per year over the same period. German imports from countries outside the EU increased more rapidly, at 15 % per year.

As a result of the strong competition from outside the EU, the extra-EU imports share of total apparent consumption increased from 7 % in 1984, to 11 % in 1993.

## MARKET FORCES

### Demand

Demand for domestic electrical appliances is mainly driven by consumer expenditure levels, residential construction and penetration rates (defined as the percentage of households in possession of a particular appliance). A market segment with

a high penetration rate tends to be more affected by economic cycles as demand will depend essentially on replacement which is likely to be postponed in times of recession. A favourable trend in consumer expenditure and residential construction in the mid-1980s led to an average growth in domestic electrical appliances of 6.4 % per year in current prices from 1984 to 1989. Following the economic slowdown of the late 1980s and the early 1990s, with the exception of 1991 which was positively affected by the German reunification, annual growth in apparent consumption fell between 1990 and 1993, from 3.2 % to -3.6 %. High penetration rates (close to saturation levels in some segments, e.g. refrigerators) have also affected the industry negatively.

Other factors may have positive effects on demand for domestic electrical appliances. One of the most significant is product innovation: the introduction of electronic components in order to improve efficiency and to simplify use may stimulate demand to a certain extent. Changes in the social structure of the population over the last few years, have also stimulated demand. An increase in single person households has led to a rising number of households making first purchases. Another important factor in the recent past has been the German reunification, resulting in a significant increase in demand for German products as well as for those of other EU producers.

**Figure 7: Domestic electrical appliances  
Origin of EU imports**

Source: Eurostat

As a result of the structural problems in the former East Germany, however, demand growth has stagnated and production growth has returned to pre-reunification levels.

### Supply and competition

Competition in domestic electrical appliances is fierce. Smaller manufacturers are finding it increasingly difficult to compete on price and performance with major multinational companies such as Electrolux or Whirlpool. The gap is now widening between the world's largest multinationals and the second tier of national producers. Major players are expanding their production and sales efforts in order to become active on a global scale. Only they are able to fully exploit the economies of scale inherent in a capital intensive industry.

Due to relatively high transportation costs, extra-EU exports and imports represent only a small share of production and consumption. In 1993, the most important source of extra-EU imports were the EFTA countries, representing some 29 % of the total. Competition from Eastern Europe has increased considerably over the last few years. In 1988, Slovenia, Russia and Poland exported goods at a value of 60 million ECU to the EU, whereas in 1992, the export value was eight times higher, representing a market share of nearly 10 %. Slovenia alone reached a market share of 6 % in 1993. In the field of small appliances, competition also comes from developing countries and the South East Asian NICs. In irons, for example, Singapore is a major competitor, providing nearly 50 % of extra-EU imports.

Competition among EU producers has increased over the last few years as well. This development has been stimulated by increasing concentration in the industry, and by the efforts of EU firms to increase market shares in order to compete on the Single Market.

## INDUSTRY STRUCTURE

### Companies

Compared to other sectors of the manufacturing industry, the domestic electrical appliances sector is highly concentrated. The manufacturing process is characterised by mass production, to achieve economies of scale. The world's largest producer of large domestic appliances is the firm Whirlpool (USA). Europe's largest producer is Electrolux (S), with a market share of around 23 % in the EU. However, most of

its production facilities are located within the EU. Other important European producers are Bosch-Siemens Hausgeräte (D) with an estimated EU market share of 17 %, Merloni (I) with 10 %, Brandt Electroménager (F) with 9 % (an important producer of washing-machines and dishwashers). In the field of small appliances, the most important firms are Philips (NL), Moulinex (F), and SEB (F). Other important producers of white goods are Candy (I), Miele (D) and G.E./Hotpoint (UK).

### Strategies

The strategies adopted by the leading white goods companies are similar, and the attention is focused upon manufacturing costs. Low-cost manufacturers may increase their market shares but, more importantly, they will be able to secure long-term profitability. Quality and efficiency are the new watchwords of the industry. Manufacturing efficiency drives down costs, whilst quality helps support price levels and improves a product's value for money.

The existence of substantial economies of scale for the big producers has stimulated a number of mergers and acquisitions in the sector. In 1980, some 810 producers of domestic appliances were active in the EU; by 1989, the figure had declined to 430. Remaining overcapacity is expected to lead to continued consolidation efforts during the 1990s as well. Some important regroupings have taken place over the last few years: Bosch (D) and Siemens (D) merged their appliance divisions and Whirlpool (US) now owns the appliances division of Philips (NL). The merger of Thomson (F) and the Elfi Group (I) was inspired by the need to exploit manufacturing economies of scale. Rosières (F) was taken over by Candy (I) and Scholtes (F) was taken over by Merloni (I). Today, France has no production of washing machines, refrigerators or dishwashers under domestic ownership. The only French-owned producers of white goods are Moulinex and SEB in the field of small domestic appliances. Another important consolidation took place in late 1993 when Electrolux acquired AEG's white goods business and the AEG brands.

Another strategy aiming at reducing costs is the re-localisation of production facilities to low cost countries, a move made possible by the fact that white goods are, relatively speaking, low-technology products. Production of microwave ovens for instance, has shifted away from Europe (especially Western Europe) and North America towards Asia, particularly Japan and South Korea. Asia's rapidly rising importance in the production of such appliances is almost entirely due to the emergence of China and South Korea as significant bases for manufacturing. Eastern Europe also has strong appeal as a candidate for re-localisation. Merloni, for instance, is considering production in Eastern Europe and Turkey. Even Bosch-Siemens which, just as AEG, is found at the quality end of the market spectrum, is looking very closely at production in Eastern Europe.

Apart from cost reduction measures, new markets have to be found, mainly in the fast growing regions of South East Asia and in potential markets in Eastern Europe. Electrolux, for example, bought Lehel the Hungarian producer of refrigerators, in 1991. This may serve as a springboard for similar activities in other countries in the region.

### Impact of the Single Market

The realisation of the Internal Market has not greatly influenced the domestic electrical appliances sector. Actually, the sector had already shown a relatively high degree of integration, as extended standardisation of products had not allowed technical standards and requirements to become effective barriers to trade. Further, since the EU market has become almost saturated (with demand coming mainly from replacement needs), the producers' main aim has been to increase third country market penetration, especially towards Eastern Europe and East Asia. Internal Market issues are therefore not essential as far as intra-EU trade is concerned. Environmental issues

**Figure 8: Domestic electrical appliances  
Trade intensities**

Source: DEBA

have nevertheless had a sizeable impact on the sector: the Directives on Electromagnetic Compatibility and on Low Voltage are particularly important, together with packaging standards and CFCs.

## ENVIRONMENT

The domestic electrical appliance industry is faced with a number of environmental issues. The most important is the use of CFCs in refrigerators. CFC use must be eliminated by 1995. Some firms have already introduced refrigerators without CFCs. Other environmental impact comes from the use of water and energy in appliances. In order to reduce related environmental stress, the industry's efforts are oriented towards the manufacture of products that use less water and energy.

White goods production that is environmentally friendly necessitates increased investment in the production process, and in research and development especially. This in turn increases the competitive advantage of the largest manufacturers.

In addition, environmentally friendly white goods are also seen by the leading manufacturers as a key to shortening product replacement cycles. The industry is now bringing the message to the market that upgrading to a "green product" saves money for the consumer through lower running costs, saves energy and spares unnecessary damage to the environment. On top of that, modern appliances offer greater value, convenience and performance.

Another problem resides in disposal regulations. German law already states that, as a minimum, 95 % of products must be recyclable and similar legislation may be expected on the EU level by 1997/1998.

## REGULATIONS

There are two Commission Directives that are particularly important for the free movement of domestic electrical appliances within the EU. These are the Low Voltage Directive 73/23/EEC of February 1973 (JO no. L77 of 26 March 1973) and the Electromagnetic Compatibility Directive 89/336/EEC of May 1989 (JO no. L139 of 23 May 1989).

Another relevant piece of legislation is the Directive 92/75/EEC on the indication by labelling and standard product information of the consumption of energy and other resources by household appliances.

## OUTLOOK

Prospects for the European domestic electrical appliances industry are relatively positive for the near future. Demand was expected to slowly rise again in 1994, following a recovery in both consumer expenditure and residential construction activity. Production forecasts for 1994 anticipated an increase of 4.8 % in industry output.

Environmental concerns are expected to be a driving force behind market growth, in particular for refrigerators and freezers, with the phasing out of CFCs in these products in 1995. High penetration levels should nevertheless dampen the demand for some product categories.

In the medium term, an improvement in consumption and production can be expected, as economic recovery boosts demand for domestic electrical appliances. Product innovations in energy and water saving should stimulate demand for a new generation of appliances. Dishwashers and freezers are expected to raise the growth rate of the industry in the 1990s, as these products to date have much lower penetration rates.

(1) Ratio of production in the sector compared to manufacturing industry for each country, divided by the same ratio for the EU. Estimates.  
Source: DEBA

European white goods manufacturers are looking increasingly at the potential for growth in newly industrialised and developing regions, as the developed markets have reached maturity or are rapidly maturing and offer only limited prospects. The greatest potential lies in South East Asia (with the exception of Japan) Central and South America, the Middle East and the countries in Eastern Europe.

Competition is expected to increase during the 1990s, particularly in the field of small appliances. EU producers will thus have to increase their efforts to reduce production costs. Rationalisation efforts are likely to result in a further decline in employment in the industry during the course of the 1990s.

# Electric lighting

## NACE 347

After a period of fast growth in the period 1983-92, the electric lighting industry in the EU experienced a fall in both production and consumption in 1993. This was mainly due to a downturn in business and residential construction cycles, the driving forces within the sector.

Competition from producers in East Asia (NICs and China) has increased in the last few years. The EU market share of these producers has risen accordingly, mainly to the detriment of traditional suppliers from the EFTA countries, Japan and the United States.

In the medium term, EU producers of lamps and lighting equipment should see a recovery, as the expected economic upturn leads to an increase in demand. Product innovation, particularly in the field of energy-saving lamps and lighting equipment, should provide an additional boost to demand over the next few years.

### INDUSTRY PROFILE

#### Description of the sector

The electric lighting industry can be divided into two main subsectors:

- electric lamps, which include incandescent lamps, discharge lamps and dual lamps for lighting purposes;
- electric lighting equipment, which comprises indoor electric lighting equipment, special purpose electric lights, portable lights, outdoor lights, spotlights (excluding lights for motor vehicles) and parts for electric lights.

In the EU, the sector carries minor economic weight within the larger aggregate of electrical engineering. Its value added in 1993 was equivalent to 28 % of consumer electronics. The most important EU producer of electric lamps and lighting equipment is Germany, with some 44 % of the total value added, followed by the UK (14 %), France (13 %), Italy (11 %) and Belgium (6 %).

#### Recent trends

Until recently, the industry in the EU enjoyed a favourable growth climate: whereas production in the manufacturing sector as a whole grew by 1.9 % per year in constant prices from 1984 to 1993, production of electric lighting equipment increased by around 4.7 % per year during the same period. Nevertheless, employment in the lighting equipment sector has fallen steadily since 1989 to reach an anticipated 95 300 in 1994.

The high rates of growth over the period mainly took place in the second half of the 1980s, driven by a healthy economic climate that boosted demand. In the beginning of the 1990s, EU production decreased (by 3.6 % between 1990 and 1993) in real terms.

Demand, as measured by apparent consumption, on average grew at a positive real annual growth rate of 5 % from 1984 to 1993. Meanwhile, production grew by 4.6 % per year. During the same period, extra-EU imports grew rapidly: approximately 10 % per year in real terms.

Extra-EU exports increased less rapidly than imports, by 4.7 % per year. The EU trade balance remained positive over the entire period, however.

#### International comparison

The largest producer in the world of electric lamps and lighting equipment is Japan, with a total production that in current

**Figure 1: Electric lighting**  
Value added in comparison with related industries, 1993

Source: DEBA

prices was nearly 20 % greater than that of the EU in 1993. The USA ranks third, closely behind the EU. US growth has not been as rapid as that of its competitors. From 1984 to 1993, EU production on average grew by 4.7 % per year in real terms, whilst production in the United States only increased by 1.2 % and that of Japan grew by 6.9 % per year. Consequently, EU and US shares of world production have shifted over the last decade, to the benefit of EU producers.

#### Foreign trade

Extra-EU exports showed strong growth (6.7 % per year on average in current prices in 1984-93), although weaker than that of imports. For EU producers, the USA and Japan are markets of secondary importance, as they account for a mere 14 % of extra-EU exports. More important are the EFTA countries with an export share above 27 %.

Over the last decade, EU imports of lighting equipment have showed substantial growth, at an average of around 12 % per year in nominal terms. As a result, 1993 extra-EU imports

Source: DEBA

accounted for nearly 16 % of apparent consumption in the EU, compared to 11 % in 1984. Important competitors are China with approximately 22 % of total extra-EU imports, and the USA with nearly 13 %. More than a third of extra-EU imports, however, come from the aggregate rest of the world, mainly developing countries. In this context it is important to note that traditional suppliers lost market share in the EU to developing countries: Japan's market share dropped from 20 % to 8 % between 1988 and 1993 and the US share also fell, from nearly 16 % to below 13 %.

### MARKET FORCES

#### Demand

Demand for electric lighting products is driven mainly by the replacement market (for lamps) as well as equipment needs for new buildings, and development projects (for lighting equipment). Much replacement demand is insensitive to cyclical fluctuations, although the growth rate of disposable income, as well as technological innovations and fashion trends, can affect replacement rates. Demand for equipment for new buildings, on the other hand, is highly cyclical, depending as it does on the level of construction activity.

Electric lamps are used mainly in residential buildings, office and industrial buildings and for street lighting. A smaller part of demand for electric lamps comes from the automotive and photographic industries. For electric lighting equipment, private and public construction are the more important sources of demand. Thus, the industry benefited considerably from the boom in EU construction in the second half of the 1980s. The recent downturn in private and public construction activity, as well as the critical situation for the automotive industry, considerably affected demand for the products of the industry.

Product innovation has also been an important driving force behind demand over the last years. New products, such as halogen lamps, discharge lamps and compact fluorescent

Destination of EU exports**

Source: Eurostat

lamps, which last longer and use less energy, have increasingly gained acceptance, causing a gradual shift in demand from inexpensive incandescent lamps to high-grade equipment. Finally, one of the most important trends in lamp technology is the development of increasingly compact light sources.

### Supply and competition

In 1984, among the Triad (the USA, Japan and the EU), the USA was the most important producer of electric lighting equipment and lamps, with about 53 % of total production, followed by the EU, at approximately 26 % and Japan in the third position, with roughly 21 %. Competition for EU producers increased considerably in the last few years, as the share of imports from outside the EU rose from some 11 % of consumption in 1984 to 16 % in 1993. In particular, imports from China increased over the same period from a few percent in 1984 to represent 22 % of total extra-EU imports in 1993. Taiwan also increased its market share in the extra-EU imports from 9 % to 12 %. Imports of halogen lamps, particularly from Japan, China and other East Asian countries, developed strongly. Trade among EU member countries grew rapidly during the last decade, at a rate of roughly 10 % per year in value. The increase in international trade in general is partly

the result of the concentration that has taken place in the industry during the last few years.

### Production process

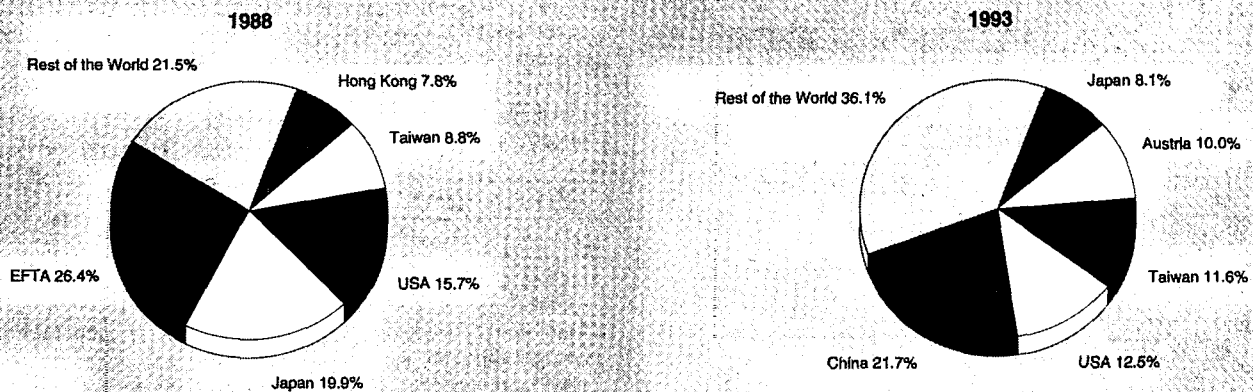

In contrast with the 7 % nominal increase in production per year from 1984 to 1993, there has been a substantial decrease in sector employment figures, from a peak of 110 000 in 1989 to an estimated 95 300 in 1994. The most significant reduction occurred in Spain, which lost 66 % of its sector workforce between 1983 and 1992. As a result of these changes, EU productivity increased by 4.5 % per year on average between 1984 and 1993.

## INDUSTRY STRUCTURE

### Companies

In electric lamps, over 80 % of the market is in the hands of only four companies. The tendency in this subsector is to concentrate activity to a few large firms in order to profit from economies of scale, and to make it possible to muster the huge resources necessary for mass production and intensive R&D activities. All of these firms are operating internationally, in most cases world-wide. The largest manufacturer in the

Source: DEBA

EU is Philips (NL), the multinational producer of electrical goods, which plays a central role in assuring the dominant position of the Netherlands as Europe's number one in electric lamps. The market share of Philips is about 40 % in Europe and 20 % in the United States. Another prominent firm is German Osram (a division of Siemens since 1990), which bought the US part of Sylvania from GTE. Osram is now one of the world's three largest producers of lamps, along with Philips and General Electric (US). The latter acquired Tungsram (Hungary), the producer of lamps, in 1990 and the lamp division of the European firm Thorn EMI (UK) in 1991.

In the electrical lighting equipment subsector, production is much more fragmented, with no large initial investment acting as a barrier to entry. Many of the firms are niche players and operate only regionally, or even locally. The most important firms are Siemens (D), Trilux (D), AEG (D), Philips (NL) and Thorn Lighting (UK). Large groups in other countries are Zumtobel in Austria, and Lithonia, Cooper and GTE in the United States.

**Figure 8: Electric lighting  
Trade Intensities**

Source: DEBA

## Strategies

There has been a great deal of restructuring and transferring of activities among the major lighting multinationals. Some of the larger suppliers are investing in production facilities where they can manufacture at lower cost, for example in Eastern Europe or in East Asia. This is the case of GE Lighting which is concentrating its production of incandescent and compact fluorescent lamps to Hungary.

In the field of technologically advanced products, EU firms in the electrical lighting industry are faced with stiff competition from traditional competitors from the United States, Japan and the EFTA countries. In the field of technologically less advanced products, the main competitors are the East Asian NICs and China, benefiting from lower costs of labour, raw materials and energy.

As a result, EU producers have to increase their efforts to improve productivity in order to compensate for unit cost advantages in lower value added products, presumably through increased substitution of capital for labour, i.e. increasing automation. For technologically advanced products, on the other hand, EU firms have to increase R&D expenditure, in order to maintain competitiveness vis-à-vis other industrialised countries. This also means that the trend towards concentration is likely to continue in the next few years and be accompanied by further labour force reductions.

Licenses for intellectual property rights are often assigned, at a price, from one manufacturer to another. Philips e.g. holds patents on the compact fluorescent lamp but the other three leading lamp suppliers have been licensed to manufacture the same product.

## Impact of the Single Market

The completion of the Internal Market is bound to have a positive impact on the electric lighting industry. Even though the free movement of goods has been enhanced by technical harmonisation and cross border facilities, the industry nevertheless pledges for further simplification of procedures and regulations. The achievement of a truly integrated EU market for electric lighting is in fact likely to reduce the difference in consumer market size between Europe and the US. Also, the industry feels that the realisation of the program will entail streamlining of production and diversification, alongside with considerable developments in products energy saving. The move towards a Single European currency and the elimination of double standards and regulations are considered key issues for future progress in this area.

## ENVIRONMENT

Compared to other industries, environmental issues are of minor importance in the electric lighting industry. Gas-discharge lamps contain some toxic elements and materials, such as mercury, antimony and lead. Another problem in this context is the use of packaging materials, given the fragile nature of the products. Industry efforts are dedicated towards the reduction of toxic materials and the reduction of packaging materials through the development of reusable or recyclable materials.

## REGULATIONS

Important directives for the sector are the Low Voltage Directive (73/23/EEC), the Electromagnetic Compatibility Directive (EMC; 89/339/EEC) and, to a lesser extent, the Machinery Directive 89/392. Manufacturers whose products comply with the relevant provisions of these Directives and who have demonstrated this conformity by following the applicable procedures set out in the Directives may affix the CE-mark. This allows free movement of the products throughout the European Economic Area.

---

## OUTLOOK

---

Prospects for the EU electric lighting industry are relatively optimistic in the short term with the construction industry beginning to show a recovery in most parts of Europe.

Ongoing replacement demand, little affected by cyclical fluctuations, will support this upward trend. In the medium term, consumption and production are expected to regain momentum, stimulated by the expected general economic upswing. A compound annual growth rate of just over 3 % is forecast for the market between 1993 and 2000.

Product innovation is likely to continue to boost demand, as recent R&D efforts of EU firms are oriented towards electronically regulated lighting devices, improvements in light emitting efficiency and in colour, and further reduction in the size of electric lamps. These developments will presumably lead to a decline in EU production of incandescent lamps, which will be displaced by growth in high-grade products. Lamp prices in general are expected to fall, whilst prices of light fittings are forecast to rise over the coming years. Extra-EU competition, particularly in the field of low-end technology, can be expected to increase throughout the 1990s.

Written by: LEK

The sector is represented at the EU level by: The European Lighting Council (ELC). Address: Rue Montoyer 31, B-1040 Brussels; tel: (32 2) 513 6085; fax: (32 2) 514 3386.

## Overview

### NACE 33, 344, 345

The development of a strong electronics sector (including sub-sectors such as computers and office equipment, telecommunications equipment, electronic components, and consumer electronics) is strategically important for the development of the overall EU economy. According to the Bangemann report, the electronics sector is at the centre stage of EU attention, in order to ensure that it remain competitive in the new knowledge intensive global economy. 1992-93 were difficult years for the EU electronics industry as the total market declined, as well as production, due to increasing competition and a dramatic drop in prices. In 1994, the electronics industry benefited from the overall recovery of the EU economy. The EU trade deficit in electronics has more than doubled over ten years and in 1993 it approached 22.5 million ECU. The only subsector with a positive trade balance is telecommunications equipment, although the surplus is declining. Due to increasing automation, employment has continued to fall and in 1994 reached 1.3 million.

In general, US and Japanese companies are more internationalised than EU electronics companies and benefit from higher economies of scale. However, the EU has points of strength on the electronics market. This is reflected by the fact that there are at least three EU companies among the world's top fifteen in each subsector and all of them are well diversified into complementary electronics sectors. Moreover, EU telecommunications equipment manufacturers rank among the top performers in the world. Most EU electronics companies recovered in 1994, in particular those in the micro-electronics and consumer electronics sectors. Computer companies try to establish new partnerships and to focus on their core business in order to overcome their difficulties. The role of the EU is indispensable in supporting co-operative R&D, ensuring fair competition and promoting the integrated European market.

### INDUSTRY PROFILE

#### Description of the sector

The electronics industry includes: computer and office equipment (NACE 33), telecommunications equipment (NACE 344), electronic components (NACE 345), and consumer electronics (NACE 345.1 and 345.2).

The products manufactured by the computer and office equipment sector are:

- hardware: portables, notebooks, microcomputers, minicomputers, workstations, mainframes, network equipment;
- peripherals: printers, disks, monitors, keyboards, CD-ROM players;
- office equipment: electronic typewriters, electronic calculating machines, electronic cash registers, electronic accounting machines, dictation equipment.

Telecommunications equipment's main product categories are: public switching, transmission, terminals, private switching, data communications and mobile communications. Consumer electronics comprises audio-visual products for domestic use and its accessories, such as colour and monochrome television sets, video recorders, video cameras and camcorders, audio equipment in general, wireless telephones and videogames.

Figure 1: Electronic engineering Value added in comparison with related industries, 1993

Source: DEBA

The electronic components sector includes active, passive and electromechanical components.

The electronics sector is a very important part of EU industry: in 1993 the value added equalled 92 % of the motor vehicles and parts industry, and nearly 80 % of the mechanical engineering sector whereas it was more than five times larger than that of the instrument engineering sector. In 1993, telecommunications equipment represented 38 % of the total EU electronics market, computer and office equipment accounted for 27 %, consumer electronics 25 % and electronic components 10 %. Germany is the largest EU producer followed by France, the UK, Italy and Spain. These five countries generate approximately 90 % of the total value of the electronics sector. Because of the prominent part it plays in information economies, the electronics sector has strategic importance for

Source: DEBA

the development of the overall EU economy. Moreover, the industry is expected to grow more than any other major sector of economic, such as the automotive industry and transports.

**Recent trends**

Apparent consumption in current prices in the EU increased at a compound annual growth rate of 5.5 % in 1984-93, whereas production increased by 5.1 % per year on average and extra-EU exports at a rate of 6.4 % per year. In spite of increasing exports, the trade deficit increased to reach a peak in 1991. It then fell slightly, to reach 22.5 million ECU in 1993, which is more than twice the size of the deficit of 1984. In 1994, employment reached 1.3 million, 40 000 less than in 1984. From 1991 to 1993, both apparent consumption and production of electronics decreased, due to the recession and the continued fall in prices. 1994 saw some signals of recovery, mainly thanks to the recovery of the overall EU economy.

**International comparison**

In 1993, EU production of electronic goods amounted to 168 billion ECU, US production equalled 237 billion ECU, whereas the value of Japanese production was 168 billion ECU. Since 1984, Japanese production in current prices has almost doubled, EU production has grown by 57 %, whereas US production has remained more or less at the same level. The international comparison of production in constant prices reveals that, in the period 1990-93, EU production grew by only 4 %, whilst Japanese production declined by roughly 4 %. Meanwhile, the USA increased its production by nearly 15 %.

In general, EU companies compete on a world-wide basis, in all market segments. However, the consumer market is dominated by Japan and, to less extent, by newly industrialising countries (NICs), such as Korea, Malaysia and Singapore, in the low value added consumer products. EU companies are strong in the TV segment and in innovative products, such

**Figure 4: Electronic engineering

Destination of EU exports**

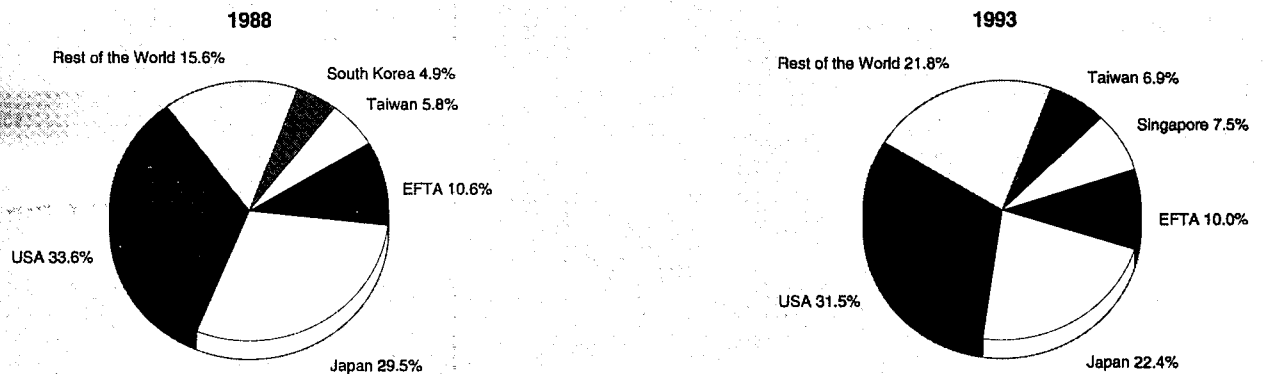

Source: Eurostat

as optical and digital products, e.g. Compact Disc, CD-I (Compact Disc Interactive) and digital television. American and, to less extent, Japanese companies dominate the computer and office equipment market. American companies established the world-wide standards in this sector, and thereby set the guidelines for information technology developments. American and Japanese companies dominate the microelectronics market as well. In the microprocessor segment, US companies, such as Intel, Motorola and IBM, establish world-wide standards, whilst Japanese companies are strong especially in the DRAM (Dynamic Random Memory) market. EU companies compete in many high value added segments of the market, e.g. ASIC (Application Specific Integrated Circuit) products. EU companies are highly competitive in telecommunications equipment, where American companies (e.g. AT&T, Northern Telecommunications and Motorola) and Japanese companies (such as Fujitsu and NEC) are also very strong. In general, US and Japanese companies enjoy vast domestic markets and rely on highly sophisticated users in order to offer innovative products that afterwards may be launched on the EU market. Conversely, many EU manufacturers are at a disadvantage as they cannot offer their products to a fully integrated market at the European level.

### Foreign trade

On average, extra-EU imports grew faster than extra-EU exports in the period 1984-91 (compound annual growth rates of 3.5 % and 2.8 %, respectively). However, between 1991 and 1993 the trend was reversed, and the EU trade deficit declined to 22.4 billion ECU in 1993, although it was still roughly 2.5 times the 1984 level. The only sector where the trade balance is positive is telecommunications equipment, although the surplus is shrinking. Computer and office equipment and consumer electronics have the largest trade deficits in the sector. From 1988 to 1993, the percentage of exports to the USA (21 % of total exports in 1993) and Singapore (3 %) remained more or less stable, while export to the EFTA countries decreased from nearly 29 % to 21 %. In the same period, exports to Japan increased from 2.9 % to 4.7 %. China's share rose to 3 % and the rest of the world (mainly NICs) increased its share to 47 % of the 1993 total, in comparison with 42 % in 1988. From 1988 to 1993, the percentage of imports from the USA, EFTA and Taiwan remained more or less stable, whilst imports from Japan decreased (from 29.5 % to 22.4 %) Imports from Singapore and other NICs increased consistently.

## MARKET FORCES

### Demand

Business customers is the main market for electronic goods, as information and communications technology is of strategic importance in increasing efficiency and reaping competitive advantages. The manufacturers of computer and office equipment, telecommunications equipment (especially voice networks and private data) and electronic components (which constitute basic components in every manufactured electronic product or system) all target business customers. The public sector is an important market due to the fact that national public operators constitute the main customers in telecommunications equipment. The consumer market is targeted not only by the consumer electronics manufacturers but also increasingly by producers of telecommunications terminals (e.g. wireless telephones) and personal computers. Cellular phones and computers for the SOHO (Small Office, Home Office) are two of the fastest growing segments of the market.

Demand for electronic goods depends heavily on the economic cycle, in part since investments in information and communications technology represent a consistent share of overall industrial investment. The recovery of the EU economy in 1994, following the recession in 1992 and 1993, is the key factor behind the recovery in business demand for electronic goods. However, budget restraints in Member States also have an impact on telecommunications expenditure, despite the fact

that network operators in the Member States are implementing significant modernisation plans for their networks. The electronics market has expanded in volume due to large price decreases, despite the recession. Demand is also becoming more differentiated and sophisticated and competition is spreading also to the most protected (and more profitable) public sector markets.

All electronic goods, whether directed to consumers or to business, are based on microelectronics and the dynamics of the electronics sector are directly determined by technological developments in the microelectronics field. Increasing intelligence and functionality, down-sizing and down-pricing characterise the production in each subsector.

### Supply and competition

The market for electronic products is global, but new products require higher and higher investment in R&D. This means that large production volumes are needed to meet rising R&D costs. Because competition in the electronics sector is global, it is projected that no important producer will survive until the year 2000 if it does not attain world leadership in at least one, albeit small, niche of the world market.

Many American and Japanese electronic companies have R&D and production units in Europe, especially in the UK, Ireland, Germany and France, although the number of new sites is falling due to recession and overproduction. These plants account for a significant proportion of overall employment in the electronics field. Other competitors have preferred to acquire European firms (e.g. the Fujitsu (J) acquisition of ICL (UK)) or to set up joint ventures (e.g. IBM and NEC acquiring minority shares in Bull (F)). The need for technological and commercial partnerships including EU and, above all, non-EU companies will surely grow because of the technological strengths of the latter. However, non-EU manufacturers are generally less widely present on the European telecommunications equipment market than they are in other electronics sectors. Many European companies are also active globally, especially in the telecommunications equipment and consumer electronics sectors. However, in the computer and office equipment sector, EU companies are at a disadvantage since they are not as internationalised as their American and Japanese counterparts. It is acknowledged that EU companies have a high degree of scientific and technological expertise, but they also have the disadvantage of high labour costs (especially in comparison with the South East Asian countries) and a high cost of capital (in comparison with the USA and Japan). Productivity increased by 21 % from 1990 to 1994, although labour costs increased as well (by 17 %).

### Production process

The supply of electronic goods is characterised by very high levels of R&D expenditures. R&D costs may amount to 15-20 % of the revenues of electronic component suppliers. In microelectronics and in the telecommunications equipment

100 or more employees	3 210	4.5	78.5	79.7

(1) Estimates.

Source: Eurostat "Enterprises in Europe"

sectors, R&D is often more costly than production. Moreover, supply is affected by a dramatic reduction in product life cycles, due to the high pace of innovation in microelectronics. Therefore, large economies of scale and rapid returns on investment are necessary. In the latter respect, it is becoming increasingly important for large manufacturers to be vertically integrated or to have strong links with component suppliers, as well as to be appropriately diversified in order to share high R&D costs and to quickly reap returns on investment.

Innovation, combined with establishing world-wide standards, creates new business opportunities that allow early market entry and the reaping of high profits before prices fall as a consequence of increasing competition. Major innovations in the electronics field will be pocket computers, the PDA (Personal Digital Assistant), digital TV, broadband networks to transmit voices, data and images, and cellular digital networks for mobile telecommunication.

## INDUSTRY STRUCTURE

### Companies

In each subsector there are at least three European companies among the top fifteen world-wide. These are: Philips (NL), SGS-Thomson (F) and Siemens (D) in the components industry; Siemens, Olivetti (I) and Bull (F) in the computer industry; Alcatel (F), Siemens, Ericsson (S), Nokia (SF) and Bosch (D) in the telecommunications equipment industry; and Philips, Thomson and Nokia in consumer electronics. All of them are diversified into complementary sectors. Apart from the globally active manufacturers, there are approximately 70 000 small and medium sized companies that target the EU market, supplying components and electronic equipment, or focusing on certain market niches.

Although many of the largest EU companies suffered losses in 1992 and 1993, with the exception of the telecommunications equipment suppliers (which still had to face lower profit margins), most of the companies recovered in 1994, in particular in the microelectronics and consumer electronics sectors. To overcome their difficulties, EU computer companies try to establish new partnership and focus either on their core business or on the fastest growing segments of the market.

### Strategies

EU electronics companies are engaged in efforts to restructure and to cut costs, to become leaner, and to reduce marketing time for new, innovative products. Technological and commercial partnership agreements have become commonplace in the industry. Joint ventures, alliances and take-overs between EU and non-EU companies frequently take place, in order to reach the size necessary required in order to compete on the global market and to share technological know-how and market power. In the near future, the trend towards the setting up of networks of alliances for specific products and/or markets will intensify. In fact, the convergence of the telecommunications, computer, software and media industry, is limiting the ability of companies to face the new and increasingly complex market on their own.

## Impact of the Single Market

All sectors of the electronics industry are dominated by multinational companies selling standardized product throughout the EU. The industry benefits from the free movement of goods, people and capital within the EU, and relies on the provision of trans-European services such as banking and telecommunications. Common standards such as those drawn up by ETSI on GSM and digital broadcasting are essential. The abolition of telecommunications monopolies and the liberalization of public procurement have had a major impact on this sector, as have had certain decisions of the EU competition authorities (e.g. the privatization of Bull in France and Alcatel SE in Spain). Common external tariffs and anti-dumping measures (or the threat thereof) have encouraged foreign companies to set up production facilities within the EU. As a result, non-EU manufacturers account for a significant and growing share of EU electronics production.

## ENVIRONMENT

In relative terms, the EU electronics industry does not have a very substantial impact on the environment. Waste or emissions are relatively insignificant in most of the production processes, at least in comparison with most of other industries. Moreover, the electronics industry is highly innovative and frequently modifies its production processes with the partial aim of reducing polluting emissions. CFC (chloro-fluorocarbon) emissions have been reduced before the legislation that will completely ban CFC use has entered into force. Important goals are to minimise the residual waste and to re-cycle hardware. Some of the main problems to be solved concern the re-cycling of cathode ray tubes, which contain toxic materials, and plastic components.

Environmentally sensitive policy is often a successful strategy for electronics companies to pursue. Consumers are becoming more and more sensitive to environmental problems and prefer to purchase products that are not harmful to the environment.

## REGULATIONS

The EU plays a central part in the industry's development by promoting European market integration and fair competition among EU and non-EU companies and other actors (e.g. through anti-trust legislation and Directives concerning e.g. public procurement). One of the main goals of the EU is to open the EU market, on the assumption that it will generate a mutual response from non-EU countries, thereby enabling a reduction of the trade deficit.

The EU is also funding strategic and co-operative research programs (e.g. JESSI in microelectronics and ACTS and ESPRIT in telecommunications) and is promoting new advanced applications (such as Trans-European digital Networks) that benefit the EU electronics industry. According to the Bange-mann report, the electronics sector is at the centre stage of EU attention in order to ensure that it remain competitive in the new knowledge intensive global economy. The EU also

## OUTLOOK

Although in real terms the EU electronics market is not likely to grow fast in the next few years, and despite a projected further reduction of employment, there are few doubts that in the medium and long term, it will grow at a higher rate than any other mature industry in the EU. However, it is also very likely that the EU trade deficit in electronic goods will increase over the next years. Competition from American and Japanese companies will increase and the EU companies will have to maintain large R&D and other industrial investments to meet the competitive challenge on the global scale.

East Asian countries, and in particular China, represent highly attractive market opportunities because of the untapped potential of their large and fast growing economies. Innovative markets and products, created by the convergence of consumer electronics, telecommunications, computer and media technologies, are projected to create significant opportunities in the next years. Multimedia systems and networks constitute the major opportunity for the future.

allocates financial support to less developed and disadvantaged EU regions, with the aim of upgrading the technological content of their capital stock.

# Electronic components

## NACE 345

After years of moderate or even declining growth, the European electronic components industry has experienced an increase of production and consumption in 1994: it is the beginning of a typical growing cycle for this industry. Most of the increase is due to expansion and innovation in the PC's and mobile communications markets and to the recovery of automotive demand. For the first time in history, all European semiconductor producers were profitable in 1994.

In 1995 the European market is expected to grow by 4 %, while the European production will probably still lose market share on both the internal and international markets, because of its historical weakness in the semiconductors, the fastest growing segment.

The structural decline of employment in the electronic component sector - mainly due to engineering and manufacturing processes innovation - is expected to decelerate. Employment might even start to increase.

A general trend is the rapid convergence of computing, communications, video and audio technologies in a single Information and Communication Technologies market that will lead the components demand for many years.

The USA are gaining market share with respect to Europe and Japan, Intel (USA) has the largest market share in the EU. Only three European manufacturers of semiconductors (Philips, SGS-Thomson and Siemens) are present in the top 20 list of worldwide manufactures, and there is a very limited number of small and medium manufacturers able to feed the European market requirements with advanced niche products. But the European components industry is likely to react to past difficulties, by taking advantage of the new opening opportunities, both developing a stronger integration between suppliers and vertical industries and reinforcing the alliances with USA and Japanese suppliers.

### INDUSTRY PROFILE

#### Description of the sector

The electronic components sector includes three main categories of products:

Active components: integrated circuits, discrete semiconductors, electronic tubes, optoelectronic components and flat panel displays;

Passive components: capacitors, resistors, wound and ceramic components;

Electro-mechanical components: connectors, relays, switches, keyboards, printed circuit boards, hybrid circuits/MCMs and other functional devices.

Electronic components is the smallest of the electronic engineering sectors - computers and office equipment, telecommunications equipment and consumer products - analysed in Panorama. These three sectors are the main markets of the electronic components sector. Other outlets, while smaller individually, all together make up about a quarter of the total electronic market and employment and absorb a significant portion of electronic components production (about 20 % of active components and 30-35 % of passive and electro-mechanical components). These sectors are: automotive (electronic parts, accessories), civil and military avionics and defence, medical equipment, industrial controls and instruments, measuring and analytical instruments, clocks and watches, photographic and optical equipment, transportation.

**Figure 1: Electronic components**  
Employment compared to total EU manufacturing industry

Source: EECA, DEBA

Production of components is driven by market demand from the electronic equipment manufacturing sector: innovation in components in turn drives those markets.

Electronic components are used exclusively by original equipment manufacturers (OEMs) or as spares for maintenance and repair markets. Components are increasingly specific to each OEM application, although dependent on common underlying design and production technologies.

#### Recent trends

The long term trend of this industry is positive, especially for the most innovative sectors of the industry and relevant products.

According to many sources, the worldwide market for semiconductor components will grow up to 160 billion ECU by 2000, i.e. the double of that expected for 1995: that means that the average annual growth rate (13.5 %) will be just lower than that of the last thirty years (15 %), but very far from justifying any "mature market" perspective.

In the same period, the European market will grow less than the average and particularly less than the fastest growing area (Asia and Pacific), but it will still account for 14 % of total (22 billion ECU), out of which 2-3 billion ECU are due to East European markets.

From mid-1993 onwards, the electronic components apparent consumption has recovered, after a three year period of stability due to economy recession: it is the beginning of a typical growing cycle for this industry, similar to those happened in 1973-75, 1983-85 and 1987-90. The increase of production allowed the trade deficit to shrink, from 9.1 billion ECU in 1992 to 8.9 billion ECU in 1993.

In 1994 and 1995 the European market is expected to grow by 5 % and 4 % respectively. The European production will still lose market share on both the internal and international markets, because of its small size in semiconductors, the fastest growing segment.

Most of the increase is due to continuous growth and innovation in the PC's and mobile communications markets and to the recovery of automotive demand.

In 1993 and in the first half of 1994, the computer business has been threatened by a tightening in the availability of spe-

cific components (dynamic RAMs). This was a consequence of fast innovation in PC's (memory requirements doubled in 2 years, new microprocessors, changes of operating systems, etc.) and because producers were slow to add new capacity as memory prices were believed to be too low to return a decent profit.

A better integration between producers and OEM's, also including market forecast and capacity planning, would have positive effects on the flexibility of suppliers to react to the changing market requirements.

Total employment fell from 208 000 in 1992 to 203 000 in 1994. The structural decline of employment in the electronic component sector - mainly due to engineering and manufacturing processes innovation - is expected to decelerate. Employment might even start to increase.

With regard to employment, the importance of the electronic components sector depends more on the size and prosperity of the electronic equipment markets and relevant applications and services, than on the size of the sector itself; however this industry has still the opportunity to contribute to employ high quality European engineers and technicians.

It is very important to note that the electro-mechanical component subsector includes a large number of small and medium enterprises focused on the European market and that nearly 50 % of employment in the component sector belongs to the electro-mechanical sub-sector.

A key success factor for these sectors is R&D activity in order to identify the future application niches, also through the collaboration and vertical integration with OEM's, and the globalisation and innovation of marketing and distribution strategies.

Following the R&D investment through programmes such as Esprit, the European semiconductor industry has reduced a two-year gap to a six-months lag behind the state-of-the-art CMOS, and is now even leading the world in areas such as BICMOS, fast CMOS and power technologies.

**International comparison**

Japanese equipment manufacturers are highly integrated but, on average, they still produce in-house only 50 % by value of their component requirements. From a trading block point of view, however, Japanese companies are largely self sufficient. This is not the case in Europe.

 Source: EECA

From a market point of view, Asia & Pacific (including China and the Four Dragons) and the USA are gaining market share with respect to Europe and Japan, but the most interesting fact is the consolidation of the market leadership by USA based semiconductor manufacturers, after a period of strong competition pressure from the Japanese.

USA companies have turned around their fortunes by reducing their engineering and production costs, by investing in world-class performance systems and plants, by partnering with major customers, by revising their marketing media and distribution channels and investing heavily in R&D.

The largest manufacturer of high technology electronic components is Intel, an American company. Intel produces most of the microprocessors used in personal computers.

**Foreign trade**

Total extra-EU exports of electronic components recorded a remarkable growth in 1993 (+34 %); although the extra-EU imports increased from 13.7 billion ECU to 15 billion ECU (+10 %), the trade balance reduced its negative spread, with the exports/imports ratio up to 0.41 in 1993 in comparison with 0.33 in 1992. The destination of EU exports is quite fragmented, the most important market being the USA (22 %).

Europe has a very weak position in Japan, which represents only 3 % of exports.

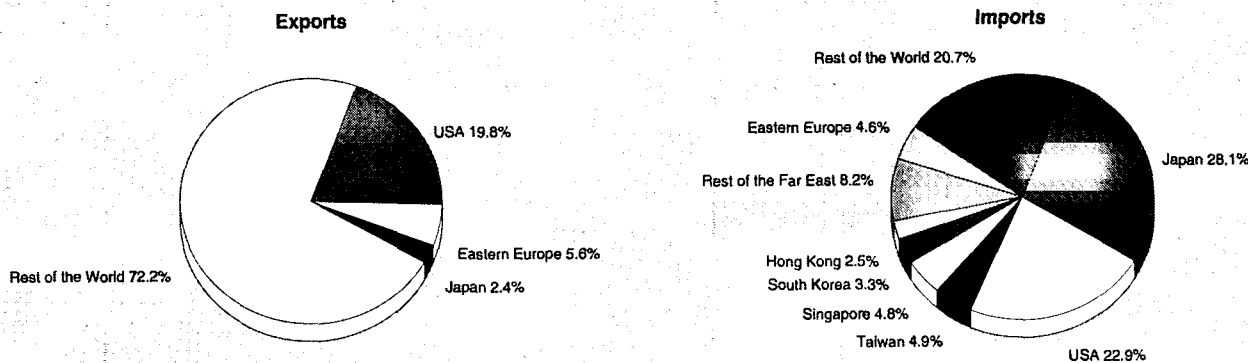

Most of the EU imports comes from USA (30 %), followed by Japan (22 %). The south-east Asian countries represent about 19 % of total imports.

As for active components, extra-EU exports increased from 4.4 billion ECU in 1992 to 5.8 billion ECU in 1993. Extra-EU imports grew at a smaller rate: the exports/imports ratio passed from 0.61 in 1992 to 0.63 in 1993. The USA are the main supplier, while most European exports are absorbed by developing countries (the "Rest of the World" category).

The export of passive components also increase in 1993, passing from 1.2 billion ECU to 1.8 billion ECU. The exports/imports ratio is stable. The breakdown of imports origin and exports destination shows an important cross trade with the USA (20 % of export destination and 23 % of import origin). Japan is the most important supplier but it absorbs only 2 % of European exports.

In the electromechanical components market, the exports/imports ratio was at 1.61 in 1993.

## MARKET FORCES

### Demand

An important general trend is the rapid convergence of computing, communications, video and audio technologies in a single Information and Communication Technologies market that will lead the electronic components demand for many years.

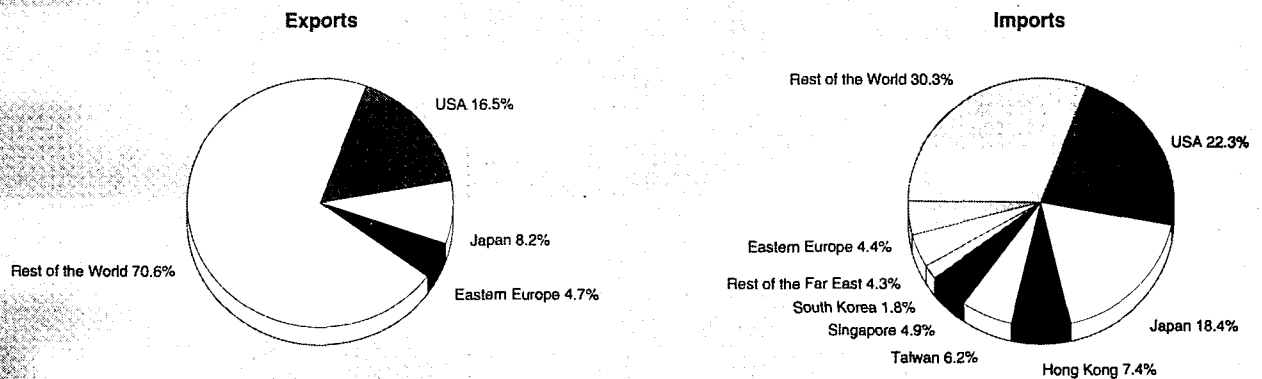

In the 1980s, the birth of the PC opened a huge new market for semiconductor vendors. Today many of the same vendors are trying to penetrate the emerging video-based markets, such as multimedia and cable TV, which will probably rival the PC business in size and importance. Other new businesses and consumer applications based on television, such as digital television, VCRs, video conferencing and CD ROM will also take off over the next few years. Moreover, PC might be equipped to send and receive video through satellites, fibre optics networks and even telephone lines. There is also a new generation of dedicated video processors and chips which, thanks to wide programmability and general purpose nature, can serve a wide range of applications beyond video (video conferencing equipment, multimedia workstations, fingerprint recognition products and integrated image processing systems combining printing, copying, faxing and document scanning).

The displacement effect will continue to increase the proportion of value added attributable to active components at the expense of passive and electro-mechanical components.

On the other hand, new functionalities made possible by advances in microelectronics create new end user products which, in turn, increase demand for the other components: mobile communications and automotive electronics are two examples of this.

In 1994, the market drivers for the semiconductor segment have been the increasing demand for communication chips, the falling prices of 486-based PC, the stiffening competition and the impact of PowerPC-based computers. In the passive components market, the Surface Mount Technology (where some components are encapsulated in plastic casings) for capacitors, resistors and connectors is growing at 30-40 % per year. Passive components demand in 1993 has been fuelled primarily by PC's and communication, although a few suppliers report an upsurge in demand from the automotive industry. Other issues characterising the market are the increasing miniaturisation, the demand for customer-specific and high performance (faster speed, higher reliability, higher volumetric efficiencies, etc.) components and the development of fibre optics and opto-electronics.

### Supply and competition

The electronic components industry is almost completely globalised in the semiconductors segment. The other components segments are also moving steadily towards globalisation for both commodity products, and for application-specific niches, that are becoming transnational markets too.

Nearly all the large electronics OEM's were vertically integrated and producing many of their own strategic components. Many of them are now either abandoning their internal components operations (as for Printed Circuit Boards (PCB), for instance) or forming new divisions supplying components to other OEM's. More than half the PCB's are made by independents and their share will grow in the next years.

Competition from large manufacturing companies increases, threatening the small and medium manufacturers which currently represent most of the offer. A common trend is towards diversification and innovation of distribution channels (distributors, dealers, retailers...), also including direct marketing and telemarketing media.

### Production process

The approach to design and manufacturing of semiconductors has been changing recently for 2 main reasons: Japanese companies, utilising techniques such as Kaizen (continuous improvement), have forced European and USA companies to abandon design for performance and replace it with application-specific design. Moreover, the product development is

becoming market based not technology based, different variants of a product are intended for specific applications.

As more and more system functions are integrated on silicon, chip makers have evolved from being suppliers of building blocks to the role of system designers. The relationship between semiconductor suppliers and OEMs has been transformed into much more a partnership, changing the way integrated circuits are developed. Customers guidance is vital as a system can be designed in a few months and have a life cycle of less than one year. However, silicon production is not the only relevant factor: the added value of test, interconnect and assembly technologies are also important and are areas of relative strength in Europe. Another example of strength of the industry in Europe is given by the collaboration between silicon suppliers and the systems industry (e.g. telecommunications), where more complex and technically challenging chips and systems (e.g. mixed analog and digital) are produced.

As all the system design is being done at chip level, and there is very little differentiation at the board level, most of the financial risk and technology is now at the semiconductor companies.

For electro-mechanical components suppliers the challenge is to focus on custom-design products for specific applications rather than for commodity products. For instance, connectors suppliers are stepping up efforts to move closer to key customers, as interconnected systems become more critical.

**Table 7: Electronic components**

Total market	8 888	9 412	13 225	100.0	26.7

Source: Dataquest

The issues affecting the semiconductor industry, and particularly the microprocessors and memory chips industry, are quite peculiar. The world-wide average R&D investment intensity in this industry is between 12 % and 15 % of revenues. Capital investments are ranging between 10 % and 13 % of revenues. In the 1992-93 period Japan had the highest R&D investment rate, followed by Europe and the USA. In the same period, Europe presented the lowest capital investments rate.

Between 1984 and 1992, worldwide capital investments in this industry have grown up to a cumulative value of about 87 billion USD. Of this total, Europe accounts for 10 % only, Asia and Pacific for 12 %, the USA for 33 % and Japan for 43 %.

The cost of developing a new "top end" semiconductor component (e.g. the next 256Mbit microprocessors or the future 1Gbit chip memories) can already reach 10 billion USD per project and will grow further.

At this level there is a need for long term capacity planning and the risk has to be spread between consortia of companies, as it happened for example with Concorde and Airbus in the aerospace industry.

These consortia are forming now, most of them aiming to combine American design know-how with Japanese or Asian manufacturing expertise, but they can involve European manufacturers as the agreement between IBM, Siemens (D) and Toshiba (JPN) can demonstrate.

## INDUSTRY STRUCTURE

### Companies

In the semiconductor industry, there is a strong European presence of USA and Japanese companies.

In 1993 Intel (USA) gained the largest market share in the EU, overtaking Philips (NL) which had been ranking first for years. The increase of Intel sales comes from the huge demand for 486 microprocessors for PCs. The introduction of the Pentium (the "586") and of the clock tripled 486 will consolidate Intel's leadership.

Motorola has the second largest market share, thanks to the increasing sales of mobile communications components. The introduction of the PowerPC microprocessor will favour its growth.

Philips is losing market shares. The decrease of the consumer market is the main reason explaining this result. Siemens keeps the fourth position thanks to the telecommunication and the discrete components, as well as its DRAM business.

SGS-Thomson (F) is aiming at the USA and Asian markets, concentrating its efforts on the EPROM, FLASH and ASIC technologies. In this context, it is worth to notice the SGS-Thomson - Mitsubishi alliance in the field of flash memories.

For years, system companies such as IBM, AT&T (USA), DEC (USA) have developed sophisticated technologies and manufacturing processes only for their proprietary systems, but this is no longer true. The high cost of developing and manufacturing the new generations of components, is forcing these companies to find ways to share the costs.

Initially they looked for strategic alliances to reduce costs and risks: AT&T teamed up with NEC, IBM with Siemens and then with both Toshiba (JPN) and Siemens.

The deteriorating finances have also forced them into the merchant business. The main problem affecting the systems manufacturers is not the technology, it is marketing and distribution. None of them has distribution channels to compete with companies such as Intel, AMD (USA), Texas Instruments (USA), National Semiconductor (USA). Moreover they have to face two major competitive problems which need new strategies: to become reliable suppliers to their long-standing competitors and to compete with their own current suppliers

### Strategies

Only three European manufacturers of semiconductors (Philips, SGS-Thomson and Siemens) are present in the world largest 20 manufacturers, and there is a very limited number of small and medium manufacturers able to feed the European market requirements with advanced niche products.

But the European components industry is likely to react to past difficulties, by taking advantage of the new opening opportunities. For the first time after many years, the Japanese semiconductor suppliers were forced to reduce their R&D investments in 1993, because of their profitability decline.

This is giving to EU producers a unique opportunity to reduce the gap, by developing a stronger integration between suppliers and users, such as automotive and telecommunications, and to develop application oriented and market oriented components.

Another strategic direction is to reinforce the alliances with US or Japanese suppliers: the joint venture between Siemens and IBM, extended later to Toshiba, is seen as a paradigm to imitate. Interestingly, America's SEMATECH - the government supported R&D consortium - has opened discussion on collaboration with JESSI, which can be considered its counterpart in the EU (although the scope of JESSI is broader).

### Impact of the Single Market

In the words of EECA, the industry trade association, the Single Market is "not a real issue". The electronic components industry operates on a world-wide basis with little concern for national boundaries. Of course the free movement of goods is essential. The industry is very capital intensive and requires highly trained personnel. Therefore, the free movement of capital and people is also important. The recent GATT agreement has sanctioned the EU's external tariffs which are designed to protect the indigenous industry. These are criticized for placing EU client industries at a competitive disadvantage. They have also encouraged foreign component manufacturers to open plants in Europe, thereby increasing competition for local producers.

Successful companies must operate world-wide. A major, but difficult, objective of European semiconductor manufacturers is to reduce their dependence on the European market. In doing so, they face various "non-tariff barriers" such as the vertical integration of the Japanese and South Korean electronic industries.

---

### REGIONAL DISTRIBUTION

---

Electronics manufacturing is now for the most part a global business: the globally coordinated production of globally standard products by multinational enterprises.

The location of manufacture is determined solely by the size of regional markets, the economics of production (including regional incentives) and the availability of skills.

To compensate for the attraction of the newly industrialised and newly developing countries of the Far East, offering low wage costs together with a well educated work force and rapidly growing local markets, some European regions have very good chances to attract future investments thanks to financial support (structural funds).

The growing investments of Texas Instruments in the Centre of Italy (Avezzano) is a good example of this, as it is the decision of the Siemens Group to create a new production plant for integrated circuits in Dresden.

Production is kept close to home when the product or process is at a technological leading edge, while they are still in development or where volumes are low

So far, the availability of high quality designers, engineers and technicians, as well as of high quality machinery and product/process services suppliers are key factors in persuading multinationals to invest in Europe.

---

### ENVIRONMENT

---

Environmental regulations, such as the Montreal Protocol to avoid CFC (chlorofluorocarbons) releases in the atmosphere, will have a strong impact on the electronic components industry.

Tightening environmental legislation has reduced profit margins to the extent that many companies are relocating to regions where the environmental control is less strict: it was the case of the Printed Circuit Boards industry in Germany, whose expenditures to comply with protection regulations have risen to between 6 % and 8 % of sales.

Many of the indigenous producers in Germany have closed down their mass production plants and are instead importing from the Far East or from nations with less strict environmental controls.

To meet both the industry economics requirements and the environment requirements, some markets or marketing advantages should be considered for "green" electronic manufacturers.

For instance, after the USA Environmental Protection Agency (EPA) launched the Energy Star programme, aimed to promote the production of "green PC's" (i.e. Energy Saving Personal Computers, made by fully recyclable materials) the Federal Government decided that, starting October 1993, only PC's respecting the new EPA programme would be introduced in the Federal Administrations.

---

### OUTLOOK

---

In the coming years, market developments will be driven by the user industries. The continuous growth and innovation of the PC and the emerging video based markets are expected to support the demand for more sophisticated and specific components.

Future "top end" active component technology will require international consortia to share the risk, allowing European participants the opportunity of entering the product and equipment markets at the same time as the competition.

Accordingly, national or regional responses as manifested in projects as JESSI or SEMATECH will need to be replaced by global initiatives. Similarly, trade quotas and competition policies based purely on regional markets will be outmoded.

In the active components sub-sector, Japanese and America transplants will be among the largest creators of new employment. Policy towards transplants should aim at encouraging high value added manufactures to be located in Europe.

In conclusion the European market is expected to grow less than average in the period 1994-1998, particularly less than the fastest growing area of Asia and Pacific.

# Computer and office equipment

## NACE 33

The computer and office equipment sector has experienced poor market growth since 1991. The main cause has been the overall economic recession in Europe and the substantial restructuring of the sector due to technological innovation, changing customer requirements and the shift of the computer and telecommunications markets in particular. In 1994, the market has re-entered its growth path although double digit growth rates are not likely to re-occur in the years to come, due to the present price/performance levels. The information technology (I.T.) sector is expected to have a strong potential for growth in the coming years thanks to technology transfer, new applications, and increasing supply and demand against the background of multimedia, local and wide-area information and communication user requirements and the development of a pan-European information infrastructure to meet these needs.

### INDUSTRY PROFILE

#### Description of the sector

The computer and office equipment sector comprises the following product categories:

- large, medium and small Electronic Data Processing (EDP) systems, workstations and personal computers;
- EDP-peripherals such as printers, monitors, keyboards and disk drives;
- data communication equipment;
- office equipment such as typewriters, calculators, cash registers, mail and money handling equipment.

The sector is steadily merging with the software and computer services sector and has become related to the electronic components and the consumer electronics sectors. In the new product generations of today, information, telecommunication and

**Figure 1: Computer and office equipment Market value in comparison with related industries, 1994**

(1) 1993 data.  
Source: EITO, Eurostat

software functions are an integral part of the product solution. The traditional division into office, computer and telecommunication products is therefore growing obsolete.

In 1994, the computer and office equipment sector reached a market and production volume of 50 billion ECU of which office equipment represented 15%. The sector's market volume is twice the size of the market of the electronic components and telecommunications hardware sector, with 22 billion ECU each, and is comparable to the market volume of the consumer electronics sector with 47 billion ECU. Production (1994) is concentrated to Germany (29.7%), the UK (28.3%), France (15.2%) and Italy (15.0%).

#### Recent trends

In the 1980s, the use of office automation increased rapidly in industry and administration; as a consequence the I.T. market boomed, and outperformed overall economic growth, with yearly double digit growth rates. Between 1984 and 1990, production grew by 8% per year, and demand was satisfied

Source: EITO

to a growing extent by imports which grew by 9 % per year in the same period. Meanwhile, extra-EU exports grew by only 6 % per year and the EU trade deficit rapidly increased to reach 13 billion ECU in 1990.

In the 1990s, substantial changes in the market environment, in part influenced by the overall decline in economic activity, have necessitated a strategic re-focus and restructuring of the computer and office equipment sector. Because of this, the market declined by 1 % between 1990 and 1992, and grew by a mere 1 % between 1992 and 1994 to reach 49.6 billion ECU. This stagnation was also influenced by further increasing price/performance ratios whereby unit shipments in specific segments grew substantially. Production experienced a similar trend with a compound growth of 2 % between 1990 and 1992 and 1 % between 1992 and 1994 to reach 49.9 billion ECU. Despite an annual growth rate of 2 % between 1990 and 1992, employment decreased by 10 % annually between 1992 and 1994 to reach a total of 218 000 employed in the sector, due to industry restructuring.

Whereas in the 1980s the I.T. market outperformed overall economic growth, the economic slowdown at the beginning of the 1990s demonstrated that the I.T. market had reached a mature stage and had entered into a cyclical trend where market growth approached the main GDP and investment trends. Therefore, for the I.T. market a nominal growth of 5 % in 1995 is expected, in line with GDP growth.

### International comparison

At 30.1 billion ECU, EU production in 1984 equalled 44 % of the US production of 68.4 billion ECU and was roughly on a level with the Japanese production of 32.1 billion ECU. Whereas EU and US production between 1984 and 1994 on average grew by 5 % and 4 % per year, respectively, the Japanese production increased at a compound growth rate of 10 % per year. In 1994, the Japanese production of 80.0 billion ECU amounted to 81 % of the US production of 99.1 billion ECU. EU production in 1994 had reached 49.9 billion ECU. Due to cost developments in Japan and relocations from the US and the EU, several Pacific rim countries such as Singapore, Taiwan, HongKong and Malaysia have substantially increased their contributions to world production. Meanwhile, China is emerging as a new important host country for production.

In 1994, the value of the world market for computer and office equipment reached 202 billion ECU. At 81 billion ECU, the US is the largest market followed by Western Europe with 57 billion ECU (40 % and 28 % world market shares, respectively). Whereas production and consumption lie within the same range in the EU and the US, the Japanese market of 38 billion ECU, equalling a market share of 19 %, only represents 47 % of the value of the country's production in the sector. This indicates Japan's global orientation. Eastern Europe today represents 1 % of the world market. Apart from Japan, Eastern Europe and the Pacific Rim countries will be the fastest growing markets until 1996, with overall growth

**Figure 3: Computer and office equipment  
Employment compared to EU total manufacturing industry**

1994 are DEBA estimates.  
Source: DEBA

rates of 20-30 %. For Western Europe and the US, growth rates of 11 % and 8 %, respectively, are anticipated.

### Foreign trade

The main characteristic of EU foreign trade in computer and office equipment is a growing trade deficit. Between 1988 and 1993, the trade deficit increased by 4.4 % per year, from 10.8 billion to 13.3 billion ECU. In recent years, the trade deficit growth has slowed down to an average of 2.1 % between 1990 and 1993. Extra-EU exports have grown by 8 % per year from 1988 to reach 12.0 billion ECU in 1993. They are still highly focused on the European market but have begun to penetrate foreign markets. Whereas in 1988 Europe represented 46 % of extra-EU exports, its share decreased to

38 % (4.6 billion ECU) in 1993. With a compound growth of 27 % from 1988 to 1993 and a share of 7.5 %, Eastern Europe is the fastest growing European market. The US represents the largest non-European destination with a share of 29.4 % (3.5 billion ECU) of total EU exports in 1993. It is followed by Japan with 849.5 million ECU (7.1 %) and the Four Tigers (HongKong, Singapore, South Korea and Taiwan) with 595.1 million ECU (5.0 %). The latter two reached compound annual growth rates of 34.2 % and 17.2 %, respectively, between 1988 and 1993.

With a share of 54.9 % in 1993 (13.9 billion ECU) and a compound annual growth rate of 11.3 % since 1988, East Asia is the dominating source of extra-EU imports. In 1993, Japan's share was 21.5 % (5.5 billion ECU), whilst imports from the US accounted for 38 % (9.6 billion ECU). European imports represented only 5.2 % (1.3 billion ECU) of total EU-imports. China has emerged as the sixth largest exporter to the EU.

## MARKET FORCES

### Demand

Over the last few years, market patterns for the computer and office equipment sector have changed substantially. I.T. customers have become increasingly sophisticated which has made more advanced definitions of user requirements necessary.

As the Internal Market develops, the EU industry is becoming increasingly pan-European and is globalising its business with substantial impact on I.T. strategies and requirements as a result. The sector industry is undergoing a process of business re-engineering towards decentralised and customer-oriented structures and processes, where new information and communication requirements must be met. The accelerated merging of office, computer and telecommunications technology and applications has created many potential market opportunities. These factors have greatly influenced the market development of the different I.T. product categories.

For multi-user systems, down-sizing and decentralisation have had a substantial negative impact on the market for large systems. Between 1992 and 1994, this market segment declined by 12.3 % per year. Further price cuts and the holding back of investment decisions, due to anticipated new product announcements, will result in a further decline in the large systems market by 4.7 % per year until 1996. Whereas

down-sizing from larger systems to smaller, distributed computing solutions has had a positive effect on the midrange market, the continued shift towards smaller systems and PC-based solutions has had a negative impact. Hence, the market declined by 2 % per year between 1992 and 1994. Between 1994 and 1996, a growth of 2 % is anticipated. As the price gap between PC solutions and small systems is narrowing and open systems solutions are gaining further importance, this market segment is experiencing a recovery, and a compound growth of 6.4 % is projected for the period 1994 to 1996. The multi-user systems together accounted for 36 % (15.2 billion ECU) of the total computer products market in 1994.

Personal computers and PC-peripherals have been the most important driving forces behind the computer market for the last few years and will remain in this position. PCs and PC printers in 1994 represented 46 % of the computer market. Although double digit unit shipment growth struck a blow to the ongoing spread of PC solutions on the market, due to further increasing price/performance ratios and absolute price cuts, the PC market grew by a compound average of 2.9 % between 1992 and 1994 to reach 15 billion ECU. It is projected to grow by 6 % between 1994 and 1996. PC printers, with

Source: EITO

a market of 4.2 billion ECU, grew by 2 % in 1994 and a 4.5 % growth between 1994 and 1996 is expected for this market segment. The shift from impact to non-impact, and from monochrome to colour solutions constitute important developments in the printer market. In the professional business environment, PC market growth is driven by network solutions to meet the information and communication requirements in a decentralised environment. This fuelled the data communication equipment segment to grow by 18 % between 1992 and 1994, thereby achieving the highest average growth of the computer market segments. The segment will grow by another 8 % until 1996.

A second prominent driving force is the emergence and growing importance of the small office and home office market (SOHO). The declining prices of PCs, and new private consumer-oriented applications in the multimedia environment, have made the PC more and more attractive for home use. It is estimated that 22 % of the European households now own a PC. In 1994, 6 million PCs were sold on the home market. As I.T. product solutions have increasingly penetrated the larger professional business environment, I.T. manufacturers are now focusing their interest on the SOHO market. It is estimated that less than 30 % of small businesses in Europe have purchased I.T. equipment and solutions. This explains why growth in this market segment remains above 10 % per year. 25 % of the PCs sold in Europe in 1994 went into the SOHO market.

Office products represented 15 % (7.5 billion ECU) of the I.T. hardware market in 1994. The market declined by 2.3 % between 1992 and 1994 but is expected to grow by 4.1 % between 1994 and 1996. Whereas traditional office product categories such as typewriters (which went down by 14.4 % between 1992 and 1994) will further decline, there are growth opportunities, especially in the field of copiers which represent 54 % of the office products market. Major driving forces in this market segment are the transition from analogue to digital technology, the merging of traditionally separate applications such as telefaxing, printing and copying in multifunctional equipment, and electronic imaging.

#### Supply and competition

The computer and office equipment sector is a global industry with a high degree of international work-sharing and extensive international exchange and flow of goods and components. I.T. suppliers therefore have to be competitive not only in a given market area but on a global scale. Hence, regional economic factor conditions play a key role in decisions regarding manufacture localisation and sourcing. As Europe is the second largest world market for I.T. products all international suppliers are active on this market. European manufacturers of computer and office equipment have to supply their customers with price-competitive products. International cost differences therefore play a decisive role in sourcing and manufacturing decisions.

In addition, the market success of personal computers has changed the market environment substantially on the supply side. A high innovation rate, a price/performance ratio that continues to increase, short product life cycles of less than one year and the development of the PC to a high-technology

mass-market product, have brought about a need for modularisation of the PC design and economies of scale in manufacturing. It has also spurred a high degree of specialisation in specific PC components with fierce cost management. Together with European factor conditions in the 1980s, this development spurred out-sourcing and the transfer of manufacturing steps to countries such as Taiwan. Conversely, the shortening of the product life cycles and the increasingly consumer-driven market environment makes it necessary for I.T. suppliers to be close to the end markets in order to be able to quickly react to changing customer requirements and to ensure short delivery times. Hence, in the last years new manufacturing plants have been opened or have been expanded in the EU by international as well as domestic manufacturers. To some extent this development can be seen in the official statistics. Value added on production in constant prices fell from 43 % in 1984 to 32 % in 1994 in the EU. Meanwhile, this ratio remained more or less stable in the US (49 % in 1984 and 47 % in 1994), whilst in Japan it declined from 36 % to 31 %. Purchases of goods and services between 1984 and 1994 grew by 7 % per year in the EU compared to 4 % in the US and 10 % in Japan.

Not only have I.T. supply side conditions changed, but the customers' market environment has undergone substantial changes as well. In the multi-user systems market, direct sales dominate, whereas in the field of PC, peripherals and office products area a wide range of distribution channels have been created. In 1994, for instance, 25 % of the PCs for use in private homes were sold by PC dealers, 21 % by large-scale merchandisers, 18 % by advertiser resellers and 17 % by direct mail in 1994. Department stores and direct retail are additional channels. It is estimated that by 1996 large-scale merchandisers will be the largest channel for home-PC purchases.

#### Production process

The most notable development in the area of products and production recently is the increasing convergence of the office, computer, telecommunications and consumer electronics sectors with regard to technology, media and applications. Whereas in the 1980s a move from mechanical to digitalized solutions for office applications occurred (typewriters/word processing, cash registers), in the 1990s we are witnessing the shift from analogue/optical to digital technologies. More and more copiers, scanners, telefaxes and printers already incorporate the same technology and offer multifunctional applications and use. New PC generations now incorporate as integral parts communication, video and sound product features in order to fulfil the requirements for multimedia applications. CD-ROM's are used in the consumer electronics field as well as in the I.T. environment. Requirements in speed and memory capacity due to software needs, are increasing further, as are information and communication data flows,

especially with regard to image processing. Moreover, portable computers are creating new requirements for wireless data transmission.

### INDUSTRY STRUCTURE

#### Companies

In 1990, there were 7 600 computer and office equipment manufacturers in the EU. 89 % of these enterprises had less than 20 employees and contributed 5 % of the turnover and 8 % of the employment in the sector. Enterprises with 100 or more employees accounted for 90 % of the turnover and 85 % of the employment. The top ten manufacturers in each EU member state in represented a total market share of 68-82 % in 1991. In 1993, these market shares had fallen to 51-63 %, due to the fact that new domestic and international manufacturers entered the market whilst others re-focused their business.

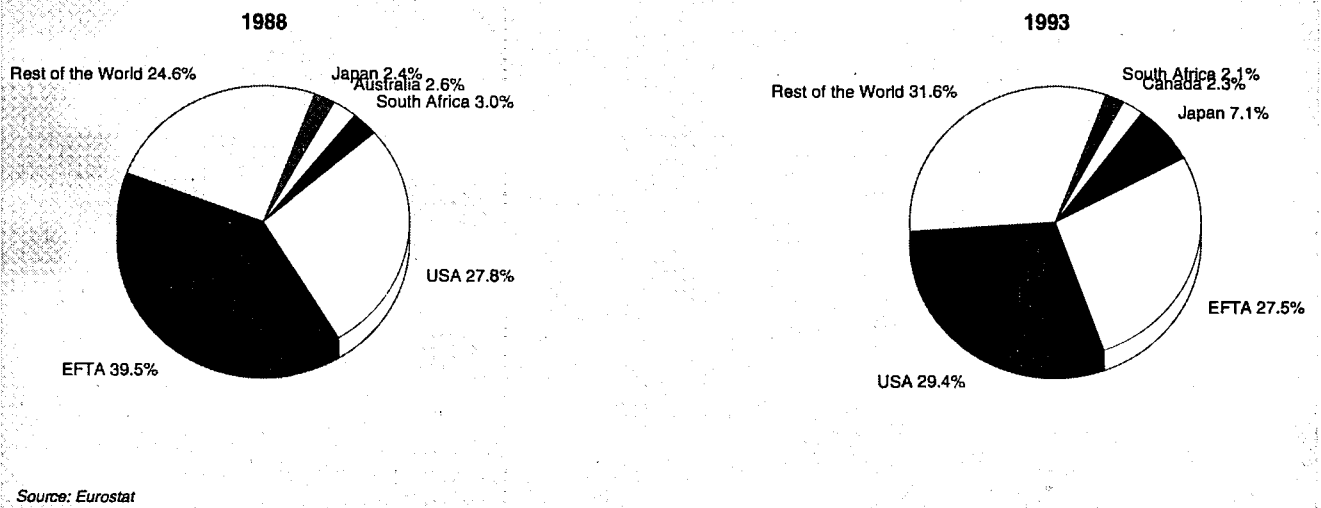

With revenues of 22 billion US dollars, IBM was the largest I.T. manufacturer in Europe (including Software and Services)

in 1993, followed by Siemens-Nixdorf at 6.3 billion US dollars and Digital Equipment at 5.7 billion US dollars. Groupe Bull was the sixth largest with revenues of 3.4 billion US dollars followed by Olivetti with revenues of 3.1 billion US dollars. Compaq and Apple as PC manufacturers followed with 2.0 and 1.9 billion US dollars, respectively.

#### Strategies

The recent market developments show that company strategies are not homogeneous. Companies are re-focusing on their core business or are placing strategic emphasis on specific market segments or links of the market chain. Manufacturers have thus focused on providing complete hardware and software solutions for the banking and finance sectors, or begun to provide PCs for the home market. The merging of computers and telecommunications, and the increasing customer demands with regard to information and communication, has resulted in the integration of computer and telecommunications hardware, software and services solutions in areas such as multimedia and portable computers. Large and globally oriented customers furthermore require appropriate solutions to meet

**Figure 7: Computer and office equipment  
Origin of EU imports**

**Figure 8: Computer and office equipment  
Trade intensities**

Source: DEBA

their computer and communication requirements. Due to changing customer preferences and the growing SOHO market, the choice and mix of distribution channels has become an increasingly strategic issue. Whereas technological and strategic alliances and joint ventures within the sector dominated until recently, alliances with related industries, such as media and information manufacturers and distributors, are gaining increased significance.

### Impact of the Single Market

The European computer and office equipment industry is dominated by non-European multinational companies mainly, American in the case of computers and Japanese in the case of other office machines, many of which have production facilities in Europe.

The free movement of goods within the single market has therefore been of at least as much benefit to American and Japanese companies as to European ones, especially as Japanese and American companies operate Europe-wide whereas European companies have until recently tended to concentrate more on their national markets.

The opening up of public procurement has also been of benefit to non-European companies. Public administrations are major clients for computers and office equipment. However, although "national champions" can no longer be favored as in the past, they do have local knowledge and contacts which makes them attractive to foreign partners (ICL-Fujitsu, Bull-NEC, Olivetti-DEC).

The computers and office equipment industry is a global industry. Standards are established world-wide, often de facto by a dominant supplier (IBM, Microsoft). Therefore Single Market measures have had little impact in this respect.

A feature of the internal market which has a negative effect on the industry in Europe is the imposition of external tariffs on electronic components. These are blamed for the fact that prices of equipment such as PC's are higher in Europe than in the US.

### ENVIRONMENT

I.T. is making an essential contribution to breaking the link between economic development and the consumption of natural resources through the integration of 'raw material information' into products and processes. It thereby helps to reduce the amount of raw material and energy used in industry pro-

duction and administration as well as to reduce the pollution caused by these activities.

The I.T. industry itself has developed recycling concepts which take account of the complete life cycle of a product, beginning with the design and development of the hardware, through environmentally friendly production, to the recycling of used equipment. In addition, methods of integrated environmental protection, such as environmental auditing and efficient resource management, are increasingly being applied.

In 1994, the European commission initiated a Priority Waste Streams project on waste from electrical and electronic equipment. Among other tasks the project addresses the relevant technical, logistical and financial issues in order to fully analyse the waste stream and to identify the areas which may have significant repercussions on end of life issues. European I.T. Industry supports this initiative in view of its lead waste experience in recent years.

### REGULATIONS

Regulation of I.T. products is based on Directives that mainly deal with technological parameters on safety, compatibility and access in the field of telecommunications. By now, all relevant technological regulations are based on EU Directives such as the Low Voltage (73/23/EEC), the Electromagnetic Compatibility Directive (89/336/EEC) and the Telecommunications Terminal Equipment Directives. For technical requirements, there are European harmonised standards such as the EN 60950 for low voltage and the EN 50022 for EMC. By 1996, at the latest, I.T. products will have to be marked with the CE sign to prove their legal and technical conformity.

### OUTLOOK

It is expected that the computer and office equipment hardware market will grow by 5 % per year between 1994 and 1996. Moderate growth in production is anticipated as well. However, these growth rates do not give a true picture of the further growing importance and development of the sector. Whereas until recently I.T. mainly penetrated the professional business environment, I.T. solutions have entered private homes and thereby begun to influence the whole social environment. The industry has introduced the technological and application solutions for the growing needs of the professional and private customer for mobile computing, multimedia information and communication purposes, which has created significant potential for growth in the coming years. The setting-up of a pan-European information infrastructure as a requirement for speedy communication and massive data flows will further support this development.

Written by: Eurobit

The industry is represented at the EU level by: European Association of Manufacturers of Business Machines and Information Technology (Eurobit).

# Telecommunications equipment

## NACE 344

In 1993, the value of EU production was 18 425 million ECU, which was 16 % more than in the USA and 53 % above that of Japan. Telecommunications equipment is one of the few high-technology sectors where the EU trade balance is positive and European vendors have a sound position in the world market.

European telecommunications technology is in a strong position with respect to other competitors in the world market. This is reflected by significant developments of standards, such as ISDN (Integrated Services Digital Network), GSM (Global System for Mobile Communication) and DECT (Digital European Cordless Telecommunication), all of which originated in Europe. The European telecommunications industry is thus competitive in international terms and is holding its ground world-wide.

The large national telecommunications markets in the EU (but also the USA and Japan) have historically developed as closed markets run by public operators, usually with strong links to domestic manufacturers. Thanks to EU legislation and the process of products standardisation, national markets are now opening up. The other two segments of the market, business and consumers, are already open and highly competitive, and, although smaller than the former, are growing faster. Demand is stimulated by the development of two main categories of services, data and voice network services and mobile communications.

In the next few years, the trend towards globalisation, rising competition, increasing supplier concentration and, eventually, lower employment in the sector will be accentuated. The European public telecommunication operators (most of which will be privatised) will increasingly act like private customers vis-à-vis manufacturers. The telecommunications equipment industry is likely to continue to grow in the next few years. Advanced telecommunication services will acquire strategic importance for the economic development of nations and will drive demand for telecommunication systems, such as ATM (Asynchronous Transfer Mode), capable of transmitting high-speed multimedia services.

## INDUSTRY PROFILE

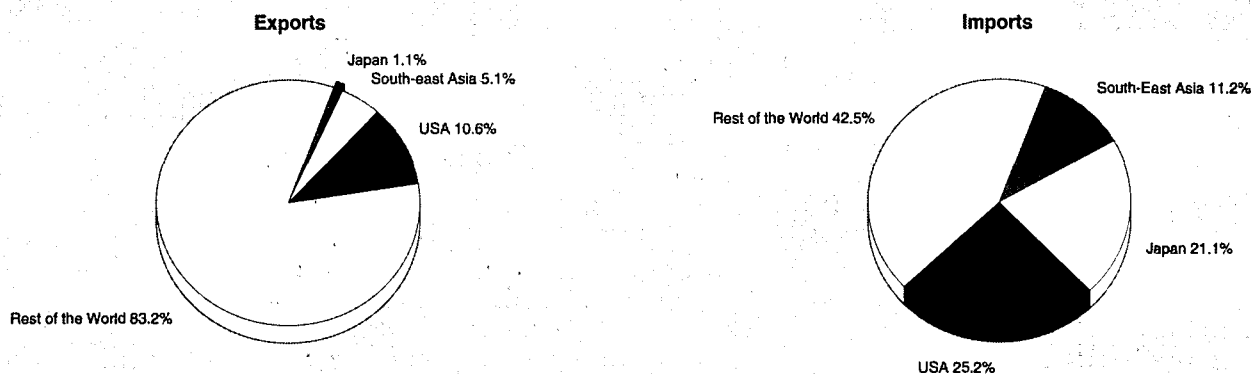

### Description of the sector

The main product categories manufactured by this industry are: public and private switching equipment, radio communication and public broadcasting equipment, user terminals, such as fax and telex machines, telephones, equipment for data and mobile communication; and transmission equipment for cable, fibre, microwave, satellite, etc.

The production of telecommunications equipment is a strategically important industry as it is becoming more and more interconnected with other technologies and industries, such as electronic components, computers, aerospace (satellites), software, consumer electronics and, more recently, television, media and publishing industries.

In previous years, telecommunications equipment was mostly sold to domestic public operators and the range of equipment and terminals offered to the private sector was very limited. Since then, telecommunications equipment manufacturing has

become a multi-product, multi-market industry, with the scope of equipment ranging from large public switching installations to small PABX (Private Automatic Branch Exchange) for private offices, and from mobile networks - used by both public and private operators - to video conference equipment for business customers and video telephone for individual customers. The importance of business and consumer markets is growing and the market as a whole is becoming global and highly competitive. Also, there is a trend towards greater functionality at network periphery, i.e. terminals and private networks. Because of the rapid changes in digital technology, with microcomputer technology in the lead, the life cycle of telecommunications products is dramatically being reduced.

In 1993, the total value of the telecommunications equipment market was 24.6 billion ECU (source: EITO). Extra-EU exports amounted to 6 930 million ECU, contributing to a trade balance surplus of 1 409 million ECU.

Production in the telecommunications equipment industry is very high also in comparison with other sectors of the industry. In 1993, production in the EU telecommunications industry amounted to 18 425 million ECU, which equalled approximately 75 % of electrical domestic appliances production, 73 % of instrument engineering and 41 % of office and data processing machinery. Germany is the largest EU market (5 406 million ECU in 1993) and the largest EU supplier (6 166 million ECU), followed by France, Italy, the UK, Spain and Belgium.

Due to the strong growth of both the public and private telecommunication services markets, the EU telecommunications

equipment market will expand quickly in the next few years. It is projected that it would grow at an average rate of 8.6 % in 1994 and in 1995, and by 8.8 % in 1995 and 1996, in current prices.

#### Recent trends

Between 1984 and 1989, the EU telecommunications equipment market expanded rapidly, with an average annual growth rate of 8.9 % in current prices. However, the growth rate fell markedly from 1989 to 1993, to 2.4 %, due to the increase in competition and the fall in prices linked to the full introduction of microelectronics technology in every telecommunications segment.

Due to increasing automation, EU employment has been declining since 1988 and in 1993 reached a total of 808 900 employed, which was approximately 4 % less than the previous year.

#### International comparison

In 1993 EU production amounted to 18 425 million ECU, which was 16 % more than in the USA and 53 % above that of Japan. The ex-EFTA countries, Canada, South Korea, Taiwan and Brazil are the other large producers.

European manufacturers maintain prominent positions on the world market. Four European companies (Alcatel (F), Ericsson (S), Siemens (D) and Bosch (D)) rank among the top ten in the world along with four North American (AT&T, Motorola, Northern Telecom and IBM) and two Japanese companies (NEC and Fujitsu).

European telecommunications technology is highly competitive on the world market. This is reflected by major developments such as ISDN, GSM, DECT, all of which originated in Europe. Hence, European telecommunications industry is competitive in international terms and is holding its ground world-wide.

In broad terms, the USA is the world leader when it comes to new products and technologies targeted at sophisticated business users, such as high-speed data transmission systems, whilst Japanese suppliers are ahead as far as consumer products (e.g. fax machines and telephones) are concerned. The US telecommunications market claims to be very open to foreign competition. Northern Telecom, the Canadian telecommunications company, is challenging AT&T to become the major supplier of both services and equipment. European companies, such as Siemens and Ericsson, compete in this sector as well. Moreover, Alcatel, Ericsson and Nokia (SF) compete with Motorola for supplying US mobile services operators with cellular networks for mobile communications. The Japanese market, where NEC and Fujitsu are the main suppliers, is almost closed to foreign competition, although imports from the USA (in particular) and the EU are growing as a result of moves towards liberalisation of Japanese telecommunications services.

#### Foreign trade

Since 1984, the EU trade balance in telecommunications equipment has been positive, which is quite an exception compared to other high technology sectors. Moreover, the surplus almost doubled from 1992 to 1993. However, the surplus was much higher in the early 1980s: in 1984 the export/import ratio was 1.66 compared to 1.26 in 1993.

The USA (at 11 % of the total EU exports) is the single most important destination of EU exports. Japan and South East

Asia account for only 1 % and 5 %, respectively. The rest of the world (i.e. the ex-EFTA countries, China, India and other developing countries) represents the biggest share of exports (83 %). The USA (25 %), Japan (21 %), and South East Asia (11 %) are the main exporters to the EU. A weakness in the external trade structure of the EU is that exports are directed mainly towards less developed countries, whilst imports mainly come from the most industrially advanced nations (Japan and USA). The EU countries mainly export large network systems (i.e. switching, transmission and radio communication related equipment), whereas imports are dominated by fax machines and other terminals, mainly from Japan and South East Asia.

#### MARKET FORCES

##### Demand

The market for telecommunications equipment may be divided into three overlapping categories. The first, and by far the largest, is public switching and transmission systems for traditional telephone networks. The other two, the business and the consumer markets, are smaller but are growing faster. The major national telecommunications markets in the EU (but also in the USA and Japan) have historically developed as closed markets dominated by public operators, usually with strong links to domestic manufacturers. Thanks to EU legislation and the process of product standardisation, national markets are now opening up.

The business and consumers market segments, are already very open and highly competitive. Demand is supported by the development of two main categories of services: data and voice network services and mobile communication. Demand for mobile services stimulates the markets for infrastructure and services. Demand for business data and voice communi-

(2) Excluding Greece, Luxembourg and Portugal.

Source: Elsevier Advanced Technology, Oxford, UK - Yearbook of World Electronics Data 1995

cation networks is also very dynamic because of the increasing need of EU companies to co-ordinate their activities, either at the national or international level. Whereas some segments of the telecommunications equipment markets have already reached, or are in the process of reaching, saturation (e.g. modems, fax machines, electro-mechanical multiplexer and private exchanges), new markets are emerging, such as frame relay systems (for remote connections between local area computer networks), digital PABX for connecting both computers and telephones, wireless PABX and digital or multifrequency telephones, as well as ATM switching equipment for private and public multimedia networks.

### Supply and competition

Over the last decade, labour productivity has risen significantly, due to the rapid increase in automation. Between 1990 and 1993, labour productivity increased by 19 %, whereas unit labour costs index grew by only 2.2 %, despite rising wages.

Equipment prices are falling very fast, similar to price developments in computer products, because of rapid innovation in basic fields, such as microelectronics and optics. Price declines are pronounced both in the consumer market and in the business market. Because of global competition, it is the opinion of the author that there would be no more than five or six full-range suppliers of public and private telecommunications systems by the year 2000, but telecommunication markets are expanding so quickly and are becoming so segmented that it is now becoming apparent that it would be inconceivable for a handful of suppliers to control the whole market.

Generally speaking, domestic manufacturers traditionally have strong links with the national telephone operators, i.e. the main buyer of telecommunication systems and products. In the EU, as in the USA and Japan, public operators supplying basic telecommunication services have long-standing relations with their suppliers. Market accessibility is associated with the share of the national telecommunication market held by the largest domestic supplier. Market accessibility is e.g. around 50 % in France and Sweden, and roughly 40 % in Italy.

Due to recent EU legislation, and the projected privatisation of nearly all EU telecommunication operators in the next few years, the link between domestic operators and manufacturers will become weaker. Newly privatised operators will demand faster returns on investment and higher profits, also in the short term, and will push for increasing competition between manufacturers. Hence, barriers to domestic competition will fall in the next years, and competition will spread also to suppliers of telecommunications equipment to national operators.

In the business and consumer arena there is already stiff, global competition. In the dynamic field of data communications equipment for business customers, the highly inno-

vative US networking companies, originating in the computer sector, are threatening to marginalise the European equipment suppliers. It is interesting to note that the success of the innovative US companies has been supported by the more favourable US regulatory market regime. Systems are increasingly based on sophisticated computer software, and networking companies, such as Novell, Cisco Systems and Synoptics (all USA) are bringing products to the market faster than the largest European companies with a background in telecommunications. For this reason, the leading equipment manufacturers are hoping that telephone operators will commit themselves to broadband networks, which require high-capacity systems, such as ATM, that can switch and transmit large quantities of voice, data and image information. These systems are increasingly requested for delivering interactive services both to the business and consumer markets, e.g. video conference and video-on-demand services.

In the consumer market, the competition from Japanese and South East Asian companies is becoming stiffening. Many low value added products, e.g. telephone hand sets, are manufactured in East Asia at low prices. However, with regard to high value added products, such as cellular telephones, Ericsson, Motorola and Nokia are the leading suppliers in the world. Nevertheless, as consumer electronics companies (e.g. Sony) diversify into mobile telephones, competition with telecommunications companies will increase.

### Production process

Product costs are increasingly being dictated by high R&D costs for hardware and software. In telecommunications systems, the R&D costs (depending on the volumes produced) already notably exceed the value added generated by manufacturing. It is estimated that investments in R&D to develop the latest generation of digital public switching were around 700 million ECU. R&D subsidies, agreements on pre-competitive research between EU telecommunications manufacturers, or free technology transfer from network operators, will therefore continue to influence competition substantially.

Demand for intelligent services (e.g. credit card calling), provided by the public networks both to businesses and private consumers, is becoming stronger. Manufacturers therefore must increasingly provide sophisticated software integrated into hardware systems (e.g. in switching) and into networks. Software development has become one of the most distinctive and important feature of telecommunications equipment and suppliers.

The most innovative and sophisticated telecommunication technologies currently under development are SDH (Synchronous Digital Hierarchy) and ATM, which is a switching technology for broadband multimedia communications, such as video-on-demand or cable TV. SDH is a high-speed transmission technology that is increasingly being employed by public operators in order to replace or supplement existing transmission systems. Moreover, in the next few years, public operators will adopt ATM. Companies have already begun to

install ATM systems to increase the speed and widen the range of services of their private networks.

## INDUSTRY STRUCTURE

### Companies

European companies are very well positioned on the global market of telecommunications equipment and, generally speaking, all of them have seen solid growth in revenues and, to less extent, in profits in the last years.

As precise rankings can quickly become outdated, the largest manufacturers are better defined in broad groupings: In the first group we find Alcatel, Siemens, the German group diversified into energy, industrial equipment, computers, and semiconductors, and AT&T.

In the second group we find Motorola, NEC, Ericsson and Nortel. Ericsson depends on its domestic Swedish market for less than 20 % of its total revenues and has operations in 100 countries all over the world. In the past few years, the company has increased its revenues mainly thanks to the growth of its radio communication operations. Ericsson and Motorola are firmly established as the leading suppliers on the world market for cellular telephone networks.

In the third group we find Fujitsu, Nokia and Bosch. Nokia showed big increases in its telecommunication revenues in 1993 and 1994, thanks to its strength in the mobile communications segment, and is the largest supplier of cellular telephones in the world, along with Motorola.

In 1994, the Italian company Italtel set up a joint venture with Siemens with the aim to increase technological strength and to expand on foreign markets. In order to expand, EU companies will have to take advantage of the opportunities

on the markets in Asia and in Eastern Europe. Alcatel, Siemens and Ericsson are already well positioned in China, India and in the Eastern European countries. Siemens is using its position in East Germany for leverage to get the biggest share of orders for Deutsche Bundespost Telekom's massive upgrading of the public network in that region.

### Strategies

The largest European companies have to balance the goals of expanding into new business and consumer markets, such as mobile communications and data services, and continuing to look after existing customers, the national telephone operators. Rapid technology innovation and the creation of international commercial operations and production units are, and increasingly will be, the most important challenges for telecommunications companies. India, China and other Asian markets may represent great opportunities as they grow at annual double-digit rates. Telecommunications companies can thereby escape the risks linked to the saturation of the public sectors of the markets (telephony) in the more industrialised countries. Newly Industrialising Countries will develop their fixed and mobile digital networks with the technological and financial help of the large EU players, such as Siemens, Alcatel, Ericsson and Nokia.

The trend towards further market concentration continues through mergers and acquisitions, mainly directed towards the acquisition of new technology and penetration of foreign markets, which have traditionally been dominated by domestic companies. In general terms, to win orders in foreign markets, a supplier has to form a joint venture or buy a stake in one of the established suppliers. In 1994, Siemens and Italtel set up a new fifty-fifty joint venture after the failure of the previous one, in order to get a major share of the Italian Market, whilst strengthening their exports from Italy to foreign markets. Many

joint ventures, mergers and acquisitions have taken place in the last few years for the same reasons (e.g. between Siemens and GPT of the UK, Northern Telecom and STC of the UK), and supplier rationalisation is far from over as well. Another factor behind the increasing concentration in the industry is the need to find a partner to share the burdens of high R&D expenses with. Alcatel and Sprint (USA) set up a joint venture to develop a new ATM switching system. Many telecommunications companies try to set up technological partnership networks with computer companies in order to share the costs of R&D in new products and systems (e.g. ATM) and for entering new markets, such as video-on-demand, and home and office automation.

### Impact of the Single Market

Traditionally each national state had its own telecommunications equipment industry supplying its own, usually state-owned, monopoly telecoms operator with everything from subscriber equipment to cables and public exchanges and on an exclusive basis. This traditional structure is in the process of totally disappearing under the pressure of technical developments, telecoms deregulation and the advent of the Single Market. A European-wide, and even a global, industry is taking its place.

The most spectacular and influential technical development was the advent of the digital exchange in the 1970's. Only three or four groups in Europe had the financial and technological strength to develop these systems. To recuperate their investment they have been obliged to become multinational and sell world-wide. The pressure of increasing R&D expenditure continues to affect the structure of the industry.

The deregulation of the telecommunications market is destroying the monopolies of the state controlled operators in the provision of subscriber equipment, private networks, data transmission, mobile communications and, by 1998 at the latest, the basic fixed voice network. This means equipment suppliers now have a larger but much more competitive potential market with many more network operator clients and the possibility of selling subscriber equipment direct to the final user. Moreover, the range of services being offered (e.g. Video conferencing, video on demand) by operators is growing and therefore so is the demand for equipment.

Finally, specific Single Market measures are having widespread repercussions. Public procurement regulations now call for open tenders rather than the private deals previously negotiated between operators and equipment suppliers. Technical

harmonization is in the process of creating Europe-wide, indeed world-wide, markets for equipment such as GSM terminals.

### REGULATIONS

The Single European market should be increasingly favourable for the telecommunications companies since it will help them to achieve economies of scale through standardisation of network systems and terminal interfaces. ETSI (European Telecommunications Standard Institute) is putting great effort into establishing common European standards, although full European standardisation will be possible only when new systems, such as narrow band ISDN, broadband ISDN and GSM have been introduced and widely diffused in all EU countries. The importance of supporting common European standardisation is displayed by the success of the GSM digital mobile radio system: in addition to 22 European countries, 32 non-European countries have opted for, or are considering to introduce, the European standard (as well as European equipment).

Previous opinions of the EU Commission against vertical integration between network operators and domestic equipment manufacturers are currently being re-examined due to the trend towards global competition with integrated companies outside the EU, and the ongoing privatisation of EU telecommunication operators. Other important EU Regulations concern the opening of public procurement contracts for bidding by EU and non-EU companies. Generally speaking, the basic principle of the mutual opening of markets and non-discrimination must apply not only within the EU, but also in other markets of the world. National markets must be accessible under fair and non-discriminatory conditions. It is generally acknowledged that until now it has not been possible to create all the conditions for an effective open market in the public sector within the EU. Until 1995, the EU will continue to support the Race programme for advanced communication aimed at sharing the expenses for pre-competitive R&D. It is also promoting the new ACTS (Advanced Communication Technologies and Services) programme with the objective of speeding up the process of introducing harmonised advanced networks and services across Europe, and helping new commercial pilot projects in the new high-speed and multimedia technologies. Finally, also the programme ESPRIT is contributing to the creation of an effective open market.

### OUTLOOK

In the next few years, the major trends towards globalisation, rising competition, increasing concentration of suppliers and, eventually, lower employment in the sector will be accentuated. The European public telecommunication operators (nearly all of which will be privatised) will act more and more like private customers vis-à-vis manufacturers. However, the telecommunications equipment industry should grow in the next few years. As the Bangemann Report (issued by the European Commission) clarified, advanced telecommunication services will acquire strategic importance for the economic development of nations and will drive demand for telecommunication products and systems. Massive investment projects in new digital networks, such as ISDN, GSM and broadband multimedia networks for video-on-demand and cable TV services will be essential to the development of the equipment sector. However, it is likely that US and Asian companies will increase their market share in some of the fast growing EU markets, i.e. data communication and consumer products.

A promising product for the next few years, a result of the convergence of computers, consumer electronics and telecommunications technologies, is the PDA (Personal Digital Assistant), a pocket personal computer that will also be able to communicate data and voice. Although the commercial launch of certain PDAs that do not yet match the user requirements

has met with some failure, there are few doubts that PDA will become the next generation of advanced mobile telephones. For the rapid growth of the sector, the promotion of new applications by the EU and the execution of pan-European pilot projects will be very important as well. Two prime examples are TEN (Trans-European Network) and EPAN (European Pilot ATM Network). The former will connect integrated broadband communication "islands", the latter will be used to test innovative technologies, such as ATM.

# Consumer electronics

## NACE 345.1, 345.2

In 1992 and 1993, the EU market (and EU production) experienced difficult times because of over capacity, demand saturation, price erosion and economic recession in Europe. In 1994, the market saw some recovery and EU production grew by 8 % in comparison with 1993. Japanese companies dominate the audio-visual sector world-wide, especially in products such as VCRs and camcorders, whilst US companies play a marginal role. The top ten companies, out of which six are Japanese, two European and two South Korean account for three quarters of world production. Above all, EU companies are strong in the colour television segment. Apart from Italy, where there are still some medium-sized TV manufacturers, small and medium-sized European consumer electronics companies have almost disappeared because of the globalisation of the market. In 1994, thanks to their diversification in different segments of the market, cost rationalisation and the recovery of the EU economy, the most important EU companies indicated revenue and profit growth after having experienced decreasing profitability in the last few years. Because automation is increasingly dominating the production process, employment in the consumer electronic sector has decreased more than in the manufacturing industry as a whole since 1990. Employment is expected to maintain its downward trend over the next years. Product innovation, economies of scale, user friendliness, promotion and distribution are the key factors for success in the consumer markets. In the short term, the recovery of the EU consumer electronics companies hinges upon the successful completion of the vigorous restructuring programs undertaken by the leading companies in order to return to structural profitability. Companies are likely to concentrate on their core competence, but increasingly need to set up new joint ventures with companies that originate even from other sectors such as media, satellite and cable broadcasters, computer and telecommunications as well. In the long term, awaiting the new era of multimedia, success will depend on the ability of EU companies to increase their global market share, to establish common and world-wide standards in satellite and cable digital TV and to market innovative products (such as the Digital Compact Cassette, the Compact Disc Interactive, widescreen receivers, Digital Audio Broadcasting and the Personal Digital Assistant).

### INDUSTRY PROFILE

#### Description of the sector

The consumer electronics sector includes all audio-visual products for domestic use and their accessories, such as colour and monochrome televisions, video recorders, video cameras and camcorders, CD readers and audio equipment in general (NACE 345.1). Other 'brown goods' are classified in this sector (NACE 345.2), including cable terminals and pay-TV decoders. Other products are: antennas and satellite dishes, in-car entertainment and traffic guidance systems, mobile phones, home computers and telecommunications terminals. Video games is another category of increasing importance that may be included in the consumer electronics sector.

However, with the migration from analogue to digital technologies and the convergence of telecommunications, computing and consumer electronics technologies and applications, the traditional definition of consumer electronics as "brown goods" becomes less and less relevant.

Some products, such as TV sets and VCRs, are experiencing increasing market saturation and have entered the phase of maturity of their life cycle. After the launch of VCRs, walk-

Figure 1: Consumer electronics  
Value added in comparison with related industries, 1993

Source: DEBA

mans, compact discs, satellite dishes and camcorders in the 1980s, in the early 1990s innovations have been mostly incremental. Innovative products released in Europe in 1993, such as the Digital Compact Cassette (DCC) by Philips and the MiniDisc by Sony, are based on optical technology and will be the next generation of products for playing and recording music (though they are still far from the market success of the Compact Disc). The CD-I (Compact Disc Interactive), a new interactive multimedia system connectable to TV sets, is also based on optical technology but is still in the initial stage of market penetration. Widescreen (16:9 format) and improved definition television receivers have recently entered the market: in 1994, total European sales of 16:9 widescreen TV sets reached 150 000 units (100 000 in France only, as 16:9 broadcasting started there first).

#### Recent trends

Compared to the years of expansion in the period 1984-91, with growth at a compound annual rate of 9.7 %, EU consumption and production have experienced difficult times in

Source: DEBA

1992 and 1993. By 1993, apparent consumption had dropped to 90 % of the consumption in 1991. In 1994, the sector began to recover, coming out of the general European industrial and economic recession. Production in 1994 grew by 8 % in comparison with the previous year. In 1993, the consumer electronics sector generated a value added of 13 008 million ECU, which was more than the domestic appliances sector but less than the office and data processing machinery sector and less than the telecommunications equipment sector as well. France contributed most of the value added (4 986 million ECU in 1993), followed by Germany (2 337 million ECU), UK (1 671 million ECU), Italy (1 493 million ECU) and Spain (658 million ECU).

Employment maintained its negative trend. Since 1984, employment has declined every year except for 1987, and since 1990 it has been falling more than in the manufacturing industry as a whole. In 1994, EU employment in consumer electronics was 315 600, which was around 15 000 less than in 1993. Employment is expected to continue to fall in the

next few years. In spite of increasing extra-EU trade exports (in 1993 they amounted to 10 789 million ECU), the trade balance deteriorated every year between 1984 and 1991. In 1992 and 1993, the trade deficit (11 769 million and 11 675 million ECU, respectively) decreased in comparison with 1991.

**International comparison**

Japanese companies dominate as producers of consumer electronics goods for the world market. In 1993 the Japanese production value was nearly twice as high as that of the USA and more than three times as high as in the EU. In the audio-visual sector, Japanese suppliers control more than 99 % of the domestic market but export around 25 % of their production. Moreover, Japanese companies account for approximately half of the production in the USA and one quarter of the production in Europe. It is estimated that EU companies manufacture around 16 % of all audio-visual products in the world, whilst US companies produce 8 %. South Korean com-

panies account for approximately 10 % of the total and export most of their production. Developing countries, where many production plants of western and Japanese companies are located, account for around 16 % of total production. Both the USA and the EU are significant net importers of consumer electronics, and have negative trade balances in the sector.

#### Foreign trade

Since 1992, extra-EU exports have grown faster than imports, resulting in a declining EU deficit. More specifically, in 1993 extra EU exports (10.8 billion ECU) increased by 21.4 % in comparison with the previous year, whilst extra EU imports (22.5 billion ECU) only increased by 9 %. EU exports destinations changed during the period 1988-1993, in fact the percentage of exports directed to the EFTA countries decreased, whilst exports to Singapore, Malaysia, Malta and the rest of the world (i.e. the less developed countries) grew. In 1988, exports to the rest of the world accounted for 41 % of the total, whereas in 1993 they accounted for 47 %. Very few products from the EU are exported to Japan which is a very closed and highly competitive market. Parts & accessories, TV sets and blank tapes & discs are the main categories of exported products. Imported products mainly come from Japan, China, South East Asian countries and the USA. Direct

imports from Japan have declined since 1988, whilst imports from the USA, the South East Asian countries and the rest of the world have increased. Parts & accessories, home audio, TV sets, camcorders and blank tapes & discs are the main products imported.

#### MARKET FORCES

##### Demand

In the EU, purchases of audio and video hardware represent around 1 % of total consumer expenditures, a share that has not varied significantly over the last ten years. Meanwhile, however, prices have remained the same or fallen, whereas products have improved. As market developments are related to the total income of the consumers, the ongoing economic recovery in the EU is likely to favour market growth. However, since 1990 the sales volumes of some more traditional key products have ceased to grow. In fact, the proportion of households in the EU with at least one colour TV set is close to 100 %. Household penetration of VCRs is just over 50 %, but this equipment is not yet old enough for replacement demand to be an important part of the market. Sales mainly depend on the smaller number of new customers. It is estimated that TV sales will stabilise at around 20 million sets per year,

Source: EACEM

and VCR sales at approximately 11 million per year. In spite of the increasing saturation of the more mature segments of the market, more than 20 % of audio-visual hardware consumer expenditure is going to products which did not exist before the late 1980s, notably camcorders, CD players and satellite reception equipment.

Broadly speaking, consumer demand may be divided into two main segments. High end users ask for high quality products and services (for example improved definition and 16:9 format screen TV sets and VCRs) whilst low end users ask for less expensive products that are easier to use. It is also acknowledged that many functions of volume products (such as VCRs and camcorders) are not actually used because of their complexity. User friendliness, price and quality of products and services are the main factors of success in the consumer markets, and suppliers try to balance these features to get the right mix for the different segments of the market.

### Supply and competition

In real terms the cost of products such as colour television sets and VCRs have fallen by at least 50 % between 1980 and 1993, and a colour television set or a VCR in 1993 is a much more sophisticated and reliable product than in 1980. The reduction has been made possible by improved production methods and economies of scale, but lower trade margins and more efficient distribution systems have also contributed. Japanese companies dominate the sector world-wide, especially in products such as VCRs and camcorders by selling high volumes at low prices and with low profit margins. Europe still has a strong television tube industry. All television sets manufactured in Europe, whether by European or Asian companies, use tubes manufactured by European companies, with the exception of Sony which produces its own Triniton tube in the UK, and Samsung which is about to begin tube production in Berlin. This is important since the tube represents 30 % of the cost of a TV set. Above all, EU companies are strong in the colour television segment. South Korean manufacturers, such as Samsung, are improving their positions in the world ranking of consumer electronics companies, favoured by their low labour costs. They are particularly strong in the most mature and low end products, but also in VCRs and camcorders. Very few US companies can be found among the top ranking consumer electronics companies, due to the dominance of Japanese and EU companies (Philips and Thomson) on the US market itself. Japanese strengths in the sector are well known: Japanese companies benefit from large economies of scale, low capital costs and a highly skilled work force. They are also favoured by large investments in R&D, and international marketing expertise. Above all, Japanese companies are able to profit from their vertical integration and diversification. In fact, many large Japanese producers are also prominent in the electronic components market. Many of them are well diversified into other fields as well, such as computing, electronic professional systems and telecommunications. They are therefore able to share the large investment in R&D required in electronics, among the different divisions. Another key factor is brand image and the expansion of distribution channels, such as department stores for the mass market, or specialised retail channels for high quality and sophisticated products. Distribution is becoming increasingly concentrated, as large multiples and buying groups take a higher share of the market. The number of independent specialist retailers is declining in all countries. There is also a trend towards an increasing proportion of sales being made

Source: EACEM

through large non-specialist distribution channels, especially for more inexpensive and less sophisticated items. As products have become more reliable, customers no longer deem it necessary to buy from specialists who can ensure after sales service. This is also the reason behind the decline in the importance of rentals, which, in the UK, have declined from 50 % of the TV market in 1982 to 15 % in 1992. A number of consumer electronics companies maximise the use of their sale and distribution networks, selling subscriber telecommunications equipment. On the whole, however, many consumer electronics companies do not manufacture such equipment. Similarly, "home and office" equipment, i.e. office equipment such as PCs, fax machines and photocopiers for use at home, are also suitable for sale through the channels used for consumer electronics. Again, these products are not usually manufactured by EU consumer electronics companies, in fact much of the technology used in fax and photocopiers is controlled by Japanese.

### Production process

In the period 1984-94, the EU productivity index increased by more than 60 %, whilst unit labour costs have increased by almost 20 % since 1990. Both Japanese and European companies are trying to rationalise their production facilities (in the EU there are approximately 125 plants manufacturing audio-visual products), and to move low value added production to South East Asian countries where labour costs are lower. In EU companies the trend is to have R&D, sales and marketing staff that is relatively large and to have less staff employed in production. There are exceptions to this general

trend, as some companies specialise in manufacturing TV sets on an OEM basis for large retail organisations. These companies maintain a very high proportion of their workforce in production. Due to the relocalisation of the production of low end products and the conversion of EU production sites into centres for piloting new production techniques, as well as for some production of high end products, the average skill levels of production workers will rise. The more important EU suppliers attempt to revitalise the market by introducing new sophisticated products and enhanced standards for new products. Philips launched the Digital Compact Cassette (DCC) for recording digital sound. Sony responded by launching the MiniDisc on the market, another optical product for recording digital sound. Both are trying to emulate the success of the -compact disc, replacing traditional analogue cassettes. They are also attempting to establish their standards through alliances with hardware suppliers (e.g. the Philips DCC is also produced by Matsushita, the largest Japanese electronics company). For both contenders, partnerships with the "software" industry, i.e. the music recording industry, is vital for the success of their new products. Philips also introduced CD-I, an interactive multimedia optical device connected to a traditional TV set and compatible also with the compact disc. In this case a partnership with the movie industry is seen as the key to success.

However, EU companies have not participated in the development of camcorders, the technology of which is exclusively controlled by Japanese. In the face of new digital compression technologies, both the HD-MAC system in Europe and the

HD-MUSE system in Japan were abandoned as competing world standards. In the field of HDTV the European Digital Video Broadcasting Consortium is now expected to be the enabling forum for the definition of the future HDTV standard.

HDTV is a new standard for TV sets providing high definition images (comparable with the level of image definition of movie screens). In the past years, the EU has supported strong efforts in R&D to promote an EU analogue standard of HDTV competing with the existing Japanese one. However, the US electronics companies promoted a more advanced digital HDTV standard that will eventually become, in a modified version, the European standard. Philips and Thomson, already deeply involved in R&D development of the US HDTV digital standard, will eventually support the introduction of the new digital standard also in Europe (no target date has been set for digital HDTV).

New enhanced analogue TV sets with a 16:9 format screen have already been launched on the EU market. Moreover, the most prominent attempt to revitalise the mature market of TV sets will be the new initiatives to develop digital television. In fact, it is not necessary for digital television to be high definition. It can be broadcast from terrestrial transmitters as well as satellites and over cable, and allows broadcasters to offer far more services on the same channel than analogue technology does. Digital television will allow for a massive increase in the number of channels offered, as well as other facilities, such as interactive TV and video on demand services. The potential market is very large. To benefit from digital TV, consumers will need either a digital/analogue adapter for their existing set or, in the long term, a new TV set. Broadcasting will begin by satellite and over cable, perhaps in 1995. Terrestrial broadcasting will follow after satellite and cable transmission. There will also be an increasing demand for satellite reception equipment. Digital TV will create a demand for advanced electronic components and particularly semiconductors, which may be produced by EU companies. Large flat screens will be needed as well. Although the Japanese are more advanced than US and EU companies in the related R&D, much research is currently done in Europe in this and other technologies, through the Eureka, ACTS (Advanced Communications Technologies and Services) and JESSI programmes. Digital TV will also increase the need for TV programming and other media products, such as video and data banks. The digital TV standard will most likely lead the way in a hierarchical manner to digital HDTV with an intermediate digital 16:9 format.

In the long term, innovation in the field of consumer electronics is closely linked to the trend of convergence of telecommunications, computer and media technologies. Traditional industrial boundaries are disappearing and cross-sectoral competition will increase. Video-telephone and Personal Digital Assistant (PDA) are examples of technological convergence that promise increasing competition and more alliances. Mul-

timedia PCs is another example of technological convergence of the TV and the computer industries.

## INDUSTRY STRUCTURE

### Companies

The top ten companies account for three quarters of world production. Six of them are Japanese, two European and two South Korean. The only EU companies among the top ten are Philips and Thomson. Nokia is the third largest European manufacturer. Apart from Italy, where there are still some medium-sized TV manufacturers, such as Seleco that is attempting to develop into a Southern European multinational on the TV market after having acquired the Spanish manufacturer Elbe, small and medium-sized European consumer electronics companies are active only in the audio business, or in peripheral areas such as satellite TV reception equipment. Philips, Thomson and Nokia are vertically integrated and diversified, although to a lesser extent than the Japanese companies. Philips is also the main EU producer of electronic components and Thomson is one of the main shareholders in the semiconductor manufacturer SGS-Thomson. Nokia is getting an increasing share of its revenues, and the biggest share of its profits, from mobile telecommunications equipment and cellular phones.

Thanks to their diversification, cost rationalisation and the recovery of the EU economy, the most important electronics companies showed positive signals in 1994, after having suffered significant losses in the previous years. Many analysts claim that very few companies have been making profits in Europe in the last few years by producing only consumer electronics products. Although consumer electronics is a mature market, where established companies normally are in a position to consolidate good profits, fierce global competition and overcapacity seems to have forced the industry to give away the biggest share of its productivity gains to the customers.

### Strategies

The strategies of the consumer electronics companies are directed towards controlling costs, rationalising production, improving the quality and the user friendliness of the existing products, entering new fast growing markets and launching innovative products. On the one hand, companies are likely to concentrate on their core competence, and on the other hand, to co-operate and to establish joint ventures with companies that in fact may originate from other sectors, such as media, computer, satellite and cable broadcasting and telecommunications. In general, stiff competition is forcing companies to create networks of alliances and partnerships in very different segments of the market, such as audio, video, cable and satellite pay-TV and intelligent telephones. After a wave of mergers and acquisitions in the 1980s, strategies have shifted towards agreements concerning a limited range

Source: DEBA

of products or R&D in some technologies in the highly differentiated sectors of the consumer electronics market. Philips and Thomson, once partners in developing a European HDTV standard, are jointly developing a flat TV screen and LCD (Liquid Crystal Display) technology.

The digital TV standard in Europe will be developed by the Digital Video Broadcasting Group formed in 1993 by 120 interested parties, including television manufacturers, broadcasters, satellite operators, governments and the EU Commission itself. One of the objectives of the group is to establish common European standards for transmission and pay-TV decoders. However, it seems unlikely that these will be mandatory. Digital Audio Broadcasting (DAB) is another field of R&D co-operation.

The more important companies attempt to enter the new fast growing consumer electronics markets, especially in Asia. China and India are quickly expanding broadcasting networks and in these countries an increasing number of people are buying new TV sets and other TV equipment. This represents a strong business opportunity for the globally active EU companies.

### Impact of the Single Market

The European consumer electronics industry now mainly consists of a small number of multinational companies selling standardized products throughout the EU. The free movement of goods has enabled production to be concentrated on a smaller number of large units. As a consequence of this rationalization, employment has fallen and numerous small independent producers have gone out of business. The common external tariff and the threat of anti-dumping procedures have encouraged Japanese and other Asian manufacturers to establish production facilities within the EU. Foreign manufacturers now account for over 30 per cent of EU production.

Problems of technical harmonization are largely a matter of the past although the rival PAL and Secam color TV standards persist. For future technologies good progress has been made in establishing digital audio and video broadcast standards (DAB, DVB), and standards for information highways and multimedia will be established in due course.

The major area in which a Single European Market does not yet operate is distribution. Few manufacturers have European wide distribution systems. This is partly because, despite the existence of some Europe-wide buying groups, the retail distribution structure of each country is historically very different.

but also because of differing national legislations in areas such as trade practices, packaging and advertising.

## ENVIRONMENT

Laws on waste disposal have already been introduced in Germany and France. EU and national laws will push the suppliers to adopt recyclable materials. Consumer electronics companies are taking environmental questions seriously. This involves design that enables equipment to be recyclable and non-toxic, providing customers with facilities for disposal, providing return systems for packaging, and using non-polluting manufacturing processes and materials, such as water based paints.

## REGULATIONS

The Digital Video Broadcasting Group aims at setting up a multiplex digital standard for Europe (i.e. a standard that allows several channels to be broadcast on each digital signal) and works together with European standard-setting bodies, such as the ETSI and Cenelec. The purpose of the Commission is to avoid a proliferation of competing systems in Europe for encoding subscription satellite channels, as well the transmission standard themselves. In fact, it is not in the interest of the consumer to buy a variety of different decoders for each pay-TV channel. Whilst EU governments do not wish to dictate the exact standard for the future digital TV and HDTV, an EU regulation is however expected to establish the transmission standards policy for the future of digital and widescreen TV services in Europe.

## OUTLOOK

The future of the consumer electronic industry is heavily dependent on the developments of new technologies, such as digital TV, encryption systems and widescreen format TV, as well as on the successful marketing and adoption of new products, such as DCC, CD-I, DAB, in-car traffic guidance systems and personal electronics. Despite the recovery of the EU economy as a whole, difficult times are likely to continue in the next few years, because of market saturation, fierce price competition and production overcapacity. In the short term, the recovery of the electronics industry hinges upon the continuation of rationalisation programs initiated by the important companies in the sector. In the long term, the success of the EU consumer electronics industry also depends on its ability to increase its share of the global market and to create a wide range of technological and commercial alliances. The emergence of the new multi-media industry will present the biggest business opportunity, indicating convergence of the consumer electronics, computer, telecommunications and software industries.

The development of the "information society" is likely to accelerate the integration of certain classes of consumer electronics items (e.g. TV, in-car services, etc.) into intelligent computer and communication based systems. This in turn will drive new functionalities, e.g. embedded services that will enable the user to deal with the substantial increase in the range of services to which he/she will be connected and the need to profile these services to fit his/her individual requirements.

Written by: Databank Group - Teknibank

The industry is represented at the EU level by: European Association of Consumer Electronics Manufacturers (EACEM). Address: Rue d'Arlon 69-71, Bte 8, B-1040 Brussels; tel: (32 2) 230 5010; fax: (32 2) 230 9608.

## Overview NACE 35, 36

The transport equipment industry ranks among the major industries in the EU, and has a significant impact on important supplying sectors. Consequently, the deep recession that the industry has experienced in the past three years has had a dramatic effect on its suppliers. In 1994, the gradual economic recovery throughout the European Union has paved the way for improved performance of the transport equipment sector. Prospects are rosier for the next three year period too, thanks to the long awaited come back of the market.

In spite of this recovery however, the ongoing restructuring of the industry will continue, leading to further important layoffs in the EU transport equipment industry.

### INDUSTRY PROFILE

#### Description of the sector

The transport equipment industry covers a number of sectors that manufacture all types of vehicles, which may be motor driven or not. According to the NACE classification, it covers the following sub-sectors:

- motor vehicles (NACE 351 and 352);
- motor vehicle parts and accessories (NACE 353);
- shipbuilding (NACE 361);
- railway rolling stock (NACE 362);
- cycles, mopeds and motorcycles (NACE 363);
- aerospace equipment (NACE 364)
- perambulators, invalid chairs, etc. (NACE 365, not included in this Chapter).

The transport equipment sector ranks among the major industries in the EU, both in terms of turnover and of employment. It also has a significant impact on important supplying sectors, such as metals, rubber and plastics or mechanical and electrical engineering. The major category of the transport equipment sector is by far motor vehicles, which accounts for 82 % of the sector's output (including the manufacture of bodies and parts and accessories). Aerospace ranks second both in terms of production and employment.

Germany, France, the United Kingdom and Italy are the four largest producers in the EU. These four countries accounted for 87 % of the value added created by the EU transport equipment sector in 1993.

#### Recent trends

The transport equipment sector maintained sustained growth between 1985 and 1989, driven by the particularly dynamic performance of the motor vehicle industry over the period. The aerospace industry also contributed significantly to the sector's growth. During the same period, EU shipbuilding production was under severe competitive pressure especially from Far-East producers.

1990 marked a turning point for the transport equipment sector. After a slowdown reported in 1990, real production started to fall in 1991 and 1992. 1993 saw a deep depression and will be remembered as the bleakest year in the EU transport equipment sector since World War II. Domestic demand, as measured by apparent consumption, plunged to 297 million

Figure 1: Transport equipment Value added in comparison with related industries, 1993

Source: DEBA

ECU, implying a tremendous 14.8 % drop over twelve months. All the segments of the industry have been affected, but the motor vehicles sector was hit hardest by the weakness of domestic demand. Demand for aerospace equipment was also very poor, as a result of a severe crisis in both the sector's military and civil markets.

The only good news came from a strong increase in extra-EU demand, which limited the fall in production to 14 % in real terms over the twelve months of 1993. This slump was much more pronounced than the 3.4 % fall registered in manufacturing production over the same period.

In such a climate, massive layoffs were reported in the sector in 1993. The transport equipment industry lost 196 000 employees, or 7.6 % of its total workforce.

**International comparison**

The recession that hit the EU in 1993 had a profound impact on the international position of its transport equipment industry. Indeed, the EU transport equipment sector lost in 1993 the world leadership it had built up in the decade leading up to 1992 to the detriment of the USA. Thanks to a strong expansion in the decade to 1992, the EU became in that year the world's largest producer of transport equipment. The USA, after suffering cutbacks in activity in the 1988-1991 period, stepped back to second place. Japan, which had recorded an outstanding performance throughout the 1980s, attained third place in 1992.

1993, however, witnessed a reversal of fortunes for the EU transport equipment industry. Boosted by economic recovery, the USA achieved strong production growth, and again became the leading manufacturer of transport equipment. Japan climbed up to second place in spite of severe production cuts in 1993, leaving the EU with the third rank of the Triad.

Considering the decade leading up to 1993 two important facts stand out. First, and in spite of the recent downturn, the EU has emerged as a leading producer of transport equipment (through the outstanding growth of its aerospace equipment industry). Second, Japan has shown an impressive ability to penetrate markets world-wide, and has risen to the second place of the world's leading transport equipment manufacturers.

**Foreign trade**

In 1993 the EU transport equipment industry exported almost 20 % of its production outside the EU. More than 14 % of EU expenditures on transport equipment was produced outside the European Union. Export intensity increased substantially in 1993 compared with the previous five-year period, which illustrates the shift operated by EU transport equipment manufacturers towards export markets to compensate for shrinking domestic demand.

**Figure 4: Transport equipment  
International comparison of production in current prices**

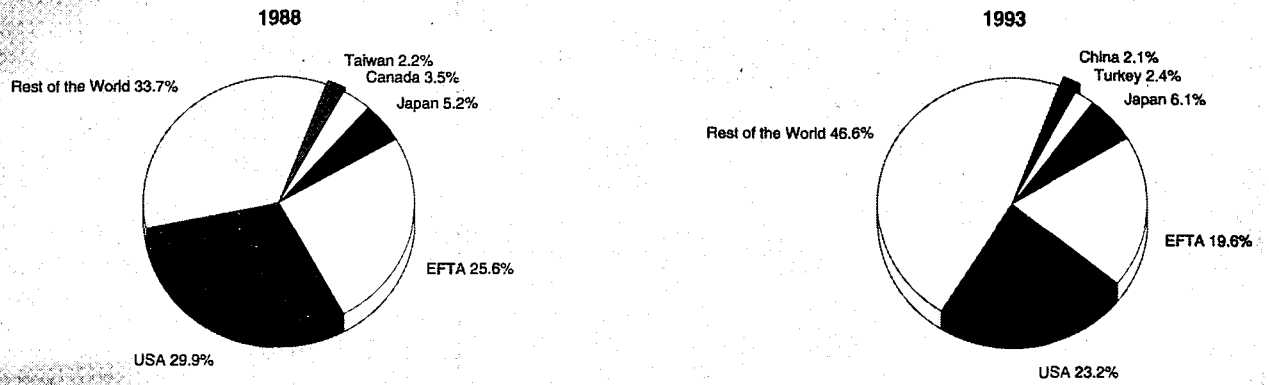

Source: DEBA

**Figure 5: Transport equipment  
International comparison of production in constant prices**

Source: DEBA

**Figure 6 : Transport equipment  
Destination of EU exports**

Source: Eurostat

Trade intensities differ significantly across sub-sectors. For example, in the motor vehicle sector imports account for less than 10 % of domestic apparent consumption, while only 12.5 % of production is exported. This peculiar aspect is the result of the strategy of internationalisation implemented by the major automotive producers, aimed at locating production plants near demand, leaving little need for extra-EU trade. In contrast, the aerospace industry is very open to trade, with both export intensity and import penetration at about 35 %.

Like in other industries open to trade, swings in currency values have made imported transport equipment cheaper than EU-produced equipment. This was among the factors that has tripled the value of extra-EU imports over the past decade and has significantly reduced the EU's trade surplus.

Since the mid 1980s, the EU transport equipment sector has experienced a number of major shifts in both the destination of extra-EU exports and the origin of intra-EU imports. Japan accounted for a higher share of EU exports in 1993 compared to 1988, to the detriment of the EFTA region and the USA. The notable decline in the share of exports destined for the USA can be mainly attributed to the depreciation of the dollar during that period. For the same reason, the USA has increased its share of extra-EU imports to 23.7 % in the five-year period

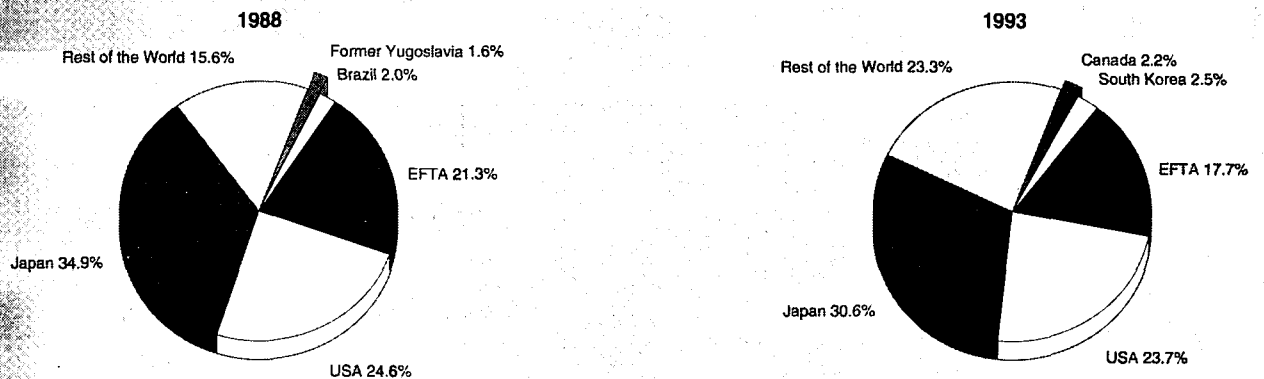

leading up to 1993, mainly to the detriment of the share imports from the EFTA countries and Japan. The latter country nevertheless keeps the lion's share of extra-EU imports, with more than 30 % of total extra-EU imports originating in Japan.

## MARKET FORCES

### Demand

The nature of demand for the different categories of transport equipment varies significantly. Private consumers are the single most important group of buyers for the bicycles industry, the mopeds and motorcycle industry, and for the motor vehicle industry (through demand for passenger cars). Consequently, overall economic activity, personal disposable income and demographic trends are overriding factors influencing demand for such equipment. It is no wonder, then, to observe that these sectors are characterised by a combination of short term cyclical fluctuations and long term growth. By contrast, the government sector is the aerospace industry's largest outlet through its military orders, followed by airline companies. As the latter, still constrained by financial difficulties, are not yet ready to make large investments, and demand for military equipment is severely constrained by shrinking de-

Source: DEBA, Eurostat

fence budgets, the aerospace industry is going through difficult times.

The shipbuilding and railway rolling stock industries have a relatively small number of customers, usually national or regional companies, which may be either private or public. These two industries are more sensitive to transportation and infrastructure policies, rather than to general income developments.

Certain factors may have a different impact on the various segments of the transport equipment industry, to the extent that forms of transportation are substitutes for each other (travelling by car versus rail or air travel, for example). For instance, an increased awareness of transportation's impact on the environment on the part of governments or of the general population may increase the use of public transportation, benefiting the manufacturers of public transportation equipment to the detriment of passenger vehicle producers.

### Supply and competition

As a whole, the EU transport equipment sector is fully capable of meeting the demand for transport equipment within Member States. As a matter of fact the EU maintains a trade surplus, albeit declining, in transport equipment on an annual basis. In the motor vehicle industry, Japanese competition clearly constitutes the main challenge faced by European producers over the next two decades. In response to such competition, EU car manufacturers need to further implement the lean pro-

duction techniques in order to at least maintain market shares. In the aerospace industry, the USA remains the formidable competitor, but newcomers, such as Indonesia, might represent a serious threat over the next two decades.

In the bicycle, mopeds and motorcycle industries, the EU has a growing trade deficit, and faces increasingly stiff competition from Asian NICs. In shipbuilding, countries such as Korea already are, while the CIS might become, strong competitors, challenging the EU's world market share.

The world-wide recession has been strongly felt in EU companies' profitability. The sales margin (ratio of profit to turnover), which peaked in 1989, has sharply declined since then. The most notable rise and subsequent fall in this trend occurred in the aerospace sub-sector, which experienced a considerable drop in orders for both civil and military aircraft.

### Production process

Confronted by a highly competitive market, the transport equipment industry has been forced to produce faster, better and cheaper. New forms of organisation and management of production have been implemented, along with new production methods. Innovations in the production process are particularly noticeable in the automotive industry, and to a lesser extent in the aerospace industry, where new techniques such as just-in-time production and increased emphasis on quality control are reducing production times and improving cost efficiency. The latter is of major concern for the transport equipment industry, which has experienced a strong deterioration of its cost structure, simultaneous to the inflation of unit labour costs.

Further rationalisation and implementations of automated production techniques are reducing employment in the sector. In spite of a brief period of relief in 1989 and 1990, the trend in employment is sharply downward. Since 1991, the decline has actually accelerated, with job losses of 2.6 % in 1992, followed by a further slump of 7.6 % in 1993.

## INDUSTRY STRUCTURE

### Companies

The transport equipment sector is well represented among the leading European companies. Daimler-Benz (D) is the largest European transport equipment manufacturer in terms of turnover. It is the third largest industrial company in Europe, and the eleventh in the world. The sector is highly concentrated. The top 6 % of the companies (i.e. companies with more than 99 employees in 1990) accounted for 94 % of the transport equipment industry's turnover.

The leading corporations in the transport equipment sector have interests in several segments. Many of the large volume car manufacturers, such as Renault (F), Fiat (I) and Daim-

Breakdown by size of enterprise, 1990 (1)**

(%)	Number of enterprises (units)	Share of number of enterprises	Share of employment	Share of turnover
Less than 20 employees	12 065	78.9	3.1	1.8
20-99 employees	2 092	13.7	4.9	2.9
100 or more employees	1 130	7.4	92.0	95.3

(1) Estimates.

Source: Eurostat "Enterprises in Europe"

ler-Benz, also have interests in the truck industry. Peugeot SA (F) produces mopeds, motorcycles and bicycles, whereas both Fiat and Daimler-Benz are involved in both the motor and aerospace sectors. Although there does not seem much evidence of industrial synergy in general, companies with dual interests are at least able to allocate risks across their diversified branches.

### Strategies

The long term strategy of the European transport equipment industry follows two parallel tracks; globalisation and rationalisation.

The consolidation of the European motor vehicles industry advanced in another major step early 1994 with the acquisition of Rover (UK) by BMW (D). The merger has created a seventh large producer of passenger cars in Europe, and has introduced BMW firmly as a competitor on the markets for off-road vehicles and small cars.

While no new mergers took place in 1994, the industry pursued its consolidation through partnerships, alliances and joint ventures. Collaboration is strengthening the links not only among EU companies, but also between EU companies and their American and Japanese rivals. The aim of such ventures is generally the development of new models and components. Cooperation in development through transnational alliances is regarded as the most efficient way to both increase development speed and share development costs. Usually, the products resulting from these cooperative ventures are marketed separately by the partners in the venture, under their own name, to maintain a clear distinction between brands.

Japanese companies are favoured partners for joint manufacturing agreements. Examples of such collaboration include General Motors' arrangement with Isuzu (JPN) to jointly produce vans in the United Kingdom, and Piaggio's (I) agreement with Daihatsu (JPN) which led to their common development

of a new microvan called Hijet, which was introduced on the market in March 1993. The Rover-Honda (JPN) alliance has existed for over ten years, but will end soon. After the acquisition of Rover by BMW, which Honda opposed, Japanese firm announced that it would dispose of its minority stake of 20 %, and increase the licensing fees charged to the existing cooperative ventures.

The European aerospace industry also continues to move towards greater consolidation. Compared to its American competitor the European aerospace industry is very segmented, resulting in a cost disadvantage. Mergers and cooperative agreements are seen as a way to achieve economies of scale in production and share development costs of new aircraft. In the last few years the number of transnational mergers has increased markedly in the EU. In the area of space systems Matra (F) and General Electric Company, a subsidiary of British Aerospace (UK) are currently planning a joint venture. In the segment of regional aircraft, DASA (D) acquired Fokker (NL) in 1993, and British Aerospace is currently in talks with ATR about merging their regional aircraft activities. In large aircraft the three leading producers, Boeing (USA), Airbus (EU) and McDonnell Douglas have been discussing collaboration in the development of new aircraft, notably a very large aircraft with 600 to 800 seats.

Consolidation is proceeding slower in the defence-related segments, where governments are reluctant to reduce control over national companies. Large economies of scale in production and development are forcing the industry towards cooperation, however. The intention to integrate the future large military transport aircraft programme into the Airbus commercial aircraft manufacturing and development system is significant. The integration of military projects within the Airbus structure is seen as a chance for Europe's industry to compete more efficiently against its US competitors.

### Impact of the Single Market

In general terms, the Single Market programme had a positive effect on the EU transport equipment sector. The chief achievements of the programme have been the free circulation of goods and capital, as well as the progress made in the field of cross-border payments. As a result of the measures enshrined in the programme, there has been enhanced competition within the various subsectors.

The full completion of the Single Market programme requires further harmonisation in the areas of public procurement, indirect taxation and cross-border payments. The general feeling in the industry is, however, that both competition and environmental policy should be implemented by taking into account the situation at world level, in order to avoid a deterioration of the competitiveness of the EU transport equipment industry.

### REGIONAL DISTRIBUTION

In 1992, about 87 % of EU production was concentrated in four Member States: Germany, France, the United Kingdom and Italy. For motor vehicles, these four countries accounted for 91 % of all value added within the EU. In the aerospace sector, EU's Big four countries produced about 94 % of value added in Europe.

The opening of frontiers with Eastern Europe promises to have a significant impact on the distribution of European production facilities, particularly for the motor vehicle industry. For example, many major West European manufacturers have already entered into agreements with East European producers, in anticipation of future rewards. Opel (the German subsidiary of General Motors), Volkswagen (D), and Mercedes-Benz have all set up production units in former East Germany. Fiat took over FSM in Poland at the end of 1992, and acquired a 30 % stake in VAZ, the Russian car producer. Among the other deals which have been successfully finalised, it is worth mentioning the purchase by Volkswagen in 1991 of a 31 % stake in Skoda, the Czech manufacturer.

In the aerospace sector, the CIS and the EU have agreed on principles of cooperation in the space industry.

## ENVIRONMENT

Transport has been one of the main targets of environmental regulations for several years. Transport services account for one-quarter of total carbon dioxide emissions (carbon dioxide is the main gas responsible for the "greenhouse effect"). Given the strong link between carbon dioxide emissions and energy consumption, heavy energy users such as the products of the aerospace and motor vehicle industries are likely to be under attack over the course of this decade. This could be to the benefit of some of the smaller transport sub-sectors like rail. In the area of personal transport, increasing congestion in most towns and cities, coupled with growing environmental awareness should benefit the bicycle, moped and motorcycle industry, as well as the public transport equipment sector. In the long term, the kind of solution adopted to solve the global warming problem is of major importance, given that it could lead to a significant shift in production between certain branches of the sector.

## OUTLOOK

The European transport equipment industry is recovering in 1994 from the bleakest year in its history. The market is coming back slowly, thanks to increasing consumer confidence and recovering balance sheets for the sector's customers. The gradual economic recovery is paving the way for improved performance of the transport equipment market in 1994. Exports remain the driving force in the market, but demand from within the EU also is reviving, especially in the motor vehicles industry.

The next three year period looks undoubtedly better than the previous one. The transport equipment sector will again enter a period of growth, which is expected to average 2.5 % per year to 1997. In spite of this upturn in activity however, the ongoing restructuring of the industry will continue, leading to further sizeable layoffs.

During the 1990s, European transport equipment manufacturers will face a number of important challenges, such as rising Japanese competition, environmental pressures and the development of the East European market. But the sector will undoubtedly benefit from the projected development of the European transport network, considered as a crucial factor to the harmonised development of the European Union.

# Motor vehicles

## NACE 351

The European car and commercial vehicle markets are presently recovering from the worst decline since World War II. In 1993 the industry suffered declines in sales greater than those which occurred after the first oil crisis in the early 1970s. Most of the industry operated at a loss in 1993, and car and commercial vehicle makers took drastic action to reduce production and cut jobs. The recession was accompanied by extensive short time working and increasing pressure on component suppliers to cut prices.

The recession highlighted the need for all vehicle manufacturers to accelerate the restructuring programmes needed to achieve global levels of competitiveness. All vehicle manufacturers are meeting this challenge by restructuring their development and production processes, re-evaluating their sourcing policies and improving skill and productivity levels.

### INDUSTRY PROFILE

#### Description of the sector

NACE 351 covers the manufacture and assembly of motor vehicles, and the manufacture of motor vehicle engines. Motor vehicles include passenger cars as well as commercial vehicles. All volume car producers also operate in the commercial vehicle market, especially the light commercial vehicle market.

Vehicle manufacturers also produce motor vehicle components and accessories (NACE 353) and are engaged in the distribution and maintenance of vehicles.

#### Recent trends

Worldwide sales of new cars increased from 33.1 million units in 1993 to about 35.0 million in 1994. In the EU market, 1994 sales recovered to 11.2 million units from 10.7 million in 1993.

While the UK (+7.7 %), Spanish (+18.7 %) and French(+13.5 %) car markets recovered in 1994, the demand for new cars declined further in Germany (-0.6 %) and Italy

**Figure 1: Motor vehicles**  
Value added in comparison with related industries, 1993

Source: DEBA

(-2.6 %). Recovery in the French and Spanish market was boosted by government-sponsored incentives for car replacement.

Sales of light commercial vehicles of less than 6 tonnes gw rose by 3.6 % from 1.57 million to an estimated 1.63 million between 1993 and 1994. Sales of trucks of more than 6 tonnes gw increased from 191 800 in 1993 to an estimated 199 300 in 1994 - an improvement of only 3.9 %. 1993 was the worst year for truck sales in Europe for some time.

According to Eurostat, the vehicle assembly industry employed 1.02 million people in the EU in 1994 (see Table 1), down from 1.23 million in 1990. Productivity improvements, restructuring, and rationalisation have all contributed to a steady decline in the level of employment in the industry. The downturn of the early 1990s exacerbated this situation and in 1993 many vehicle manufacturers announced the long term aim of large reductions in their workforce.

**Figure 3: Motor vehicles**  
**Vehicle assembly employment in the 5 principal EU manufacturing countries**

Source: DEBA

Imports from outside the EU accounted for 10 % of total consumption and exports to countries outside the EU accounted for 16 % of production in 1993.

The industry is a net exporter and an important positive contributor to the EU trade balance. Between 1985 and 1992 the surplus declined from 16.2 billion ECU to 5.6 billion ECU. The trade surplus recovered to 11.9 billion ECU in 1993. The main reason behind the decline was the loss by EU car-makers of third-country markets.

Vehicle manufacturers adopt pan-European if not global strategies, while exploiting strengths of specific countries and expanding their presence in the major markets through new investments, joint ventures and alliances.

Between 1984 and 1990, production increased in real terms by 33 % (see Figure 2). In the early 90s the industry was hit by recession, so that in 1993 production exceeded the 1984 level only by 11 %. In 1994 the industry recovered, but production still remained 11 % below the peak reached in 1990. New competitive dynamics have led to significant struc-

tural changes and implementation of new organisational and production processes. This has led to a reduction in employment levels. Total employment in the EU vehicle assembly industry fell from over 1.3 million in 1983 to 1.08 million in 1993, a reduction of 20 % (see Table 1). Employment, or rather unemployment, remains an important issue for the industry and the sharp downturn of vehicle production in 1993 exacerbated the situation. Over 260 000 jobs have been lost between 1984 and 1994. The recovery in 1994 did not prevent further job losses.

Figure 3 illustrates the employment trends in the five major EU countries. The German industry, which until 1991 witnessed increases in levels of employment, has suffered the largest job losses in recent years, as almost all manufacturers accelerate their rationalisation and productivity improvement programmes.

**International comparison**

In 1992, EU accounted for 37.2 % of worldwide cars sales, but this figure fell to 32.2 % in 1993 and 31.9 % in 1994. 37.3 % of worldwide car production took place in the EU in 1992 and this figure fell to 32.6 % in 1993 and 33.8 % in 1994. The EU was both the largest consumer of vehicles and the largest producing region for automobiles during the period.

In 1994, sales of cars in EU countries (including the three new Member States) amounted to 11.55 million compared to 9.79 million in North America and 4.20 million in Japan. Production of cars in EU in 1994 was 12.82 million compared to 7.82 million in North America and 7.80 million in Japan.

Between 1988 and 1993, in a world market which declined by 0.8 %, sales of cars in EU countries declined by 9.3 %. North American sales dropped by around 19.0 % and sales in Japan rose by 13.5 % (see Figure 4). In 1992, car sales in EU countries exceeded sales in the North American market by 3.4 million units. However, in 1993, this gap had narrowed to 1.2 million units as EU sales declined and North American sales picked up. In 1994, the gap increased again to 1.7 million units, following general economic recovery in the EU and the success of car replacement incentive schemes.

Trends in motor vehicle (car and commercial vehicle) production in value terms in the EU, USA and Japan are compared in Figure 5. The value of EU production in real terms has grown at a compound rate of 1.1 % p.a. between 1984 and 1993. This contrasts with 2.2 % per year in the USA and growth of 7.6 % per year in Japan (see Figure 6).

### Foreign trade

In the mid-1980s, North America was the most important export market for EU car manufacturers, and the major outlet for European cars above 3 000 cc. Unfavourable currency movements, recession in North America, increased competition from domestic car manufacturers and encroachment into the luxury sector by Japanese manufacturers have all contributed to the decline in exports of EU produced cars to North America (see Figure 7). 1993 saw the start of a recovery in exports to the USA and Japan, a trend which has been confirmed in 1994.

In recent years, some EU car manufacturers operating in the luxury cars segment have responded by announcing plans to invest in North American production facilities. As this capacity comes on stream, the EU trade surplus with North America could be reduced further. Car manufacturers based in the USA are well established in Europe, and the absence of direct imports from the USA has contributed to the EU trade surplus.

Figure 8 shows the share of various regions of origin in the number of passenger cars imported into the EU (unit terms). Figure 9 also shows the distribution of the origin of EU car

imports, but in value terms and for the entire motor vehicle market (including commercial vehicles). The share of Japan in EU car imports has fallen by more than 20 % in unit terms between 1988 and 1994. In value terms the fall was just under 6 % between 1988 and 1993, indicating the move upmarket by Japanese manufacturers. The increase in the number of Japanese vehicles assembled in Europe helped offset the fall in imports. EFTA's share has declined in value terms, while imports from Korea increased sharply from 21 000 units in 1988 to 99 000 units in 1994. In 1993, Korea and the USA accounted for 3 % and 8 % respectively of the total imports in value terms, compared to 1 % and 2 % respectively in 1988.

## MARKET FORCES

### Demand

#### Cars

Demand for cars is determined by a number of factors including personal disposable income, wealth and consumer confidence. Changes in these factors account for the cyclical nature of sales over the past two decades with economic downturns generally triggering slumps in new car registrations.

The West European passenger car market has grown steadily over the last twenty years, punctuated by two periods of downturn (see Figure 10). Demand for passenger cars slowed down in the early 1990s, and 1993 marked a deep drop of sales in most EU markets. In 1994 demand recovered modestly.

In the long term, as motorisation rate continues to grow, demand for cars will continue to rise. Average car ownership figures vary widely across countries as illustrated in Figure 11. It was nearly 600 units per 1 000 inhabitants in Western Germany prior to unification. In the larger EU economies (with the exception of Spain) over 400 cars per 1 000 inhabitants are counted, but in countries as Portugal, Greece and Ireland car ownership is considerably lower. There is further scope for increases in car ownership throughout the EU, especially in countries where car ownership per capita is currently low.

#### Trucks

Demand for trucks is highly correlated with trends in industrial output and in investment in plant and machinery.

Long term demand for trucks is highly dependent on trends in the road haulage industry, which in turn is affected by the

**Figure 7: Motor vehicles**  
Destination of EU exports

Source: Eurostat

**Figure 8: Motor vehicles**  
Share of EU car imports of passenger cars

Source: DRI Europe

level of economic activity and by the competitiveness of road haulage with respect to other transport modes. Over the past two decades, the road haulage sector has consistently gained market shares against rail and inland waterways. This trend is expected to continue.

While demand for freight transport is expected to grow strongly in the future, demand for trucks will not follow all the way. Harmonisation and deregulation of the road haulage industry is resulting in the use of larger trucks and in increased efficiency. The EU truck fleet will still grow, but truck replacement patterns will be dominating factor in determining the overall levels of demand of new trucks.

The commercial vehicle market is highly cyclical. The market suffered dramatic downturns in the mid-1970s and the early 1980s. In the late 1980's, increased economic activity led to very strong growth in road freight transport demand, with a corresponding growth in the size of the EU fleet. This was accompanied by high replacement demand (to replace the vehicles initially registered in the late 1970s) and led to a boom in the truck market.

1990 saw the beginning of a cyclical downturn in EU sales of trucks of more than 6 tonnes gvw. Booming sales in Germany after the re-unification cushioned this decline but sales dropped sharply in 1992 and in 1993, with only the UK showing signs of recovery. In 1994 a more general recovery was underway.

**Supply and competition**

Cyclical under-utilisation of capacity is one of the key issues facing the European vehicle assembly industry at present. During the boom of the late 1980s, the industry was operating very close to full capacity. In this period the European assemblers expanded total capacity, mostly through elimination of bottlenecks and new shift practices.

With the recent addition of new transplant capacity as well as capacity in Eastern Europe and a steep decline in sales, there are serious implications for vehicle manufacturers' profitability. In stagnating markets, increases in productivity are only possible by further manpower reduction.

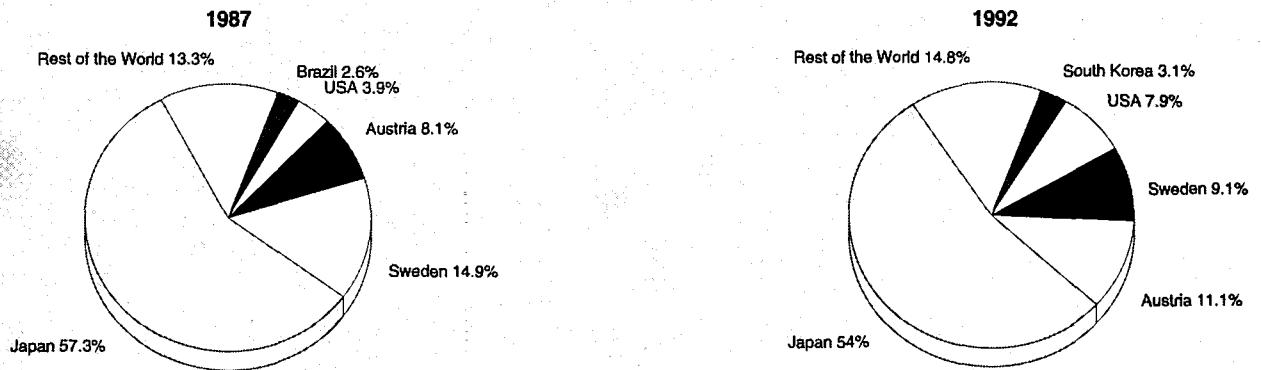

A challenge for European manufacturers is posed by Japanese production in Europe, where Nissan, Toyota and Honda are already claiming global competitive levels of quality and efficiency. While Japanese imports are liable to remain broadly stable in market share terms, chiefly as a consequence of the rise of the Yen and high labour costs in Japan, significant growth in Japanese manufacturers' market share will come from the output from these transplants.

Newly industrialised countries, for example in East Asia, and East European countries are adding to the competition in the EU. Although the volume of imports into the EU from these countries is still at a relatively low level, the EU market is attractive to importers. Plans for new models and distribution capacity indicate an ambition from Korean companies to raise European sales substantially. This would have a direct impact on European produced passenger car sales. Japanese car manufacturers played a key role in the development of the Korean and Malaysian automotive industries with Mitsubishi having close ties with Hyundai of Korea and Proton of Malaysia, and Mazda having ties with Kia of Korea.

Several studies have shown that Europeans have a relatively high cost to productivity ratio. Figure 12 shows an international comparison of wages and social costs for 1992. The data shown should be interpreted with caution, in particular the high labour costs of the German industry.

Employers in most EU Member States have higher social costs and have less flexibility to make adjustments to the

**Figure 9: Motor vehicles**  
Origin of EU imports

Source: Eurostat

**Figure 10: Motor vehicles  
Historic demand trends**

Source: DRI Europe

labour force in response to changing commercial requirements than their global competitors.

Reduction in unit costs through productivity improvements in all parts of the supply chain is, along with the search for innovation and quality, the most important issue facing the industry.

**Production process**

In recent years, changes in the production and operational philosophies in the motor vehicle industry have led to widespread adoption of "lean production" techniques, resulting in lower levels of vertical integration and substantial changes in the nature of :

- relationship between vehicle manufacturers, its suppliers and dealers;
- coordination between product design and the production process;
- production and logistic operations;
- workforce responsibility, flexibility and skill levels.

**Figure 12: Motor vehicles  
International comparison of wages and social costs, 1993**

Source: VDA 1992

**Figure 11: Motor vehicles  
Comparison of car ownership levels in the EU**

Due to a change of statistical source, figures for 1992 and 1993 are not comparable.  
Source: DRI Europe

Benefits have included a reduction in the development time from initial concept to production, improvements in quality and productivity, and increased flexibility and responsiveness.

Changes in the interaction between vehicle manufacturers and component suppliers are widely seen as instrumental to achieving global standards of competitiveness. These changes imply a restructuring of the automotive component supply chain with ramifications for the production and logistics processes (see section on Industry Structure). It is now common for the level of co-operation between vehicle manufacturers and suppliers to extend to joint development of complete subsystems and assemblies, and their supply to the assembly plant on a Just-In-Time basis.

Shorter reporting lines, improved interfaces between management and workforce and better communication systems are contributing to the successful implementation of Total Quality Management, Quality Circles and Continuous Improvement programmes, with resulting improvements in productivity and quality. Flexible shift-working is already leading to better utilisation of plant and equipment.

Improvement in flexibility through reduction in machine set-up time, optimisation of batch size and reduction in raw materials, work in progress and finished goods inventory are all part of common continuous improvement programmes. The recession has placed additional emphasis on the need to reduce break-even volumes.

The Simultaneous (or Concurrent) Engineering approach, involving the use of multi-disciplinary teams to control a design project with the use of specific techniques such as QFD (Quality Function Deployment) and DFMA (Design for Manufacture and Assembly) and complemented by widespread use of tools such as Computer Aided Design (CAD) and Computer Aided Engineering (CAE), is widely implemented by car manufacturers.

New automated equipment has been introduced in the production steps, where working conditions are hardest and most repetitive. Widespread use of robot painting and welding in the industry is improving quality, reducing labour costs as well as reducing the mundane and hazardous manual operations. Optimisation of capital to labour ratio will remain a key factor in improving competitiveness. The latest trend no longer features an ever-increasing automation of operations. Final assembly largely remains the domain of the manual employee, due to the variety and complexity of the operations. While "state of art" work practices have been adopted in many

of the newer vehicle assembly plants. EU manufacturers face the task of extending these practices to all their plants and all aspects of their activities.

The abolishment of major elements of selective and exclusive distribution will constitute a barrier for the introduction of innovative integrated manufacturer-dealer partnerships.

## INDUSTRY STRUCTURE

### Companies

BMW's acquisition of the Rover Group has turned the "big 6" into the "big 7" EU manufacturers (see Figure 13). In 1993 the Japanese market share fell to 11 % from 12 % in 1992.

While five manufacturers have car market shares of between 10 % and 13 % at European level, a different picture emerges at country level. The individual markets are still dominated by domestic manufacturers. Vehicle manufacturers tend to have larger distribution infrastructure in their respective domestic markets and preference for locally produced cars still plays a significant role in some markets.

In the market for light trucks Renault and Ford have the largest shares due to their successful range of vans (see Figure 14).

In the market for trucks over 6 tonnes gvw, Mercedes-Benz is the clear leader. Its market share has risen from 23 % in 1989 to 31 % in 1993. Both Mercedes-Benz and MAN benefited from the reunification boom in Germany in 1992 and were the only manufacturer to record higher levels of sales in 1992 than in 1989 (see Figure 15).

### Strategies

Vehicle manufacturers' strategies respond to long term trends affecting the industry. The 1993 slump in motor vehicles sales has accelerated the implementation of long term strategies and resulted in a re-examination of the more ambitious expansion programmes. Key long term trends which shape vehicle manufacturers' strategies include:

- Globalisation: the need to reduce traditional dependencies on domestic market and improving ability to compete initially at European level and subsequently on a global level. While non-EU manufacturers have been investing in transplant production facilities in EU, EU manufacturers have been active in investing outside their home country as well

in non-EU countries, particularly in Eastern Europe and North America. Asian markets are enjoying high growth rates and this region has already attracted a lot of attention. EU manufacturers are expected to increase their presence in this region, especially through joint ventures.

- Product Development : the rate at which new vehicle models are introduced into the market place has become one of the key basis for competition in the automotive industry. Car manufacturers are speeding up and restructuring their innovation, product and process activities (Simultaneous Engineering) to reduce the time from initial concept to production. Continuous improvements in the flexibility of designs and processes are needed to ensure maximum customisation to consumer requirements. Evolution in manufacturers' market shares reflect the rates of new model introductions.
- Improved competitiveness through improvements in organisational processes: cost structure, productivity, quality and flexibility have all become crucial elements of competitiveness.

The 1993 recession in the industry has highlighted the need for all vehicle manufacturers to accelerate the restructuring programmes needed to achieve global levels of competitiveness. Manufacturers are:

- restructuring their design and production processes (see section Production Process);
- re-evaluating the degree of vertical integration, out-sourcing policies and supplier relationships;
- improving workforce skill levels.

In the short term, each EU manufacturer is faced with different priorities and this is reflected in their strategies.

The late 1980s and the early 1990s saw a reduction in the number of independent motor vehicles manufacturers, as niche producers were acquired by volume manufacturers. As product and business development costs escalate, partnerships and alliances are increasingly regarded as providing the most cost effective method of developing a competitive product portfolio and reducing dependence on domestic markets.

Alliances between Ford and Iveco in the light commercial vehicle market, between PSA and Fiat, and Ford and VW for development and production of a multi-purpose vehicle, and between Ford and Nissan for development of a four wheel

drive vehicle, are examples of joint product development and production alliances.

Rover and Honda worked together on a number of collaborative projects before taking a cross share holding of 20 % in each others UK businesses in 1990. Both companies now produce versions of jointly developed cars. This alliance has come to an end by the acquisition of the Rover holding company by BMW AG.

### Impact of the Single Market

According to the industry, the Single Market programme had a definitively positive impact on the car manufacturing sector. The free movement of goods has opened up new market opportunities, which the major manufacturers seized by spreading their production facilities throughout the EU. Carmakers' operations with subsidiaries have been also eased by the achievement of free movement of capitals and progress on the front of cross-border payments.

The full completion of the Single Market still requires the harmonisation of taxation systems and further progress in the field of cross-border payments. More specifically to the sector, the free movement of goods is still hampered by different national registration formalities. The first important step towards the free circulation of cars within the EU was the European type approval, i.e. a car whose technical specifications are approved in one Member State must be approved all over the EU. Since January 1, 1993, EU type approval has been in force on an optional basis, prior to its mandatory application in 1996. Since then, manufacturers have only needed to take into account a single set of rules to market their products (whole vehicles, or parts thereof) throughout the EU. Nowadays, harmonisation is still required in the national registration procedures, which still vary from country to country. Finally, the industry also asks for the harmonisation of classification systems within the EU: what is considered a passenger car

in one country can be defined as a light commercial vehicle in another country. This entails taxation differences and blurs the statistical picture.

### ENVIRONMENT

The reduction of emissions achieved by the EU motor vehicles in the past few years industry has been impressive. However, further technical improvements are becoming harder to achieve. Progress in the areas of driver education, more frequent and stringent vehicle inspection and the use of road telematics to reduce traffic congestion are likely to prove more effective strategies for reducing emissions.

Since the early 1970s, EU legislation has controlled the emission of both unburned hydrocarbons and carbon monoxide. In 1978, oxides of nitrogen also became subject to control. The "Luxembourg Agreement" of 1985 marked a significant step for future emissions standards and effectively initiated developments which were to lead to directive 88/76/EEC and the requirement of the 3-way catalyst system.

The EU has moved rapidly in introducing a series of further light duty vehicle directives, 89/458/EEC and the present newly consolidated Directive, 91/441/EEC. This directive added a high speed test to the standard test cycle to take account of emissions in suburban driving situations. In March 1994, the Commission issued directive 94/12/EEC aimed at tightening car emission limits further. This directive also incorporates a totally new method for conformity of production (COP) testing. These limits will come into force in 1996/1997.

Emissions of light commercial vehicles have been reduced to the level of passenger cars emissions with Directive 93/59/EEC of June 1992. Following the introduction of the most recent emissions standards at the end of 1992, passenger car CO emissions will have been reduced by over 90 % com-

pared to 1970 levels and HC plus NO<sub>x</sub> emissions by 80 % from 1970 levels.

During the last decade, the European automotive industry has invested heavily in improving the environmental performance of vehicles. The technical changes required to meet these regulations were substantial, with the consequence of higher costs which could not always be passed on to consumers. Gasoline engine passenger cars needed to be fitted with closed loop catalytic converter systems, which in turn required electronic fuel injection and management systems.

During the next decade, while vehicle ownership levels and traffic levels will continue to increase, older models will be replaced by models equipped with 3-way catalyst systems and the European car park is expected to produce substantially less emissions of CO, HC and NO<sub>x</sub> than today.

Legislation for heavy duty diesel vehicles followed along a similar path. Regulation No. 49 was introduced in 1982 and established limits for CO, HC and NO<sub>x</sub>. Directive 88/77/EEC lowered the emissions limits but it was not until the introduction of 91/542/EEC that fundamental changes in technology became necessary.

Euro 1 regulations came into force in 1992-93 and Euro 2 limits will come into force in 1995-96. Complying with Euro 2 limits without increasing fuel consumption and without using expensive after-treatment equipment presents a major technical challenge for the European industry. A further tightening of

emissions limits (Euro 3) can be expected before the end of the decade but this is still under discussion.

With the introduction of new limits for cars and trucks, a complete set of stringent standards, acknowledged to be as severe as the US 1994 requirements will be in force by 1996. These will set the EU on course for substantial improvements by the end of the century

Road transport is estimated to account for around 20 % of total European carbon dioxide emissions and reducing fuel consumption is the only method of reducing these emissions. Vehicle manufacturers have made substantial progress improving fuel efficiency, (for example through reducing drag factors and improving the combustion process and weight reduction) but in order to contribute to the goal of stabilising carbon dioxide emissions at 1990 levels by the year 2000, improvement in both traffic efficiency and fuel consumption will be needed.

Disposal/scraping of vehicles at the end of their lives, is another issue receiving attention, by the vehicle industry, regulators and environmental groups. Some of the manufacturers have already set up recycling plants and EU manufacturers appear to be leaders in this field.

## OUTLOOK

1993 will be remembered for the sharpest downturn in European production since the 1974 oil price induced recession. Output fell by 15.4 % or nearly 2 million units to 11.4 million units. Of the major EU markets, Germany, France, Italy and Spain all showed reductions in sales in 1993 of around 20 %, but the UK market recovered and increased by over 11 %.

Car production recovered to 12.8 million units in 1994, with Japanese transplant production accounting for a significant part of this growth, increasing from 316 000 units in 1993 to 330 000 units in 1994. In 1994, car sales in the EU also rose by 5.6 %.

According to DRI, total EU sales are expected to increase in 1995 by around 4.0 %: 1995 should see growth in all the major EU markets. Sales in Germany, and France are expected to grow slowly (1.7 % and 1.3 % respectively); on the other hand, growth will be stronger in the UK (2.7 %) and particularly Italy (7.3 %). EU sales are not expected to reach 1992 level of 12.6 million units until 1997.

After achieving 5.1 % growth in 1992 (re-unification boom), the light truck market declined by 18.3 % in 1993. A 2.6 % recovery took place in 1994 and sales will not return to 1992 levels until 1997.

Truck sales dropped sharply in 1993, after sputtering for four years. The market declined by 23 %. Sales were down in all markets with the exception of the UK. Germany, Spain and the Benelux countries, in particular, suffered major falls in

**Figure 15: Motor vehicles**

Source: DRI Europe

demand. Demand for 1994 remained weak and the market grew by 2 %. A revival of demand of around 10 % is expected in 1995.

All EU vehicle manufacturers are expected to continue to streamline their operation to reduce costs and improve competitiveness. Introduction of four-wheel drive and multi-purpose vehicles will dominate car product development programmes in the short term. Joint development and production, already used with success in such programmes, is expected to continue as complexity increases, development costs escalate and manufacturers look for cost effective alternatives.

Apart from remaining financially viable in a difficult market, the attention of truck manufacturers will be focused on meeting the 1995-96 emissions legislation (Euro 2).

# Motor vehicle parts and accessories

NACE 353

The motor vehicle parts and accessories industry employs nearly the same number of people (approximately 1 million) as the motor vehicle industry it supplies. The parts and accessories sector presently includes a sizeable number of small firms; however, greater industry concentration is expected as trends in vehicle production techniques increasingly demand tighter cooperation with the parts and accessories industry. The business climate for parts and accessories is strongly tied to the cyclical performance of the motor vehicle sector. While supply of parts for new cars closely reflects fluctuations in new car demand, superimposed on this are several trends with long term influences. There has been a steady upgrade in car model mix to larger and better equipped models. At the same time, equipment levels on all vehicles is continuously improving, thereby increasing the value to component suppliers. Acting contrary to this, however, is the demand for improved durability and life expectancy of all vehicle components which has a significant effect on replacement demand. While the European car parc will continue to grow through the 1990's, much of the new car sales growth will be taken by Japanese transplants. The challenge for the European parts industry is to supply this demand and, in doing so, raise its performance to best world standards.

## INDUSTRY PROFILE

### Description of the sector

The parts and accessories market is traditionally broken down into two main segments. The first is the market for original equipment (OE), that is parts that car manufacturers buy from specialised producers for assembly into new vehicles. The second is the replacement market (or AM: after-market) which comprises parts destined for maintenance and repairs and automotive accessories. Roughly 75 % of the production goes to the OE market and 25 % to the AM market, although this can vary depending on the country and the individual product.

The precise coverage of the component industry in terms of products is difficult to assess. Data which corresponds to NACE 353 (parts and accessories for motor vehicles) is too narrow in its coverage as it excludes, for instance, heavy construction vehicles, tyre manufacturers who supply vehicle manufacturers, and most of the electrical and electronic components that are so important in vehicle manufacturing today. Furthermore, existing statistics, which are based on the production of companies of more than 20 employees, marginally understate the value of production of this highly fragmented industry.

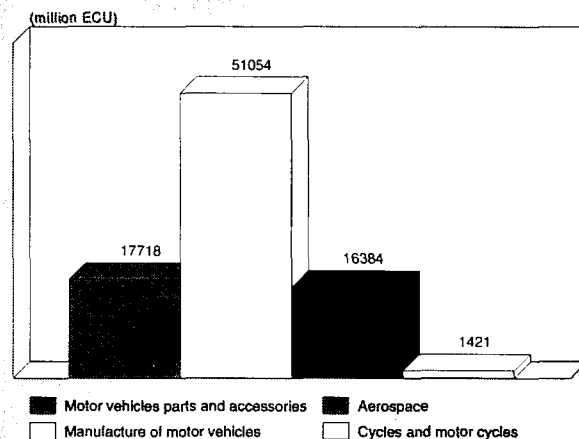

A study carried out for EU DGIII, also sourced in this monograph, covers a wider range of products than the strict NACE definition.

### Recent trends

With turnover estimated at almost 100 billion ECU, the EU parts industry is about half the size of the auto industry. In terms of employment, however, the parts and auto industries are much closer in size, with each having over 1 million workers. Figure 1 shows that the auto component industry adds more value than other well known industries in Europe.

Within the parts and accessories sector, independent manufacturers account for nearly 90 % of both production and

Figure 1: Motor vehicles parts and accessories Value added in comparison with related industries, 1993

Source: DEBA

employment, with the remaining 10 % stemming from subsidiaries of vehicle manufacturers.

Turning to the breakdown of production by Member States, leading vehicle producing countries are also leading parts manufacturers. Germany accounts for more than 45 % of EU turnover, followed by France, the United Kingdom, Italy and Spain (see Figure 2). Similar rankings can be observed in the auto and parts industries. This is explained by a frequent geographical clustering of parts manufacturers in proximity to vehicle production sites.

During the 1980s, the parts industry expanded somewhat faster than its main industrial end-market, the auto industry. It grew consistently between 1982 and 1990, remained flat in 1991 and then dipped in 1992 and 1993, following the downturn in the vehicle market (see Figure 3).

After a 16 % drop in 1993, EU demand for passenger cars and light commercial vehicles increased by 5.6 % in 1994. Car makers are expecting new car demand to continue on its

Source: DEBA

way to recovery in 1995, although not quite to the 13.5 million level of 1992. This will continue to affect components suppliers, although they have the replacement parts market to marginally help buffer the fall in original equipment demand. In addition, a reduction in new car purchases results in the car parc (cars in use) getting older on average, resulting in more maintenance and replacement part expenditure.

Productivity improvements in the parts industry have been marginally faster than improvements in the vehicle manufacturing industry, on average. Improvements have been achieved thanks to rapidly expanding production rather than lay-offs and, as a result, employment was still higher in 1991 than in 1982. A substantial proportion of productivity gains have been transferred, by negotiation and sometimes by imposition, to the car makers so that upward price adjustments of parts and accessories have lagged far behind vehicle price increases. Car makers have partially reinvested their differential pricing gains in enriched vehicle equipment, thus keeping their suppliers' level of activity buoyant well into 1992. The sharp downturn in vehicle demand and production did not become visible until 1993 due to German reunification.

### International comparison

Once relatively sheltered from foreign competitors, EU component suppliers are now facing increased domestic, European and world-wide competition. This trend is fostered by several factors:

- The creation of the single market is forcing European suppliers to intensify cross-penetration of each others' markets.
- The increased internationalisation of EU car producers results in a geographically enlarged supply base, with tougher competition prompting a constant search for lower cost suppliers.
- The trend towards global supply contracts, rather than national and regional contracts of the past.

The Japanese component industry has several serious competitive advantages over its European counterpart. Although smaller than the EU industry (280 000 employees in first tier

suppliers, compared with 1 million people), the Japanese component industry is much less fragmented and already benefits from the tiered structural shape which the EU industry is presently constructing. Aside from the 40 000 sub-contractors who form the second and third tiers of the pyramidal structure in the Japanese industry, there are only 310 first tier component suppliers, compared to 3 200 companies in Europe. The average size of the first tier enterprises is 900 people compared with the European average of 270. Including the sub-contractors, the per company average of employees would be just 5.5. Of the Japanese firms, 45 % employ more than 500 people, compared with only 10 % in Europe.

Japanese companies have close organisational and financial links with vehicle manufacturers, and most of them are attached to groups around a major manufacturer. For instance, Nippondenso (the largest Japanese component producer) is partly owned by Toyota. Many component producers are owned by more than one vehicle producer. This system has resulted in an industry which is more specialised and concentrated than the European industry.

According to a study undertaken for the EU Commission, the EU industry remains competitive with Japan in terms of technology, but suffers (in its first-tier segment) from several disadvantages such as lower labour productivity, lower product quality, lower stock turnover, and slower design and development cycles.

When the Japanese car manufacturers started building cars in North America, their inclination was to put pressure on their traditional suppliers to come with them and set up new plants. While they needed high local content, they did not think that existing US component companies would be willing or able to provide them with components and systems of the quality and at the price they were accustomed to receiving from their close knit "keiretsu" suppliers. As a result, Japanese component companies set up over 300 plants in the US during the 1980s to support the growing vehicle production.

For several reasons this has not been repeated in Europe. One reason is that the projected volume of cars built in Europe

is, in many cases, too small to justify setting up new plants solely for transplants. The financial performance of the Japanese component companies in the US, to date, has been a growing cause for concern and, with falling margins throughout the Japanese car industry, they are not looking to repeat this mistake. Another reason is the intense political concern in Europe over the arrival of the Japanese transplants. The Japanese car companies have taken pains to reassure governments that they will be good Europeans, and one way of doing this has been to choose European component suppliers. While there have been some 50 new component plants set up by Japanese companies to date, and a few notable acquisitions or joint ventures (such as Calsonic and Nippondenso), for the most part, Japanese car producers have selected existing European companies to supply their components. What is

more, the Japanese car companies, particularly Nissan and Toyota, have set out, where necessary, to bring these companies up to Japanese standards. In so doing, they are making a real contribution to the European component industry. In Europe there has traditionally been an adversarial relationship between the vehicle makers and their suppliers, with the vehicle makers continuously demanding lower prices and threatening to use competitors. While this is now beginning to change, the Japanese have been much more concerned about their suppliers' costs, and helping them to improve their quality and efficiency. Thus, they have developed more constructive and certainly more long-term partnerships. The long-term result of the arrival of the Japanese transplants in Europe will be to accelerate the restructuring of the components industry and to help raise its standards to world class. The benefits of this will be available, not only to transplants, but to all European vehicle makers.

Starting from this idea that the collaboration between automobile manufacturers and automobile suppliers should be based on a mutual trust and a mutual gain relationship, ACEA, the representation of the European automobile industry, and CLEPA, the association of the European automotive supplier industry, have recently agreed on "European guidelines for cooperation between automobile manufacturers and their suppliers". These guidelines aim at further improving the two industries' relationship by means of joint problem and solution sharing, and joint search for perfection in quality, logistics, administration and customer satisfaction.

Figures 4 and 5 compare component production in the USA, Japan and Europe. In the USA production stagnated in the period from 1984 to 1993, while it doubled in Japan and increased by 75 % in Europe. However, while the USA was recovering in 1992 and 1993, Japan and Europe were still feeling the effects of recession.

### Foreign trade

The internationalisation of the industry has been a determining factor in the substantial increase in foreign trade since 1980. The expansion of intra-EU trade has been particularly rapid in recent years as intra-EU trade reached the 14 billion ECU level in 1991, a threefold increase compared to 1980. The industry remains essentially intra-EU oriented and intra-EU imports are more than 4.4 times higher than extra-EU imports, a ratio which is usually in the 2 to 2.5 range for most of the other engineering and transport industries. Given the difficult nature of defining the industry, a word of caution regarding trade figures is in order. Statistics on trade are not necessarily related to the independent component industry's products, but frequently include the movements of the vehicle makers own in-house products to and from assembly plants across national borders, thus causing significant distortions in the data.

The industry is a traditional balance of payment earner. After a peak in 1985, when it reached 6.5 billion ECU, the EU trade surplus decreased to almost 2.5 billion ECU in 1991. The second half of the 1980s were marked by a rapid increase

in extra-EU imports and a relative stagnation in extra-EU exports. This situation is partly attributable to a change in the classification of trade statistics and, more importantly, to the rapid growth of car demand experienced in Europe between 1986 and 1990. During that period, European parts producers were predominantly busy trying to meet increased demand from EU car manufacturers. As a result, their export effort remained limited, while imports were boosted by the buoyancy of the EU car market. Nevertheless, the trend was not really reversed in 1990 and 1991 when European vehicle demand was somewhat weaker. The dwindling European trade surplus certainly signals some of the structural problems presently encountered by the European industry.

Extra-EU exports are relatively diversified in terms of destinations with the EFTA countries and North America respectively accounting for about 24 % and 20 % of total shipments. Developing countries also remain an important end market with a share of more than 35 %. In terms of extra-EU imports, flows are more concentrated with 50 % of total non-EU supply originating from the EFTA countries, Sweden in particular. With a share of 20 %, Japan is the second largest supplier to the EU. Trade with North America has dwindled considerably in recent years both in terms of imports and exports. With regard to the EU trade surplus, Germany continues to be the major contributor.

**Figure 4: Motor vehicles parts and accessories  
International comparison of production in current prices**

**Figure 5: Motor vehicles parts and accessories  
International comparison of production in constant prices**

**Demand**

Component demand is linked to the level of automotive production. However, some components benefit from faster growth than the auto market in general. This situation exists where a component's rate of penetration of vehicles is still on the rise, such as where equipment which previously was optional (primarily in the upper car segment) is now fitted as standard on most models. Some examples include: electronic fuel injection, anti-lock brakes and air conditioning systems. In addition, component manufacturers have benefited from a trend towards increased out-sourcing.

On the other hand, demand for replacement parts depends on the usage of cars and other motor vehicles, as opposed to new sales. Demand is likely to be more stable in this market than in the original equipment market. The replacement parts market differs greatly from country to country. Market features in various EU countries depend largely on the annual mileage per vehicle, the age of the car parc and the existence of specific legislation with regard to obligatory inspection of vehicles when they reach a certain age.

**Supply and competition**

The supply of original equipment is undergoing fundamental structural change. Increasing internationalisation of vehicle manufacturers calls for the emergence of large international (sometimes world-wide) component manufacturers. In addition, the pattern of relationships between manufacturers and suppliers is being substantially modified. A rising share of the value added generated in the auto industry is transferred from vehicle to component manufacturers. To some extent, the balance of power is now shifting from the former to the latter. A good example is the Ford Mondeo launched in 1993, which uses the same supplier for many components in both North America and Europe.

A major reason behind such a change arises from the necessity for car manufacturers to limit investment and resources to essential activities which represent the core of their industry. One method is to increase out-sourcing and to pass on the responsibility for product development, manufacturing and quality assurance functions to their suppliers (systems suppliers and/or specialised affiliated companies). Component producers contribute to the competitiveness of the industry, and the two sectors become increasingly interdependent.

Although conceiving, designing and producing in accordance with manufacturers' specifications, the component producer is increasingly technically autonomous. This is typically the case with systems suppliers who possess proprietary technology and product know-how. As a result of these transfers of value added, car manufacturers reduce the number of their suppliers to a smaller number of large producers, who in turn out-source part of their output to smaller companies; thus, the whole supply chain forms a tiered structure.

It is generally accepted that the overall level of outside purchasing carried out by European car manufacturers (60 % to 70 % of total component requirements) is more important than in the US industry (40 % to 50 %), but less than in Japan (around 80 %). However, within the EU there is a great variation between manufacturers.

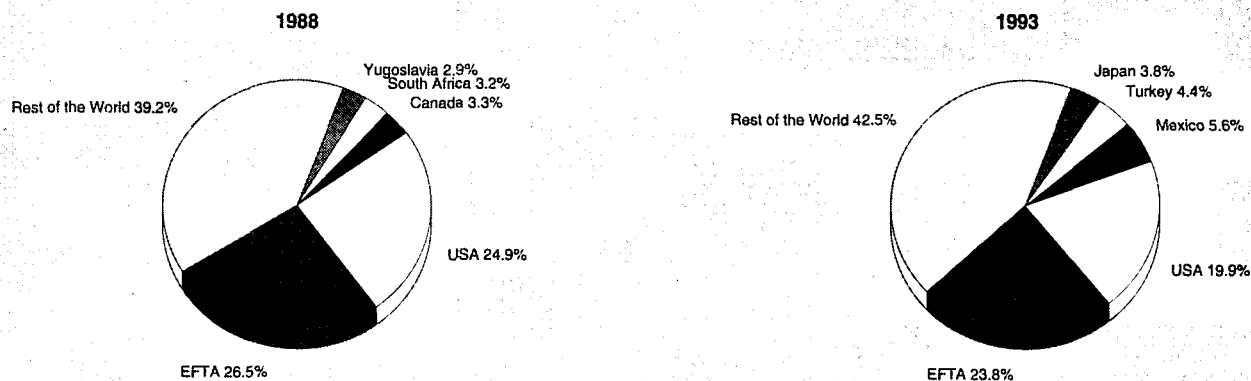

Turning to the market for replacement equipment, it is estimated that about 70 % of the market is supplied by independent parts manufacturers, with the remaining 30 % controlled by car manufacturers via their distribution and service networks. With regard to the origin of such parts, however, car manufacturers only take a 10 % share of the market.

**Production process**

The nature of automotive products, together with shorter product life cycles, has put increased emphasis on the technological content of automotive parts. More use of electronics and new materials has led to increased collaboration with other leading high-tech industries, and a sizeable investment in R&D at all levels of the pyramidal structure of the component sector. Once almost exclusively oriented towards applied engineering, R&D resources of the sector are now taking greater initiative in terms of new technologies offering improved performance, fuel economy, emission control, safety and comfort. Suppliers have an increasing involvement during the early stages of the development process of new vehicles.

Competitive pressure on costs, prices, quality and delivery standards has led the industry to restructure in a parallel manner to that of car manufacturers. Automotive parts suppliers compete on the basis of price, as well as, delivery and quality. Just-in-time, zero-defect, CAM (Computer-aided manufacturing), automation, and faster communication systems are some of the features which have allowed substantial productivity gains while improving flexibility and allowing quality assurance schemes to be put in place. Linking of these various systems, combined with electronic linking of component sup-

**Figure 7: Motor vehicles parts and accessories  
Origin of EU imports**

Source: Eurostat

pliers and vehicle manufacturers will provide long term efficiency benefits. However, this process (requiring sizeable investment and a recourse to skilled manpower) is far from being complete, especially among small to medium-sized producers.

## INDUSTRY STRUCTURE

### Companies

The industry is basically composed of three types of producers: large system suppliers with a global presence and substantial R&D capability; medium-sized first-tier component suppliers also increasingly with in-house R&D capability; SME second- and third-tier parts suppliers.

The trend towards more component out-sourcing by car manufacturers combined with fundamental changes in the nature of the industry are having a dramatic impact on the number of independent operators present in the industry. Vehicle manufacturers are cutting back on the number of suppliers and committing larger shares of their purchasing requirements to preferred systems suppliers. These systems suppliers then out-

source part of their work to second or third tier suppliers. Overall, during the period 1988 to 1993, it is estimated that each single vehicle manufacturer has reduced by almost 50 % the number of its direct independent suppliers. A large part of this reduction has been achieved via mergers, take-overs and consolidations among previous competitors or companies having industrial synergies, such as Valeo and Neiman and also Magneti-Marelli, Solex, Jaeger and Weber. However, the total number of suppliers directly servicing the vehicle makers should not have decreased by more than 25 %. Supply relationships are, however, very difficult to estimate given the large number of models produced by manufacturers, and the underlying groups of parts suppliers supporting each model line.

In spite of the increased presence of large international companies, the original equipment sector continues to be very fragmented. The average size for firms is about 270 people, but 64 % of these enterprises employ less than 100 persons. Only 4 % of the companies account for 50 % of total employment (firms with more than 1 000 employees). This is essentially due to the nationally based nature of parts procurement. Although intra-EU trade has grown to extremely high levels during the past decade, most vehicle manufacturers continue to source largely from their domestic suppliers. For instance, Daimler-Benz procures approximately 90 % of its needs from Germany, Renault, about 70 % from France, and Fiat, about 85 % from Italy.

The independent German industry dominates the European market with over 45 % of total European production (estimated at 79 billion ECU in 1988). This strength comes from the sheer size of the German motor vehicle industry, the importance of the upper market segment, and from strict legislation on car maintenance. The large German firms have played a major role in developing new products as illustrated by Bosch (the world's largest unaffiliated auto parts producer) which is a pioneer in the fields of fuel injection and anti-locking brake systems. Bosch alone is estimated to account for nearly a quarter of German production. The leader's vitality aided many smaller firms and contributed (together with other large firms such as ZF, Fichtel and Sachs, Teves, and VDO) to Germany's unchallenged leadership within Europe.

The French industry is the second largest in Europe, with about 23 % of the European total. Its structure is still characterised by a large number of nationally oriented small to medium-sized producers. Major restructuring has taken place in recent years, led by the three international scale groups: Valeo, Bertrand-Faure and ECIA (PSA group).

Italia	6.3	3.1	9.4
United Kingdom	6.9	4.3	11.2
Rest of the EU	1.9	2.8	4.7

Source: Boston Consulting Group

The Italian industry (which accounts for about 14 % of European production) is dominated by the Fiat group. The leading producer is Magneti-Marelli (a subsidiary of Fiat) which now has an increased presence in all major European markets. Widely dispersed in the early 1970s, the sector is being tightly restructured under the influence of Fiat.

The United Kingdom components industry (10 % of the total sector) has been badly hit by the decline of British vehicle production and its excessive dependence on domestic manufacturers. However, the major British component producers (such as Lucas, T&N and GKN) have performed well in the important replacement market. The increased rate of (Japanese) investment in automotive production in the United Kingdom has strengthened their position in a home market with considerable potential. British component manufacturers have expanded overseas through investment and acquisition. In addition, the decline in value of the pound sterling has greatly assisted the UK industry's exports during the 1992 to 1994 period.

The Spanish industry has emerged since the late 1970s as another important producer of automotive components, having reached a size comparable with the United Kingdom. Originally developed to comply with local content requirements, the industry has grown considerably since the early 1980s thanks to the increased importance of Spain as a car manufacturing country. However, most of the component producers present in Spain are subsidiaries of foreign companies.

### Strategies

As the Japanese car industry has shown, the trend for car manufacturers to rely on a smaller supply base implies fundamental changes in the structure of the sector. This means an increase in the out-sourcing of high-value added products, faster growth in R&D expenditure and a need for organisations to adapt to new constraints (excellence in quality, delivery and price, not to mention production flexibility). Finally, there is a need to share productivity gains with car manufacturers, and to finance a growing share of development and machinery costs (tooling and specific equipment) necessary for production dedicated to one vehicle manufacturer.

In return, car manufacturers are offering longer term purchasing commitments and closer co-operation, both of which contribute to improved stability in supplier/customer relationships.

As a result of this process, the component industry will increasingly be reshaped into a pyramidal structure. First tier suppliers with a world-wide presence, proprietary technology and scale economies will design and supply full systems rather than single components. They will out-source part of their work to smaller second or third tier suppliers. The observed trend toward increased concentration will continue during the decade, but a further radical reduction in the number of independent producers is unlikely since many will survive as second or third tier suppliers.

### Impact of the Single Market

The impact of the Single Market programme on the automotive components sector has been globally positive. Both production and trade of the industry's products have been greatly enhanced by the elimination of controls at internal borders and by the abolishment of all non-tariff barriers. Distribution channels have also been positively influenced by the creation of a Europe-wide trade area, albeit the impact has been reduced by the fact that distribution channels only play a significant role for the components destined for the replacement market (which represents only 25% of the market).

Additionally, the measures aiming at achieving free movement of capital and easing cross-border payments have been beneficial to this internationally-oriented sector.

The main remaining obstacle to the completion of Single European Market for automotive components is identified to be in the field of indirect taxation, where the lack of harmonisation makes trading conditions among Member States more complex.

### OUTLOOK

Automobile sales in 1994 are expected to rise to 12.0 million, an increase of 5.1 % over 1993. In addition, further increases of 4.2 %, 6.3 % and 6.5 % are expected for 1995 through 1997. In 1997, total European car production will exceed 14 million for the first time. The medium term outlook is therefore bright. However, most of the European industry expects a cyclical downturn around 1999 to 2000. The main source of overall component market growth will come from the Asia-Pacific region (excluding Japan); particularly China, Malaysia, Thailand, Taiwan and South Korea.

With regard to the original equipment market, most of the growth will result from: vehicles increasingly fitted with such standard equipment as automotive electronics, anti-pollution devices and more efficient safety restraint systems; the general "up-market" move in car demand with customers demanding more equipment, comfort and power; and, the increase in high added value component out-sourcing by car manufacturers.

With regard to the replacement market, it should be remembered that this segment is governed by the number and the condition of vehicles on the road, as well as changes in consumer behaviour. These changes can either come about spontaneously, or be spurred by legislation on vehicle testing or compulsory maintenance. The constitution of the single market makes it likely that such measures will spread to countries where they have been absent until now. This, combined with the consumer's desire for safer and more comfortable driving, and the expected growth of the total car parc in Europe, implies that there will be promising demand growth in the replacement parts market. Technological advances should, however, result in more durable parts and slow replacement cycles. Increased opportunities in East European markets will also have a positive influence on demand for automotive components.

The overall outlook for growth in motor vehicle parts and accessories is good, but major adaptation and competitive efforts from the industry are urgently required.

Written by: DRI Europe

The industry is represented at the EU level by: Liaison Committee of the Automotive Components and Equipment Industry (CLEPA). Address: Rue de Stassart 93, B-1050 Brussels; tel: (32 2) 511 2919; fax: (32 2) 513 3802.

# Mopeds and motorcycles

NACE 363

Apparent consumption of mopeds and motorcycles increased steadily in the EU from 1985 to 1992 before falling in 1993 as the recession began to bite. Production value rose, albeit intermittently, until 1993, fell sharply in that year but showed slight growth in 1994. The EU has a substantial trade deficit on mopeds and motorcycles, following very sharp import growth throughout the last decade. The EU industry is instituting measures aimed at increasing competitiveness - restructuring, mergers, licensing production to low-cost labour markets, investment in R&D. With strong growth returning to EU Member States, the short term outlook is quite favourable. There are prospects of rising demand and a gradual increase in output of EU-produced mopeds and motorcycles from 1995 onwards. In the medium term continued growth in demand and output is expected, with the rate of growth slowing marginally.

## INDUSTRY PROFILE

### Description of the sector

NACE 363 comprises the manufacture of mopeds, motorcycles, scooters, bicycles and their parts and accessories (bicycles are discussed in another monograph). The largest component of the industry is the production of mopeds and motorcycles where mopeds are defined as motor driven vehicles of two to three wheels and an engine displacement not exceeding 50 cc and a maximum design speed of 45 km/h. Motorcycles are motor driven vehicles with two to three wheels with an engine displacement greater than that of mopeds. This sector covers a wide range of products with varying demand profiles. In both the moped and motorcycle sectors there are scooters, roads sport, trail and U-frames models. The motorcycle sector varies from small capacity motorcycles (51-125cc) which may be used for commuting, to large capacity 650cc to 1200cc sports and touring models.

### Recent trends

Production of mopeds and motorcycles stagnated during the first half of the 1980s, with a turning point of sorts in 1988 and 1989 when demand began to increase. Production value in current prices more than doubled between 1984 and 1992 before falling sharply in 1993 as recession in the European markets reached its nadir. Output value is estimated to have risen slightly in 1994 as markets began to recover. Thus, in 1994 the value of EU production is estimated to be below its 1990 level. Growth in moped and motorcycle production compares poorly with most EU manufacturing industries. Output growth in constant prices between 1984 and 1993 was less than half of that achieved across all EU manufacturing. Similarly, employment has declined much faster than in most manufacturing sectors.

Italy dominates EU moped and motorcycle production in terms of volume and value. In 1993 Italian output accounted for 50 % of moped and 70 % of motorcycle production in unit terms. In value terms Italy accounted for over 40 % of total EU output.

Trends in production in Italy over the last ten years have run counter to those in other EU Member States. Output value in the Italian moped and motorcycle sector rose by 66 % and 51 % in current and constant prices, respectively. This increase has compensated for declining production in other Member

Figure 1: Bicycles, mopeds and motorcycles  
Value added in comparison with related industries, 1993

Source: DEBA

States. The fallout in terms of job reductions has been similar with employment falling by a third.

Italy's dominant position reflects its historically strong industry and government policy which promoted market growth and protected the industry by banning imports of mopeds and of motorcycles with an engine content of less than 380cc. Italy has also benefited from Yamaha's (JPN) license agreement to manufacture engines in cooperation with Minarelli and the establishment of a Honda (JPN) factory.

These favourable production trends have motivated Italian component manufacturers to invest, and has created in Italy's a relatively strong component industry. Italy was therefore better positioned to compete with other global companies when the market was reopened due to EU agreement.

In value terms Germany is the second largest producer with a 20 % share followed by France and Spain with 14 % and 6 % respectively. Of these major producers, only in France has real output fallen over the last 10 years. More recently,

1994 are DEBA estimates.  
 Source: DEBA

output in Italy rose by nearly 13 % in current prices in 1994 and in Germany by 3 % but fell in most other Member States with a particularly sharp downturn in Spain, by 22 %.

Including vehicles produced or assembled by Japanese manufacturers, which account for approximately 200 000 units, the EU produced 1.5 million vehicles in 1992 of which 80 % were mopeds. In 1993 output was lower with approximately 1.1 million mopeds and 250 000 motorcycles. Production in 1994 is expected to have recovered to the 1992 level.

Apparent consumption in value terms of mopeds and motorcycles in the EU in 1993 was 91 % higher than a decade earlier. In real terms growth averaged a respectable 3.4 % per annum, between 1984 and 1993, although EU consumption fell by 13.6 % in current prices and by 11.2 % in constant prices in 1993. Annual purchases of vehicles in the EU amounted to approximately one million mopeds and 550 000 motorcycles in 1993. In volume terms, the EU manufactures more mopeds than are purchased within the EU, but EU consumers purchase over twice as many motorcycles as are manufactured in the EU.

In value terms apparent consumption of mopeds and motorcycles is highest in Germany. In 1993, Germany accounted for 30 % of the value of EU consumption, following 11 % growth in 1993. In the motorcycle segment Germany accounted for approximately 40 % of all motorcycle sales in 1994. The second largest market in value terms was Italy with a 20 % share, although consumption fell sharply by more than 30 %, in 1993. In 1994 Italians bought nearly half of all mopeds sold in the EU and more than one tenth of the motorcycles. French consumption in value grew slightly to an 18 % share. In Spain consumption fell by 15 % in 1993 to under 9 % of the EU total. The UK and the Netherlands each accounted for approximately 7 % of the value of EU consumption.

With the exception of 1989 and 1990 employment in the moped and motorcycle sector has fallen steadily over the last decade. In the ten years to 1994, jobs in the sector fell by over a third, three times faster than in the EU manufacturing sector as a whole.

#### International comparison

EU moped and motorcycle production in 1993 prices was equivalent to 65 % of Japanese production and three and one-half times the USA's output. This ranking reflects growth

trends over the last ten years. Trends in the moped and motorcycle industry have varied considerably between the EU, Japan and the USA. Only the EU experienced output growth which was significantly more rapid in current than in constant prices, i.e. average output prices increased. In contrast, output prices fell quite sharply in the USA and hardly changed in Japan.

Reflecting this, while real output in the USA increased moderately between 1984 and 1992, the current price value of this output fell. In the EU over the same period production in current prices increased by 36 % and in constant prices by 7 %. In Japan production in current prices grew by 88 % from 1984 to 1993, and in constant prices rose by 82 %, easily surpassing growth in both the EU and USA. Total numbers produced in Japan fell during the 1980s indicating a shift towards production of large motorcycles. The extent of the divergence between Europe, the USA and Japan is evident in the average annual production growth rates in constant prices from 1984 to 1993. For the EU, the USA and Japan these were respectively 0.7 %, 1.7 % and 6.9 %.

#### Foreign trade

Extra-EU exports have remained stable throughout most of the last decade, but with intermittent growth in some years contributing to an overall increase of 18 % over the 1984-93 period. Most growth years were in the second half of this period, with particularly sharp rises in 1989 and 1993. In 1993 export growth was an impressive 12 %. The value of extra-EU exports in 1993 amounted to 14 % of the total value of 1993 production. The export/production ratio showed no overall increase between 1983 and 1993.

Conversely, import growth has caused a sharp rise in the EU's external trade deficit. During the period 1984-1993 extra-EU imports increased by 263 % in current prices, an annual average growth rate of 15 %. Over this period growth in extra-EU import value slowed from a peak of 36 % in 1989 to 5 % in 1993. Import penetration in the EU in 1993 was 44 %, equivalent to 68 % of the total value of 1993 EU production. The EU's external trade deficit is driven by substantial imports of motor-cycles on which the EU runs a large trade deficit. The EU is a marginal net exporter of mopeds.

As a result of strong export growth and slowing import penetration, the increase of the external trade deficit slowed to

**Figure 4: Bicycles, mopeds and motorcycles  
International comparison of production in current prices**

3 % in 1993 compared to increases of 36 % and 10 % in 1991 and 1992. Overall, however, in the period 1984-93 the EU trade deficit in the moped and motorcycle sector grew nearly seven fold to 2 517 million ECU, equivalent to 54 % of EU production in current prices. Reflecting this the value of extra-EU exports as a proportion of imports fell from 77 % in 1984 to 21 % by 1993.

Intra-EU trade experienced strong growth during the 1980s and into the 1990s. Internal trade increased 92 % in current prices from 1988-1992.

Growth in extra-EU exports in the last five years has seen some diversification of export markets. In both 1993 and 1988, the then EFTA countries accounted for the highest share of extra-EU markets. However, while these countries purchased 41 % of EU exports in 1988, their share had fallen to 30 % by 1990. Over the same period the proportion of extra-EU exports to the USA also fell. There was slow growth in exports to Japan and significant growth in the share of the rest of the world. Worldwide, Asia is the largest market for mopeds and motorcycles with almost 3 out of 4 motorcycles and mopeds being sold in that continent, with China alone accounting for around a third of worldwide demand, about three times that of the EU.

This reflects the low car ownership and large population in Asian countries. These markets are also expected to grow rapidly over the remainder of this decade - in China moped and motorcycle ownership stands at only 3 per 1 000 inhabitants compared to 420 per 1 000 in Taiwan, which has the highest density in the world. While EU producers command a significant market share in Europe and despite recent, albeit small, advances they are virtually absent from these growth markets. In volume the EU's share of the USA market is approximately 3 % and in Japan less than 1 %.

The majority of imports to the EU (56 %) come from Japan with the main importing companies being Honda, Yamaha, Kawasaki and Suzuki. The proportion of Japanese imports declined in recent years, reflecting the transfer of Japanese production to the East Asian NICs. These countries are now major exporters of Japanese (and EU Member State) brands back to the EU. Between 1988-93 Taiwan more than doubled its share of extra-EU imports and consolidated its position as the second largest supplier. The third largest extra-EU supplier, the USA, also increased its share over 1989-93 period. The main USA exporter to the EU is Harley Davidson, which specialises in the 750cc plus market niche.

**Figure 5: Bicycles, mopeds and motorcycles  
International comparison of production in constant prices**

## MARKET FORCES

### Demand

Overall economic conditions, personal disposable income and population trends, particularly the number of males aged 15-24, are key determinants of demand for mopeds and motorcycles. The recent recession led to a sharp fall in EU demand for these products as personal disposable income fell and unemployment increased.

Mopeds and motorcycles are an attractive means of transportation as they are more economical to run and generally carry a lower purchasing price than a car. Mopeds and motorcycles are also perceived to be more energy efficient and faster in congested traffic. Increasing congestion and pollution in European cities is likely to lead to increased restrictions on automobile access to sections of city centres. More cities may follow Rome and Milan in passing laws governing automobile access, which should increase the attractiveness of mopeds and motorcycles.

Increased traffic volumes can have a negative effect on demand as safety concerns surface regarding the operation of mopeds and motorcycles in dense traffic. Also, increasing safety requirements for drivers of these vehicles (helmet requirements, training, testing and licensing) serve to distract attention from the attractiveness of purchasing a moped or motorcycle.

Of the approximately 7.2 million motorcycles (excluding mopeds) operating in EU Member States during 1992, 78 % were in the EU's major markets of Italy (34 %), Germany (17 %), the United Kingdom (14 %) and France (13 %). Excluding the UK, where the number of motorcycles in use fell by 18 %, these countries experienced double digit growth rates in the numbers of motorcycles in use from 1987 to 1992 (Italy, 30 %, Germany, 16 % and France, 12 %). While the demand for new motorcycles had fallen in the UK it maintains a relatively large motorcycle park and there was 13 % growth in the number of motorcycle in use in 1993. Italy has the highest density of motorcycles per capita in Europe with 43 in use per 1 000 inhabitants, followed by Switzerland with 40, Spain with 24 and Luxembourg with 21. Similar statistics are not available for mopeds, although ACEM estimates the total park of motorcycles and mopeds at around 20 million vehicles. However, in 1990, the total number of motorised two-wheeled vehicles (mopeds and motorcycles) in use per 1 000 inhabitants was highest in the EU in Italy (142) followed by France (110), the Netherlands (64) and

**Figure 6: Bicycles, mopeds and motorcycles  
Destination of EU exports**

Source: Eurostat

Belgium (52). Switzerland lead Europe with a density of 145 vehicles per 1 000 persons. These figures must be treated with caution, however, since they include estimates of un-registered vehicles.

**Supply and competition**

Within the EU, Italy has consolidated its dominance as the most important producer of mopeds and motorcycles over the 1990s. About one third of Italy's total production of mopeds and motorcycles is bound for countries outside the EU. Extra-EU exports of motorcycles from all Member States declined 28 % from 1991-1992, while foreign sales of EU produced mopeds increased 40 % from 159 000 to 222 000 units during the same period. Foreign demand is most important for Italy, whose exports of mopeds increased by nearly 60 % from 1991-92.

The recent EU recession hastened restructuring with an estimated 20 % fall in employment between 1990 and 1994. In Italy, which accounts for nearly 35 % of EU employment in this sector, employment fell by 7.6 % between 1992-94. Over the same period employment in this sector fell by 10 % in France and Germany, and by 27 % in Spain. In 1994 France was the second largest employer with 18.5 % of EU employ-

ment, Germany was third with 18.2 % and Spain fourth with 9 % share.

Labour productivity has risen steadily, alongside the shake out in employment, with increases particularly evident in the second half of the 1980s. Unit labour costs, on the other hand, have shown little change, while total unit costs rose. Difficulties in reducing costs of production in the EU has helped spur the growth in production in the East Asian NICs as EU producers license the manufacture of their products to low-wage countries.

In the motorcycle segment European producers are lagging behind their Japanese competitors in terms of manufacturing cost and the ability to mass produce technologically advanced components. For certain key components European manufacturers are entirely dependent upon non-EU suppliers whose main customers are the Japanese firms which dominate the world market for motorcycles and mopeds. To some extent this constitutes a strategic risk. This risk is magnified by weakness in Europe's component suppliers who are in the main relatively small firms and characterised by relatively high prices and moderate output quality. Some companies manufacturing components for the car industry also supply the motorcycle/moped sector, and those are relatively large

**Figure 7: Bicycles, mopeds and motorcycles  
Origin of EU imports**

Source: Eurostat

**Figure 8: Bicycles, mopeds and motorcycles  
Trade intensities**

Source: DEBA

and secure. Among specialist motorcycle/moped parts suppliers, however, losses, under-capitalisation and a predominance of family-owned enterprises have restricted the availability of investment funds for expansion and increased R&D. The specialist component supply sector requires development and restructuring if European dependence on foreign suppliers is to be reduced. ACEM is currently campaigning for more inter-firm cooperation to help ameliorate this problem. A programme of joint purchasing and pre-competitive joint R&D for component suppliers has been suggested as a step in this direction.

The existence of many tariff and non-tariff barriers, particularly in the growth markets of Asia also restrict growth of European firms. Barriers relate to local manufacturing by European companies as well as product imports. In particular, these barriers limit or preclude sales of upmarket motorcycles, a niche where European brands' reputation for design and technical quality often give them an important competitive advantage. Restricted access to these markets, by constraining growth of European firms, limits the extent to which they can benefit from economies of scale and resulting lower unit costs.

### Production process

Falling levels of production as the 1980s progressed led to plant closures, restructuring and lower employment. Associated improvements in productivity have been one factor of increased competitiveness. The impetus to improve competitiveness has also come from the Single Market as major EU manufacturers actively pursue strategies to help capitalise on opportunities offered by the new EU environment. Common standards adopted by the EU will lead to further rationalisation and automation of manufacturing processes. Standards currently differ widely across the EU. This is apparent from differing requirements on the gearing on mopeds. In Belgium, France and Portugal, automotive gears are required; in Denmark, the maximum number of gears is 2 and in Spain, 4. The opportunities arising from the single market will also depend on a common transport policy and the result of trade talks with Japan regarding the opening of its market and easier access to its distribution network.

The industry is developing new technologies both in terms of the design of the vehicles and their construction. The use of CAD/CAM and robotics, laser cutting machines, improved

painting systems and more sophisticated quality control systems are assisting productivity improvements as manufacturers begin to produce single models marketable across the entire EU. In the large motorcycle segment European producers are leading in important areas of technology such as anti-lock braking systems.

The adoption of modular design concepts has allowed manufacturers to improve production and increase their range of models. A survey by ACEM of European manufacturers suggests substantial progress in output quality and in the introduction of "lean production" methods, with further advances in the pipeline.

Labour productivity varies, depending on the type of model produced by each company. Thus, in 1987, labour productivity ranged from 18 units per employee per year at BMW (D) in Germany to 102 at Honda (JPN) in Italy, and 122 at Moto Vespa (E) in Spain. On average, labour productivity is around 100 units per employee per year for the larger companies.

## INDUSTRY STRUCTURE

### Companies

The European moped and motorcycle industry is very concentrated, composed of a few large and very many small companies. However, by global standards the top European companies are relatively moderate in size by comparison to their global competitors. In the motorcycle segment sales of the 10 most popular European models accounted for approximately 27 000 units in 1992 while the top 10 Japanese models accounted for approximately 140 000 units.

The three largest manufacturers, Piaggio Group (I), Peugeot MTC (F) and MBK (F) account for more than 60 % of European production of mopeds and motorcycles. The remainder are produced by more than 30 small firms, including assemblers, and Japanese owned or controlled producers. More than half of the EU firms are located in Italy. Based on sales, the Italian Piaggio Group is the largest supplier of moped and motorcycles to the EU market. Piaggio is followed by Peugeot MTC.

The Piaggio Group includes Piaggio, Gilera (I), Puch (A) and Moto Vespa (Spain's largest producer). Other important Italian producers are the Cagiva Group (Cagiva, Ducati, Husqvarna and Moto Morini), Aprilia and the Moto Guzzi Group. Ducati and Moto Guzzi specialise in the large capacity motorcycles from 750cc to 1100cc. In 1993, the Piaggio Group announced the closure of its Gilera subsidiary's Arcore plant. Gilera will now only manufacture one line, the Typhoon 50 cc scooter. Production of this will be shifted to Piaggio's Pontedera plant. It is estimated that this cutback has resulted in a 40 % decrease in Piaggio's 125 cc production in 1993. Italy also has a large number of smaller producers.

France's largest producer is Peugeot MTC, primarily engaged in the manufacture of mopeds and scooters (50-80 cc). Some Peugeot scooters and 50 cc engines are built under licence by Honda (JPN). In Spain, Moto Vespa and Derbi are the main manufacturers accounting for 59 % of Spain's output of mopeds and motorcycles. The assembly operations of three Japanese companies, Honda, Yamaha and Suzuki, account for one-third of local production in Spain.

Germany's largest producer is BMW. It focuses strictly on the manufacture of top of the line motorcycles with large capacity engines. In Portugal, SIS Vehiculos Motorizados LTDA is the largest manufacturer, producing mopeds equipped with engines either from Fichtel & Sachs (D) or Franco Morini (I). The second largest manufacturer in Portugal is Famel. In the Netherlands, the most important manufacturer, Sparta BV, produces light mopeds. The assembly of mopeds and motorcycles is also carried out by Tomos (E).

Source: DEBA

March 1991 saw the start of production by the new Triumph Motorcycle Company in the United Kingdom. This company accounted for more than two-thirds of UK production in 1993. Triumph has successfully established distribution throughout the EU, Japan, Australia and New Zealand and entered the Canadian market at end-1993 and the USA market at end-1994. Further sales have been made to a number of other markets including South America. To supply these new markets, production has increased substantially rising from 2 800 units in 1992 to 8 500 units in 1994. The other, much smaller, UK producer is BSA, who specialises in the supply of machines for the African market.

Japan controls 15 % of EU production through licence agreements and financial holdings in local plants. Yamaha, Suzuki and Honda are the three largest Japanese producers in the EU. These companies target the larger engine market (251 cc). They held 82 % share of this market in the EU in 1992.

Some Peugeot MTC scooters are built under license from Honda, which owns a 25 % share of Peugeot MTC. The second largest manufacturer in France, MBK Industrie, is fully controlled by Yamaha and assembles Yamaha scooters and light motorcycles and manufactures mopeds under the Motobécane design. SIS (P) also assembles Yamaha trail bikes.

### Strategies

Since the early 1980s, many European manufacturers have carried out major investment projects to improve competitiveness, yielding advances in the area of moped, scooter and low capacity motorcycle production. To capitalise on the improved demand outlook at the end of the 1980s, companies undertook investment to improve production facilities and to develop new models.

Investment in R&D to develop new, more advanced, cleaner burning models is becoming increasingly important in the face of heightened competition.

In recent years some European manufacturers have implemented a successful niche strategy whereby their range of models are designed to meet the specific tastes and requirements of buyers and are therefore more attractive than mass produced vehicles. This strategy builds on a unique European strength in design and reflects European producers ability to produce specialised vehicles as a result of their small scale. In line with this strategy European producers have primarily focused on the introduction of new products in existing markets.

In response to the poor economic situation of the early 1980s, a number of companies engaged in merger and acquisition

activities to buy market share and to take advantage of economies of scale in production. For example, the Italian Piaggio Group acquired Puch (A), and Cagiva Ducati (I) merged with Moto Morini (I) and Husqvarna (I). However, merger and acquisition activity has been dominated by Japanese companies interested in acquiring a base in Europe. For example, Suzuki bought Avello-Puch of Spain in 1986, while the following year, Yamaha bought Banesto (E). The investments are now showing positive returns. Although the Japanese have acquired about 15 % of EU moped and motorcycle enterprises, they accounted for 36 % of sales in 1989.

There has also been increasing international cooperation, both among European producers, and between European and the globally dominant Japanese manufacturers. An example of the former is the cooperation between BMW (D), Rotax (A) and Aprilia (I) to develop and produce the F650. BMW leads the cooperative venture, and is responsible for the concept, testing and marketing. Rotax has provided the engine design and produces the engines. Aprilia is responsible for sourcing components and assembly. Minarelli (I) is manufacturing 50cc engines under license from Yamaha (JPN). It produces approximately 250 000 units and serves a quarter of the EU market. Franco Morini(I) produces 50cc engines under license from Suzuki (JPN), but on a much smaller scale than Minarelli. The aim of the strategy of international industrial cooperation is to gain scale and competitive strength by accelerated technology and captive volume transfer through international alliances.

### Impact of the Single Market

The full integration of the Internal Market for mopeds and motorcycles will only be completed with the implementation of a European Whole Vehicle Type Approval, which is expected by the end of the decade. Nevertheless, the strategies adopted by the producers of mopeds, motorcycles and components in anticipation of the completed Single Market are already transforming the sector towards greater efficiency and competitiveness. Notably, motorcycle producers and component suppliers, both European companies and international companies active on the European market, are integrating their operations on a European scale to achieve economies of scale. Closer links between manufacturers and suppliers are established to improve the quality and productivity of the components industry. In this restructuring process the fragmentation of the sector is reduced and efficiency is enhanced. However, even after the adoption of the European Whole Vehicle Type Approval, a number of internal barriers remain, preventing manufacturers from marketing the same type of motorcycle in all Member States. Those barriers are mainly related to the insufficient harmonisation of driver license categories and to the differences in categories of vehicle taxes and as applied by insurance companies across Member States. The motorcycle industry regards the timely completion of the European Whole Vehicle Type Approval as the prerequisite for future policy initiatives to improve the functioning of the Internal Market for mopeds and motorcycles. The levelling of user regulations (for instance concerning driver license), and of road tax and insurance categories) should allow additional effects of scale and market expansion.

### ENVIRONMENT

The main environmental considerations that may have an effect on the moped and motorcycle industry relate to urban traffic congestion and exhaust emissions. Mopeds in particular provide a flexible transport mode that uses space efficiently with relatively low energy consumption. Manufacturers of both mopeds and motorcycles continue to concentrate on more fuel efficient and cleaner burning engines.

The adoption of Directive 94/12/EU on measures to reduce air pollution from motor vehicles amends the earlier 1970

Directive 70/220/EU. The main features are limiting pollutant emissions from private cars - for new designs from January 1996, and for all new cars from January 1997 - and setting conditions under which Member States may give tax incentives for new vehicles sold. While it is too early to assess the impact of this Directive it is likely to increase the cost of new cars. To the extent that they are regarded as substitutes for cars this will make motorcycles and mopeds a more attractive purchase option. Similarly the introduction of broader or stricter government restrictions on traffic circulation in the larger cities, may stimulate demand for mopeds and motorcycles.

## REGULATIONS

The Community is putting in place a harmonised type-approval procedure for two and three-wheel motor vehicles in order to insure the proper functioning of the internal market. The Council of Ministers adopted a framework Directive relating to the type-approval of these vehicles in June 1992 (Directive 92/61/EU). This provides the conditions attached to the granting of vehicle and component type-approval and contains an exhaustive list of components and characteristics to be approved in conformity with specific requirements laid down in ten separate Directives. So far, all but one of these separate Directives have been adopted.

The so called "multi-directive" relating to certain components or characteristics is the last act required to complete the vehicle type-approval procedure for these vehicles.

The chapters on noise limits, emissions and anti-tampering measures contained in the proposal for a Directive on certain components or characteristics of two or three-wheel motor vehicles are currently being examined by the Council and the European Parliament.

Under the provisions of Directive 87/56 EEC, the maximum noise limit value for newly-built motorcycles with an engine capacity of more than 175 cc was reduced to 80dB(A), effective from 1 October 1993. The proposals on limiting exhaust emissions are in line with those of the existing regulations and limit values are already met by the vast majority of manufacturers.

The purpose of the proposal to fit anti-tampering devices is to ensure that vehicles such as mopeds and motorcycles remain safe and secure. The proposed anti-tampering measures, initially restricted to mopeds only, have been extended to all motorcycles. The anti-tampering proposal reflects concerns that tuning may significantly change the performance characteristics of these vehicles and render them unsafe. This proposal may increase the price of EU produced motorcycles and would have a detrimental affect on EU manufacturers, such as Triumph, who produce a range of engines based on a modular design concept.

Safety regulations, such as the 1986 Italian crash helmet requirement, and increased regulation governing the registration of mopeds in Germany, may have dampened demand in the short term but are unlikely to affect long term demand as consumers adjust to the new regulations. In the UK tighter controls on drivers have reduced demand. Toughened regulations include a Compulsory Basic Training (CBT) course which must be completed before driving on the road, a two part motorcycle test required before machines exceeding 125cc can be driven, and a restriction of moped speed to 30 mph.

Competition policy has an important impact in the area of design and distribution. Current proposals regarding design protection are meeting opposition from the motorcycle and moped industry.

Reflecting different technical standards and procedures at national level the industry is fragmented with producers having to offer many different models. The harmonisation of norms and standards in line with the Single Market programme has only begun, but should allow manufacturers to standardise parts and products. This would increase economies of scale by lengthening production runs and could instigate further rationalisation in the industry.

## OUTLOOK

The main factor affecting future consumption of mopeds and motorcycles is the forecast upturn in world economies and consumer spending. Consumption in 1994 is estimated to have increased by approximately 5 % in current prices from a low 1993 base. A further increase from 1994 to 1995 of approximately 9 % is forecast, implying a growth rate slightly higher than over the period 1990-1992. It is expected that stronger growth will occur in the larger capacity machines which are expected to gain ground in volume as the volume of smaller motorcycles and mopeds declines. Due to this shift to larger capacity machines the value of this sector is likely to increase faster than volume. Medium term prospects look good with consumption forecast to increase at a rate of approximately 9 % per year from 1995-7.

Similarly, the optimistic outlook for European economies suggests short term prospects for the EU production of mopeds and motorcycles are favourable, with growth of 6 % in 1995. European motorcycle manufacturers should also increase EU market share. Production is also expected to increase in 1994 and 1997, albeit at a slightly slower rate.

The moped and motorcycle market is likely to broaden. Demand is expected to increase for smaller machines, for learning and commuting, and for larger sports and touring models for recreational use. Production is expected to see continued growth as economies show moderate growth rates, particularly the economies of Italy, Germany, France and Spain.

Future success will depend on the sector's ability to benefit from economies of scale in production and research and development resulting from increased cooperation. Standardised parts development could also help bring costs down and help encourage further restructuring of the sector. Continued environmental concerns may result in limitations on automobile access in many congested urban areas, thus encouraging demand for mopeds and motorcycles.

Significant improvements in the EU manufacturers' medium to long term prospects are dependent upon their ability to access the higher growth rate markets, particularly those in Asia. As a result of continued consolidation efforts, which will leave the remaining firms in a better growth position to take advantage of a future upturn in consumer spending, employment is forecast to fall only marginally in the medium term.

# Bicycles

## NACE 363

Overall bicycle consumption in the EU has been increasing in the last decade. However, most of this increased consumption was accounted for by cheaper imports from non-EU countries, particularly from the Far East. Since 1992, the economic recession and changes in fashion have severely reduced consumption levels. European manufacturers expect a revival to take place in the course of 1995.

The importance of bicycles as an alternative and environmentally friendly means of transport has been recently recognised by the European Commission in its White Paper on Transport Policy. It is widely recognised that action to promote the use of bicycles can make a useful contribution to the solution of traffic congestion problems in urban areas.

### INDUSTRY PROFILE

#### Description of the sector

Bicycles are considered within the NACE 363 category, which also includes mopeds and motorcycles.

There are different types of bicycles, according to the end-user to whom they are destined: sports/touring bicycles (light weight), conventional adult bicycles, All Terrain Bicycles (ATB, or mountain bikes), hybrid bicycles (a cross between a mountain bike and a touring bicycle), small wheeled bicycles (for short distances, mainly aimed at the commuter) and children's bicycles.

#### Recent trends

In 1993, about 11.3 million bicycles were produced in the EU according to data published by the association EBMA. Bicycle production in the EU has been decreasing since 1991, when output reached a peak of 13 million units.

In 1992 and 1993, production fell by 5.4 % and 8.4 % respectively, as manufacturers adjusted production levels to falling demand. The only bright spot was Italy where the currency devaluation has greatly benefited local manufacturers who have strongly increased their export activity.

Consumption of bicycles in the EU rose in the years 1990-91, mainly thanks to the boom in the German market, where reunification has propped up bicycle sales from 4.6 million units in 1989 to 6.2 million units in 1991.

The general economic recession which hit Europe in 1992 and 1993 negatively affected bicycle consumption in the EU: sales dropped by 8 % in 1992 and by a further 8 % in 1993. Preliminary estimates confirm that the fall in consumption is set to continue in 1994.

#### Foreign trade

In 1993, bicycle imports from non-EU countries stood at around 5.7 million units, down 9.2 % from the level of 1992. Geographically speaking, most of EU imports (about 88 % in 1993) come from the Far-East, and particularly from those countries which enjoy a preferential trade treatment under the Generalised System of Preferences (GSP) scheme.

Taiwan remains the most aggressive exporter to the EU (2.4 million units in 1993). The most dramatic change concerns the sharp reduction in bicycle imports originating from China, following the application of anti-dumping legislation. The drop is from about 2.2 million units in 1991 to 395 000 in 1993, that is a 76.5 % fall. Over the 1992-93 period, there has also been a decline of exports from Thailand (-13.3 %) and Indonesia (-8.6 %).

Figure 1: Bicycles  
Breakdown of EU bicycle consumption, 1993

Source: EBMA

The gap left by falling Chinese exports has been largely filled by other South-East Asian countries, notably Malaysia (52.8 % rise in export in 1993), India (193.0 %) and South Korea (81.1 %). It is also worth to note the sudden appearance of Vietnam, a complete newcomer on the bicycle market: in 1993 it exported 310 000 units to the EU, that is a 233.7 % increase over 1992. There are reports of Chinese factories using Vietnam as a convenient way to circumvent the anti-dumping duty recently imposed on Chinese bicycles.

On the other hand, bicycle imports from Japan and the USA are quite low (about 27 000 and 119 000 units respectively in 1993). Imports from East European countries are generally increasing. Some West European producers are said to have relocated production units in the region. The most important exporter to the EU is the Czech Republic (237 000 units in 1993), followed by Poland (178 000) and the rapidly rising Slovenia (106 000).

### MARKET FORCES

#### Demand

The surge in bicycles sales which has taken place in most recent years can be fully attributed to the success encountered by mountain bikes, particularly among persons of the 15-39 age group. At the same time, demand for traditional adult bicycles has been falling rapidly.

Since 1992, however, the boom in sales of mountain bikes has levelled off. It is still questionable whether the fall in sales is due to the fact that the mountain bike boom is over, or is the fall a function of the recession only. The answer to this question will soon become apparent. It is incontestable, however, that average prices of mountain bikes have been falling throughout Europe.

Demand for bicycles is principally related to leisure and fun activities, and secondarily to the desire of consumers to keep fit. Fashion considerations also play an important role in this respect. Other popular reasons to buy a bicycle are for recreational purposes, for local trips (i.e. shopping), or to commute to the workplace.

Concerning this last reason, the use of bicycles as an alternative to private and/or public transport is increasing particularly in large cities, where traffic congestion is strong. Recently, there have been encouraging signs of growing cooperation from various local authorities to bolster the use of bicycles in town by providing safer driving conditions.

### Supply and competition

Within the EU, the two largest bicycle producers are traditionally Germany and Italy, which in 1993 produced respectively 3.9 million and 3.8 million units. These two countries account together for about 70 % of total bicycle production in the EU. The third largest producer in Europe is the United Kingdom (1 million units in 1993), while domestic French output has been rapidly falling since the beginning of the decade to reach 850 000 units in 1993.

In terms of international competitors, Taiwan has become in the recent past the largest source of EU imports. Other major competitors are located in the Far East, namely China, Malaysia and Thailand.

These countries enjoy low labour costs, which allow them to undercut the prices offered by European producers. Moreover, Far East producers often make use of the so-called "screwdriver plants", i.e. they produce locally all the components which are later assembled in factories located in other countries. As a consequence of this unfair competition, several European manufacturers were thrown out of the market or nowadays design bicycles which are produced in the Far East and imported as finished products.

The component market is dominated by Shimano, a Japanese manufacturer which specialises particularly in the gear and brake mechanisms. The other dominating source of components is Taiwan: Taiwanese producers are reported to have shifted production lines in China in order to further reduce costs and to get the preferential GSP rate.

The entry in the market of Far-East manufacturers has seriously affected the level of activity of their European counterparts, which is now mostly confined to the most expensive models' segment (i.e. racing bikes). On the other hand, European manufacturers have increased their R&D efforts in order to promote innovative product developments.

The bicycle sector in Europe has also witnessed a major change in distribution channels. Not a long time ago, bicycles were sold uniquely in specialised shops, while at present an increasing share of bikes is sold in large department stores, supermarkets or by mail order.

The domination of mass-distributors in the bicycle market is becoming more marked. For example, in France and Spain large distributors account already for about 75 % of total sales, while the correspondent figure for Germany is 50 %. The only market where traditional dealers have for the moment maintained their control of the retail market is The Netherlands.

### INDUSTRY STRUCTURE

#### Companies

The industry is composed of a number of large, medium and small-sized companies, some specialising into niche-markets such as children's bikes. At the same time, each European country has local producers which operate in all market segments and which take the biggest market share.

The following enterprises are the market leaders within their respective countries: Kynast, Derby Cycle Werke and Nürnberger Hercules (Germany); Bianchi, Rizzato and Carnielli (Italy); Peugeot, MBK and Gitane (France); Raleigh, Townsend and Dawes (United Kingdom); BH, Orbea and Rabasa (Spain); Gazelle and Batavus (Netherlands).

#### Strategies

In order to face the threat represented by import competition from Far East manufacturers, European companies have established alliances or cooperation agreements. The main aim of these alliances is to rationalise the production process and realise economies of scale in purchasing components.

In 1992, for example, the largest Spanish bicycle manufacturer BH announced the creation of a consortium with Peugeot and Gitane under the name of Cycleurope. Other major consortia are the Derby Group (formed by Raleigh, Gazelle and Derby) and the ATAG group (formed by Batavus and Dawes).

**Table 2: Bicycles  
Significant bicycle imports to the EU**

## Impact of the Single Market

The impact of the creation of the single market on the EU bicycle industry has been globally positive, albeit somewhat limited. This is mainly due to the fact that the EU bicycle market is still characterised by fragmentation along national boundaries: intra-EU trade is not very developed, and manufacturers have adapted to the situation by chiefly producing for their national markets.

The most important set of measures of the Single Market programme for the EU bicycle sector is the legislation aimed at achieving the free movement of goods. The elimination of controls at internal frontiers has speeded up formalities and reduced the timing of delivery and of stocking. Distribution channels have also been positively influenced by the creation of a Europe-wide trade area.

The most important remaining internal obstacle is the mutual recognition of rules, as specific technical requirements still hinder trade between EU countries. Secondly, the access to finance for SMEs is still to be improved: this would mainly benefit bicycle components segment of the market.

## REGIONAL DISTRIBUTION

The largest market for bicycles in the EU is Germany. In 1993, one out of three bikes sold in the EU was sold in Germany (5.7 million). France comes second with 3.1 million bikes sold, and the United Kingdom third with 2.0 million units.

The Netherlands and Denmark are the two countries with the highest bike density in the EU. However, the highest growth rates in bicycle consumption in the last years come from Southern countries such as Spain, where bicycle sales nearly doubled from 860 000 units in 1990 to 1.6 million in 1993. On the other hand, in recent years consumption has been decreasing or stagnating in traditional bicycle markets such as the United Kingdom, the Netherlands and particularly Denmark.

## ENVIRONMENT

The bicycle is increasingly viewed as one of the most environmentally friendly means of transport. Its contribution to the solution of traffic congestion problems in large urban areas is undergoing a revival with local authorities within the EU.

In order to promote the use of bicycles in urban areas, it is necessary to provide facilities for cyclists such as bicycle lanes and specific parking areas. Unfortunately, this is still more the exception than the rule in most large urban areas of the EU. In some European countries where the bicycle is traditionally a popular means of transport (i.e. the Netherlands, Germany and the Scandinavian countries), facilities are widespread. On the other hand, in the Southern European countries the absence of such infrastructures makes the use of bicycles in the city quite hazardous.

## REGULATIONS

The unfair competition and dumping practices which are commonly used by Far East producers have been recently sanctioned by the EU authorities.

In August 1993, the European Commission proposed a council regulation which imposes a definitive anti-dumping duty on imports into the EU of bicycles originating in China. The European Council subsequently adopted the regulation: the rate of the duty has been set at 30.6 %.

The latest action of the European Commission is to investigate a complaint by EBMA of dumping by producers in Indonesia, Malaysia and Thailand. A decision on this case is expected by the end of 1994.

## OUTLOOK

The general economic recession which is affecting Europe has badly influenced sales of bicycles over the last couple of years: in fact, during recessionary periods, consumers tend to postpone the purchase of new bikes. Moreover, if there is a lessening of the consumers' excitement for mountain bikes, this will further reduce consumption, at least until a new cycling fashion appears.

On the other hand, the action of the EU authorities to prevent unfair competition practices by Far East manufacturers is expected to help reducing the price gap which hampered the activity of EU producers.

Finally, the new regulations and conditions which will result from the Uruguay Round ratification will certainly have a reshaping effect on the European cycle market.

# Shipbuilding

## NACE 361

*In 1993 and 1994, the world shipbuilding industry faced the problems it has been dealing with for years: i.e. a bulk fleet which still comprises a number of substandard ships and the general overcapacity of the shipbuilding nations. Uncertainty about South Korea's move towards capacity expansion, as well as concern for environmental and safety issues, has shifted the industry's focus onto quality over quantity.*

*The affirmed need for newer, more efficient ships and more advanced technology have led to legislative requirements for ship design which favour some of the EU acquired expertise, offering it the potential to remain competitive with the Far East into the future. The outlook for the EU shipbuilding industry would appear to be positive overall, in light of the substantial increase of new orders in 1993 (up more than 100 % since 1992), principally for passenger ships and container ships.*

### INDUSTRY PROFILE

#### Description of the sector

NACE 361 comprises the building and repair of seagoing vessels (NACE 361.1); building and repair of vessels for inland navigation (NACE 361.2); building and repair of boats and yachts (NACE 361.3); painting of ships (NACE 361.4); and ship breaking (NACE 361.5).

Most of the industry is accounted for by the construction of seagoing merchant vessels (NACE 361.1). Given the smaller economic significance of the other sub-sectors and the limited availability of data, this article deals primarily with trends in the manufacture and repair of seagoing merchant vessels.

#### Recent trends

In 1993 the growth of world trade was moderate, staying at a level of 2.5 %, according to OECD estimates. World seaborne trade (measured in tonnes miles) increased by approximately 3.1 % in 1993 compared to 2.0 % in 1992. AWES (The Association of West European Shipbuilders, i.e. the EU plus Finland, Norway and Sweden) member associations recorded a decrease in shipbuilding production (measured in compensated gross tonnes, or cgt) of around 12 % since 1992. This gave the region a 24.3 % share of world production (cgt), down from 28.0 % in 1992. On its own, the EU contributed 21 % of world production in 1993, down from almost 24 % in 1992.

On the other hand, the volume of new orders within AWES increased by 73.5 %, after having reached its lowest level

ever of 2.1 million cgt in 1992. At 3.7 million cgt, the order volume of AWES members was dominated by the share of container ships, with 27.9 %, followed by passenger ships (1.1 million cgt or 25.3 %). The EU is the world leader in the production of passenger ships (74 %), and contributes almost 32 % to the world production of full container vessels.

Thus, the AWES area had a 25 % market share of world new orders and a 26 % share of the world order book.

The EU's market share of new orders was 20.1 % for 1993. Despite this dramatic in new orders' volume, the workforce of AWES (and, specifically, EU) shipyards was reduced in 1993.

International freight rate performance, which is an important factor in scrapping and new-building decisions, generally improved in 1993 compared to the end of 1992, when freight market prices reached their lowest point in years. World freight rates for oil tankers almost doubled during 1993, whereas freight rates for bulk carriers showed a more moderate growth.

Meanwhile, newbuilding prices fluctuated in 1993, but weakened for most ship types, in spite of the vigorous ordering activity. This was caused in part by the assertive sales drive of South Korean shipyards. In the case of tankers, especially VLCCs, the higher cost involved in implementing new designs to match the double hull requirements were not reflected in the level of prices. Instead, the appreciation of the Japanese yen against the Korean won - which continued to depreciate - resulted in world price setting based on the activity of Korean shipyards.

The short period of surging tanker oil movements and storage following the Gulf War in early 1991, and the attractive prices which ensued, seems to have come to an end, as the slow evolution of oil prices has dampened interest in increasing stocks, thereby limiting the possibility for more energetic demand. Similarly, in the bulk carrier market, the freight level had become increasingly stagnant by the early months of 1994.

In May 1991 the AWES Working Group on Market and Forecast issued a report on the development in global capacity for the construction of merchant ships which concluded that available world capacity, having decreased by one-third from 1975 to 1990, would rise by some 15-20 % up through 1995. Developments since then show not only that capacity has been expanding at a rate approximately 35 % higher than actual output (much higher than that projected initially), but also that substantial capacity expansions may be realised in the coming years, which will lead to a level estimated at 20 million cgt in the year 2000.

This increased shipbuilding capacity has arisen from the ongoing efforts to improve productivity (e.g. better work planning, standardisation and automation), as well as the substitution of naval ship production to merchant ship production (e.g. in the US). Furthermore, physical capacity has

been and will continue to be bolstered by the addition of new facilities planned in South Korea (from 5 to 9 million cgt). According to AWES and SAJ (Shipbuilders' Association of Japan) estimates, this will cause an increase of the already existing overcapacity.

### International comparison

The EU's major competitors in shipbuilding are Japan, with a world share of almost 40 % (up from 36 % in 1992) and South Korea. The AWES countries marginally lost share in 1993 (down 4 % from 1992), whilst Japan's share increased by 3 %. South Korean yards, which increased their share from 11.5 % in 1985 to 16.5 % in 1992, maintained a 15 % share in 1993.

The 1993 EU share of its principal product lines in world production is as follows: passenger ships (74 %); ferries (46 %), full container (32 %); general cargo (31 %); LPG carriers (23 %), fishing vessels (19 %); oil carriers (17 %) and chemical carriers (11 %). The EU is the leading world producer of combined carriers, general cargo ships, roll on/off vessels, ferries, passenger ships and fishing vessels.

Within the EU, the most important exporting countries by cgt in 1993 were Germany, Spain, Denmark, the Netherlands, and the UK, in order of rank.

## MARKET FORCES

### Demand

As was seen above, demand for manufactured vessels in 1993 took a huge leap from its low levels in 1991 and 1992. The 1992 result of new orders of 1.8 million cgt was a substantial decline from the 3.2 million peak in 1989, which was not surpassed in 1993 (2.9 million cgt). The EU reached a 20.1 % share of the world market, which is comparable to that which it had previously (19.9 % in 1992).

In 1993, the largest ship producing Member State was Germany (853 thousand cgt for a share of 33 %), followed by Italy (19 %), Spain (14 %) and Denmark (13.7 %). The order book for the EU producers at the end of 1993 kept Germany in the pole position with 30 %, while putting Italy in second place with almost 20 % and Denmark in third place with almost 14 %.

### Supply and competition

Three-quarters of world shipbuilding is carried out by industrialised countries. During 1993, the EU had a good performance as far as combined carriers, general cargo ships, ferries and passenger ships are concerned, while South Korea and Japan dominate in LNG and dry bulk carriers, and tanker shipbuilding. The EC yards continue to maintain a good record in the high value added segment of the market. For instance,

although the Japanese industry has had a virtual monopoly on LNG carriers, the French yard of Chantiers de l'Atlantique recently won an order for a series of five LNG carriers. And, in 1994 it again beat out Japanese competitors for two steamship contracts.

There are several hundred shipyards in the EU that manufacture and/or repair vessels of varying sizes. However, of these, only a small number are capable of producing and/or repairing ships over 5 000 cgt. Shipyards have suffered greatly in the past few years from the combined effects of recession, poor markets and currency fluctuations, causing many to shut down despite a dearth of new orders (e.g. Ostend's Beliard Polyship). At the same time, the repair industry has been faced with declining business as owners and operators have tried to strike a balance between keeping costs low and maintaining the absolute minimum level of maintenance required to match the demands of the various regulatory bodies. This, despite an ageing fleet, which should necessitate more maintenance.

#### Ship repair

Lingering effects of the recession and a loss of market share to the Middle and Far East (i.e. repair of tankers in the former and bulk vessels in the latter), as well as Poland, made 1993 another painful year for the AWES shiprepairing industry, which hit its lowest point in the last three years. Very low prices did not adequately cover costs, and the cost-saving measures by ship owners mentioned above, combined with a higher quality of ships overall, led to a lower amount of work.

Within the EU, increased competition was seen from the UK, Italy and Greece, partially due to the currency devaluation in these countries. In the same way, Finland also became more competitive. New areas of competition sprung up outside of the EU, namely in Albania and Croatia. Of perhaps greater concern is the emerging strength of China, where lower labour costs and therefore more attractive prices reign. China is joined by Singapore - which, in anticipation of a renewed period of

boom yet to materialise, is increasing its capacity through an expansion programme and investment in low wage countries - and Korea. Hence, the Far East market will motivate the EU ship repair sector to find ways to strengthen its market position.

Some EU companies have held on to their success by becoming highly specialised (e.g. Société Bretonne de Réparations Navales (Sobrena) in Brest, the 25 container repair companies in Antwerp, or northern companies engaging in ferry refits). But others remain more sensitive to the cutbacks, reorganisations and closures of shipbuilding companies throughout Europe.

The US aggressively began to promote its shipbuilding and ship repair market in early 1993. However, it will have to overcome its inflated pricing level (with prices typically 20-30 % higher than those of northern European shiprepairing companies) and continue efforts to improve its quality and productivity levels before it becomes a competitive threat to the European industry.

#### Scrapping

The scrapping of ships at the end of their usable life is decided not only by the age of the ship but by a combination of factors such as the vessel's operating profit margin, changes in environmental legislation, quality considerations and market psychology (i.e. the expected return on a vessel). Given the aforementioned criteria, it is not surprising that many shipping firms have decided to scrap their vessels. By the end of 1993, 59 % of the tanker fleet was 15 years old or more, while the average age for dry bulk vessels was 15.5 years. This is indicative of the fact that a considerable number of ships were retained during the favourable economic climate in the late 1980s.

However, the surplus in the bulk carrier fleet has been on the decline (down another 1.3 % from 1992 by the end of 1993). This decrease in surplus has led to a decrease in the total of laid-up tonnage, from 11.4 million dwt (dead-weight tonnes) in 1992 to 8.8 million dwt at the end of 1993. Comparably, the fleet of combined carriers experienced a decrease in million dwt laid-up at the end of 1992 (2.3 million dwt) to only 0.7 million dwt at the end of 1993.

Given the substantial increase in scrapping since 1989 (3.9 million dwt as compared with 15.3 million dwt in 1992), the prices paid for scrapping in 1992 have declined for nearly all vessel types, the major exception being vessels containing high-quality stainless steel (such as chemical carriers). Despite the maintenance of these low price levels in 1993, scrapping yards increased their activity another 25 % over that in 1992 (20.4 million dwt).

#### Labour

Employment in the EU shipbuilding industry has experienced a prolonged period of downsizing. The world shipbuilding industry underwent an unprecedented period of expansion during the 1970s, when shipbuilding tonnage doubled over a ten-year period. The sudden influx of new tonnage resulted in an overcapacity, which the shipping industry has yet to recover from, despite the fact that a number of ships were prematurely scrapped in the mid-1980s (some after less than 10 years of service). A secondary development was the shift in production centres away from Europe and the USA towards new shipyards in Japan and South Korea. For example, South Korea launched only 0.1 % of new ships in 1972. By 1992 that share had become 16.5 %.

In 1993, the European shipbuilding workforce reduced further, despite the improved order situation described above. The number of all workers in the shipbuilding sector within the AWES region decreased by around 9 %, to 132 436 in 1993. Likewise, the percentage of those employees active in merchant ship newbuilding declined by 6 %, to 85 647 (65 % of total employment). Cutbacks in the EU new shipbuilding workforce continued in 1993, standing at below one-third of the 1975 total of employment for the current Member States.

Employment is dominated by Germany, which employs 35 % of the total, followed at a significant distance by Spain with almost 15 %. Denmark comes in next, with almost 11 %, and then Italy with 10 % (unless one includes also the number of currently inactive employees, which gives it a total of over 12 %). The country that has seen the most substantial decrease in employment over the last two decades is the United Kingdom, with a labour force one-tenth of what it was during the mid-1970s- which, at that time, was the largest individual workforce of the current Member States. And, 1994 marked

the year when north-east England would see its last shipbuilder, Swan Hunter - formerly Europe's biggest shipbuilding and shiprepairing consortium going through severe difficulties.

### Production process

A highlight of 1993 was the large-scale investment in the modernisation of shipbuilding yards, with the focus on improved or advanced steel fabrication and materials handling systems. In the EU, the industry has had to invest in automating the production process wherever possible, e.g. by using computerised sheet-cutters and automated welders, in order to respond to increasing competition from the lower-cost manufacture taking place outside the EU. Part of the process of adjustment has included the adoption of eastern-style management techniques, multi-skilled work practises and purchases of complete systems and sub-systems from external suppliers. Several European shipbuilding firms already have finished or at least started selective schemes aimed at ensuring their position in the business, now that quality has become so significant a factor.

## INDUSTRY STRUCTURE

### Strategies

West European yards decreased their capacity by almost 60 % between 1976 and 1990, and do not intend to reopen obsolete facilities. Still, they have to think of ways to stay competitive with shipbuilders in the Far East. The number of shipbuilding firms in the EU has been reduced by yards either going out of business or by mergers and acquisition activity, and many of the remaining shipyards have been forced to find niches in the shipbuilding market in order to survive. The EU shipbuilding industry in general seeks to differentiate itself from its main competitors in Asia by specialising in the construction of ships with relatively high value added rather than somewhat simpler dry-bulk vessels or oil tankers. Examples of such ships include dedicated refrigerator vessels ("reefers"), dedicated container vessels, gas tankers, chemical tankers and cruise ships.

The most outstanding centre of activity has been the privatisation of shipyards in former East Germany by the Treuhandanstalt, the German agency responsible for privatising former East German industries following unification. Most of the largest acquisitions have created Germany's largest shipbuilding group, Bremer Vulkan. Other firms, such as Norway's Kvaerner, also have acquired facilities in the new Länder and other Member States.

One of the features of 1993 was the spread of cooperation between yards in forming joint bidding groups for major contracts or fleet development programmes. This has been encouraged by the client market, since purchasers often commission more than one shipbuilder to guarantee deliveries of a series of newbuildings within a set amount of time. In Europe, the E3 collaboration between five of the biggest shipyard organisations resulted in the innovative VLCC design proposals. And, it yielded a firm contract for Spanish partner Astilleros Españoles (AESAs) for one newbuilding, as well as a deal between the Italian E3 participant Fincantieri and the well-respected Danish shipbuilder Burmeister & Wain Skibsværft, thus helping to attract orders for panamax bulkers.

Germany's Howaldtswerke-Deutsch Werft and South Korea's Daewoo Shipbuilding & Heavy Machinery paved the way for collaboration with American President Lines' boxship pro-

gramme. Observers will be watching to see if such Europe-Far East cooperation expands in the future.

### Impact of the Single Market

After many years of decline, world ship production began to recover in 1989. However, at the beginning of the nineties weaker than hoped for growth in sea-borne trade and the lingering overcapacity in the shipping industry worked against the prospect for an immediate upturn in production volumes or employment.

Concerning the EU shipbuilders, exchange rate fluctuations (particularly vis-à-vis the US dollar) have also helped weaken them. So pushed by the increasing competition from lower cost manufacture taking place outside the EU, they have had to invest in automating the production process wherever possible, usually by introducing computerised sheet-cutter and automated welders. Part of adjustment has included the adoption of Eastern style management techniques, multi-skilled work practices and purchases of complete systems and sub-systems from external suppliers. Thus, the number of shipbuilding firms in the EU has been reduced by yards either going out of business or by mergers and acquisition activity, and many of the remaining shipyards have been forced to find niches in the shipbuilding market in order to survive. The EU shipbuilding industry in general seeks to differentiate itself from its main competitors in Asia by specialising in the construction of ships with relatively high value added rather than relatively simpler dry-bulk vessels or oil tankers.

Concerning the European legislation the competition policy, more precisely the monitoring of state-aid, is relevant to the sector as the global shipbuilding industry is subject to competitive distortions due primarily to differing levels of subsidies by geographic region. With regard to environmental regulations, the EU and the USA are leading the industry with the preparation of legislation designed to reduce solvent emissions resulting from particular paint substances. In addition, increasing pressure on the shipping industry on maritime safety may act as a boon to the shipbuilding industry depending on the level and degree of legislation that is applied. Besides, the longer term outlook is potentially positive for the EU shipbuilding industry as the world fleet becomes increasingly aged, and legislative requirements for ship design favour some of the EU acquired expertise.

## ENVIRONMENT

1993 was a year in which issues surrounding marine casualties came to the fore. The US Oil Pollution Act - OPA 90 - and debates on double-hulled tankers focused on environmental protection, while concern was expressed within the industry about the value and safety of human life and not only the insured gross tonnage involved in such casualties (see Regulations).

Oil spills are often considered to be the greatest environmental threat posed by the shipping industry as a whole, as evidenced by the IMO regulations for new tankers to be constructed with double hulls. However, the prevention of oil spills is by no means the only major environmental issue confronting the shipbuilding sector. Rather, much of the current focus has been on the painting of ships where the paint and coating (anti-fouling) substances and abrasive blasting done to prepare a painting surface are of particular concern.

A number of anti-fouling substances have been brought under scrutiny. Paint components, e.g. red lead (Pb3O4) and zinc chromate (ZnCrO4), and tin compounds are expected to be banned along with previously discontinued substances such as cadmium and other heavy metals. The development of effective tin-free antifouling in response to environmental concerns over tributyltin (TBT)-containing systems has widened the choice for operators. Unfortunately, while such tin-free antifouling have proven to be environmentally-correct indeed, none is yet available that has achieved the same standard as the best self-polishing copolymer (SPC) antifouling. Hence, most operators are still opting for SPCs, with Japan being the only country to have adopted the tin-free antifouling widely. The race is now on to find an economically viable alternative to TBT-based antifouling, through either the development of new generations of environment-friendly biocides, or the development of alternative biocide-free coatings.

Meanwhile, other substances used such as carbonates, silicates, coal tar, organic chloride compounds and polyurethanes are all suspected to cause specific health hazards. Abrasive blasting is another source of concern because of the vast amounts of hazardous dust which result from the preparation of metal or concrete surfaces before painting.

## REGULATIONS

The global shipbuilding industry is subject to competitive distortions due primarily to differing levels of subsidies by geographic region. The EU level of subsidies to shipbuilding comes under the rules of the 7th directive on aid to shipbuilding (approved in November 1990) which was extended through year-end 1994. Each year, the Commission determines the common ceiling for state aid, which is based on the difference in costs between the most efficient EU yards and their major competitors (typically from the Far East). A level of 9 % was maintained in the years 1992-1994. This means that ships contracted in 1994 for delivery in or before 1997 may be allowed a maximum level of 9 % of the contract value. The ceiling for ships with a contract value less than 10 million ECU was 4.5 % of that value. In connection with the decision to maintain the same subsidy level again in 1994, the Commission stipulated that in case an OECD agreement was reached on the elimination of all subsidies for the industry, a further lowering of the subsidy ceiling for 1994 would be reconsidered.

In fact, the OECD negotiations, which involved the world's largest shipbuilding countries and had been ongoing since 1989, were finalised in the summer of 1994. Home credit schemes, e.g. those of Japan and South Korea; injurious pricing control instruments; and the US Jones Act, which requires that a fixed proportion of cargo passing through US ports be

carried in US-registered ships, were perhaps the most controversial issues blocking agreement. Resistance against the overall content of the agreement came most strongly from the French, who found it to be beneficial to those countries already with strong internal markets, and the Japanese, who feared further breakdown of the market.

While the talks were originally pushed for by the US shipbuilders' council, the EU Commission saw the OECD agreement as crucial to its efforts to phase out national shipbuilding subsidies in this sector worldwide. The accord will effectively end all forms of governmental subsidies, allow for anti-dumping duties and cap the tonnages covered by the Jones Act while providing for counter-measures in the case of misuse. Overall, the deal was a welcome one, as it eliminated the risk of a subsidy war between the bigger shipbuilding nations.

In parallel to the OECD negotiations was the Communication from the Commission (COM (93) 526), "The European Maritime Industries Forum: Towards the Implementation of a Comprehensive policy for the Maritime Industries: the First Tangible Results." The Communication was an assessment of the recommendations of the report of the Maritime Industries Forum (Athens, 1993). In this respect, it was recommended that Member States which are supporting their shipbuilding industries consider amending the terms of their Home Credit Schemes in line with the objectives of the OECD agreement, even before it was approved. Further, it encouraged the EIB and EIF to expand their role in ship finance.

To facilitate collaboration, and to show its support for the work of the maritime regions in Europe, the European Parliament created the Alliance of Maritime Regional Interests in Europe (AMRIE).

With regard to environmental regulations, the EU and the USA are leading the industry with the preparation of legislation designed to reduce solvent emissions resulting from particular paint substances. Such legislation is expected to be similar to the German TA Luft legislation. Member States such as Denmark and the Netherlands have already initiated programmes designed to reduce solvent emissions.

Recent research has shown that of the bulkers of over 20 000 dwt which have gone missing or sunk during the past ten years, 40 % of the incidents were resulting from structural and equipment failures. The industry has taken the matter to heart. In March of 1994, the AWES, Korean Shipbuilders Association (KSA) and the SAJ agreed on a common statement regarding substandard vessels which stressed the need for better enforcement of existing rules and stricter implementation of new ones.

The main targets of tightened inspection of environmental and safety standards by flag states (Classification Societies) and Port State Control (PSC) are crew skills (i.e. operation and manoeuvring) and safety and fire-fighting equipment. Particular emphasis will be placed on hull structures and stability, especially of vessels aged over 20 years, and action is to be taken by each national government, with joint research and development activities by and between them and international organisations and/or related industries.

Increasing pressure on the shipping industry to ameliorate maritime safety may act as a boon to the shipbuilding industry, depending on the level and degree of legislation that is applied. This, due to the potential for shipbuilders to incorporate additional, high value added safety features in new vessels, as well as for ship repairers to outfit existing shipping with add-on equipment.

## OUTLOOK

Although the outlook for the EU shipbuilding industry does not appear to offer obvious change from the persistent contraction of production and employment in the short term, the

surprising upsurge in new orders in 1993, combined with signs that the recession felt worldwide is nearing an end (a more balanced growth of between 2.3-2.5 % is anticipated for 1995), offer some hope for the future of the sector.

Additionally, as the relevant authorities apply more stringent ship surveys to ensure the improvement of sub-standard tonnage, there should be a substantial pick-up in repair demand in the short term. And, as over half of the current fleet will be over 25 years old by the year 2000, up to one-third will need to be replaced during the interim period. The realisation that the initial higher cost of producing safer ships will be offset in the long run by the reduced risk of loss, damage and ecological disaster will up the demand for value added ships.

In short, the new, large-scale commitments to the modernisation of shipbuilding yards seen during 1993 will contribute to the future structural well-being of the industry. Such commitments have stemmed not only from the factors mentioned above, but also from the acknowledgement that the future of the industry impinges upon the repercussions of any possible increased capacity, perhaps one of the most pertinent issues for shipbuilding today.

Thus, the EU shipbuilding industry will be keenly focused on the development of the next generation of shipping vessels which are predominantly being developed in Japan by Mitsubishi Heavy Industries. Although Mitsubishi is the primary developer of the super conductive electromagnetic propulsion (SEMP) vessels, certain EU firms are performing crucial roles in the development of the SEMP project. The most significant contributor is Germany's Motoren und Turbinen Union division of Daimler-Benz, which won a prestigious contract to develop two high-speed engines used to power the SEMP's innovative magnetohydrodynamic (MHD) propulsion system.

# Railway rolling stock

## NACE 362

Supply and demand both rose strongly during the early 1990s. Employment fell in 1993, following the pattern of the last decade and it is likely that any future employment growth will be very low as a result of productivity improvements, increased concentration within the industry and the elimination of overcapacity as competition increases. The industry has relatively few clients and demand for rolling stock is dependent upon transport and infrastructure policies. Products are tailored to clients and continuous innovation is necessary to satisfy them and to ensure that EU firms stay competitive. The industry is concentrated but as national governments open bidding procedures to all EU manufacturers the industry will become increasingly competitive. Supply and demand are forecast to grow, but at a declining rate. Future demand depends largely upon the railway operators' ability to attract public and private financial support for Europe's high-speed railway and for developing urban transport systems.

### INDUSTRY PROFILE

#### Description of the sector

The railway rolling stock industry includes the manufacture of standard large and narrow gauge railway and urban transport railway equipment. This includes:

- locomotives;
- heads of motor coaches and motor coach trains;
- mainline passenger coaches, metro cars and tramways;
- goods wagons;
- rolling stock equipment;
- fixed track equipment;
- electric signalling, safety and control devices for railways.

Production of passenger coaches includes coaches for regional services and for additional services such as mail vans, restaurant cars and sleeping cars.

The performance of the industry is dependent upon transportation needs and on public policies regarding the development of the railway lines and purchase of rolling stock. In 1993, the railway rolling stock sector generated nearly 3 billion ECU in value added, equal to approximately one sixth of the value added by the aerospace industry.

#### Recent trends

Production of railway rolling stock in current prices fell between 1985 and 1987, remained static during 1988-89 but showed continued growth in 1990-93, with a particularly strong increase in 1992. In 1993, the value of production exceeded 7 billion ECU which was more than 80 % above its 1987 level. Growth in railway rolling stock production compares favourably with most EU manufacturing industries. Output growth in constant prices between 1984 and 1993 was nearly two thirds higher than that achieved across all EU manufacturing.

In value terms, Germany is the main EU producer followed by France. Between 1992 and 1993, German production fell by nearly 20 % in current prices with a marked decline in the production of passenger coaches and goods wagons. Over the same period, French production grew by more than 25 % in current prices with the value of goods wagon production doubling, and that of locomotives increasing by a quarter.

Source: DEBA

In terms of production specialisation, the railway rolling stock sector as a proportion of total manufacturing was particularly important in Italy, the UK and Spain in 1984. By 1993 it was less significant in Italy and the UK and much more important in France. While Germany is the main EU producer, and has become more specialised in this sector, it is the least specialised of the main EU producers.

Apparent consumption stagnated over the period 1985-88 with a slight upturn in 1989 and more than 20 % growth in 1990. Consumption fell slightly in 1991, grew by more than 40 % in current prices in 1992 and, following continued growth, was twice as high as its 1984 level by 1993. Between 1984 and 1989, consumption grew by less than 1 % per year in real terms. The strong recovery of the sector in the 1990s led to a real annual growth rate in consumption that was nearly 12 times higher over the 1989-93 period.

Declining production between 1984 and 1989 led to a 30 % fall in employment, followed by slight growth in 1990 and 1991 and strong growth in 1992. Reflecting increasing pro-

Production and employment compared to EU total manufacturing Industry**

1994 are DEBA estimates.  
Source: DEBA

ductivity, employment fell back to its 1990 level despite an increase in production in 1993. The sector now employs approximately 70 000 people compared to 90 000 in the mid 1980s. It is interesting to note that in 1992 employment grew by about 10 000 units, as a consequence of the privatisation and subsequent restructuring of the industry in former East Germany. However, over the period 1984-93 employment in the railway rolling stock sector fell more than twice as fast as employment in all EU manufacturing.

The trade balance in the sector remained positive but fell consistently between 1984 and 1990 and was less than a quarter of its 1984 level in 1990. This reflects a strong decline in exports and in the exports/imports ratio. The trade balance recovered from 1991 onwards and strong export growth in 1992 resulted in the trade balance surpassing its 1984 level. Despite a fall in 1993, the balance of trade remained higher than at any time between 1986 and 1990.

### International comparison

In 1993, the EU was the world leader in the production of railway rolling stock, outpacing Japanese production by nearly 90 % and producing 130 % more than the USA. Japan, previously not considered to be a major player in the high-speed rail market as its technology appeared to be less advanced than that of European countries, has become the largest rolling stock producer in the world in recent years.

Real growth in the Japanese industry's output exceeded EU growth in the 1980s, whilst real growth in the EU in the 1990s has been 40 % higher than in Japan, reflecting the strength of the Yen. Overall, Japanese production in current prices grew more than three times faster than the EU between 1984 and 1993. Production in the USA has fallen in current prices and stagnated in real terms over the last decade, but the growing popularity of light rail transit systems in the USA has provided a potential export market for EU producers.

### Foreign trade

The value in current prices of extra-EU exports in 1993 was similar to that in 1984, although there was considerable fluctuation in the intervening years. In the second half of the 1980s, the value of extra-EU exports fell and by 1989 it was barely one third of its 1984 level. Following slight growth in 1990 and exceptional growth in 1991 (8.5 % and 201.5 %, respectively, in current prices), the value of extra-EU exports trebled compared to 1989, but declined sharply in 1993. The value in current prices of extra-EU exports in 1993 was equivalent to 16 % of EU production.

In 1985, nearly 80 % of extra-EU exports consisted of parts and passenger coaches. There was a marked decline in extra-EU exports of passenger coaches in the late 1980s whereby parts alone accounted for over 70 % of the exports by 1989. The very strong export growth in 1991 was due to a massive increase in the export of passenger coaches and a sharp increase in the export of goods wagons. There was continued strong growth in passenger coach exports in 1992, followed by a decline in 1993. Exports of goods wagons fell by over 40 % in 1992 and 1993. Reflecting the high value nature and irregular delivery of long term contracts, the destination of extra-EU exports changed significantly as EU exports increased by 58 % between 1988-93. Exports to China which

had accounted for over one fifth of extra-EU exports were replaced by exports to Russia which accounted for nearly a quarter of the exports in 1993. Exports to the USA decreased by 47 % during this period, whereas those to the EFTA countries increased by 24 %.

Over the last decade, extra-EU imports have achieved an average real annual growth of nearly 4 %, whilst exports have fallen by more than 5 % per year on average. The ratio of extra-EU imports over consumption rose to over 9 % in 1991 but fell in 1992 and 1993. In 1993, extra-EU imports accounted for less than 6 % of EU consumption. The source of extra-EU imports shifted as imports increased by 134 % between 1988 and 1993. EFTA countries remained the primary source of EU imports. However, their share fell from nearly 80 % to approximately 60 % during that period. Canada became the second largest exporter to the EU in 1993 and imports from the rest of the world increased by more than three times. The EU imports relatively few locomotives and passenger coaches, whereas parts and goods wagons represent the majority of extra-EU imports. The strong growth in extra-EU imports can be attributed to a rapid rise in imports in both of these sectors in 1991, and slight growth in 1992.

**Figure 7: Railway rolling stock  
Origin of EU imports**

Source: Eurostat

**Demand**

The industry has a relatively small number of customers: national and regional railway companies, urban transport companies, private rental and leasing companies and industries with their own railway rolling stock. The demand for railway rolling stock is dependent upon transport and infrastructure policies. The planning of new networks and increases in the provision of rail services tend to be on a long-term basis. Both the political and economic climates affect the railway companies' ability to generate short term investment funds and influences the phasing and size of orders.

The main factors affecting the supply of railway rolling stock are the development of a Trans-European High-Speed Rail Networks, growth in the use of rail-based public transport as a means to solving congestion and pollution in urban areas and the continued upgrading of conventional rail systems.

Increased demand for fast transportation led to the development of the high-speed rail technology and product innovation which has resulted in plans by many countries for new high-speed networks. France is increasing the network of its Train à Grande Vitesse (TGV), Germany is expanding its InterCity Express (ICE) network, Spain has invested in a new high-speed link between Madrid and Seville (in operation since 1992), and by the end of the century most Western European countries are expected to have high-speed rail connections.

The implementation of a Trans-European High-Speed Rail Network by 2010 will have a positive impact on the activities of rolling stock manufacturers, and currently there is considerable investment in the high-speed railway sector. To provide the proposed EU network it is estimated that an investment of 10 billion ECU in railway rolling stock will be required until 1999 with a further investment of 15 billion ECU over the period 2000-2010. However, the development of a high-speed network depends upon the availability of finance. At present, Europe's railways are reliant on government contributions to cover their operating costs. To make the large financial investment required to develop a European high-speed network, increased public investment is required, with funding from institutions such as the EIB and the World Bank, as well as private funding.

As each country's rail system evolved largely as a separate entity, there are technical incompatibilities throughout the EU. For European high-speed rail links to become a reality, trains must be able to deal with a host of electricity voltages, signalling systems and safety standards on different national rail systems. Technical specifications on interoperability, which will eventually be transformed into mandatory standards, are currently being prepared by industry and operators: the European Commission played an important role in initiating this process (via the draft Directive on inter-operability).

Whereas the high-speed rail links have a high profile, demand for rail links in urban and suburban areas are expected to account for a higher proportion of future railway equipment demand. Many cities in Europe, and in the rest of the world, encounter heavy road traffic congestion and pollution which may be solved by faster and more efficient rail-based public transport solutions. The demand for rail transit systems is expected to show continued growth as such systems provide improved mobility in expanding cities and urban areas.

Many European regions also wish to improve their connections with the high-speed networks and to modernise their conventional rail systems. The total conventional rail network in Europe covers approximately 123 000 km, with 33 000 km in France, 28 000 km in Germany and 17 000 km and 16 000 km, respectively, in the UK and Italy. Data indicate that the total number of rail passengers carried in the EU between 1981 and 1991 increased by 8 % to over 4 billion. This is a result of steady growth in urban and suburban traffic and a sharp increase in national intercity trains, counterbalancing losses in traditional medium distance services. In 1991, the four largest rail passenger markets in the EU were Germany (1 045 million passengers), France (822 million passengers), the UK (708 million passengers) and Italy (438 million passengers). Between them, these countries carried 72 % of European rail passengers. Other important markets are Spain and the Netherlands both of which showed strong growth in the early 1990s. As the demand for railway rolling stock is a derived demand, depending primarily upon rail transport usage, the larger EU countries will remain the main EU markets for railway rolling stock. However, future demand in these markets may be constrained by the availability of financial resources. Also, the globalisation of the rail market has seen the emergence of new markets in Asia, such as South Korea, Taiwan and China, and North America.

Combined transport offers another potential market for the future activity of the industry. Combined rail/road haulage offers an environmental and energy saving solution as goods can be transported by rail for long distances and dispatched to their final destinations by trucks. Quick loading and unloading systems are essential for the success of combined rail/road traffic. Currently Germany and France have a usage of the rail network for freight services that is higher than average. However, rail's share of the freight market within the EU has fallen, particularly since road freight was deregulated.

Traditionally, railway operators were responsible for the design of rolling stock equipment, with suppliers applying technical specifications prepared by railway engineers and providing an end product. As railway operators focus more on their primary role of service providers, the design function is transferring to rolling stock suppliers. Similarly, maintenance operations, the cost of which may represent half of the total life cycle cost of a train system, are being increasingly taken over by the suppliers. Hence, demand from railways is expanding beyond that of rolling stock equipment to include complete system supply i.e. rather than focusing solely on the initial capital cost of equipment the demand is for the overall package covering the total cost of the rolling stock over its life cycle. Whereas demand historically has been for railway rolling stock with a long life cycle, approximately

30-40 years, it is shifting towards equipment with a much shorter life cycle, 15-20 years.

### Supply and competition

Traditionally, national railways have displayed a great propensity to purchase from national suppliers. Apart from the Netherlands, Spain and more recently the UK, there have been few cross-border orders from countries with indigenous railway rolling stock manufacturers. Decades of cross-reliance between railways and suppliers has created a recognised excess capacity in supply resources which has only been partially offset by exports to non-EU countries. If warnings of over-capacity in the European industry are valid, some of the national suppliers may disappear.

While the prospects for demand appear healthy, the competition to supply rail contracts, and in particular high-speed rail contracts, remains fierce. This is largely the result of the nature of the industry. The market for railway rolling stock is comprised of a relatively small number of clients with large projects which arise infrequently and generally last several years. For railway rolling stock manufacturers this time lag makes each contract critical. The experience acquired on one puts the manufacturer in a stronger position for the next. Similarly the economies of scale obtained by winning several contracts allow cheaper pricing in future bids.

The French/UK company GEC-Alsthom leads the world high-speed train market with 570 high-speed trains having been manufactured or ordered from the company by the beginning of 1994. The comparable figure for the Siemens-AEG (D) consortium was 120 trains. GEC-Alsthom's strong market position also reflects the fact that the French TGV has a proven track record, having been in service for over a decade whereas the German ICE services have only been running since 1991.

As demand shifts, the major railway rolling stock manufacturers are increasingly becoming system suppliers or integrators. Railway operators thus tend to deal with companies that are able to take full responsibility for providing a train system rather than dealing with a large number of vendors. The pricing of individual components is being replaced by total life cycle costs. A pyramidal organisation is therefore emerging in the railway rolling stock industry. At the top end a few large system suppliers interfacing with the railway operators are taking over the design, procurement of subsystems and maintenance over the life cycle of the rolling stock. Subsystem suppliers are becoming more specialised. At the bottom of the pyramid is a competitive pure supply industry, making parts and components at the request of subsystem suppliers.

As employment in the railway rolling stock sector fell there was continued improvement in labour productivity over the period 1984-93 with the labour productivity index showing a 30 % improvement between 1990 and 1993. This trend should help restore the EU's competitiveness against countries with lower labour costs. Excluding 1988, unit labour costs rose steadily between 1984 and 1991 before falling by 6 % and 14 % respectively in 1992 and 1993. Total unit costs also rose over the 1980s, increasing by over a third between 1984 and 1992.

Depending upon the level of technological transfer, the long-term threat to the European rail industry is likely to come from countries with lower labour costs, such as Central European countries and other developing economies.

Competition between high-speed rail and air transport is increasing in Europe. It is generally accepted that rail will triumph over air travel in cases where trains can deliver passengers within a travel time of two and a half hours. There will be competition between them where the train takes up

to three hours, and air will have the competitive advantage where the journey by train exceeds three and a half hours. In the future, rail transport and railway rolling stock suppliers will face increased competition not only from road and aviation, in terms of alternative 'mobility' options, but also from improved telecommunications in terms of 'communication' opportunities. The development of telecommunications may result in potential customers choosing communication tools rather than rail transport solutions. Competition is also taking place beyond products and services, and increasingly includes financing. Leading industrial groups involved in the provision of rail systems may follow aircraft manufacturers and set up financial structures to assist operators in acquiring equipment.

### Production process

Since the industry has only a few clients, it works very closely with its customers and producers tend to develop new equipment in collaboration with clients. The Single European Market should make co-operation easier, as requirements will be harmonised through European standardisation.

Innovations have been numerous in the industry. For example, high-speed and tilting car body technology allow higher average speeds on curved tracks. Multi-micro processor control equipment and three phase drives have become standard in various countries. The use of new materials such as light alloys, composites, carbon fibres to replace traditional steel parts, and the use of new propulsion systems with low weight transformers have reduced vehicle weights significantly and lead to increased power efficiency.

Technological developments will also address: information and telecommunication technologies regarding signalling and safety systems allowing trains to cross national borders; advanced telematics that will allow e.g. identification and localisation of vehicles; and software applications, e.g. experts systems, aiming at total predictive maintenance.

Other significant technological innovations include bogies for locomotives and coaches with radial steering wheel sets to minimise lateral forces on track and wear of rail and wheel flange; satellite-oriented control and communication systems; integrated transport systems for passengers and freight; innovative aerodynamic and sound-proofed trains, and automotive train control systems for mass transit transport. Low-floor and advanced propulsion systems are also being used more widely in urban transport vehicles.

### Companies

Historically, the railway rolling stock industries throughout the EU have been shaped by their understanding of the specific requirements of their individual railways and have formed close working relationships with their customers. As a result of selective buying and technical incompatibility among different rail systems, the main industrial groups have developed their own systems and there has been a lack of standardisation. Access by an individual supplier to new national markets has tended to have been achieved through the process of acquisition, part ownership or via the medium of a consortium. In the late 1980s, the industry became much more concentrated with most of the mergers and acquisition occurring between suppliers of specialised rail technology.

Even though the railway rolling stock industry has become more concentrated, following the rationalisations which have occurred within a number of the supply industries, there remains a large number of suppliers within Europe. The industry comprises approximately 100 locomotive, coach, and wagon builders, and a similar number of railway equipment manufacturers.

Locomotives tend to be produced by divisions of large industrial groups engaged in other industrial activities, typically electrical engineering. Passenger coaches and goods wagons are usually the primary product of smaller firms. Some firms work in niche markets producing only one or two types of products. This range of producers results in the size of companies varying widely, from less than one hundred employees to several thousand workers.

The industry is characterised by a number of large companies that are divisions of multi-national groups which are very diversified (e.g. equipment for the production and distribution of energy, telecommunications and transportation materials) and produce in many fields other than transportation. These include GEC-Alsthom (F, UK), ABB (S, CH), Siemens (D) and AEG (D), Fiat Ferroviaria (I), Ansaldo (I) and Breda (I).

In 1988 ASEA (S) merged with Brown-Boveri (CH) to form ABB. Although transportation represents only a small sector of the group's total revenue, its transportation business comprises companies in Denmark, Germany, Italy, the Netherlands, Portugal, Spain and the UK, as well as in Norway, Sweden, Austria and Switzerland. ABB acquired a 40 % interest in BREL (UK) when it was privatised and separated from British Rail.

GEC-Alsthom Transport Division (F, UK) is another important European multinational. Alsthom (F), a large supplier of rolling stock and equipment to the SNCF, designed and built the range of high-speed TGV trains. Its parent company, CGE (F), merged its railway operations in 1989 with those of the GEC Power Systems Group (UK). The latter includes AEI, BT-H, Dick Kerr, English Electric, Metropolitan Vickers and the Vulcan Foundry. Metro Cammell Ltd was added later in 1989. The French companies include Brissoneau et Lotz, Franco-Belge, CIMT, CEM Oerlikon and Jeumont Schneider. Other European subsidiaries include ACEC Transport of Belgium, Ateinsa, Macosa and Maquinista of Spain and Kiepe Elektrik of Germany. GEC-Alsthom has also gained the majority shareholding of Linke-Hoffman-Bosch (D) which is a supplier to the ICE consortium.

Two major all-German groups have been formed since 1988. Siemens has a 60 % interest in rolling stock manufacturer Duewag and a 25 % stake in the Krauss-Maffei locomotive plant. Daimler-Benz joined the railway activities of AEG (D) with the US company Westinghouse and has merged the railway building activities of MBB with those of MAN.

Canadian railway supplier Bombardier Inc. of Montreal, having acquired ANF-Industrie (F) and a controlling interest in

BN (B), set up Bombardier Eurorail which had a strong involvement in manufacturing double and single deck wagons for the Channel Tunnel.

## Strategies

The primary strategies for the leading firms of the industry are increased innovation and technology and increased concentration. The major rolling stock suppliers have formed consortiums in order to develop and supply the new high-speed trains. GEC-Alsthom for the TGV (and its derivatives, the Trans Manche Supertrain, and Paris-Brussels-Cologne-Amsterdam); AEG-Siemens and ABB for the ICE; Ansaldo, Breda, ABB and Fiat for the ETR 500.

The commercial drive behind mergers of railway suppliers are derived from the expectations that the Single European Market will add impetus to investment in rail systems of all descriptions but particularly in light rail vehicles for urban transit and high-speed trains (mainly as an effect of Directive 93/38). It is also envisaged that there will be more open competition for contracts and that these new contracts will require the suppliers to provide comprehensive capabilities and the supply of complete systems.

Companies must also be large enough to withstand extra-EU competition. The specialised nature of products does not currently enable large economies of scale, but knowledge of different standards and requirements by different EU customers does give European firms an advantage over non-European firms. This advantage may be reduced as standardised European norms are introduced. Technical harmonisation at the European level may enable manufacturers to apply standardised specifications and increasingly benefit from improved economies of scale. This should also improve the overall competitiveness of rail transport through more effective and more economic production methods as costs associated with specialised and diversified production are removed.

The major European suppliers are increasingly marketing themselves on a world-wide basis. The two main European manufacturers of high-speed trains have both formed alliances with US partners in order to have access to the US market. GEC-Alsthom has linked up with Morrison-Knudsen, and Siemens-AEG with General Motors.

## Impact of the Single Market

In the past, the rail industry had the reputation of being every closed industry. The activities were mainly local, as the industry had few clients, mainly the national and regional railway companies. Moreover, the rail carriers did not do much to increase their attractiveness to the customers. However, the liberalisation of transport has contributed to large benefits to the modes of transport other than rail. To remain competitive, the rail transport sector must improve its competitiveness and become more customer-oriented. In that sense, the Internal Market programme has been a catalyst of change for the rail transport sector, and also for the railway rolling stock sector. The two measures of the Internal Market programme which had most impact so far have been the technical harmonisation at the European level, which has contributed to economies of scale, and the opening up of bidding procedures to all EU manufacturers which has contributed to increase the transparency of this market and therefore to reduce the cost associated to these transactions. However, the technical harmonisation procedures imply further large investments, as an interoperability between all the different national infrastructures of the rail transport and also between the rail and the urban transport become necessary.

The three priorities for the sector are

- an accelerated technical harmonisation procedure,
- the liberalisation of financial services and capital markets leading to a cheaper access to credit, and

- the establishment of a fairer fiscal policy between the different modes of transport. This third aspect will have to take into account a number of factors such as security, or the environmental damage from production and use of the equipment.

---

## ENVIRONMENT

---

Rail transport, both conventional and high-speed, offer a number of environmental benefits in comparison to road and air transport. In terms of land use a double track for a high-speed train occupies less land than a motorway and can carry more passengers. Similarly, increased use of high-speed trains on shorter journeys should reduce air traffic congestion at many major European airports and enable them to cope more efficiently with longer-haul services. Other environmental benefits of the high-speed trains are that they are more energy efficient and emit less pollutants than air and road transport. The development and upgrading of new and existing rail links and services, upon which the demand for railway rolling stock depends, would appear to be consistent with Europe's environmental policy.

Environmental concerns about noise and other environmental impacts of high-speed rail links have already slowed down development or altered the alignment of proposed routes in France, Germany and the UK. As environmental concerns in Europe grow, the EU railways will have to adapt to stricter measures. It will be increasingly important for manufacturers to develop and employ light weight-saving materials; become more energy efficient; increasingly design cooling system with recyclable components; and research technologies which minimise environmental impacts from noise, air pollution and vibration. In designing and constructing new rail links, particular attention will be paid to the environmental impact of such projects in terms of cutting longitudinal lines through the countryside, the effects on flora and fauna and possibly on water flow. There will also be a need to reduce the negative environmental impact of high-speed rail projects during construction.

---

## REGULATIONS

---

After years of restricted access to national markets, the implementation of the EU Directive 90/531 (recently replaced by Directive 93/38) on public procurement in previously excluded markets, including transport, has created new business opportunities for European suppliers. The so-called "Utilities Directive" imposes four requirements to the public contracting entities: information, non discriminative specifications, transparency and fairness. It is too early to assess the precise impact of this Directive but some basic changes have already occurred in procurement practices amongst European railway companies as purchasing departments have already enlarged their vendor lists. The impact will depend upon the ability of new entrants to provide competitively priced and higher quality products than incumbent, suppliers although it seems unlikely that the close relationships between the national supply industry and the national railways will change materially except for in the long run.

Under the Directive on the Development of the Community Railways (EEC 91/440), the financial structures of European railways have been reformed. This involves the separation of the management of railway infrastructure from the operation of rail transport services, with compulsory separation of accounts. The physical or institutional separation of the infrastructure and service provider is optional. Under this new structure the railway undertakings which provide the rail services will be charged a fee by the manager of the infrastructure in order to cover the cost of the railway infrastructure. The Directive also provides the right of access to each Member State's railway infrastructure for any authorised operator,

whether it is another national railway or a new private enterprise.

This separation of rail infrastructure and operators should enable private operators to enter the rail transport business and lead to railway services being provided on a more competitive and commercial basis. It is likely that the denser and more profitable routes will attract private operators and may increase demand for railway rolling stock. However, on the thinner routes, railway service providers may reduce services and delay fleet expansion. This Directive has already led to changes in the structures of several national railway companies and will be a major influence on the future development of the European railway industry. In Germany the Bundesbahn and the Reichsbahn have been transformed into a competitive commercial business (since January 1, 1994), and in the UK privatisation is being implemented.

The draft Directive on the Interoperability of the European High-speed Train Network proposes that a regulatory framework for high-speed trains be created in order to ensure the establishment of a cohesive and interoperable network: national regulations and technical specifications relating to rolling stock will be harmonised. Since the introduction of this draft directive, the European railway networks (represented by UIC and UITP), and the industry (represented by UNIFE) have founded a new legal body entitled "European Association for the Interoperability of High-speed Trains" (AEIF). Its Board of Directors comprises 12 members, one half of them appointed by the European operators and the other by the industry. AEIF will approve the technical specifications of interoperability under preparation in eight working groups, gathering around 80 experts appointed on an equal basis by operators and manufacturers. These specifications are being prepared under a mandate to be delivered to the EU. The harmonisation of rolling stock specifications will assist the Utilities Directive on the opening up of contracts in previously excluded sectors.

---

## OUTLOOK

---

It is difficult to forecast the future of the railway rolling stock industry as it is dependent upon external and often unforeseeable factors. For example, changes in a country's political climate or budgetary situation may lead to the cancellation of long-standing contracts. Future demand depends largely upon the railway operators ability to attract public and private financial support and the suppliers ability to produce less expensive equipment. Future demand is expected to come from growth in urban rail transit systems, resulting from concerns arising due to road congestion and motor vehicle pollution, and the increased focus on high-speed lines as an alternative to air travel. The outlook for the mid 1990s looks promising with continued consumption and production growth of approximately 7 % in the short term. In the medium term the rate of growth for both consumption and production is expected to decline between 1996 and 1997.

Employment growth will be very low as a result of productivity improvements, increased concentration within the industry and the elimination of overcapacity as competition increases. Marginal employment growth is forecast in the short term with employment stagnating in 1996 and 1997. An important factor affecting market development will be the reorganisation and restructuring of European railway operators into infrastructure and service providers. There may be a delay in infrastructure and rolling stock investments in several EU countries as this process continues. The opening of public procurement in previously excluded markets is likely to lead to increased competition in the medium term. The former Soviet Union offers EU manufacturers a potentially vast market assuming that funds are available. The primary risk facing the industry is the availability of finance and the ability of rail infrastructure projects to compete with other infrastructure projects, namely telecommunications and roads, for limited funds.

# Aerospace equipment

## NACE 364

Activity in the aerospace equipment industry is traditionally characterised by its cyclical nature. Since the beginning of the nineties however, the European aerospace manufacturers have been experiencing their worst crisis, aggravated this time by worrying structural problems. The slump in civilian demand for aircraft could have merely generated a cyclical downturn in the aerospace industry, but in fact, it translated into the largest depression ever through its coincidence with the dramatic reduction of military orders. Now, the European aerospace industry is facing problems of structural adjustment. The EU aerospace industry is increasingly operating in a global market, and its future will depend on its ability to surmount the current problems, in particular by increasing its export market share in spite of the emergence of newcomers and increasingly determined US competition.

### INDUSTRY PROFILE

#### Description of the sector

Data available for the aerospace industry divides total turnover into four subsectors: complete systems (aircraft, missiles, etc.) engines, equipment, and space. Complete systems represent about 50 % of the sector's turnover. Equipment represents some 26 % of the turnover of EU aerospace industry, followed by engines with 18 % and space with 6 %. These products have both civilian and military applications. Civilian businesses cover several products: large commercial jets, regional aircraft (turboprops and small commercial jets), helicopters, space hardware (satellites and launchers).

Military operations comprise the manufacture of aircraft, missiles, helicopters and space hardware. The share of military activities in total aerospace manufacturing has been constantly decreasing since the early 1980s, as a result of political détente. In 1991, the sales of civilian equipment overtook sales of military equipment for the first time.

#### Recent trends

The European aerospace industry achieved spectacular growth during the 1980s. Demand for large commercial aircraft and for space equipment indeed expanded at a strong pace in the second half of the eighties, which somewhat counterbalanced the cutback in the production of military aircraft. Consequently, the aerospace industry produced at a substantial rate throughout the eighties, a rate which actually jumped in 1989 and 1990.

1990 turned out to be a dramatic turning point. Hit by a sharp recession in both military and civil activities, EU's apparent consumption of aerospace equipment fell by as much as 14 % (in current ECU) between 1990 and 1992.

In 1993 the airline industry's overcapacity, along with the ongoing contraction in defence budgets continued to dampen activity in EU's aerospace industry. Production was down 7.4 % in value, on declining domestic demand and stagnating exports.

Employment, which had been regularly declining since 1988, shrank for the fourth year in a row, evidencing deep adjustments to the cyclical and structural turmoil.

#### International comparison

The EU emerged as a powerful competitor in the world's aerospace industry in the last decade. The founding of the Airbus Industrie consortium, composed of four companies: Aérospatiale (F), British Aerospace (UK), Deutsche Aerospace

Figure 1: Aerospace equipment Value added in comparison with related industries, 1993

Source: DEBA

(D, to be renamed Daimler Benz Aerospace in 1995), also known as DASA, (D) and CASA (E) marked the return of Europe to the large civil aircraft market.

Competitive pressure to EU manufacturers still essentially stems from the US. The world aircraft industry has always been dominated by the United States, which posted 79.1 billion ECU of production value in 1993. As a matter of fact, the ten leading world companies include seven American firms for only three European. In addition, world leader Boeing has a turnover twice as large as DASA, Europe's largest contender, and nearly three times as large as British Aerospace, Europe's second largest aerospace manufacturer.

Japan is also a sizeable aerospace manufacturer, with production value averaging 6.1 billion ECU in 1992 (as such, Japanese turnover is nearly seven times smaller than EU's).

New players are emerging in other places. Far East Asian countries are endeavouring to build up an aerospace industry, often from scratch. To reach this objective, manufacturers in

these countries are engaged in negotiations aimed at setting up joint ventures or alliances with western companies. The Indonesian industry has actually emerged as an aerospace manufacturer, as this country managed to build up an industry in about one decade, which is now about to manufacture its own turboprop.

The former USSR is another potential entrant. The CIS, in particular, has one of the world's largest aerospace industries and holds an impressive technological know-how in aerospace manufacturing. This industry is nevertheless suffering from serious handicaps in terms of efficiency, organisation and over-manning. There is thus a long way before the east European aerospace industry becomes competitive and up-to-date. Meanwhile, principles of cooperation (in the space sector particularly) have already been agreed upon between the CIS and the EU.

**Foreign trade**

It is no wonder, given the global nature of the aerospace industry, to find that aerospace equipment ranks among the most trade intensive sectors. As a matter of fact exports are the sector's largest outlet. More than 40 % of EU's production is exported, a share which exceeds 60 % in France. A large proportion of this trade reflects manufacturing specialisation within Europe. Within the European Union, trade takes the form of flows of semi-finished equipment to be processed or assembled in another Member State.

A large part of extra-EU flows are directed to North America, which represented 33.1 % of EU's exports and 55.7 % of total imports to the EU in 1993.

Exports and imports to/from the EU broadly balance in terms of size. The very large fluctuations of the American dollar compared to European currencies have largely influenced EU's trade balance during the 1980s. In particular, the weakness

**Figure 4: Aerospace equipment

Destination of EU exports**

Source: Eurostat

of the dollar since 1986 has dampened EU's export competitiveness, which coupled with increased purchases of American aircraft by EU airlines, led to a deterioration of Europe's trade balance. In 1991, EU's trade deficit amounted to 1.8 billion ECU. In 1992, the balance rebounded with the largest surplus in ten years (about 3 million ECU) but the improvement largely reflected plummeting imports due to declining domestic demand, rather than a surge in exports. In 1993, EU's trade balance continued to improve, with extra-EU imports falling by 4.1 % in value, while extra-EU exports fell only slightly (-1 %).

## MARKET FORCES

### Demand

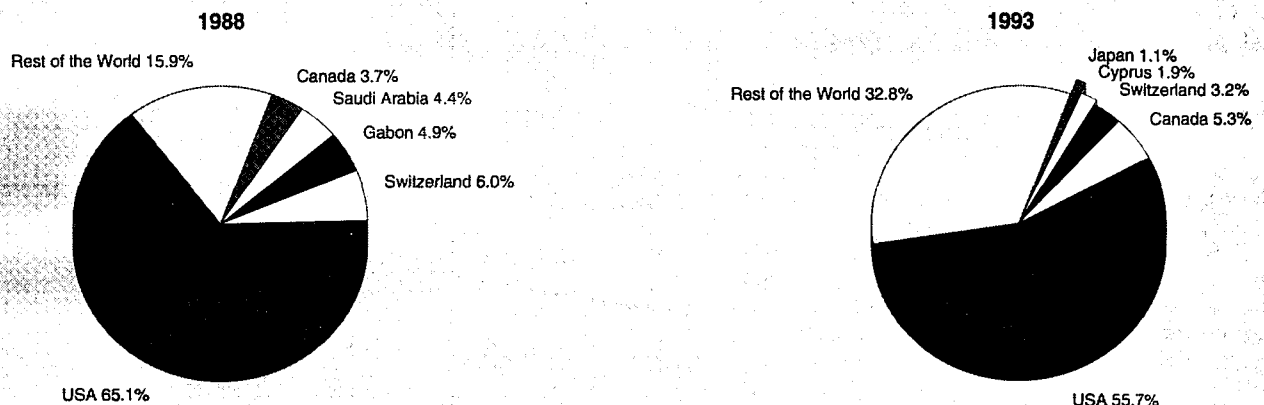

Apart from export markets, the largest outlet for aerospace equipment is the government sector, through its military orders. The government sector actually represents more than half of the sector's domestic sales. It is then easy to understand how severely governments' drastic cuts in defence budgets have affected the aerospace industry as a whole. Under strong budgetary constraints, governments started cutting defence budgets in the middle of the eighties, that is far before the fall of the Berlin Wall. This trend has nevertheless accelerated over the

recent past, in line with the end of the Cold War. The shrinking of the defence market revealed in cancellations or postponements of new or existing programmes.

Airline companies are the other major outlet for the aerospace industry, through their demand for new aircraft, replacement parts and maintenance services. Since 1990, airline companies have faced sluggish and, on occasion, negative traffic growth, fierce competition and rising costs, an occurrence of factors which translate into deep financial losses. Also enduring large over capacity due to the investment boom of the late eighties, most airline companies have severely revised their investment plans, often postponing or even cancelling orders for new aircraft. Regional airlines are suffering more from the recession than their larger counterparts, due to their difficult financial position, and their smaller market share. They have drastically cut orders.

Civilian and military activities have traditionally posted asynchronous cycles. But since 1991, the aerospace industry has been subject to one of its worst crisis since the second World War. This recession, which combines sharp falls in both civil and military activities, is a consequence of sharp cuts in defence spending and the airline business's financial turmoil.

This time, civil operations have not offset the dramatic decline of defence businesses for the aerospace industry.

### Supply and competition

As indicated earlier, the world's aerospace industry is clearly dominated by US firms, which enjoy the advantage of a large domestic market, and lead in production volume, range of models and rate of production. In addition to these competitive advantages, the low level of the US dollar with respect to European currencies further handicaps the EU industry.

The relationship between the EU and the US is an outstanding mix of cooperation and competition. Collaboration exists, particularly in the case of engine manufacturers where strong links have been built up between EU and American manufacturers. Competition is, nevertheless, harsh between the major producers, and takes place both in civilian and military businesses.

Such intense competition led the EU aerospace industry to implement changes in the production process, which brought about significant changes in the organisation of work. Forced to shorten production cycles and to cut costs to remain competitive, the industry shifted towards increased automation. Simultaneously, new forms of organisation and management are being introduced, which aim at producing faster, cheaper and more efficiently. In particular, the aerospace industry is introducing just-in-time management. Airbus is also imple-

menting simultaneous engineering, in order to efficiently manage the wide range of activities the group traditionally coordinates.

The development of such new forms of production (inherited from the Japanese automotive industry), is pushing the industry to a substantial reduction in the number of component suppliers, and contributing to the restructuring and consolidation of the aerospace supply sectors.

### Production process

One of the most salient features of EU's aerospace industry has been its spectacular growth in productivity reported throughout the 1980s. The sector achieved gains of above 5 % on an early average between 1985 and 1990. Space appears to be the segment which has reported the largest productivity gains among aerospace divisions. As a more labour-intensive sector, equipment posts a lower output per employee.

The aerospace industry is also characterised by important synergies between the military and civilian segments of the market. Most of the synergies take place at the research and development stage. Generally, new technologies are first developed for military applications, and are in a second stage adapted for civil purposes, mainly in engines and avionics.

Another important feature of the aerospace industry is the importance of economies of scale in the production process. Research and development costs are the most important sources of economies of scale, although some scale economies may also be achieved at the production stage. The initial cost in R&D that is necessary to develop a new model is one of the largest of all industries. For example, the development of a large commercial aircraft requires between 4 and 8 billion USD spread over four or five years, and the length of the product cycle is characterised by very long periods of time before reaching break-even. Economies of scale can also be achieved on the demand side, by enabling the costs of maintenance and training to be held in check.

Along with these economies of scale, the aerospace manufacturers can also benefit from "family economies". The existence of a learning curve and production overheads indeed provide manufacturers with a cost advantage when developing and producing new models. This actually gives manufacturers a strong incentive to produce a full range of models.

## INDUSTRY STRUCTURE

### Companies

Unlike its American competitor, the European aerospace industry is largely segmented. This feature stems from the fact that the aerospace industry has largely developed on a national basis, in order to guarantee national independence for its defence activities. Moreover, the main European aerospace manufacturers are smaller than their American competitors,

**Table 6: Aerospace equipment**  
**The ten largest companies in the EU, 1993**

(million ECU)	Country	Turnover	Employment
DASA	D	9 029	73 800
British Aerospace	UK	7 636(1)	68 220(1)

(1) 1992

Source: Companies (DGill survey - annual reports - press)

which constitutes a serious competitive disadvantage in an industry bound to have high and increasing R&D spending.

Of the world's ten leading aerospace manufacturers in 1992, only three were European: DASA, British Aerospace and Aérospatiale. On a segment by segment basis, the aeroengine industry is dominated by four main players: Rolls Royce (UK), SNECMA (F), General Electric (USA) and Pratt & Whitney (USA). Boeing, McDonnell Douglas (USA) and Airbus are the only contenders in the large jet aircraft industry.

Over the past decade, EU's Airbus has managed to more than double its share of the world market for large commercial jets, reaching about 30 % of outstanding orders in 1993. In the turbo prop segment, Europe is the leading producer, but is handicapped by the segmentation of its production base: six manufacturers co-exist in the market, all proposing models which are sometimes direct competitors. These are British Aerospace, Fokker, ATR (a joint venture between Aérospatiale and Alenia), DASA, Saab and CASA. In the regional jet segment, BAe and Fokker share the market.

Apart from the leading European producers, a substantial number of small and medium sized firms account for a significant share of the production. An aircraft is a complex system, so its production and design can be divided into parts and sub-contracted. Sub-contracting activities are organised, like in the automotive assembly industry, in a hierarchical structure. The prime contractor, i.e. the aircraft manufacturer itself, delegates the production and sometimes even the conception, of complete systems to large suppliers which in turn out-source parts of the operation to a third level of sub-contractors. Overall, France's Aérospatiale estimates that sub-contracting represents over 25 % of the production of an aircraft.

In Germany and in the United Kingdom, the production is very concentrated under the wing of a single national company, respectively DASA and British Aerospace.

### Strategies

After two years of a continuing shake up in both civil and military businesses, the aerospace industry has had to adapt to new market conditions. Defence contractors have forced the trend towards greater consolidation and rationalisation in the industry. In the last two years, the number of transnational mergers and acquisitions has increased significantly in the EU. A number of companies are currently involved in talks aimed at collaborating or merging operations. For example, France's Matra and British Aerospace's space systems division are currently considering a joint venture, as are the two companies' missile divisions.

In civil operations too, partnerships, collaborative agreements and joint ventures are more than ever on the agenda. The

European aerospace industry has always suffered from a double competitive disadvantage compared to its US competitor: a lower production base - and therefore lower economies of scale; and difficulties in funding the development of new aircraft - coupled with increasingly long investment pay-back lead times. In this climate, cooperation is now considered as the only way forward. Further steps are taken in the consolidation of the European regional aircraft industry: after the acquisition, last year, of Fokker by Deutsche Aerospace, British Aerospace is currently in talks with ATR to merge their respective regional jet and turbo propellers activities. Boeing and Airbus are also discussing various risk-sharing collaborative agreements that Boeing and Airbus have been envisaging recently. Boeing and EU's consortium have been discussing during the past two years means of a collaboration on a future very large aircraft with 600 to 800 seats. The two leading producers are also in talks with McDonnell Douglas about risk sharing collaboration on the development of a successor to Concorde, given the size of the necessary initial outlay.

By contrast, forging cross-border mergers in the strategic defence segment remains a harsh process within the EU. There are discussions under way, like Aérospatiale's talks with DASA to combine their missile and space operations in joint companies, matching the merger of their helicopter operations into Eurocopter. Further steps have recently been taken within the EU, with the announced project designed to integrate the European future large military transport aircraft programme (FLA) into the Airbus manufacturing and development system. These signs are very encouraging, but considerable political and institutional obstacles still remain to the necessary consolidation of EU's military aerospace industry.

### Impact of the Single Market

The completion of the Single Market has had a beneficial though relatively modest impact on the aerospace equipment sector. This sector is highly internationalised, both in terms of trade flows and in terms of cross-border M&As and joint-ventures. Consequently, European companies have benefited from measures aiming at facilitating cross-border operations, increasing labour mobility or reducing the costs of cross-border payments. However, the impact of these measures on the sector's performance has remained modest because changes in activity and in industry structure are essentially dictated by worldwide developments falling outside the scope of the Internal Market. Further progress could nevertheless be made in a number of areas. A statute for a European company would be particularly welcome in an industry characterised by numerous cross-border M&As or joint-ventures. Similarly, though the removal of cross-border controls has eased intra-EU trade, paperwork linked to trade still remains cumbersome. Another area where further integration would be beneficial

is the opening up of defence procurement. Military equipment have been so far excluded from the Internal Market but the necessary rationalisation of the European defence industry would be greatly facilitated if a European procurement policy could replace the largely nationalistic approach still practised in several Member States.

---

## REGIONAL DISTRIBUTION

---

In spite of efforts from both national and EU levels, the manufacture of aerospace equipment remains divided between numerous highly specialised production sites situated in different Member States. France and the United Kingdom account for close to two thirds of total European production. The two countries have traditionally jostled for European leadership, but the United Kingdom lost ground in recent years.

Recent trends in production and employment by country confirm the growing importance of Germany and Italy in aerospace manufacturing. Germany stepped up its share of the European turnover from 15 % in the early 1980s to 22 % a decade later. Together the three major European manufacturers account for close to 85 % of European production. Italy has also increased its share of European turnover to close to 10 %. The Netherlands, Belgium and Spain provide the remainder of EU aerospace production.

---

## ENVIRONMENT

---

Aircraft and engine manufacturers have long integrated environmental concerns in their production processes. Environmental performance has actually become an important criterion in an airline's aircraft and engine selection process. The oldest and least efficient aircraft have already been withdrawn pursuant to a number of international agreements, with major financial impact on the airline companies.

The aerospace industry is concerned with three different types of pollution. Noise created both on take-off and landing is one such problem. The aerospace industry has been dealing with this issue for a long time. However, the actual growth of air traffic, combined with the increased size of the aircraft, threatens to reduce the benefit derived from the regulations that have come into force during the last decade. Unless aircraft noise is reduced still further, current international standards may face increasing challenges as individual airports seek to impose tougher controls.

Pollutant emissions, and in particular gaseous emissions in the high atmosphere, are another crucial environmental concern. The industry has been handling this issue through several technical programmes, particularly through developments in advanced jet propulsion. The current environmental standards regarding gaseous emissions nevertheless appear to be inadequate in so far as they do not take into account the whole flight envelope: current standards do not cover emissions at cruise altitudes which can account for more than 90 % of the gaseous emissions during a long distance flight.

Lastly, aerospace manufacturers are particularly concerned with the problem of energy conservation. This issue is all the more crucial as the industry is bound to produce increasingly powerful civil engines to match the growing size of aircraft. The engines of the future will have to be increasingly efficient in order to meet such requirements as energy conservation. Further research is required into all these environmental issues, to ensure that the European industry retains its competitive position.

---

## REGULATIONS

---

Owing to the intensification of international competition, all firms are operating under similar competitive conditions. In the context of progressive globalisation of the aerospace mar-

ket, this principle applies just as much to competition within the EU as it does to external competitors. All the factors that could affect competition must be taken into account, and this includes both direct and indirect public subsidies.

When EU rules on competition, particularly Articles 85 and 86, are applied to the aerospace industry, the specific conditions such as the high level of investment needed, the necessary degree of cooperation, the long time to break even, and the comparatively small number of producers, are taken into account. Some sectors are confronted by difficult challenges of size and depth inherent in the industry: the worldwide dimension of the market, often national markets are too restricted to nourish the development of enterprises strong enough to be internationally competitive; industrial operations of such a size that no existing European enterprise can master all the technologies and acquire the production equipment needed to manage a complex programme in industrial and economic terms; financial requirements that have reached a level beyond the ability of any individual operator to accumulate; and the high degree of integration of the main competitors of the European aerospace industry.

Mergers are subject to Council Regulation (EEC) No. 4064/89 dated 21 December 1989. Their impact is generally evaluated on the world market. Consequently a merger bringing together most of the supply capacity of the EU in certain sectors of the aerospace industry does not necessarily amount to the creation of a dominant position incompatible with the Single Market.

Government subsidies for the aerospace industry are subject to articles 92-94 of the EEC Treaty. At the present time there is no sectoral aid framework laying down special directives for Member States in granting assistance to the aerospace industry. The distorting effects of subsidies on other competitors are also taken into account.

There are general regulations governing state assistance for R&D, but the special features of the sector are taken into account: the advanced technology content of the products, the fierce international competition and lastly the cooperative nature of research.

At an international level, the aircraft industry is subject to specific rules inside the WTO agreement on subsidies and countervailing measures covering matters such as R&D subsidies, ad valorem subsidisation and royalty-based loans. Negotiations on updating the 1979 GATT Civil Aircraft Code are continuing.

---

## OUTLOOK

---

Given the reduction in the share of military work, which is likely to continue, the outlook of the EU aerospace equipment sector appears closely linked to the prospects for the airline industry. Short term prospects for EU's aerospace industry remain rather gloomy. Growth in production will progressively accelerate in 1995 and 1996, but will remain largely under the rates that were achieved during the past decade.

The outlook is particularly bleak for defence aerospace. Western countries will continue to squeeze their defence budgets, with EU defence procurement declining by above 2 % per year between 1993 and 2000. Sales of military aircraft will therefore continue to fall as programmes are either cancelled or postponed.

Turning to civilian aerospace, a number of positive signs indicate that demand will start to pick up again in 1995. In 1994, reduced overcapacity and improved load factors have translated into spectacular improvement of many airlines' financial situation. After 1995, the growth in air traffic will be fully reflected in the world commercial aviation industry, translating into increased delivery rates. Economic recovery in the world and the need to replace old aircraft will keep

Source: DEBA

activity going in business aircraft and helicopters, while the market for regional aircraft will grow more slowly. The space market will continue to grow apace, particularly in the commercial segment.

Further concentration, along with an enhanced and more co-ordinated R&D effort appear necessary to enable the EU aerospace manufacturers to compete more effectively against their US competitors. In particular, with size becoming a critical factor if the EU manufacturers are to match their US competitors, the European aerospace industry will continue to restructure. Much of it will take the form of alliances, rather than straightforward mergers, as sensitivity to national defence interests, along with nationalist behaviour are acting as a brake to a real concentration process.

Consolidation is particularly needed in the regional jet and commuter turbo prop market, where manufacturers must rationalise activities in order to avoid duplication. In military activities too, consolidation will be key to survival for the EU industry. The US is now well ahead in the restructuring of its defence activities. The process, which started with the unbundling of those defence activities for which contractors did not think they had a competitive advantage, is now translating into mega mergers: the recent one between Martin Marietta and Lockheed, and the acquisition by Northrop of Grumman. The new Northrop conglomerate now posts a turnover in aerospace activities close to that of British Aerospace, while the new Lockheed-Martin Marietta group is comparable in total size to Boeing. Given such competition, the challenge for EU manufacturers is simple: strengthen or disappear. The necessary consolidation process will translate into considerable changes in the level and structure of employment in the aerospace sector. The number of employed persons will continue to shrink significantly - albeit at slower pace than in the past couple of years to adjust to production rationalisation. As a number of employees are bound to shift from defence to civil activities to answer the reduction in the share of military work, the nature of employment will change dramatically, generating a need for vocational training. In particular, training programmes aimed to make workers who are used to government work familiar to market rules, are seen as essential. Other training programmes including those in languages will be all the more necessary as the workforce will have to be increasingly mobile, i.e. able to work in plants located in different EU Member States, and with foreign partners in the framework of international partnerships.

The growth in air transport in the medium and long term will necessitate the development of higher capacity, more efficient aircraft, and the improvement of airport infrastructure. Research into environmental technologies to meet increasingly stringent standards will be essential to ensure that this predicted growth is sustainable.

Written by: DRI Europe

The industry is represented at the EU level by: The European Association of Aerospace Industries (AECMA). Address: Rue Guedelle 94, B-1200 Brussels; tel: (32 2) 726 7916; fax: (32 2) 726 7094.

## Overview NACE 37

The demand for products within the instrument engineering sector is closely linked to the health of the overall economy. As such, it was not surprising that this sector experienced a particularly difficult period during the recent recession. Despite this temporary downturn, this sector has enjoyed strong production growth over the past decade at an average annual rate of 3.1 %. Such growth is even more impressive given that it occurred at a time in which employment levels remained essentially unchanged.

Still, the driver of sector growth has increasingly assumed the form of trade. Between 1984 and 1993, both extra-EU imports and exports have grown more than twice as fast as EU sector apparent consumption and production, respectively. More generally, sector trade intensities have increased to a point where nearly half of all 1993 EU sector consumption was satisfied by foreign suppliers of which the overwhelming majority were American, Swiss, and Japanese. By the same token, 43 % of 1993 EU sector production was used to satisfy non-EU demand. It seems that the internationalisation of this sector will continue unabated. As such, the long-term prospects of EU producers depend on their ability to compete on the world stage: against the Americans, Japanese, and Swiss at the high end of the technology spectrum and against the Pacific Rim/ASEAN producers at the lower end. Product differentiation, asset migration, automation, and increased R&D expenditure will all be critical in this regard.

### INDUSTRY PROFILE

#### Description of the sector

The instrument engineering industry comprises the following sectors:

- measuring, checking and precision instruments and apparatus (NACE 371);
- medical and surgical equipment, and orthopaedic appliances (NACE 372);
- optical instruments and photographic equipment (NACE 373); and
- clocks, watches and parts thereof (NACE 374).

As Table 2 shows, there is relative parity among the subsectors of medical and surgical equipment, optical instruments and photographic equipment, and precision instruments and apparatus as measured in terms of the three listed indicators of economic activity: consumption, production, and extra-EU exports. To underscore the degree of equivalency among the three principal subsectors, each subsector leads one of these indicators. Also in all economic categories, the subsector of clocks and watches lags a distant fourth. Still, it is interesting to observe that 1993 EU consumption of clocks and watches is proportionately twice as large as 1993 EU production. This contrasts markedly with the leading three subsectors, where there is proportional constancy across the three economic measurements.

Figure 2 indicates that Germany is by far the largest producer within the sector, contributing 43.6 % of the sector's value-added in 1993. Germany was followed by the United Kingdom with 19.8 % and France with 13.9 %. Indeed, these three countries, in combination, contributed nearly four-fifths of

**Figure 1: Instrument engineering  
Value added in comparison with related industries, 1993**

Source: DEBA

the sector's value-added in 1993. Other significant EU producer-states within the subsector include Italy (9.3 %) and Ireland (5.9 %).

#### Recent trends

Despite a decline of 3.3 % between 1992 and 1993, EU production within this sector has grown at a strong average annual nominal rate of 8.1 % over the entire period, 1984 through 1993, as Table 1 shows. The decline in EU production between 1992 and 1993 would have been far steeper, however, were it not for a significant rise in extra-EU exports of 27.5 %, fuelled largely by a rise in extra-EU exports of precision instruments. At the same time, EU apparent consumption experienced an even steeper decline between 1992 and 1993 of 6.2 %. Still, EU apparent consumption grew at an average

Source: DEBA

annual nominal rate of a healthy 9.1 % between 1984 and 1993, fuelled by increasing extra-EU imports.

Table 3 suggests that, within the context of apparent consumption and production, real growth was much stronger in the 1984-89 period than in the 1989-93 period. This disparity is owed in part to the recessionary effects of the 1992-93 although it is not clear how such effects can account for a significant real rise in extra-EU imports between 1992 and 1993. What Table 3 ultimately suggests is that, between 1992 and 1993, there was a sharp decline in domestic deliveries, i.e. those products made in the EU for EU consumption.

Figure 3 provides a comparison of how production and employment levels changed for the sector and manufacturing generally over the period 1984 through 1993. On this relative basis, the sector fared rather well as production outpaced that of overall manufacturing and sector employment levels remained essentially stable while employment in the larger manufacturing realm declined by about 10 %.

### International comparison

In comparing Triad nominal output between 1984 and 1993, Figure 4 shows that the United States maintained its leadership position. However, while overall Triad output increased by 36.6 %, US output increased by only 12.2 % causing a decline in US Triad production share from 52.8 % to 43.4 %. Over the same period, EU Triad production share increased from 19.2 % to 24.2 % and Japanese Triad production share increased from 28.0 % to 32.4 %.

Figure 5 indicates real growth in production for the three legs of the Triad on an annual basis between 1984 and 1993. It is interesting to observe that, in contrast with producers in the EU and Japan, American producers enjoyed an increase in real production between 1992 and 1993, fuelled partly by a general devaluation of the US currency.

### Foreign trade

As Table 3 illustrated, international trade has played an important role within this sector, particularly in recent years. Indeed, both extra-EU exports and imports have grown at rates more than twice those of production and apparent consumption, respectively. Overall, the EU trade balance showed a growing deficit over the past decade: the entry of the new Member States will improve the situation only in a marginal way.

The United States has remained by far the largest single country market for EU exporters within this sector as Figure 6 shows. Together, the former EFTA states and the United States comprised nearly 38 % of EU exports within the sector in 1993, down from 42.5 % in 1988. This decline stems in part from the burgeoning importance of emerging markets within the Pacific Rim/ASEAN region.

Figure 7 depicts a situation in which EU imports overwhelmingly emanate from three sources: the United States, Switzerland, and Japan. In 1993, producers from these countries provided 71.5 % of all EU imports within the sector, down slightly from 75.5 % in 1988. More interestingly, combined imports from only the United States and Switzerland increased over this period from 41.4 % in 1988 to 47.7 % in 1993.

Such an increased has occurred as the percentage of total EU imports originating in Japan declined from 34.1 % to 23.8 %.

Figure 8 provides the trade intensities within the sector over the period 1984 through 1993. Both the export/production ratio and the import/consumption ratio jump sharply in 1993.

### MARKET FORCES

#### Demand

The sector is comprised of a diverse array of products used in virtually every industrial and many consumer applications. A more useful understanding of the sector's demand drivers is offered on an elemental, sub-sector basis.

#### Optical instruments and photographic equipment

- Growth in demand for eyeglassware stems from broad demographic changes within the overall EU population. Specifically, both the increase in the overall EU population and its gradual ageing have sparked demand for spectacles, lenses, frames and mountings between 1984 and 1993. In addition, technological development and a heightened fashion sense have, in combination, induced a product differentiation to a point where consumers may choose from a

menu of features and products. Such has also served to fuel demand.

- Demand for precision optical instrumentation has flowed from the effort to modernise older manufacturing entities as this kind of technology is commonly used in production processes. This, in turn, has induced increased research investment activity, particularly in the area of laser technology. Another driver of demand in this area resides in increasing acceptance within environmental management applications.
- Demand for photographic equipment has been impelled by private consumption (particularly within the hand-held camera area), product innovation (more user-friendly technology and increased film quality per unit cost), and new product application (largely through the marriage of electronics and photography).

#### Medical and surgical equipment and orthopaedic appliances

- Demand in this area has been pushed both by a general ageing of the population as well as heightened awareness of health-related matters.
- This sub-sector is highly research-intensive. In this regard, expenditures of R&D funds have induced an array of technological innovation that has had direct impact on demand.

**Figure 8: Instrument engineering**  
**Trade intensities**

Source: DEBA

#### Measuring, precision and control instruments

- While demand within this subsector is largely linked to overall economic health, there tends to be a correlation between demand for a particular instrumentation and the health of particular industries such as gyroscopic/inertial navigation instrumentation and the aircraft and shipbuilding industries.
- As electronic technology has developed generally, it has permeated the sub-sector to the point where over 90 % of all instrumentation is electronically controlled. This has provided the sub-sector with a value-added content that has served to bolster demand.

#### Clocks and watches

- Private household discretion impels much demand in this area as technological innovation is least important within this subsector relative to the sector's other three product groupings. Thus, demand for clocks and watches is closely linked to a general level of disposable income.
- Still, technological innovation plays some role in influencing demand, particularly in the higher-end industrial applications.

It should be emphasised that each sub-sector is vulnerable to the vagaries of economic circumstance. Those areas with high income elasticities of demand are particularly vulnerable during periods of economic sluggishness.

#### Supply and competition

Between 1984 and 1989, extra-EU imports grew at about the same rate as apparent consumption within the sector on an average annual basis. Between 1989 and 1993, however, extra-EU imports grew much faster than apparent consumption. Such a trend has induced a burgeoning dependency on imports to the point where nearly half of all sector demand is satisfied by foreign instrumentation. That non-EU producers have achieved such success in this area is owed to several factors. First, the Americans and, to a lesser extent, the Japanese have enjoyed both the advantages of technological competitive advantage as well as a general depreciation of their respective currencies relative to EU currencies. second, the ASEAN/Pacific Rim producers are successfully competing on a cost basis at the lower end of the technological spectrum. Most recently, these producers have begun to compete at a higher level of technological sophistication as they develop certain manufacturing proficiencies. What follows is a characterisation of the supply and competition picture among the sub-sectors:

#### Optical instruments and photographic equipment

- The Japanese and the Americans have had a significant, although declining, presence within the EU market overall. Such is especially true within the area of photographic equipment where fierce price wars have ravaged the land-

**Table 6: Instrument engineering

100 or more employees	703	2.0	53.1	60.1

(1) Estimates.

Source: Eurostat "Enterprises in Europe"

scape of EU production. Also, the combination of EU regulatory liberalisation and the NAFTA agreement has rounded to the benefit of American exportation.

- In contrast to the situation within photographic equipment, EU producers are performing well within the area of optical precision instrumentation where the local market is characterised by relative self-sufficiency.
- In eyeglassware, EU firms are strong producers internationally and locally although they have begun to face competitive pressures from Asian producers.

#### *Medical and surgical equipment and orthopaedic appliances*

- Over one-half of EU imports within this sub-sector are US made, an amount that satisfies almost 20 % of total EU demand. To this end, US producers have benefited from a depreciation of the US dollar relative to EU currencies as well as the relative absence of regulatory burden within the EU. Such serves as a sharp contrast to the labyrinth of US import regulation in this area that some consider a non-tariff trade barrier.
- The Pacific Rim producers also compete within the EU market at the lower end of the product spectrum, mostly on the basis of price.

#### *Measuring, precision and control instruments*

- American producers have enjoyed much success within the EU market in recent years because of both a clear technological competitive advantage as well as a general devaluation of the US dollar relative to European currencies.
- Japanese producers, in contrast, have not been able to penetrate the EU market beyond a 10-13 % level of total extra-EU imports. Still, the Japanese have enjoyed somewhat of a currency devaluation relative to EU currencies as well as the synergies that accompany a large research infra-

structure. They also have niche competencies in such areas as weighing instrumentation. The Japanese have begun to invest directly in such EU markets as the United Kingdom in order to compete more effectively.

#### *Clocks and watches*

- EU manufacturers face formidable price competition from the Pacific Rim/ASEAN countries in the area of less expensive electronic watches.
- At the higher end of the timepiece market, Switzerland is rapidly becoming a major player not only because of historical competencies, but also because of a significant research capability.

#### **Production process**

Within the sector of instrument engineering, the production process has experienced a movement toward greater automation and system integration. In this regard, larger manufacturers - those with the capacity to absorb significant changes in production technology - have automated certain production processes as a means to lower labour costs and achieve higher economies of scale; such is particularly true at the higher end of the product technology spectrum. Also, the impracticality or expense which attends the manufacture of certain components has compelled some producers to become designers and system integrators, subcontracting the production of components and lower-level technologies to specialty houses. Another development has been the migration of certain production assets to relatively low-wage markets such as those within the Pacific Rim/ASEAN region. This not only enables EU producers to reduce costs but also enables them to compete more effectively in the growing markets of the Asian NICs.

As showed in Table 1, sector employment levels rose by 9.1 % as production levels rose by 59.6 % between 1984 and 1990. This would suggest a significant increase in productivity as, indeed, Table 5 bears out. Between 1990 and 1992, production

rose by 11.7 % while employment fell by 1.6 % increasing further levels of productivity. The period 1992-93 marked a period of production retrenchment (-3.3 %), as productivity increased further because of an even sharper decline in levels of sector employment of 4.7 %. Table 5 also shows that sector profit margin rates have remained essentially constant over the period.

## INDUSTRY STRUCTURE

### Companies

As Table 6 depicts, the overwhelming majority of firms within this sector had fewer than 20 employees in 1990. Such a fact points to a sector comprised mostly of family-run, niche players. Table 6 also shows, however, that notwithstanding its small sector representation as a percentage of the total number of firms, it is the large firm - those with more than 99 employees - that provides the majority of employment within the sector. Perhaps more telling, as Table 6 suggests, is the fact that the large firm generates an even greater percentage of the sector's turnover.

In essence then, only 2 % of the sector's firms generated more than 60 % of the sector's revenue while over 90 % generated less than 18 % of the sector's revenue in 1990. This suggests an oligarchic structure whereby a relative few companies control the economic dynamic of the entire industrial sector. In this regard, Table 7 provides the ten largest EU firms within the instrument engineering sector.

Unlike the small and medium sized firms which tend to specialise in one product area or one particular competency, the larger firms tend to offer a broad array of products across sub-sectors. For some large companies, instrument engineering does not even represent the main source of revenue even though the instrument engineering revenue they do generate places them near the top of sector turnover.

### Strategies

Basically, there are two sources of competition for EU producers. In the high value-added end of the product spectrum, EU manufacturers face competition from American, Japanese, and Swiss producers. At the low value-added, labour intensive end, the competition emanates mostly from the relatively un-industrialized regions of Pacific Rim/ASEAN. The competitive strategies that EU producers will need to follow delineate along these two lines.

Within the area of technologically sophisticated products, EU manufacturers have achieved success largely through intensive

research efforts. Such efforts have enabled them to remain reasonably competitive with the Americans, Japanese and Swiss in most product areas. Still, the significant budgetary burdens that accompany such research requirements have proven problematic for the marginal player in the sector. To this end, there may be a further bifurcation within the sector between a relatively few major producers and a panoply of smaller supporting producers. The marginal EU producer that wants to pursue the more sophisticated product technology may choose to form or join cooperative efforts that bring together the resources of many such producers in performing conceptual, basic research.

In order to compete against mainly Asian producers at the low end of the product spectrum, EU producers may choose to invest directly in such markets as the Pacific Rim. As stated earlier, such a strategy would accomplish two basic objectives. First, it would allow EU producers to compete more effectively on a cost basis. Second, it would give EU companies a foothold in the growing markets of Asia. Such asset migration has already been occurring within the sector, particularly in the area of clocks and watches. There is also palpable evidence that EU producers are competing at the low end of the technology spectrum through the general reduction of costs vis-à-vis the automation of production processes and concomitant achievement of economies of scale.

### Impact of the Single Market

In the EU, the industry of instrument engineering is mainly composed of small and medium-sized firms. During the last few years, the industry has benefited from the strength of investment activity, induced by high capacity utilisation levels in a healthy economic climate. Investment activity was also inspired by preparations for the establishment of the Single Market in 1993 and by the need to compete in global markets.

Another element of these recent years was the increasing competition from producers outside the EU. International competition is expected to heighten. In the fields of highly sophisticated products, EU producers face fast paced technological innovation, imposed mainly by Japan and the United States. So expenditures in research and development have to increase considerably. However, this high-cost strategy can hardly be financed by small and medium-sized companies, so that a higher degree of concentration is needed. In the field of the less technologically advanced products, standard instruments in particular, increased competition come from the East Asian New Industrialised Countries who are very price competitive. So the EU firms have to invest in modernisation and automation of the production process to improve production efficiency and reduce costs.

Thus, for these EU companies the most relevant measures of the European integration have been the harmonisation of technical standards and the removal of non-tariff trade barriers. The other positive measures are the opening up of public procurement, the legislation on consumer protection (especially for the industry of medical and surgical equipment) and the support policy to small and medium-sized firms. Moreover, the industry should also benefit in the nineties from the tighter controls required to meet growing environmental concerns. In this context, beyond the initial source of demand for identification and monitoring apparatus, demand for instruments to regulate and reduce environmental damage will also develop.

## REGIONAL DISTRIBUTION

Table 8 depicts how product specialisation values have changed between 1984 and 1993. Surprisingly, the country most specialised in this sector among the EU producers was Ireland, both in 1984 and 1993. This is even more surprising given the fact that Ireland contributed only 5.9 % of the sector's total EU value-added in 1993 as Figure 2 shows. This suggests

that while Ireland is not an important contributor to total value-added within the sector, the sector is relatively important to the Irish economy. Germany, the largest contributor, was only modestly above EU average in terms of the degree to which it is specialised in the sector.

---

## ENVIRONMENT

---

The production processes of this sector are perceived to impose relatively few environmental hazards. To the extent that such hazards exist, they generally fall along the following lines:

- Photographic equipment - The disposal of chemicals used in film production and development is believed to cause some damage to natural waterways.
- Clocks and watches - In this otherwise benign sub-sector, potential risks lie in the use of small nickel-cadmium batteries whose disposal is thought to pollute the ground water.
- Medical devices - Environmental problems, here, are mostly related to the disposal of syringes and other sterilised instruments. To this end, an EU Directive provides that a certain percentage of packaging materials must be recycled or recovered by the year 2000.

Indeed, not only are there relatively few environmental concerns associated with the sector, but this sector may be in the peculiarly enviable position of benefiting from a heightened world concern over environmental matters. As the need for analysing and monitoring air, soil and water pollutants increases, there will be a growing demand for products within the sector of instrument engineering, particularly within the area of measuring, precision and control instrumentation.

---

## REGULATIONS

---

The directive on machinery which recently came into force covers all four subsectors. Because such harmonisation will make it easier for foreign producers to penetrate the EU market, the EU Commission has taken the further measure to protect against the dumping of products from abroad. In the field of electronic weighing machines, for example, anti-dumping duties have been imposed on a number of Japanese firms. Recent legislation affecting the medical device area include one which requires any device sold within the EU must meet harmonised requirements and procedures and bear a CE-mark, a token of compliance with essential safety requirements, in order for it to enjoy unencumbered movement within the EEA.

---

## OUTLOOK

---

While it is likely that sector producers have turned the corner on the recession which struck them so seriously in the past two years, the short term outlook is somewhat uncertain. Prospects remain largely a function of the extent to which corporate capital budget planners feel sufficiently confident that the worst of economic times is behind them. What is more certain, however, is that for the short and long-terms, this is transforming into an increasingly globalized industry. The budding export and import trade intensities highlight the sobering reality that indigenous product loyalty has now become subservient to international product value. Thus, the long-term survival of the EU instrument engineering sector depends largely on its ability to adapt to this reality and compete accordingly.

Written by: DRI Europe

# Measuring, precision and control instruments

NACE 371

The year 1993 was certainly a year of contrasts for EU producers. On the one hand, the subsector suffered precipitous declines in both production and apparent consumption. On the other hand, extra-EU exports and imports enjoyed a remarkable jump. Indeed, it was the rise in exports that mitigated against an even sharper decline in production. Still, this subsector has enjoyed fairly robust growth over the 1984-93 period notwithstanding the poor results in 1993.

The United States has lost considerable Triad production share over the past decade such that there is near-parity among the outputs of the Triad's three legs. Despite this reduction, the American producers still possess a tremendous technological competitive advantage. It is not surprising, therefore, that the United States has enjoyed an mounting presence within the EU market as the leading source of imports. At the same time, EU producers face increasing pressures from such low-wage regions as the Pacific Rim/ASEAN.

The demand for products within this subsector is tied to the health of the overall economy. Still, factors peculiar to the subsector may ultimately rebound to the benefit of production in the medium term. Such factors include dynamic technological development, greater dependence on environmental instrumentation, and increased EU access to the developing markets within Asia, Eastern Europe and South America.

## INDUSTRY PROFILE

### Description of the sector

The industry of measuring, precision and control instruments covers the manufacture of:

- gas meters, water meters and other liquid supply meters including petrol pump meters;
- measuring, checking or automatic control instruments and apparatus;
- equipment for navigation, hydrology, geophysics and metrology;
- drawing and mathematical calculating instruments;
- precision measuring instruments;
- precision balances, laboratory equipment and teaching equipment; and
- other precision equipment and apparatus.

The sector does not include electrical counters, or measuring, testing, regulating and control instruments, all of which are classified under NACE 344. As Figure 1 shows, this subsector slightly edges out that of medical and surgical equipment for prominence within the larger instrument engineering sector.

The measuring, precision and control instruments sector is the largest subsector within instrument engineering, accounting for about 37 % of total value added. Two countries, Germany and the United Kingdom, provide the lion's share (over 80 %) of value added within this subsector (see Figure 2). Among the second tier of EU producers within this subsector are Italy, France and Spain.

### Recent trends

The effects of the recession hit this subsector especially hard, and 1993 marked a disastrous year for EU producers. Between 1984 and 1992, this subsector saw production rise at an average

Figure 1: Measuring, precision and control instruments Value added in comparison with related industries, 1993

Source: DEBA

annual rate of a robust 8 % (see Table 1). In sharp contrast, 1993 production fell by 7.0 % over the previous year resulting in a nominal average annual growth rate of 5.8 % over the entire 1984 to 1993 period. Indeed, the 1993 decline would have been far more precarious were it not for a nominal increase in extra-EU exports of an astounding 75.3 % relative to 1992.

An even sharper change is observed in the apparent consumption of measuring, precision and control instruments. Between 1984 and 1992, apparent consumption grew at a nominal average annual rate of 9.5 %. Between 1992 and 1993, apparent consumption fell by 11.2 % resulting in a nominal average annual growth rate of 6.3 % over the decade up to 1993.

Table 2 shows how apparent consumption, production and extra-EU trade has changed in real terms. Again, note the contrast between the period of 1992 through 1993 and the entire period 1984-93.

**Figure 3: Measuring, precision and control instruments  
Production and employment compared to EU total manufacturing industry**

1994 are Eurostat estimates.  
Source: DEBA

Figure 3 suggests that both production in volume terms and employment did not kept pace with EU manufacturing overall over the period 1990 through 1993.

**International comparison**

As Figure 4 shows, nominal Triad production has risen by over 37 % between 1984 and 1993. More interestingly, the Triad's three regions have achieved relative production parity over the period. In 1984, the United States produced over 50 % of the Triad's output in nominal terms. Between 1984 and 1993, the American nominal output increased by only 4.3 % compared to 52.4 % for the EU and 89.4 % for Japan. Such a disparity in growth rates has resulted in a redistribution in nominal production share such that the EU and Japanese producers now have over 60 % of output as measured in 1993 ECU compared to 38.5 % for the United States.

Figure 5 shows how subsector production from each member of the Triad has evolved in constant prices. Note that, in

recent years, Japanese and EU output has lessened notwithstanding their success over the entire period.

**Foreign trade**

Nominal average annual growth in extra-EU exports was a healthy 15.0 % during the years between 1984 and 1993. That value, however, is deceiving. Between 1984 and 1992, nominal average annual growth was only 4.2 %. Between 1992 and 1993, extra-EU exports achieved a remarkable 75.3 % increase as mentioned earlier. Similarly, extra-EU imports of measuring, precision and control instruments enjoyed a remarkable spike in 1993. Between 1984 and 1992, nominal extra-EU imports rose by an average annual rate of 11.1 %. Between 1992 and 1993, extra-EU imports nominally rose by 75.0 %, rendering average annual growth at 25.5 % over the entire period. Although extra-EU imports have risen faster than corresponding exports, the EU trade balance grew by 22.5 % between 1984 and 1993 (see Table 3). Of course, the

**Figure 4: Measuring, precision and control instruments

Source: DEBA

**Figure 6: Measuring, precision and control instruments  
Destination of EU exports**

Source: Eurostat

EU trade balance did not ascend on a continual basis between 1984 and 1993.

Figure 8 shows that trade intensities were fairly stable between 1984 and 1992 (in the 20-25 % range for exports and in the 12-16 % for imports). An enormous jump in exports and imports in a year of sharply declining production and consumption caused export and import trade intensities essentially to double in 1993.

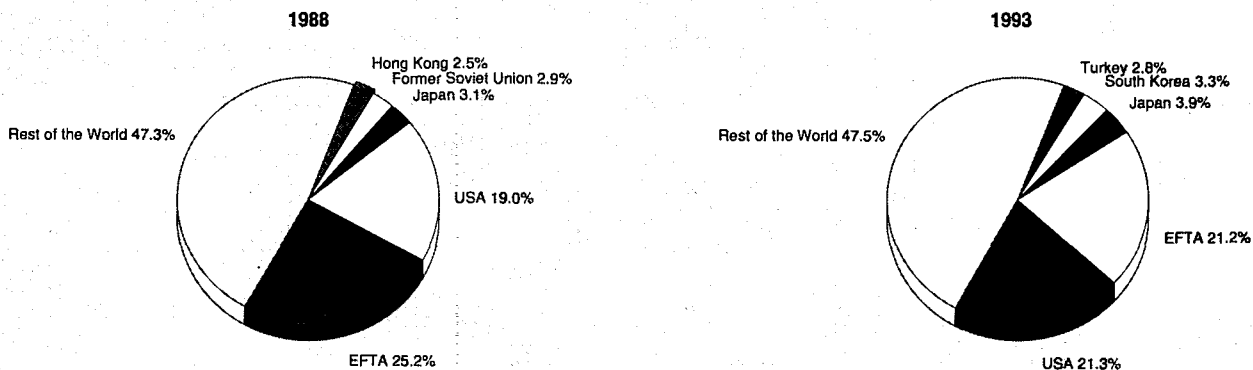

The United States has become the main source of competition for EU producers within the EU market. In 1993, 43.6 % of all EU imports emanated from the United States, up from 39.9 % in 1988. It is thought that the pre-eminence of American instrumentation within the EU market is owed both to the economies of scale which US producers enjoy, as well as a general depreciation of the USD against EU currencies in recent years. Meanwhile, there has been a deterioration in the shares of Japanese and EFTA producers such as Sweden and Switzerland (see Figure 7).

## MARKET FORCES

### Demand

In a broad sense, demand for measuring, precision, and control instrumentation is influenced by the health of the general economic activity, as such instrumentation is found in virtually every industrialised sector. Other fundamental drivers of demand include investment in technological development including automated industrial processes. Still, this is a relatively specialised subsector, and is aligned by industry end-user. Thus, demand for a particular class of instrumentation is distinctively sensitive to improvements in economic activity within certain industrial sectors. Thus, demand for measuring, checking and controlling instruments - used to regulate production processes - is sensitive to activity within the vehicle production, machinery construction, environmental protection, chemical, pharmaceutical and food sectors. Demand for navigational, hydrological, and meteorological instruments is sensitive to trends in the aircraft and shipbuilding industries. Weighing instruments are in demand by a number of industrial end-users as well as wholesale and resale traders.

**Figure 7: Measuring, precision and control instruments  
Origin of EU imports**

Source: Eurostat

It should also be noted that as electronic technology has developed, it has permeated the sector to the point where over 90 % of all instrumentation is electronically controlled. This has provided the sector with a value-added content that has served to bolster demand.

### Supply and competition

Despite world trends which show a levelling off of American production, US producers have increased their presence on the EU market in recent years. The Americans have enjoyed this success because of both a clear technological competitive advantage and a general devaluation of the US dollar relative to European currencies.

In contrast, the Japanese have not enjoyed success in the EU market beyond a level of 10-13 % import penetration (see Figure 7). Still, the Japanese are successful within certain areas (e.g. weighing instrumentation). In this regard, Japanese exporters have been assisted by a general devaluation of the Yen relative to European currencies, albeit to a lesser extent than the American exporters. Also, Japanese companies within this subsector tend to be extremely large relative to the small and medium-sized European enterprises. As such, Japanese producers enjoy a more significant research infrastructure as well as the synergies and economies of scales that usually accompany larger operations. Japanese companies also have begun to invest directly in European markets, e.g. the United Kingdom, in order to compete more effectively.

Competition from the relatively low-cost ASEAN/Pacific Rim producers has increased in recent years. This pattern should continue as producers from more industrialised nations will become less competitive, particularly at the low end of the technology spectrum.

### Production process

In the past, manufacturers within the measuring, precision and control instruments industry looked to upstream suppliers for relatively raw, unprocessed materials. The manufacturers would, in effect, supply the vast bulk of the product's value-added. To the extent that electronics and other sophisticated modularity has changed the production process, the relationship between manufacturer and supplier too has changed. Now, producers are far more inclined to sub-contract - either because producers are not able to manufacture the technology themselves or because they view the role of system integrator as

more cost-effective. As a result, knowledge of the manufacturing process has shifted generally from manufacturer to supplier. This trend shows no sign of abating.

In recent years there has been an increased integration of data processing system technology in the sector, particularly within the area of precision mechanics. Data processing system technology also has been integrated into products within the area of analytical equipment, process control systems, transducers, measuring devices, etc.

Between 1989 and 1993, employment within the subsector declined by approximately 14 %. Thus, it is not surprising that productivity has increased (see Table 4). Still, the rise in productivity is modest relative to other subsectors within instrument engineering. In fact, combined with a similar rise in unit labour costs, the rise in productivity did not result in any meaningful change in the gross operating rate.

## INDUSTRY STRUCTURE

### Companies

In general, the composition of this subsector is mostly characterised by an array of small and medium-sized enterprises, although a few large companies produce a broad range of products in various fields of instrument engineering. Some companies are active producers of instrumentation for both this sector and other fields of manufacturing, such as consumer electronics, computers and motor vehicles.

More specifically, the structure of this sector is largely product-dependent. Enterprises within the weighing industry, for example, range in size from those employing under a dozen to the few that employ several thousand, including such important manufacturers as Sartorius (D) and GEC Avery (UK). Other product areas, such as the counting instruments and checking and controlling machines sectors, consist mainly of medium-sized to large manufacturing firms. The primary EU producers in these areas include Zeiss (D), Renault Automation (F) and Dea (I). In measurement and automation technology, the majority of the firms are small to medium-sized, typically with fewer than 200 employees, although a few large companies boast more than 1 000 employees on their staff. Significant manufacturers in this area include Hartmann & Braun (D), Hottinger Baldwin (D), Krohne (D), Endress & Hauser (D) and Foxboro (UK), which was recently taken over by Siebe (UK). Conversely, the make-up of the automation technology sector comprises a few multinationals such as Siemens AG (D), Asea Brown Boveri (D) and Philips (NL).

### Strategies

Within this sector, EU producers are confronted with a two-part challenge. At the high end of the technology spectrum, EU producers are challenged by the significant technological developments driven largely by manufacturers in Japan and the United States. At the same time, manufacturers (mainly in the Pacific Rim/ASEAN region) leverage their significant cost advantage through fierce price competition within the lower end of the technology spectrum. The strategies which manufacturers should employ to counteract these competitive pressures depends on the product area. In such areas as standard instrumentation, EU manufacturers need to invest heavily in automation and other cost-reducing production technology in order to seize the advantage of economies of scales. This will mitigate the cost advantages that the Asians enjoy. In this same regard, EU producers must consider the relocation of production assets to such relatively low-cost areas as Spain, Portugal, Hungary, the Czech Republic and, perhaps, even certain countries within the Pacific Rim/ASEAN region.

Within the context of the more sophisticated portion of the technology spectrum, EU manufacturers will need to invest heavily in R&D. However, as this step is largely limited to the multinational corporations and their relatively flush cof-

**Figure 8: Measuring, precision and control instruments Trade Intensities**

Source: DEBA

fers, small and medium-sized entities will need to join forces in order to achieve the levels of investment necessary. Indeed, the subsector is already characterised by a series of mergers involving small and medium-sized enterprises. In the weighing industry, for example, Toledo (F) was taken over by Mettler (CH); GEC Avery (UK) took over Berkel; Testut (F) has purchased Trayvou (F) and Lutrana (F); and Precia (F) took over Molen (NL) and Yernaux Pesage (F). In industrial process controls, Siebe's (UK) takeover of Foxboro formed the second largest producer of such instruments in the world, behind the American firm Honeywell. Other recent takeovers in this area include the Italian company Elsag's takeover of the Sereg division of Schlumberger (D); and CGE-Alsthom's (F) takeover of the industrial control operations of the British GEC.

Another potential strategy - particularly for the smaller, niche market players - includes restricting internal activities to those of design and assembly. As mentioned, this practice already has been established with the burgeoning role of sophisticated technology and the inability or unwillingness of some firms to develop the appropriate level of expertise in this regard. Moreover, the increasing globalisation of the subsector has imposed an international marketing requirement, which will impose a wedge between the larger multinational firms that can accommodate the marketing and after-sales support required on the world market and the smaller firms that cannot. A potential solution to this problem resides in the cooperative marketing and after-sales support of smaller companies in such markets as the Pacific Rim/ASEAN regions.

### Impact of the Single Market

During the last decade, the production growth of the industry was due to increased investment activities of manufacturing and services businesses and the growing spread of electronic components in their products.

For EU companies the most relevant measures of the European Internal Market programme have been the technical standardisation of machinery and the removal of non-tariff trade barriers, which eased the development of trade between EU firms. This has also resulted in increased competition in the sector, both from other EU producers and from non-EU producers. In the nineties, the industry should benefit from the tighter controls required to meet growing environmental concerns, which will raise demand for measuring and control instruments. In fact, beyond the initial source of demand for identification and monitoring apparatus, demand for instruments to regulate and reduce environmental damage will also develop. Other relevant measures have been those to support SMEs, and the encouragement of R&D.

### ENVIRONMENT

There is relatively little concern that manufacturing within the subsector causes deleterious effects on the environment. Indeed, the larger world concern over environmental issues has proved to be a boon for EU manufacturers. To this end, there are growing needs for measuring and analytical equipment for gas, vapour, dust and noxious substances in air and water, as well as for apparatus to investigate harmful effects on humans, animals, plants, soil and food. In addition, instrumentation designed to regulate and reduce environmental damage (e.g. gas desulphurisation systems) have been in greater demand.

### REGULATIONS

The recent harmonisation of regulations affecting the technical standards of machinery within the EU should make it easier for producers such as the United States to penetrate this market. At the same time, the EU has taken measures to protect against the dumping of foreign-made instrumentation. In the field of electronic weighing machines, for example, anti-dumping du-

ties have been imposed on a number of Japanese firms and others have been considered regarding certain firms from South Korea and Singapore.

### OUTLOOK

Indications suggest that this subsector is emerging from the recessionary downturn of 1993. Still, short-term prospects are modest at best. Downstream consumers of measuring, precision and control instrumentation also have been affected by the recent recession and, therefore it would seem likely that they will exercise caution in increasing capital expenditures.

Yet, there is reason for optimism for the medium term. The export market will serve as an important source of revenue, particularly if the 1993 upturn proves to be more than a one-year aberration. To this extent, the United States will continue to be a critical market for EU producers, although the development of new markets in the Pacific Rim/ASEAN regions and increasing demand from China, South America and Eastern Europe will help diversify the export portfolio. Improved demand will also stem from the increasing international importance of environmental regulation as well as dynamic technological developments. The extent to which EU producers can successfully capture this new demand will depend on the extent to which they can transcend the barriers accompanying global competition in the twenty-first century: international marketing, R&D expenditure and production efficiency. To conclude, it would seem likely that this subsector will continue to evolve down the path of consolidation and asset migration that has characterised many such subsectors within the EU.

# Medical and surgical equipment and orthopaedic appliances

## NACE 372

The past ten years have proven remarkably strong for EU producers within this sector despite a relatively weak 1992-93 period. To this end, the ageing of the population, technological innovation, EU regulatory harmonisation, and a heightened sense of health awareness have been important factors in spurring demand.

The USA dominates the sector although their share among the Triad has declined somewhat in recent years. Still, they represent the clear competitive presence within the EU market. Although exports have grown robustly, EU penetration into the American market has been inhibited by layers of regulation that some regard as a non-tariff trade barrier.

The outlook looks promising as health care expenditures will likely rise notwithstanding efforts to control costs. The extent to which EU producers can compete with the USA will in large measure depend on their willingness to engage in product differentiation, increased R&D expenditures, as well as a co-ordinated R&D policy with the governing EU authority.

### INDUSTRY PROFILE

#### Description of the sector

The sector of medical and surgical equipment and orthopaedic appliances includes the following activities:

- manufacture of medical apparatus for diagnostic work
- manufacture of medical, surgical and veterinary equipment and instruments
- manufacture of dental instruments and apparatus, and
- manufacture of orthopaedic appliances, artificial limbs, eyes, teeth, etc.

Orthopaedic footwear is not included within this sector as it is found in NACE 452. X-ray apparatus and electro-medical instruments, including electro-medical diagnostic equipment, electro-medical treatment, electro-dental instruments, electrical hearing aids and pacemakers are also excluded as they are found in NACE 344.

Within the larger sector of instrument engineering, this sub-sector represents about 36 % of total value-added in 1993, as Figure 1 shows.

Germany is unambiguously the leading producer, with more contribution to total value-added than all the other countries combined. At more than 54 %, Germany is followed by France with 18 %, the United Kingdom with 16 %, Italy with 7 %, and Denmark with approximately 3 %. Figure 2 provides a country-by-country breakdown in terms of value-added.

#### Recent trends

In current prices, both apparent consumption and production have had strong growth records. Between 1984 and 1992, apparent consumption and production grew at a rate of 15.9 % and 13.6 %, respectively. Between 1992 and 1993, however, that growth fell sharply to 1.5 % for apparent consumption and 3.1 % for production. Extra-EU exports grew at an average rate of 12.5 % between 1984 and 1992. Yet, in contrast with apparent consumption and production, extra-EU exports grew at a robust 15 % between 1992 and 1993. Such suggests that the extent to which production grew at all in 1993 may be

**Figure 1: Medical and surgical equipment and orthopaedic appliances**  
Value added in comparison with related industries, 1993

Source: DEBA

owed, in part, to the export markets. Still, given the general recessionary environment during this period, any growth between 1992 and 1993 contrasts with other sectors and bespeaks a certain inelasticity with respect to economic fluctuations. Table 1 provides an overview of this sector's main indicators in current prices.

As Figure 3 shows, both production and employment within the sector outpaced those of manufacturing generally.

#### International comparison

As Triad total production increased by approximately 77 % (8.6 % per annum average), there has been somewhat of a shift among the respective shares. While the USA is still the clear leader, its share has declined from 66 % in 1984 to 58 % in 1993. In contrast, both the EU's and the Japanese shares have increased by 4 % individually.

Figure 5 shows that in constant terms, however, Japan has enjoyed the fastest growing rate of production between 1984

Source: DEBA

and 1993 at 14.0 %. Indeed, between 1984 and 1992, the Japanese rate of growth was 19.0 %.

**Foreign trade**

As both Tables 1 and 2 showed, the rate of apparent consumption was greater than the rate of production. This, in turn, caused extra-EU imports to grow faster than extra-EU exports. To this end, the EU trade balance within this sector significantly deteriorated between 1986 and 1992. The period 1992-93 marked a reversal of the general trend. Table 3 provides a summary of trade data for the EU within this sector. Note how precipitously the ratio of exports to imports has declined.

Clearly, the USA increased what was already an overwhelming presence in the EU market from just under 48 % in 1988 to just under 53 % in 1993. Much of this growth was owed to price competitiveness and technological advances. In contrast, the Japanese and Swiss both lost significant market share.

While both the American and EFTA states were still the biggest export markets for EU producers in 1993 as they were in 1988, their combined share declined from 47.6 % to 41.0 %. Interestingly, Russia has emerged as one of the largest single country markets for EU exports within this sector, no doubt a result of its new willingness to seek superior foreign made instrumentation.

Figure 8 shows a relative balance between exports and imports as percentages of production and consumption, respectively, within the 30-35 % range over the period 1984 through 1993.

**MARKET FORCES**

**Demand**

Notwithstanding the real decline in apparent consumption within the 1992-93 period, EU demand for medical and surgical equipment and orthopaedic appliances has been strong since 1984. An important part of this strength emanates both from

**Figure 4: Medical and surgical equipment and orthopaedic appliances

Source: Eurostat

a general ageing of the population within industrialised countries as well as a more acute awareness of health-related matters including the spread of infectious disease such as AIDS.

This sector is highly research-intensive. In this regard, expenditures of R&D funds have induced an array of technological innovation that has had direct impact on demand. Such innovation includes improvement in diagnostic instrumentation. Particular efforts have involved the development of endoscopic procedures, minimally invasive surgical treatments that often include benign ultrasound or laser applications. In recent years, there have been developments in multi-functional endoscopes which allow for complete treatment without the need to change instruments. There have also been developments in the marriage of endoscopic and optical system technology.

Other technological advances allow for better video diagnostic methodology including improvements in data transmission and picture storage. In this regard, an area of particular importance is laparoscopic technology which is regarded by some as the fastest growing segment of the sector. It is thought, for example, that the vast majority of gall bladder operations will be performed laparoscopically. Also, advances in the accuracy of corneal-measurement methods have spawned an array of

surgical techniques for the correction of eyesight. The precision of such measurement is important because this information is used by the surgeon prior to radial keratotomy or excimer laser photorefractive keratectomy. Improvements in data processing systems, generally, have transformed many applications including anaesthetic processes; there, data-based technology now operates in areas that had been the exclusive domain of unaided observation. Improvements in materials technology have redounded to the benefit of prosthetic and orthopaedic devices. Also, biomedical engineering advances have greatly improved the ambulatory benefits of particular devices including improved myo-electronic regulation of artificial legs.

Generally, medical instrumentation has become both more disposable and consumer-friendly in recent years. Such has fuelled a trend toward greater medical self-administration and out-patient therapy. This, in turn, has likely resulted in a more efficient allocation of economic resources. Yet, at the same time, greater medical self-reliance has caused hospitals in some areas to trim budgets for medical and surgical instrumentation. It is not clear whether disposability and personal convenience have benefited or dampened this sector. It is clear, however, that while past demand almost exclusively emanated from hospitals and traditional care-givers, today it

**Figure 7: Medical and surgical equipment and orthopaedic appliances  
Origin of EU imports**

Source: Eurostat

stems to a much greater extent from the private consumer. This trend seems likely to continue.

### Supply and competition

As Figure 4 depicted, the United States is by far the largest producer within the sector and, clearly, the greatest competitive threat to EU manufacturers. Indeed, over one-half of EU imports within this sector are American made, an amount that satisfies almost 20 % of total EU demand. Such represents a marked increase from 1988 where the United States satisfied about 14 % of total EU demand. At the same time, the United States represents only about 20 % of the EU's total exports, down from over 25 % in 1988. Given America's relative self-sufficiency in this area (14.3 % import intensity in 1993). That this gap is widening is owed largely to the difficult regulatory environment which characterises the American market. In recent years, legislation has been enacted which has required manufacturers of certain medical devices to establish a tracking system to contact patients in the event of product recall, maintain and regularly publish safety and effectiveness data, and perform post-market surveillance protocols for implants. These and other American regulations have impelled American producers - already endowed with strong technological advantage - to pursue the EU market. Such may also explain the lessening percentage represented by EU exports destined for the United States. Other important, albeit less systemic, bases for this imbalance include a depreciation of the American dollar as well as the trade alliance between Canada, the United States, and Mexico which was promulgated by the NAFTA accord.

After the United States, Japan is the single largest country manufacturer within this sector with approximately 17 % of the Triad output. Still, Japan maintains a relatively small presence within the EU market at about 12.4 % of EU imports in 1993, or about 4.5 % of total EU demand. This contrasts with 1988's figure of 15.6 % of EU imports, or about 5.1 % of total EU demand. Japan has particular strength in such areas as flexible endoscopic instruments in which the Japanese company Olympus overwhelmingly dominates the world market. Japan also has strength in the manufacture of blood pressure instruments.

Beyond the United States and Japan, competition resides in such less industrialised countries as Indonesia, Malaysia, and the entire Pacific Rim. Indeed, it seems likely that much of

the EU's share of lower-end product will be captured by these markets as Malaysia already represents 2 % of EU imports. Pakistan also provides competition, particularly in the field of standard instruments.

### Production process

About 30 years ago, this sector was characterised by relatively unsophisticated production processes. Much of the orthopaedic area did not involve electronic functionality at all. Today, the heightened complexities of the technologies within this sector require an array of expertise. Such has resulted in a great deal of subcontracting and product specialisation. It is likely that this trend will continue in the future, particularly with the burgeoning role of system integration.

As Table 4 shows, productivity has improved markedly over the period. Such is even more remarkable when one considers from Figure 3 that employment grew by about 23 % between 1984 and 1993. Table 4 also provides an index of labour costs and gross operating rates. The strength of the latter reflects the relative profitability of the sector.

## INDUSTRY STRUCTURE

### Companies

As mentioned, this sector is comprised of many subcontractors and only a few large organisations. The subcontractors often specialise in narrow niches of activity and may be more than one level removed from the final system integrator. Indeed, major players in medical and surgical instrumentation and equipment may, in fact, be better known for other areas of endeavour such as electronics (GEC, Siemens) or industrial adhesives (3M).

There are, however, identifiable leaders within particular product applications. Important manufacturers of fixed endoscopic devices include Karl Storz (D) and Richard Wolf (D), each with about 35 % of the world market, and Olympus (Japan), with most of the rest. Draeger Werke (D), l'Air Liquide (F), Ohmeda (UK) and British Oxygen (UK) are all major producers within the area of anaesthetic apparatus and equipment. About half of the world's output of small medical instrumentation is performed by a host of small German companies, most with fewer than 100 employees each. Aesculab (D) represents one of the few large companies in this regard. Within orthopaedic appliances, important EU countries include Smith & Nephew (UK), Dow Corning (F), Otto Bock (D), Aesculab (D), Waldemar Link (D) and the Gebr. Martin (D).

The United States has some of the largest and most important companies within the sector. Baxter, for example, is the world's largest producer of health care products, producing in virtually all areas of medical equipment including blood bags, diagnostic tools, dressings, and surgical gloves. Other important American producers include 3M, Johnson and Johnson, and Abbott whose products, collectively, include infusion sets and catheters, medical dressings, implants, dental materials and diagnostic devices.

### Strategies

Changes in the regulatory landscape have affected both indigenous and foreign producers that wish to operate within the EU. Specifically, producers who wish to sell to any EU country must ensure that the product conforms to a uniform technological standard. Such contrasts with past practice in which producers merely had to satisfy the purchaser-country's standard. The inception of a harmonised EU standard particularly benefits the major foreign producers in that they will no longer have to contend with varying and potentially conflicting regulatory standards.

Generally, the USA and, to a lesser extent, the Japanese will maintain material technological advantages. Thus, they will continue to represent formidable competition for EU produc-

Source: DEBA

ers. EU producers, for their part, will likely follow a two-track approach: upgrading and modernisation of plant capability for higher-end product and asset migration to low-cost, developing economies for production of lower-end product. Beyond outright asset migration to such countries as Malaysia and Thailand, some of the larger EU companies may prefer to engage in joint ventures. Such is already occurring with companies in South East Asia and China. More generally, research and development expenditure will be key to any effort to achieve technological parity with the USA. Unlike the Japanese and, to some extent, the USA, the EU producers have yet to reap the benefit of a coordinated governmental R&D policy which was hoped to have accompanied the establishment of a unified Europe.

Small niche players within the EU, without significant financial resources, will likely pursue the course they have charted through product specialisation. Another, although less likely, alternative for the smaller player includes a merging with larger EU manufacturers.

### Impact of the Single Market

In past years the ageing of the population, increasing health consciousness and product innovation have been the driving forces for the development of this sector. The completion of the Single Market in this sector has heightened competition between EU and non-EU producers. The technical standardisation which is underway within the EU is expected to strengthen competition from abroad, since the American and the Japanese competitors will no longer be forced to adapt their products to differing requirements in the various EU countries. On the other hand, this will also enhance the capability of EU producers to increase their share of the other EU markets. Due to its technological edge, however, the United States will remain the chief competitor in the medical equipment sector, while in the field of standard instrumentation, competition stems mainly from Japan and the East Asian Newly Industrialised Countries. Support to R&D and access to finance by SMEs are other important parts of the Internal Market programme, from the point of view of medical and surgical equipment producers.

## REGULATIONS

As mentioned, EU regulations are changing the competitive and environmental standards within the sector. In recent years, at least three important EU directives have emerged and directly affect the movement of medical and surgical devices within the EU. The Active Implantable Medical Devices directive, which became effective in 1993, concerns the manufacture and sale of pacemakers and other implantables. The Medical Devices Directive is likely to become effective in 1995 and covers medical devices generally. The In Vitro Diagnostics Directive concerns such areas as endoscopic technology. An important aspect of these legislations is the requirement that any device sold within the EU must meet a uniform standard and bear a stamp of approval to that effect in order for it to enjoy free movement within the EU.

## OUTLOOK

If past is prologue, the medical and surgical equipment and orthopaedic appliances sector should continue to enjoy strong growth in apparent consumption and production, notwithstanding a soft year in 1993. The ageing of both the EU and world populations will only strengthen demand in this area. Recent technological advances will also spur demand. Markets in China and the ASEAN/Pacific Rim regions - only marginally exploited - promise great potential in maintaining what has been a strong track record in EU exports.

Still, the horizon is not without clouds. The USA will likely remain the world leaders as they will continue to enjoy a substantial competitive advantage, particularly within the higher-end product areas. Such makes the American presence within the EU all the more problematic. Moreover, regulatory burdens within the United States render the American market relatively unattractive. Efforts to restructure health-care in certain industrialised countries will likely retard demand as well.

It would seem that the success of the next 5-10 years will, in large measure, depend on the extent to which the EU producers achieve technological equivalence with the American producers in high-end areas and transfer production of low-end applications to low-cost, less-developed markets. Regulatory parity between the United States and the EU, too, would improve future prospects. All of this, in turn, will require a sense of strategy and, perhaps, a greater government-industry coordinated effort.

# Optical instruments and photographic equipment

## NACE 373

While it is true that this sector has enjoyed general growth since 1984, that growth stumbled in 1993 as both apparent consumption and production fell. Still, the trade balance has been improving since 1991 and, in fact, it was a sharp increase in exports that helped mitigate an even more significant decline in production.

Most feel certain that recent declines in production and consumption are temporary manifestations of a recessionary environment. What is less certain, however, is whether a volatile world economy will enable the longer-term outlook to reflect the kind of growth this sector has known in the past.

### INDUSTRY PROFILE

#### Description of the sector

This sector comprises an array of instrumentation which can be thought to divide neatly into three general groupings:

- spectacles, lenses, frames and mountings and equipment for use by opticians;
- optical precision instruments (other than optician items);
- photographic and cinematography equipment.

At 24 % of total value added in 1993, the optical instruments and photographic equipment market represents the smallest component of the larger instrument engineering sector as Figure 1 shows.

On a per country basis, Germany clearly leads the EU with over one-third of total value added, followed by France (20.6 %), Italy (14.8 %), and the United Kingdom (13.0 %)-a concentration ratio of about 83 % for these countries. Figure 2 depicts value added on a per country basis for 1993.

Notwithstanding the high concentration ratio among these four countries, the sub-sector is marked by a great deal of product specialisation in which German manufacturers concentrate on high-end optical, precision and photo instruments, while French and Italian producers concentrate on relatively low-end ocular optics, primarily spectacle frames.

#### Recent trends

Between the years 1984 and 1992, the optical instruments and photographic equipment sub-sector was marked by strong growth in both apparent consumption (13.1 % per annum) and production (11.5 %). Growth in production was abetted to an extent by a corresponding increase in extra-EU exports of 3.4 % per year over the period. The year 1993, however, saw a marked decline in apparent consumption of 7.4 % compared to 1992 and a smaller decline in production of 2.6 % over the same period despite a sharp increase in extra-EU exports of 13 %. Such implies that, in the absence of this increase in extra-EU exports, the decline in production would have been considerably sharper. Still, this increase in exports has helped lessen the negative trade balance since 1991 as Table 1 indicates.

As Figure 3 shows, production and employment have both outpaced comparable levels within EU manufacturing generally. It is particularly noteworthy that as production levels within the sector are more than 9 % higher than they were

Figure 1: Optical instruments and photographic equipment Value added in comparison with related industries, 1993

Source: DEBA

in 1990, production levels within EU manufacturing generally are essentially unchanged.

#### International comparison

Although it is true that the United States is still the leading manufacturer of optical instruments and photographic equipment, its market share within the Triad has been in steady decline at least since 1984 and likely before that. Much of the decline in American market share has been seized by manufacturers within the EU and to a lesser extent by Japanese manufacturers. Specifically, in 1984 the American manufacturers held over 55 % of Triad output compared to 14 % and roughly 31 % for manufacturers within the EU and Japan, respectively. As total Triad output increased by approximately 11 % between 1984 and 1993, American output declined by 15 %. American output share within the Triad declined from 56 % in 1984 to 43 % in 1993. Over the same span of time, Japanese share increased from 31 % to 34 % and EU output increased from 14 % to 23 %.

Still, notwithstanding the relative gains by the EU and Japanese manufacturers between 1984 and 1993, all of that growth occurred prior to 1991. Indeed, since 1991, real output has remained essentially unchanged within the EU and has declined by more than 20 % in Japan. During this period, real output has increased by over 7 % in the United States. Figure 5 depicts how real output has changed over the period within the Triad.

**Foreign trade**

As Table 1 showed, growth in extra-EU exports coupled with near-constant extra-EU imports since 1991 have caused a decline in the EU trade balance as measured in current ECU. Table 2 depicts vividly how, in real terms, extra-EU exports have helped offset a precipitous decline in apparent consumption. Table 2 also shows that while real extra-EU exports

have outpaced real extra-EU imports over the period 1989-1993, that disparity was striking between 1992 and 1993.

As Table 3 shows, extra-EU imports increased by 23.2 % over the period 1988 and 1993, or 4.6 % compounded annually. Over this period, Japan has served as the EU's greatest source of imports. Still, as Figure 7 indicates, Japan's grasp on the EU import market has weakened somewhat since 1988. Indeed, 1993 represented the first time in many years that Japan did not provide the majority of the EU's import requirements. In contrast, the United States provided over 21 % of EU imports in 1993 compared to just under 19 % in 1988 and about 17 % in 1987.

While, historically, the American market has been a strong buyer of extra-EU exports, that strength has tempered in recent years. In 1988, over 36 % of extra-EU exports were targeted for the USA as compared to 31.5 % in 1993. In fact, the

**Figure 4: Optical instruments and photographic equipment

**Figure 6: Optical instruments and photographic equipment  
Destination of EU exports**

Source: Eurostat

combined purchases of the United States and the EFTA states as a percentage of total extra-EU exports declined from over 62 % in 1988 to under 52 % in 1993. The NICs of Asia helped compensate for this decline.

Figure 8 shows that 1993 marked a sharp departure from a downward trend in trade intensities. The jump in export to production ratio is particularly noteworthy and consistent with the earlier comment that the rise in exports has served to offset a decline in EU production.

## MARKET FORCES

### Demand

Notwithstanding a 7.4 % decline between 1992 and 1993, demand for optical instruments and photographic equipment as a whole has nearly doubled since 1984, achieving an average annual growth rate of nearly 10 % over the period. Yet, this sector consists of an array of products, each with differing demand characteristics. As such, it would be useful to assess demand within this sector on a relatively elemental basis.

Natural demographic changes have helped induce a general increase in demand for spectacles, lenses, frames and mountings over the past decade. Clearly, as the population of the

EU has increased in general number, so, too, has demand for eyeglassware. More significantly, the gradual ageing of the EU population has induced a particular increase in demand for spectacles. Indeed, in some countries, the percentage of the population that wears some form of eyeglassware is approaching or even exceeding 50 %.

Beyond consideration of population, demand for eyeglassware has been enhanced by considerations of fashion and technological innovation as well. A greater fashion sense about eyeglassware, particularly frames, has served to differentiate these products in a way that appeals to varying tastes and needs. In this regard, EU consumers have evinced a willingness to own several pairs of glasses across a range of aesthetic and utilitarian appeal. Moreover, in recent years, technological innovation has heightened this product differentiation to a point where consumers may choose from a menu of features and products. Such technological innovation includes gas permeable contact lenses, continuously variable lens strength, and special designs to safeguard against the deleterious effects of computer and television monitors. Still, demand for eyeglassware has been adversely affected by a number of recent developments. Since 1989, revisions in social security systems have rendered guidelines for prescription eyeglass refunds more restrictive. The general recessionary environ-

**Figure 7: Optical instruments and photographic equipment  
Origin of EU Imports**

Source: Eurostat

ment has also increased the time between purchases, thus dampening demand, particularly in the low end of the price spectrum.

The precision optical instrument market is another important element of this sector. This area consists mainly of instrumentation designed to improve industrial measurement and testing methodologies. An important advantage to optical technology resides in the fact that measurement and testing can be accomplished through light sensing mechanisms, often without physical contact. A burgeoning demand for this kind of instrumentation has emanated largely from expanding manufacturing entities and older ones which wish to modernise. This demand, in turn, has fuelled technological innovations and increased investment activity particularly in the area of laser technology for a wide array of applications in such industries as aerospace, automotive, and medical instrumentation. Precision optical instrumentation is also gaining wide acceptance within environmental management applications.

While demand for precision optical instrumentation has increased over the past decade, demand in recent years has been hurt by the EU's general recessionary environment. Additionally, recent cutbacks in military expenditures have only exacerbated this situation. German manufacturers have been particularly hard-hit as production of precision optical instrumentation has fallen in excess of 12 % since 1990.

The photographic industry can be divided into broad product segments: still and motion picture equipment; sensitised photographic film, chemical, paper and plates; and photocopying and micrographics equipment. While demand in this sector largely flows from private households, it has also been induced by certain forms of product innovations including more user-friendly technology and increased film quality per unit cost. Demand has also been impelled by new product application. Specifically, photocopying and micrographics equipment and supplies have become critical components in the electronic imaging industry. Recent demand for still picture equipment has been stimulated by continual integration of cutting-edge technologies and product enhancements resulting in improved automation and convenience. Moreover, the marriage of electronics and photography, generally, has long infused this sector with energetic demand. Increasing lens and camera applications within the fields of space and aerial photography, security and traffic monitoring, medicine, and studio and press equipment have all contributed to demand within the past decade.

Still, notwithstanding the demand inspired by product development and differentiation, there has recently been a move toward simpler, more disposable technology, particularly within the consumer photographic segment. Some believe that this phenomenon manifests a kind of consumer "innovation fatigue." The recessionary climate within the EU-reducing both research investment and consumer spending-has served to retard demand as well.

### Supply and competition

Figure 8 suggested that the EU dependency on imports has been declining, despite 1993's reversal in this trend. Indigenous production levels within this sector have never been higher as shown in Table 1. Still, the picture varies from product area to product area.

Within the overall optical instruments and photographic equipment sector, the Japanese and American products have had a significant, albeit declining, EU presence as shown in Figure 7. The competitive forces that stem from Japanese and American products are particularly striking within the area of photographic equipment where recent price wars have increased not just the Japanese and American presence, but that of the East Asian NICs as well. The few surviving EU manufacturers have had difficulty fending off foreign competition - particularly from the Japanese who are extremely efficient in satisfying the variability of consumer demand. Moreover, Europe

generally is the United States' largest export market within photographic equipment and continued regulatory liberalisation will likely redound to the Americans' benefit. Also, the NAFTA agreement, which increases the flow of goods between Canada, the United States, and Mexico should diminish the relative EU presence within these three countries.

EU firms are performing well within the area of optical precision instrumentation where the local market is characterised by relative self-sufficiency. EU exports are also strong in this regard where the American market provides the greatest source of demand.

In eyeglassware, EU firms are premier manufacturers not just locally, but throughout the world as well. Notably, French and Italian manufacturers-known for fashion design-are strong exporters as are the German spectacle manufacturers who are best known for sturdy functionality. Still, foreign competition-primarily from Asian producers-have recently penetrated the EU market. Japanese manufacturers have been particularly successful in this regard as they have benefited from concerted governmental efforts in areas of ophthalmic research.

### Production process

Certain estimates place 1994 employment within the sector of optical instruments and photographic equipment at its lowest level since 1984, continuing a downward trend since 1991 as Table 1 shows. Certainly, 1993 employment levels are the lowest they have been since 1987. In contrast, 1993 production levels (as measured in current ECU) were nearly twice what they were in 1984 with only slightly higher levels of employment.

In real terms, production grew at 4.0 % per year between 1984 and 1993 compared to only a 0.5 % annual average increase in employment level. Such would suggest an increasing level of productivity as Table 4 indicates.

In a more general sense, the manufacturing process within this sector involves highly specialised techniques that require thousands of very small components. It has been a common practice throughout the EU to subcontract the manufacture of these components as well as ultimate assemblage to smaller specialty houses as the primary manufacturers concentrate on design, research and development.

## INDUSTRY STRUCTURE

### Companies

Relatively few EU manufacturers concentrate on just one sub-sector within the larger sector of instrument engineering. Rather, they usually participate in several subsectors of which optical instruments and photographic equipment is just one.

Within the EU, most participants in the manufacture of eyeglassware are small to medium-sized firms, with generally fewer than 500 employees each. Typically, no firm manufactures the entire eyeglass; like larger manufacturers within the sector generally, prime eyeglassware manufacturers usually subcontract the work to frame manufacturers, lens manufacturers, etc. Still, these smaller manufacturer are not exclusively dependent on EU prime manufacturers as they have a thriving export business mainly to the United States. Among the relatively few larger eyeglassware manufacturers within the EU include Rodenstock (D), Bausch & Lomb (D), Carl Zeiss (D), Essilor (F), Luxottica (I), Safilo (I), De Rigo (I), Indo (E) and Pilkington (UK).

Important EU manufacturers of precision optical instrumentation include Carl Zeiss (D), Schott (D) and Philips (NL). A company of dual origin, Leica (CH/UK), has become a world leader in the manufacture of precision instrumentation. Nikon (JPN) is the world leader in this area.

The photographic segment consists of several prime manufacturers as well as specialty manufacturers. Larger prime manufacturers-almost all German-include Agfa Gevaert AG (D), Carl Zeiss (D), Rollei (D), Minox (D), Linhof (D), Durst (I), and Bosch (D). Angenieux is a French manufacturer of camera lenses.

An overview of product specialisation is seen in Table 5 which shows the relative extent to which each country concentrates on optical instruments and photographic equipment.

### Strategies

While this sector may benefit from a lessening in recessionary pressures, it is clear that longer term considerations are important. This sector, particularly within the context of photographic equipment, is a mature industry within the EU. Manufacturers face burgeoning pressures from low wage, developing nations, especially within the Pacific Rim region. As such, EU manufacturers should follow the lead of Japanese photographic manufacturers in seeking various forms of product differentiation, particularly the kind that will provide enhanced value added. It also seems likely that EU manufacturers

will transfer low-end production assets to developing economies where they can be utilised more efficiently.

Clearly, continued research and development expenditure is part of the equation - not just in photographic equipment, but in all elements of the sector. Such will permit EU manufacturers to preserve and perhaps widen their edge in areas where they have competitive advantage such as precision optical instrumentation.

### Impact of the Single Market

As a result of enhanced intra-EU trade, competition between EU Member States is on the rise. In the field of precision optical instruments, the high degree of specialisation of each firm forces producers to search for additional markets abroad since national markets are too small to permit them to reach economies of scale in production. Intra-EU competition is likely to heighten particularly after the remaining impediments to trade are eliminated. The industry may, however, benefit from new opportunities on the demand-side as increased emphasis is put on environmental protection. Thus, enhanced environmental monitoring and measuring requirements for instance will likely boost demand for measurement and control instruments, which the precision optical instrument sub-sector depends up.

## ENVIRONMENT

This sector enjoys relatively trouble-free environmental impact. While certain potential environmental concerns reside in a few areas - such as the disposal of chemicals used in the development and production of film as well as the waste processing of disposable cameras - this sector does among the least damage to the water and air supply. At the same time, manufacturers within this sector likely benefit from environmental matters more than most other manufacturers. Precision optical instrument technology satisfies increased standards of environmental monitoring. Moreover, there will be increased demand for certain instrumentation that performs chemical and other ecological analyses. Photographic equipment manufacturers will also benefit as the demand for atmospheric photographic analysis is bound to increase.

## OUTLOOK

It is clear that the recession hit hard in 1993 and it was only in late 1994 that the earliest signs of recovery emerged. Indeed, conditions would have been far worse had it not been for relatively healthy export markets. The extent to which the next few years bring prosperity or mere survival to this sector will, in large measure, depend on the extent to which manufacturers are willing to acknowledge the competitive pressures from abroad. It seems clear that, in certain markets, the EU manufacturers cannot compete adequately with manufacturers from relatively low-wage developing nations. Such is particularly true within the photographic equipment context where an insidious price war inflicted significant harm on the EU manufacturing scheme. Asset migration, product differentiation, and enhanced levels of research and development will all be key to the EU's future within the sector of optical instruments and photographic equipment. Moreover, opportunities within developing economies in such areas as the Pacific Rim and South America will not only provide EU manufacturers with cheaper labour, but also new export markets as well.

# Clocks and watches

## NACE 374

The clocks and watches industry has experienced difficult times since the early 1980s. Competition from non-EU producers has increased rapidly, causing a deteriorating trade balance. In addition, the sector was recently hit by a severe drop in demand, linked to the general economic downturn. Prospects in the medium term are more favourable and the industry will return to a modest, but positive growth path, with the upturn in general economic activity. EU manufacturers will also benefit from increased demand from developing countries such as China. The industry will, nevertheless, continue to face intensifying competition, which will not only hamper trade performance, but will also reduce manufacturers' profit margins.

### INDUSTRY PROFILE

#### Description of the sector

The clocks and watches industry includes watches, instrument panel clocks, clocks, control apparatus and timing devices using clock-work or synchronous motors and time switches, as well as clock and watch movements. The sector includes mechanical, electrical and electronic watches. The industry addresses demand from final consumers through domestic applications and investment demand through technical applications.

The sub-sector of clocks and watches is the smallest among the EU's instrument engineering industry. In 1993, it represented only 5 % of the sector's output and 6 % of its total workforce.

#### Recent trends

During the 1980s the clocks and watches industry expanded significantly slower than the manufacturing industry as a whole. However, since 1990, hit by the simultaneous occurrence of increasing competition and the economic recession that hit the sector's customers, production in current prices has decreased by 28 % to 1.2 billion ECU in 1993. This downturn is also reflected in employment trends. The workforce in the clocks and watches sector has fallen, on average, by 5.1 % per annum from 1984 to 1993. Other important reasons for the fall in employment levels are the de-localisation of manpower towards low-wage countries, and the technological progress which has considerably automated the production process in the sector.

In 1993, consumption fell by 8 % in real terms, and output was down 17 % from 1992. As a result, employment in the sector shrank significantly to 15 700 employees, a 13.7 % drop from the year before.

Production has not followed the same pattern as consumption because an increasing share of production is outsourced. Extra-EU imports have grown by 93 % from 1984 to 1993, especially from East and South East Asia, as low labour costs attracted assembly of clocks and watches in these countries. A deteriorating EU trade deficit, 1.6 billion ECU in 1993 compared to 764 million ECU in 1984, reflects the significant outsourcing activity and the increasing penetration of products originating in South East Asia.

#### International comparison

An examination of the geographical breakdown of clocks and watches production shows an overwhelming dominance by Japan. The Japanese industry posts a production value of about six times that of the EU, and five times that of the USA.

Figure 1: Clocks and watches  
Value added in comparison with related industries, 1993

Source: DEBA

Japan has managed a 41 % increase in production value since 1984, while both the EU and USA have seen their share of world production drop. In 1993 Japan had a 73 % share of the Triad's output compared to a 64 % share in 1984. However, if we consider the whole European clocks and watches industry (i.e. including Switzerland), the dominance of Japan at world level is considerably reduced.

At the world level, Japan remains the leading producer of clocks and watches (in volume terms) with 41 % of the world's output, while Hong Kong ranks second followed by Switzerland. In value terms, however, the world ranking of top clocks and watches producers differs significantly, reflecting important differences in country specialisation. Indeed, Switzerland produces by far the largest share of the world's production value, with a 55 % share. Japan only has a 22 % share, while Hong Kong has 9 % of the world's value of production. This evidences the specialisation of Switzerland in high quality mechanical watches. In contrast, Japan and Hong-Kong are important producers of electronic watches in the low price

segment. EU producers are well positioned in the traditional field of mid-range watches.

**Foreign trade**

The EU clocks and watches industry is very open to trade. EU manufacturers exported as much as 90 % of their production in 1993, while imports accounted for 96 % of consumption. This important trade orientation is the result of two factors. First, it results from the relocation strategy implemented by the major clocks and watches producers aimed at outsourcing part of the production process to lower cost countries. This often translates into outward processing trade, which consists of exporting pieces of EU origin to the far East, to be assembled and re-imported as finished products into the EU. This process may be granted special quota and tariff conditions. Second, EU trade openness results from growing competition from lower cost countries, mainly due to wage differences. This competition was mirrored in growing

imports in the low and medium-price and quality segments of the market.

Between 1984 and 1993, both extra-EU exports and imports of clocks and watches nearly doubled. In 1993, imports represented 2.8 billion ECU, or 96 % of EU's consumption against 70.6 % in 1984.

EU exports of clocks and watches are mainly oriented towards Switzerland, Hong Kong and the USA. The main countries of origin for extra-EU imports are: Switzerland, whose share in total extra-EU imports is above 50 %, Hong Kong (15.8 %) and Japan (10.9 %). China, which benefits from a significant wage cost advantage, has seen its share of the EU market increase from 4.5 % in 1988 to almost 10 % in 1993.

## MARKET FORCES

### Demand

A large portion of the clocks and watches industry is exclusively consumer-oriented and highly dependent on fashion trends. Technological content has lost importance as the same technologies have been in use for several decades, leaving design as the major factor influencing consumer choice. In recent years however, the introduction of new technologies such as solar radio watches has prompted renewed interest in some countries (e.g. Germany) for the products' technological content from the consumers' point of view.

Being consumer oriented, the sector is also influenced by trends in final expenditures. This feature was reflected in the recent downturn of EU apparent consumption of clocks and watches, which followed shrinking household expenditures of the past three years.

Another important segment of the industry is oriented towards technical applications through the production of time meters and triggers. Activity in this segment is dependent upon investment trends from industry customers, which also followed a declining trend over the past three year period.

Over the long run, however, demand for clocks and watches has benefited from increasing affluence among consumers, in line with improving standards of living, personal disposable income, and demographic factors. The ageing of the population is, in particular, an important factor explaining demand for such discretionary goods. The population group between 45 and 55 years is considered to have the highest purchasing power in the total population. This group, which tends to buy higher quality clocks and watches, has seen its share in Europe's total population significantly increase, offering growing market opportunities to the industry.

### Supply and competition

EU manufacturers mainly operate in the field of mid-range watches. They face stiff competition from China, Hong Kong and Japan on low-end electronic watches, and from Switzerland on top-of-the-line mechanical watches.

EU manufacturers are not able to compete on price with electronic watches originating in the East Asian NICs, which not only enjoy lower labour costs but also benefit from the availability of components necessary to the production of electronic movements. However, EU manufacturers can count on their

**Figure 7: Clocks and watches  
Origin of EU imports**

Source: Eurostat

strong competitive edge in design and fashion. Furthermore, the production of components (especially cases and straps) by EU firms is still very important at international level.

Switzerland has also emerged recently as a formidable competitor in the field of mid-range products, thanks to the outstanding success of the Swatch watch. This development is partially linked to the different industrial structure of the Swiss industry. Whereas EU producers are usually small to medium-sized, Swiss manufacturers are of international size, enabling them to benefit from economies of scale and implementation of formidable marketing and sales strategies.

Prices are bound to decline as competition is expected to intensify. This will add pressure to EU companies' profitability, already severely dampened by the recent downturn in activity.

### Production process

EU clocks and watches manufacturers have to operate in a highly labour intensive environment; although recent technological innovations have somewhat alleviated this feature. This, along with growing import competition from lower cost countries, has forced EU firms to relocate part of their production process outside of European borders. International subcontracting, sometimes under the form of outward processing trade, has considerably expanded in recent years.

Besides these strategic moves, EU companies have sought to streamline production costs and to increase productivity. A substitution process of capital equipment for labour has thus been taking place, leading to an important decline in employment levels.

## INDUSTRY STRUCTURE

### Companies

The clocks and watches industry is composed of a large number of small and medium-sized firms. A large portion of these small companies operate as subcontractors for large producers and are highly specialised in narrowly defined areas. Many firms have a local and family background from which some have expanded to become large multinational companies. For the most part though, SMEs in the sector operate on a local basis.

Large companies are mainly involved in the production of case and movement components. The major producers in the EU are: Junghans, Dufa-Kienzle and Kundo Staiger in Germany; Ambra, Vedette Industries, Fralsen, Isa Quartz and France Ebauches in France.

### Strategies

To meet the challenges of increasing competition, EU clocks and watches manufacturers have implemented a set of strategies: investment, research and development, cooperation, concentration, and relocation. Investment activities have shown an upward trend, with the main motive for companies being to retain their share of the market by renewing production lines and increasing productivity. Another important strategy has consisted of making large investments in low labour cost countries by establishing subsidiaries or acquiring production units, in order to streamline production costs. At the same time, EU based firms have increasingly been involved in outsourcing activities to low labour cost countries.

In order to strengthen their EU market position and to reach a critical size, a number of EU firms are being forced to regroup. This concentration movement has actually accelerated in recent years as a result of increasing competition within EU borders and tough market conditions.

Innovation in new technologies and production design is also seen as a crucial competitive factor by EU producers, and has focused important efforts in research and development.

### Impact of the Single Market

The advent of the common market in 1993 did not drastically change the landscape for the industry in the EU, since most of the firms were already operating internationally. However, it has allowed the EU companies to increase their competitiveness, even though it is too early to formulate definitive judgements about the total impact on the sector. The elimination of non-tariff barriers to trade has facilitated trade, while efforts towards technical harmonisation have led to considerable positive effects by allowing companies to benefit from economies of scale. Moreover, the establishment of the European legislation on counterfeiting has contributed to reduce significantly the flow of imitation watches from some Asian countries, while common research programmes have played an important role in the industry. Besides, the inception of the Internal Market has led some companies from outside the Community (mainly, Japanese and Swiss) to invest in the EU. This has allowed some EU companies to prosper with foreign capital. In the future, a simplification of the regulatory framework in the area of consumer and environment protection seem to be a priority for EU companies.

## REGIONAL DISTRIBUTION

Production of clocks and watches is concentrated in four EU Member States. France and Germany take the lion's share of EU production, with a 42 % share of output each. With a 12 % share, the United Kingdom hosts a number of manufacturers, while Italy accounts for about 4 % of output.

Furthermore, EU production of clocks and watches is very concentrated in particular regions. For example, the largest producing region in France is by far Franche Comté, with over 74 % of France's turnover and 72 % of employment in 1993. An important horological cluster has existed in this region for decades, which is closely linked to the region's traditions and history. Moreover, activity has benefited from close proximity to the Swiss clocks and watches industry, with which it has developed trans-border links.

Source: DEBA

## ENVIRONMENT

Environmental concerns are of minor importance for the clocks and watches industry. The only issues that affect the industry concern disposal of the small nickel-cadmium batteries used to power electrical and electronic time pieces, and the use of nickel in cases. Particularly in the latter case, the substitution of nickel in steel alloys is proving to be a real problem for the industry.

## REGULATIONS

Trade restrictions are relatively absent in the sector. However, an important matter for the EU clocks and watches industry is the progress towards proposed EU Directive (93/C 318/06 amended by 94/C 209/04) for the harmonisation and free movement of precious metal articles. The Directive addresses harmonisation of standards which would replace existing national provisions and would require Member States to comply with "fineness" conformity attestation procedures beginning 1 January 1997.

During 1993, the European Commission adopted a regulation about Community trade mark and has worked out a proposal dealing with the problem of Community design. These two instruments bring about significant simplification to the rules of intellectual property registration. The fight against counterfeiting is of particular importance for the EU clocks and watches industry, which must also face the problem of false indications of origin on watches manufactured in the Far East.

## OUTLOOK

Intensifying competition from outside the EU will continue to dampen EU production of clocks and watches and will further hamper the sector's trade performance. In light of such a competitive climate, EU producers will need to continually reduce their production costs and increase their efforts in terms of product innovation.

Positive signs are coming from the market, however. As the European Union is gradually turning the corner from the economic recession, demand will slowly recover, while a huge market potential is offered by some developing countries like China. However, at the moment the custom duties for clocks and watches to enter the Chinese market are about 70 %, which constitutes a serious restriction to EU exports: the exploitation of the market potential in China is strictly linked to the lifting of such obstacles.

Written by: DRI Europe

The industry is represented at the EU level by: Permanent Committee of European Watch and Clock Makers Secretariat (CPHE): c/o Fédération de l'Industrie Horlogère Suisse. Address: Rue d'Argent 6, CH-2501 Bienne; tel: (41 32) 28 08 28; fax: (41 32) 28 08 80.

Overview

NACE 41

The food, drink and tobacco sector has reached an advanced level of saturation of demand, and growth does not exceed 2 % p.a. Accordingly, this has determined a constant internal production, also distinguished by rather low rates of growth. With regard to foreign trade, the EU is extremely active in both internal and external trade. The trade balance is positive, and the level of imports in value terms is about 30 % lower than that of exports.

As for consumption, two main trends are recognisable which affect most of the sector: the health trend and the shift towards ready-to-use products. The distribution structure, more oriented towards large distribution networks, shows a drop in sales due to the ever more significant presence of discount stores and low-price retail outlets.

A certain imbalance exists between the industrial structure and market structure of the sector. The former is somewhat fragmented, and 90 % of enterprises employ less than 20 workers; the latter is rather concentrated, with a limited number of large enterprises (i.e. with more than 100 employees), which account for over half the turnover of the industry as a whole. The country with the biggest industrial concentration is the United Kingdom which boasts over half of the ten most important EU companies, some of which are also ranked high at the world level. Acquisitions still represent the main external growth strategy for companies which tend towards consolidation of their respective positions on domestic markets and an increase of market outlets outside the EU.

INDUSTRY PROFILE

Description of the sector

The food, drink and tobacco sector includes all processing activities involving food, drink and tobacco. Besides consumption as the final product, many outputs in the sector are utilised as intermediate products in other manufacturing industries (not necessarily food industries). Included in this group are oils and fats, flours, sugar, ethyl alcohol, etc.

The economic importance of this sector is considerable, especially compared to other manufacturing industries: in terms of value added, the food, drink and tobacco industry attains figures approximately equal to those of the transport and chemical industries, which in modern economies are expressions of the degree of development achieved. Unlike those sectors, however, the food sector has the advantage of having an anti-cyclical nature.

The member countries which contribute most to the formation of value added are Germany, the United Kingdom, France, Spain and Italy. The first three present a higher level of industrial concentration and the highest inclination towards the use of advanced production techniques because there is a greater demand for products with a strong value added content; the other two have more fragmented economies, with strong production traditions and consumer preferences for fresh, non-industrial products.

Over the last ten years, nearly all countries have undergone a restructuring process, aimed at increasing productive efficiency and lowering production costs. This has led to a progressive replacement of labour with capital-intensive

Figure 1: Food, drink and tobacco Value added in comparison with related Industries, 1993

Source: DEBA

production techniques, especially in the less diversified sectors like sugar, the grinding of seeds for oil and grain milling.

The process of rationalisation also has affected distribution companies in numerous EU countries, especially Germany. This was necessary for several reasons, but above all was the unfavourable economic situation, which has greatly increased the importance of price variables in purchasing, thus boosting the degree of competitiveness and leading to the drop in demand for consumer goods. German and French enterprises maintain their absolute leadership in terms of sales, while some UK and Belgian companies show a drop in sales and profitability.

Despite the evolution towards more uniform models within the EU, differences continue to exist among the Member States

in the shares of products consumed. In northern European countries the consumption of meat is high compared to the southern countries. In the southern countries, the second most important sector in terms of consumption is fruit and vegetables, while in the northern countries it is cereals and cheese.

**Recent trends**

In 1993, the main indicators in the food sector at current prices showed values similar to those of previous years, following the slowdown in many sectors of the industry. As regards employment figures, these went down throughout the ten-year period except in 1989-91. This drop was steeper after 1992. The balance of trade, on the contrary, was extremely favourable and on the upgrade, thanks to a greater increase of exports to, over imports from third countries.

The sectors that contributed most to production, apparent consumption and exports are meat, dairy products, alcoholic drinks, fish and tobacco. Meat accounts for 18 % of EU internal demand followed by dairy products (about 15 %). With

regard to available internal supply, the same proportions apply for both sectors.

With regard to foreign demand, the most requested products are meat, followed closely by dairy products and alcoholic beverages, which both reach more or less the same levels. As far as foreign trade is concerned, though altogether inflow beats outflow, there are some sectors where the balance of trade is in the red, e.g. oils and fats, and meat.

At constant values, growth rates during 1993 were fairly low both in terms of production and apparent consumption. Meanwhile, foreign trade was substantially negative, especially as regards exports to third countries.

Considering the entire ten-year period, the food sector recorded an internal growth equal to about 2 %, showing that large growth margins no longer exist. The relative pattern of foreign trade showed little growth, and as mentioned above, things worsened during 1993.

### International comparison

In the ten years up through 1993, there was strong growth in the food, drink and tobacco sector of the EU; greater in fact than that of the USA and Japan. While there was a drop in production in the USA in 1989, in Japan the trend was positive, but not as big as that of the EU. In 1993, the EU was the number one world producer of food products in terms of value, followed by the USA and Japan.

In Japan, which traditionally has been "closed" to EU producers, a change in eating habits more like those of Europe has taken place over the last twenty years: while rice, fish and greens still dominate in Japanese diets, meat and dairy products have gained ground in recent years. Ready-made meals also have had some success, as a result of more women going out of the home to work. In the USA on the other hand, there has been a recent drop in the demand for low-fat content products and a return to fatty foods. As a result, the demand for dairy products and dressings has risen.

The structure of food distribution in Japan is more like that of Europe than the USA, given the great fragmentation of retail outlets. Most of the major Japanese distribution com-

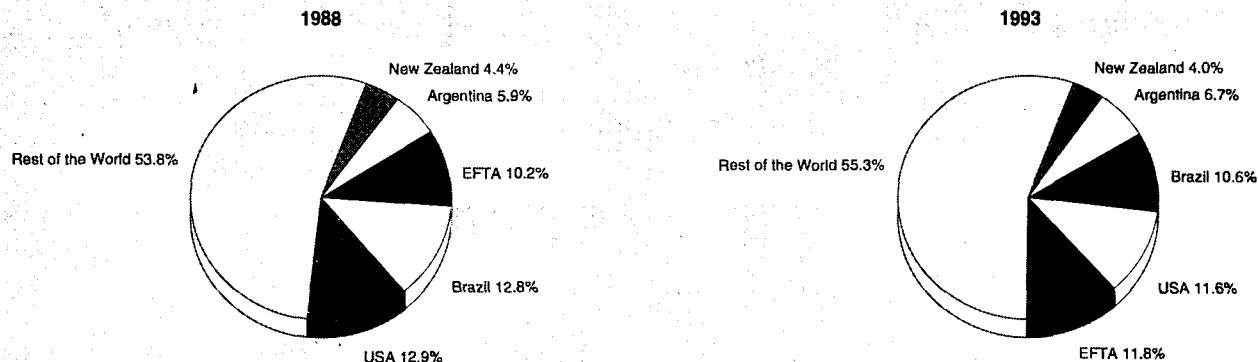

panies have met with drops in sales and profitability, although in terms of market shares, their positions have not changed.

In the USA, there was a generalised drop in profitability in 1993, due to the economic recession, a slowdown in demand for consumer goods and a generally more competitive situation. Some enterprises in the sector which were operating in the red, reacted by restructuring sales networks, selling a number of trademarks, closing down less profitable retail outlets and reducing their number of employees. The major US companies, after consolidating their positions at home, are now widening their presence in Europe.

### Foreign trade

The balance of trade in the sector, though remaining favourable for the entire period under consideration, has slowly improved, thanks to an increase in exports over imports. Some countries, however, show an extremely unfavourable balance of payments, e.g. Germany, Italy and the United Kingdom; the Netherlands, France and Denmark on the other hand have very favourable balances of payments. The export/import ratio shows EU inflow to be greater than outflow, but their rates of growth are quite similar. Furthermore, prices of the former tend to grow more than those of the latter.

Source: DEBA, Eurostat

The main EU partners are the USA and South American countries, e.g. Brazil and Argentina, from which the EU imports mainly meat and fruits and vegetables. The markets on which the EU is focusing the greatest attention are those of south-east Asia and Eastern Europe, where a low level of development and low degree of penetration exist.

As it is favoured by the elimination of customs barriers, trade between EU countries is fairly strong. In fact, it is higher than that towards third countries.

## MARKET FORCES

### Demand

The demand for products belonging to the food, drink and tobacco sector has reached an advanced stage of development and growth is slow. In terms of composition and levels of expenditure for this type of product, strong differences exist between the various countries. In the countries of Southern Europe, demand centres mainly on fresh products, with less service and innovation content. In the northern countries, on the other hand, ready-made meals and innovative products are more popular; exceptions are southern France and Italy which, though Mediterranean regions, are more inclined to follow typically northern consumption models.

Two main trends affect most subsectors of the food, drink and tobacco industry: health priorities, with a preference for

low-residue, high nutritional value, low-calorie and low-fat foods; and a tendency towards ready-made meals that are immediately available for consumption, of high quality and good tasting. Such trends have led consumers to focus on natural and ecological products, and, at the same time, to introduce increasing quantities of ready-made meals into their daily diets. The effects of these trends also can be seen in the drink sector; alcoholic drinks (including beer), and, to some extent, coffee, are experiencing a drop in demand, with a preference being given to mineral waters or soft drinks. Meanwhile, ready-to-drink beverages like tea - often aromatised with various flavours - and fruit juices are widening their market.

In terms of distribution, the food, drink and tobacco sector is undergoing significant changes. The number of discount stores is rising quickly. These attract customers with non-perishable and liquid goods, while consumers continue to turn to the large distribution networks for fresh products.

### Supply and competition

The labour productivity index continues to rise slowly, given the small increase in production and the substantial balance of the employment aggregate. Labour costs also have tended to go up in line with productivity. Over the last ten years, the food sector has undergone a process of industrial conversion towards more automated structures with greater use of capital assets, often in place of manual labour. This process is part of a restructuring project aimed at increasing production efficiency. The sectors most involved in this trend are those which produce undifferentiated commodities and where cost-inefficiency would weigh heavily on the final price of goods. France and the United Kingdom show a higher productivity per worker than do Spain and Germany.

Going along with their penetration onto the markets of Eastern Europe and Asia, EU enterprises are also trying to make headway in Japan, in an effort to capitalise on the growing similarity between their eating habits. However, strong entry barriers still exist in this country, demarcated by specific protectionist measures and by the trade structure.

### Production process

The tendency to use labour-saving production techniques and the rationalisation of production resources are factors common to many EU enterprises. In the United Kingdom, where such objectives seem to be pursued with greater tenacity, the amount of money spent on R&D in 1993 totalled 747.4 million ECU. Unilever accounted for 84 % of this figure, while the other groups, though having paid out much less, considerably increased this expense item compared to the previous year. For example, Tate & Lyle increased investments in R&D by 88 % and Devro International by 53 %.

On the international scenario, Unilever still heads the list of companies with greatest R&D expenditure, followed by Nestlé

and Philip Morris. Another EU enterprise which made strong investments in 1993 was Ferruzzi which, despite a negative growth rate compared to 1992, spent nearly 3 % of its sales figures on R&D.

## INDUSTRY STRUCTURE

### Companies

In 1990, over 90 % of the enterprises within the EU had a work force of less than 20 and 6 % had between 20 and 99, while less than 2 % had 100 or more employees. These data show that the industrial structure of the food, drink and tobacco sector is highly fragmented into numerous small firms, often of a semi-industrial nature. Because of their small size, overall turnover reaches only 12 %. The medium-sized firms, which represent 6 % of EU enterprises, account for 20 % of the overall turnover. Meanwhile, the larger companies, including the multinationals, account for a 67 % share of overall turnover.

The most important companies in terms of turnover and employment are located in the United Kingdom: of the top ten EU companies, seven are British.

Strong industrial concentration is not accompanied by any sharp production specialisation: in fact, the production specialisation ratio achieves its highest values in countries where the industrial structure is not particularly developed, like Ireland, Denmark and Greece, and is lower in Germany, Italy and the United Kingdom.

### Strategies

There were 82 acquisitions in the food, drink and tobacco sector in 1993 and 62 in 1994. Of these 144 acquisitions, 113 were made by EU enterprises. The role of UK companies was particularly prominent, accounting for 53 % of all acquisitions. The groups responsible for the largest number of

acquisitions were Tesco, Albert Fisher Group, Allied-Lyons, Matthew Clark Bros. (all in the UK), Ahold in the Netherlands and Fyffer in France.

Three trends are evident from the data on acquisitions. First, the majority of acquisitions are carried out by distribution groups looking to strengthen their presence in the sector. The second is that the acquisitions of distribution firms respond to a strategy of downstream integration promoted by industrial groups, while the acquisitions of manufacturing companies by distribution groups are rare. The third tendency is that nearly all acquisitions made by bidders of EU countries show a preference for enterprises from their country or at least which belong to the EU or EFTA. In other words, such acquisitions are aimed at consolidating a company's presence on European, if not domestic, markets.

With regard to distribution, the importance of large, organised networks has increased considerably over time, especially in the countries of southern Europe where distribution models are more fragmented and backward than those of the northern European countries. More and more, the smaller firms are tending to work as subcontractors for large distributors.

Two main organisation models outside of the less clear-cut national organisations can be identified: one in the Anglo-Saxon countries and one in France. The first is distinguished by fast growing profits - thanks to a large share of private labels - a less-keen competitive atmosphere, high-quality service and an efficient organisational structure in terms of logistics. Furthermore, labour costs are somewhat lower compared to other European countries and there is a greater capacity for self-financing.

The French model is distinguished by smaller profit margins, pushed down by lower prices as a result of more aggressive competition, which has tended to diminish brand value. The cost of labour has a 73 % bearing on value added, which is

rather weak. Consequently, the capacity for self-financing is penalised.

In recent years, the level of competition between the different forms of distribution within the EU has been affected by the increase in the number of discount stores, especially in the countries of northern Europe. UK trade is showing the first signs of restructuring, through downsizing the work force, cutting profit margins and reducing the number of retail outlets. There is also a tendency to renew assortments, with the penetration of low-cost and low-stock products and the introduction of additional services (e.g. pharmacies) inside retail outlets.

In Germany, where the first hard discount stores were born, the capacity of distribution companies to react has produced positive outcomes already. In fact, important processes of concentration and rationalisation have been achieved through acquisitions, which have given excellent results in terms of turnover growth, the highest in Europe.

In Italy and Spain, food distribution is distinguished by poorly-developed systems. In addition to large, organised distribution networks, small, non-specialised distribution outlets co-exist with hard discount stores imported from continental Europe. The latter have brought with them particularly aggressive competition, in the face of which current distribution networks have shown themselves to be fairly vulnerable.

### Impact of the Single Market

The creation of the Single Market had a globally positive impact on the food and drink sector, through the reduction and/or elimination of internal barriers to trade.

However relevant internal barriers still remain. In particular they are linked to Member States' legislation going beyond harmonised Community measures, to problems due to differences in interpretation or lack of clear definitions, to lack of acceptance by Member States and to lack of equivalence of methodologies adopted within EU countries and, in some cases, lack of coherence between provisions in vertical and horizontal directives. The practical implementation of Internal Market legislation not hindered by differences of application or in-

terpretation, the promotion of consumer protection with the delivery of meaningful information, and the set-up of health and of high safety standards in food supply remain priorities for the industry.

### ENVIRONMENT

The food, drink and tobacco sector has a low environmental impact, not at all comparable to that of other manufacturing industries. The major problems stem from the extensive use of plastic packaging for the preserved products and drinks which are typical of the sector, as well as from the disposal of polluting substances and the emission of fumes into the atmosphere.

With regard to packaging, the EU has issued specific regulations with the aim of harmonising legislation in the different countries. The need for such harmonisation has been felt for some time now to prevent distortions in terms of competition. New regulations on packaging call for the use of recyclable or biodegradable materials for preserved foods and provide measures which favour the collection and recycling of drink containers. The expected effect of the implementation of such measures is an increase in production costs and greater energy requirements.

The problem of wastes is particularly serious in the livestock rearing and oil sectors, where the dispersion of waste organic substances can pollute the environment. Many operators in this sector are implementing recovery and recycling techniques based on the use of "ecological" micro-organisms.

### REGULATIONS

Among the numerous provisions regulating the agri-foodstuffs sector, particular reference can be made to

the GATT (General Agreement on Tariffs and Trade). This agreement focuses on three main aspects of public intervention in agriculture: internal subsidies, access to markets and export subsidies. The implementation period for these measures is between 1995 and 2000.

To begin with, a 20 % reduction of internal subsidies is envisaged, taking as a reference point the global level of subsidies granted between 1986-88. Exemptions are contemplated for those internal subsidy measures which do not represent an incentive to increase production, inasmuch as they do not directly affect price levels.

Regarding access to markets, each country will reduce its simple average tariff by 36 % over the implementation period and will reduce each tariff line by at least 15 %, taking the 1986-88 period as a base. All non-tariff barriers are to be subjected to tariffs. Minimum market access equal to 3 % of average domestic consumption in the base period must be allowed in the first year of the implementation period and increased in equal instalments up to 5 % by the end of the implementation period.

(1) Ratio of production in the sector compared to manufacturing industry for each country, divided by the same ratio for the EU. Estimates.  
Source: DEBA

The provisions of the agreement do not seem likely to produce significant effects in the short term, as taxation is based on a period (i.e. 1986-88) when the gap existing between internal prices and world prices was much wider than it is today. Furthermore, the agreement between the US and the EU is not likely to result in significant changes in trade flows: realistically, for the most sensitive commodities, the only binding constraint will be a reduction of each tariff line by at least 15 %. This makes sense because all countries will achieve the 36 % reduction in their simple average tariff by larger percentage reductions of tariffs imposed on less sensitive commodities.

The lowering of customs duties can thus be restricted to a maximum of 20 % for products such as wine, powdered skimmed milk, sugar, tobacco, and fruits and vegetables, compensated for by a steeper reduction for other products, chiefly from the USA (e.g. processed turkey meat, pigs' liver, fresh asparagus, potato-based products, some cheeses, fresh grapes, honey and orange juice).

Finally, export subsidy expenditures are to be reduced by 36 % and the volume of subsidised exports by 21 % over the implementation period, using the years 1986-90 as a base. For those commodities that experienced an increase in exports between 1986-90 and 1990-91, a bilateral agreement between the US and the EU allows for a phasing in of the reduction of the volume of subsidised exports, which permits larger subsidised exports over the implementation period, taking the 1991-92 levels as the base, instead of 1986-90.

In any event, the Community will have to lower its overall level of exports. This will result in a progressive drop in production levels, to avoid the accumulation of surpluses and strains on prices on the internal market. The drop in production provided for by the CAP reform, however, could prove insufficient to comply with the commitments undertaken within GATT, making it necessary to adopt new restrictive measures.

To conclude, mention must be made of horizontal regulations affecting the food, drink and tobacco industry. Community Directive 93/43 is a horizontal directive establishing general rules of hygiene for food products as well as procedures for enforcing such regulations. The directive has a broad application, not only because it covers all sectors, but also because it lays down hygiene and safety standards for all stages of industrial production, from preparation to processing right up through transport and sale. Food enterprises are obliged to adopt procedures to guarantee food hygiene (basing themselves on the Hazard Analysis and Critical Control System), monitoring the risks for each work process, with greater emphasis placed on control within the enterprise as opposed to outside controls.

## OUTLOOK

In the future, it is reasonable to expect that there will be no major improvement as regards the saturation of the demand for consumer goods, the current economic recovery notwithstanding. Consequently, enterprises will seek opportunities for growth in new markets, perhaps in related sectors or in as yet unexplored market niches. Furthermore, there will be a strong tendency towards greater product segmentation and greater innovation in order to reach new consumers. Greater focus will also be put on product quality, guaranteed by EU-recognised certification, so that EU companies in the sector can become more and more competitive. From a structural viewpoint, greater competitiveness will ensue from rationalisation and the use of more advanced production techniques. The achievement of a greater degree of concentration will be the goal of most EU companies, pursued through either external growth or integrative development.

# Oils and fats

## NACE 411

The sector was characterised by a dwindling trade balance throughout the decade under consideration. Oil seeds are used in industry and for human and animal consumption. They typically have a fairly low value added. Both internal supply and demand in the EU rose at a reasonably rapid pace (4 %) during the 1984-93 period. The oil seed industry is highly concentrated within the EU in the grinding, raw oil extraction and refining stages. On the other hand, the olive oil subsector is highly fragmented. Total quality and cost reduction are the main strategies pursued by EU oil seed companies. Product diversification and innovation policies represent an important line of strategy pursued by olive oil, animal feed and fat producers.

### INDUSTRY PROFILE

#### Description of the sector

The vegetable oils and fats sector comprises the initial processing of raw materials, the products of which are used either as the primary inputs in manufacturing industries outside the food sector, or for direct retail. From the processing of oil seeds, protein-meals are made for the food and animal feed industries. Such oil is also employed in other industrial sectors (fuels, lubricants, paints and enamels, etc.); and soya proteins and lecithins are used in the cosmetics, chemicals and health sectors.

Oils for consumption as food can be eaten in their original state or in the form of margarine and reduced-or low-fat spreads. The major seeds used for consumption as food are: soya, colza, sunflower and, on a smaller scale, groundnuts and corn. Naturally, mention also must be made of olive oil, the "King of Mediterranean cuisine."

The products with the highest value added (protein and lecithin concentrates) have undergone favourable development over the last few years, because market outlets have become very diversified and extensive. This is the sector which can expect the brightest future. Soya lecithins are also widely used in non-food sectors, such as the cosmetic and chemical sectors. Furthermore, they could also play an important role in the health sector, as they help to reduce the levels of cholesterol and triglycerides in the blood. Moreover, soya protein concentrates are ideal for integrating or replacing animal-derived proteins in diets.

Processing is not particularly elaborate and the value added of the industry is consequently one of the lowest in the entire manufacturing industry. In 1993, it was equal to about half that of the fruit and vegetable sector, and about one-fifth of that of dairy products and meat. Among the EU countries, that with the highest value added is Germany (27 %), followed at a distance by Spain (18 %). Italy, Germany and Spain are the biggest producers and processors of oil seeds. The main olive oil producing countries are Spain, Greece, Italy and Portugal.

The main indicators in the sector display two stages: the first - from 1984 to 1987- shows a general drop of all indicators expressed at current prices. Starting in 1988, there was an upswing in production, consumption and exports. The balance of trade, though in the red, showed a trend towards slight improvement over the decade. Employment figures dropped by about 10 % in 1986 and 1989, while there was a partial recovery in subsequent years. These figures started to drop again, however, in 1992.

**Figure 1: Oils and fats**  
Value added in comparison with related industries, 1993

Source: DEBA

The production of fats of vegetable origin is prevalently carried out within the EU, though some product lines (e.g. laurics, castor and palm) are heavily dependent on countries outside the EU. On the other hand, imports of protein products exceed internal production capacity. In fact, many of these rely on raw materials which are not normally grown in Europe (e.g. coconut); and therefore the only way to meet internal demand is to turn to foreign markets. More than 90 % of the vegetable oil and protein production, excepting olive oil, is made up of soya, rape and sunflower.

With regard to final consumer markets, the biggest producers of margarine, fat spreads, reduced- and low-fat spreads within the EU are Germany (30 %) and the United Kingdom (22 %), followed by the Netherlands (12 %), Belgium (9 %) and France (7 %). The 1992/93 production of olive oil in the Community was estimated in about 1 300 000 tonnes, compared to 1 728 000 tonnes for 1991/92. Cultivated areas have remained more or less stable at around 5.6 million hectares.

**Recent trends**

In real terms, the situation revealed by the main indicators at current values is confused. In fact, both internal demand and supply went up during the 1984-93 period at a fairly quick pace (4 %). Only in 1993 was there a slight drop. Conversely, exports showed a somewhat unstable pattern with a tendency to go down, especially during 1993, while imports tended to rise slowly.

The 1990 base production index at constant prices presented a trend similar to that of the manufacturing industry as a whole with fairly high growth rates from 1987 to 1990, even though in the oils and fats sector, 1986, 1989 and 1991 were in a counter-trend compared to the total manufacturing industry. In 1993, the growth trend of vegetable oils production came to a halt and was followed by a small recovery in 1994. Employment has fluctuated widely over the last decade. Since 1991, employment has been on a downward trend.

**International comparison**

Production data at current prices shows that in 1984 the USA was the biggest world producer of oils and fats, followed by the EU, while Japan lagged behind. In 1993, US production figures fell to match those of the EU which, together with Japan, reached the same production level as 1984.

The 1990 production index at constant prices shows an uninterrupted drop in Japan. In point of fact, over the decade, this country recorded a drop of 5 %, due above all to a big index fall in 1984-87. EU and US production patterns showed a slight upswing.

As regards soya seeds, the USA has always played a lead role in production and currently has an over 50 % share. Brazil retains a share of 18 % of world production whereas Argentina has a share of about 10 %.

In terms of quantity, the world production of sunflower seeds ranks fourth among oilseed production, with a share of around

**Figure 4: Oils and fats**

Destination of EU exports**

Source: Eurostat

9 %. The biggest producer of sunflower seeds remains the area of the former Soviet Union, which currently accounts for about 20 % of world production, along with Argentina (20 %). The EU occupies an important role in the sector, and is the third biggest world producer, with a market share of around 18 %; Asian countries (China and India) account together for another 11 %.

Colza production has taken on growing importance within the aggregate of oilseeds and currently detains a 12 % share. Most of the world production of colza is concentrated in the Asian countries which currently have a share equal to about 48 % in terms of production and 53 % as regards cultivated area. However, this production is mainly for domestic use: there are almost no exports of rapeseed from these countries. Now as in the past, the EU is the second biggest world producer, with a production share that has gone up from 10 % in 1961 to about 23 % today (12 % in terms of cultivated area).

The international scenario of oil seeds can be split into two blocs: the American bloc, more export-oriented, with a 70 % share of world exports; Europe and Asia, more import-oriented, notwithstanding the growing importance of Europe as regards global export volumes.

Finally, world production of olive oil in 1992/93 was on average equal to 1 800 000 tonnes, of which 80 % came from EU countries. The other major world producers are Turkey, Tunisia, Syria and Morocco. Production varies greatly from year to year, but the development of the world market reflects, in general, that of the Community market.

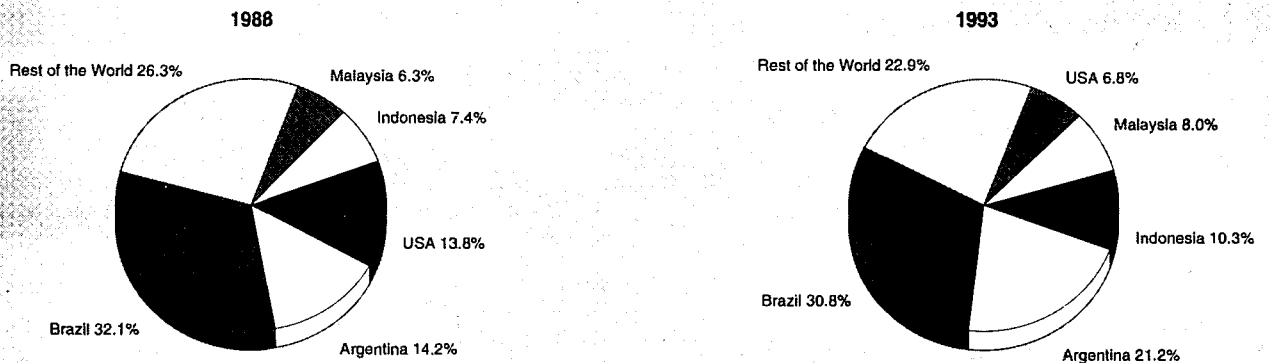

**Foreign trade**

The big producers of oil seeds are not necessarily big processors and consumers of the processed product. Consequently, a complex system of trade flows of raw materials and initial-process materials (oils and cakes or meals) has been established. For example, the top world producers of oil seeds, like the USA, Argentina and Brazil, are substantially self-sufficient as regards cakes and meals.

EU exports traditionally go to the Mediterranean area, East European countries and increasingly to China.

The trading deficit for oil seeds as a whole can be attributed chiefly to soya imports, which represent 85 % of overall seed imports, with a volume equal to more than 14 million tonnes. From 1965 to 1980 imports, compared to the almost negligible level of exports, have doubled over every five-year period.

Obviously, the Community is still far from being self-sufficient. With regard to oil seeds as a whole, only France, and, to a lesser extent, Denmark, show any degree of self-sufficiency, while the other countries are more or less dependent on imports.

In 1993, most EU exports of oils and fats (in value terms) went to the USA which had increased its market share since 1988. Conversely, Austria's share dropped. Among the major importers can now be counted Poland and Russia, which oc-

cupied third and fourth places in 1993, with respective shares of 8 % and 5 %.

On the import side, the importance of Brazil is confirmed. With a 31 % share of EU imports of oils and fats in value terms, Brazil is the biggest exporting country, while Argentina has increased its market share by 50 %. In 1993, the share of imports from Indonesia and Malaysia went up compared to 1988 and, at the same time, imports from the USA dropped.

The export/production index fell over the decade, going from 12.4 % in 1984 to 8.4 % in 1993. The import/consumption ratio also fell, going from 27.2 % in 1984 to 19.6 % in 1993.

## MARKET FORCES

### Demand

The demand in the oils and fats sector stems on the one hand from industrial uses and on the other from the human and animal food sector. The percentage of product for industrial use is around 40 % and over the last five years has gone up considerably. As was mentioned above, oleaginous substances are used in the cosmetics industry, as well as in the manufacture of soaps and detergents, lubricants, fuel and plastics. The demand for animal consumption concerns cakes and protein-rich foods which are particularly price-sensitive.

Human consumption is primarily of margarine, vegetable oils and olive oil and low-fat products, which are used as dressings or in cooking. Over the last five years, the human consumption of oils has increased by 15 % in volume, particularly in Germany, Denmark, Belgium and Portugal, while there has been a drop in the United Kingdom and France.

With regard to margarine (part of the vegetable-fat group), despite an overall growth of 4 % within the EU, there has been a steep drop in consumption in many countries, due to the fact that margarine has been replaced by low-fat spreads

or vegetable oils. The biggest drops have occurred in Italy (-15 %), the Netherlands and France (-9.84 %) and in the United Kingdom (-5.28 %), while consumption has risen in Germany, Belgium and Denmark. The per capita consumption of margarine is 4 kg and occupies a one-quarter share of that for the entire sector. It should be noted that although this demand for low-fat products rose considerably in the past, it is currently stable.

The consumption of vegetable oils shows a growth rate over the last five years equal to 15 %. The increase in the consumption of oil can be attributed to a high-quality and safe product image. The fastest growing markets are found in regional specialities, reflecting the interest in exotic foods and desire to introduce new flavours into the kitchen.

The pattern of oil consumption shows marked regional differences within the EU, due to the different eating habits and supply patterns in each country. Germany and Italy are the biggest consumers of soya oil, followed by the United Kingdom, the Netherlands, Portugal and Spain. Sunflower oil is number one in France, followed by Spain, Germany, the United Kingdom and Italy. The success of sunflower oil is due to its healthy image as a product with a high vitamin E and polyunsaturated acid content, as well as the fact that it tastes good. More than half the colza oil goes to the United Kingdom

followed by Germany and Italy; and half the corn germ oil goes to Italy, followed by France, Greece and Germany. The Mediterranean countries are the biggest consumers and producers of olive oil. Specifically, the largest production centres are in Italy, France and Greece. Olive oil has experienced the fastest growth rates, again because it is considered to be of high quality, healthy and suitable for either dressings or cooking.

#### Supply and competition

With regard to oleaginous seeds, production in the EU increased considerably during the 1980s and 1990s. The crushing of soya beans in order to obtain crude oils on one hand and meals for animal feedstuffs on the other hand is concentrated mainly in the USA, South America and Europe. The first crusher of sunflower seeds is the former USSR, followed by Europe and Argentina, which is also the biggest exporter worldwide. The biggest importer of sunflower seeds is the EU. With regard to olive oil, the countries of North Africa are more competitive than those of the EU.

Recently, many production sites have been set up near oleaginous seed processing plants within the EU. For example, in the case of soya, Italy is the top producer, but the grinding capacity in this country has not changed. Conversely, in the

Unilever	United Kingdom / Nederland	State-owned company	Kazakhstan

Source: Nomisma

Netherlands and Germany, the processing capacity has increased considerably. Due to the heavy effect of transport costs, above all road transport, the location of manufacturing plants is of fundamental importance.

The total cost of the production process per unit of product which was extremely high at the beginning of the period considered, is slowly going down, following the rationalisation of the processing cycle. The highest cost item is labour, which follows a pattern identical to that of the total cost index: high at the beginning of the period with a tendency to fall thereafter. The biggest investments in innovation in the production process occurred in 1986/89 and 1989/90 when the cost of labour shrank considerably. Finally, high labour costs are not matched by particularly high productivity levels, though these were on the increase during the period.

### Production process

Given the variety of products belonging to this sector, it is difficult to identify one single production process applicable to them all. Consequently, mention will be made only of the main stages needed to obtain the most important products.

To extract oil from seeds, a chemical-physical process is used. After going through a preliminary preparation stage (drying, cleaning, decortication and shelling), most of the seeds are crushed and then extracted by a solvent process in order to obtain crude oil. The crude oil is then refined, deodorised and bleached. The refined oil is further processed into final consumption products.

The production process of olive oil is split into five stages: pressing, from which olive paste is obtained; kneading, which favours the flow of oil and increases yields; the extraction of the oleaginous oil, which can be done using three different systems - i.e. centrifugation and settling; filtration (from which extra-virgin oil is obtained); and finally, refining and working residues.

The major companies operating in the margarine sector have introduced new technologies to maintain the quality of products distributed at long distances and in particularly hot climates.

---

## INDUSTRY STRUCTURE

---

### Companies

Companies operating in the vegetable oil sector specialise in the different phases of the production process: i.e. crushing, crude oil extraction and refining. The average crushing capacity is around 750-1 000 tonnes per day. Industries can easily work different types of seed (soya, sunflower and rape). The crushing and refining industry is highly concentrated. In fact, six groups exist which together cover about three quarters of EU activities and have plants located in various Member States. These are: ADM (USA), Bunge, Cargill (USA), Cereol (I), Unilever (UK-NL) and VDM (B). Cereol belongs to the Eridania-Bèghin-Say Group (F-I), and is the European leader in the field with a market share above 20 %.

The situation of olive oil is different. With regard to processing, there is greater market fragmentation, especially in Italy and Greece. Marketing companies tend to be large, particularly in Spain.

Manufacturing companies are both multinational and national: the first, like Eridania-Bèghin-Say, and Unilever, are integrated along the entire production cycle. The leader in the margarine sector is Unilever. With regard to raw oil, there is a highly competitive world market and reference prices are fixed by the Chicago and Rotterdam exchanges.

## Strategies

Producers in the sector employ total-quality strategies, with a careful eye on costs. The idea is to replace workers with capital investment in order to improve operating margins.

Product diversification and innovation policies represent an important line of strategy pursued by both oil and fat producers. In the sector of oil for human consumption, the main innovations relate to aromatised products and those specially-made for odour-free frying.

In the margarine sector, product types have been introduced with high vitamin content, to compete with the healthy image of low-fat spreads. Though this has resulted in higher prices compared to butter, it has also brought about an increase in value added in the sector. Other innovations concern packaging, e.g. in packets or tubes. Likewise, olive oil producers are tending to diversify by introducing completely natural processing systems, tied in particular to regional traditions, through the adoption of a Protected Geographic Indication label, acknowledged by the EU.

Growth strategies adopted by companies in the sector are directed towards the expansion of markets with good development prospects, such as those of the East European countries and Asia, either through direct acquisitions or increased exports to those countries. The large multinationals, on the other hand, implement integrative development policies towards downstream sectors or policies of penetration into new markets which are not labour-intensive and which present good prospects for.

### Impact of the Single Market

The creation of the Single European Market had an overall positive impact on the oils and fat industry, increasing international trade thanks to the elimination of controls at internal frontiers, technical harmonisation and mutual recognition of rules. Furthermore it enhanced know how and quality standards, assuring higher consumer protection. Higher costs of distribution were, however, recorded after the implementation of environmental policies.

The remaining internal barriers are linked to differences within countries in control implementation, and to differences in VAT levels.

On the export side the reduction of taxes and duties on EU export production should be taken into account.

Next priorities are linked to the reform of the Common Market Organisation regulating olive oil, the implementation of long term policies at Community level and the worldwide deregulation of the raw material market.

---

## ENVIRONMENT

---

The industries of the oils and fats sector use organic solvents, principally hexane, for the extraction of vegetable oils and fats. A proposed directive on the limitation of emissions of organic compounds due to the use of organic solvents imposes limits to the emission of volatile organic compounds.

---

## REGULATIONS

---

### Olive oil

The common organisation of markets in the olive oil sector came into effect with Regulation number 136/66, amended by the latest Regulation, number 2046/92.

Every year, the Community fixes the indicative production price; the reference price susceptible to modification during the course of the season, in the event of significant variations in the market situation; and the intervention price and threshold price, so the product sales price settles near the reference price. European prices are generally higher than those on the

**Table 11: Oils and fats  
Production specialisation (1)**

(ratio)	1984	1993
Belgique/België	1.98	N/A

Source: DEBA

world market, so the Community also intervenes with import duties and export compensations. Aid to production (and, in the oil sector, also to consumption) is provided, in the event of the indicative production price - reduced through production aid - being above the indicative market price.

### Oil seeds

The sector was profoundly concerned by the CAP reform. Regulations were established similar to those for cereals (compensation per hectare and on a lump-sum basis, determination of basic area for compensation, set aside incentives): the calculation of the amount of aid to be provided was studied so as to reach a balance with that established for cereals, with the aim of not creating any particular incentive for one of the two crops and maintaining the current ratio between cereal crops and seed crops (for this purpose, the average support price is calculated starting with that of cereals and applying a 2.1 factor).

The CAP reform, with the resulting reduction of the amount of support provided, seems to have paved the way for a considerable drop in oil seed production (the land area cultivated with seeds in the 1993/94 season was considerably lower than that of the previous year). Furthermore, soya would appear to be particularly involved in the disinvestment of cultivated areas, not only because since 1993, only first crop soya has been eligible for contributions.

### Spreadable fats

On 5 December 1994, the EU Council of Ministers adopted the Regulation laying down marketing standards for spreadable fats. The Regulation, which enters into force on 1 January 1996, lays down the sales designation for all the products concerned (butter, margarine and blends). The uniform classification will make it easier for the consumer to choose between products which are different as regards the fat content in general and as regards the plant and/or animal fats used.

### OUTLOOK

With regard to demand, it is considered that the industrial uses of oils and fats will expand (biofuels, lubricants). The use of vegetable oils for human consumption will continue to be promoted by the healthy image of the product. Also, innovative low fat products may get a bigger share of the market at the expense of traditional products like margarine.

In terms of industrial structure, the olive oil market will become less fragmentary following an increase in the number of acquisitions by multinational companies. The process of integration will also continue towards downstream sectors, and there will be a greater penetration onto new markets with good development prospects.

Address: rue de la Loi 74, Bte 3, B-1040 Brussels; tel: (32 2) 230 4810; fax: (32 2) 230 2274.

# Meat

## NACE 412

Over the next few years the meat sector will undergo important changes as a result of the ratification of the GATT treaty and the introduction of Community regulations on critical aspects of the production and distribution process. In particular, the fall in exports will limit the possibility for expansion to the high-potential markets of south-east Asia. Meanwhile, the increase in the level of concentration of large and modern distribution networks, coupled with the drop in beef, pork, sheep meat and goat consumption, is sharpening competition between enterprises within the EU. To face the changes under way, enterprises are increasing their degree of concentration on the Community market by an extensive process of acquisitions and are turning their attention to higher value-added products.

### INDUSTRY PROFILE

#### Description of the sector

The animal slaughtering and meat processing industry includes all of the processing stages following animal rearing up to final market consumption. In particular, reference is made to the slaughtering, processing and storage of beef, pork, sheep meat, goat, and poultry. Also included is the intermediate processing of products, like the manufacturing of plasma and the melting of animal fats. Further details concerning animal fats are provided in the chapters on dairy products (i.e. butter) and, more specifically, in the chapter on fats and oils. The final products to be covered are cuts of meat; processed meat, including chilled and frozen meat; and canned meat and deli meats, to which must be added pre-prepared foods.

Meat represents the biggest single item of expenditure with regard to the overall purchase of agri-foodstuffs (30 % on average). In 1990, this figure was particularly high in France, Belgium and Denmark, with about 35 %; while the lowest figures were to be found in Greece, Holland and the United Kingdom with around 25 % (source: Eurostat).

The biggest meat producers within the EU are, on average, France and Germany, thanks to the climatic conditions there, which are well-suited to stock farming. These are followed, according to subsector, by Denmark (pork), Italy (beef), the United Kingdom (poultry) and, finally, Spain (sheep meat and goat).

1993 marked the end of a five-year growth period between 1984-1992, during which there was a 51 % increase in the value of production and apparent consumption. This recent drop, underscored by the main indicators of the sector, is a result of the slow-down in all economic sectors of the EU and of the economic effects of the CAP (see Table 1).

In terms of quantity, since 1990 there has been a slight drop in the production of pork, sheep meat and goat, and a steeper one as regards beef. Conversely, poultry production increased with a growth rate higher than those recorded in the other subsectors.

During the period under consideration, improvement in the trade balance occurred, and it was again in the black in 1993 for the first time since 1991. Exports increased, while employment figures tended to fall slightly. The meat sector showed a higher added value compared to other sectors such as fruits and vegetables and dairy products, the latter being direct substitutes for meat. Among the Member States, France, the United Kingdom and Germany achieved the highest value added (1993) and were the biggest producers (1992).

**Figure 1: Meat**  
Value added in comparison with related industries, 1993

Source: DEBA

In 1992, the highest value in terms of internal production and consumption concerned pork and beef, the latter also achieving the highest volume of exports, immediately followed by pork and poultry. In these subsectors, the EU is entirely self-sufficient while it is a big importer of horse meat, sheep meat, goat and entrails.

In 1993, EU production of beef touched 8.1 million tonnes with a further drop of 3.4 %, after the 3.2 % drop of 1992. Cattle rearing in the Community, directed toward a drop in the number of milk cows, will be altered also by the activity level reduction process begun in 1991 in Germany, and the effects of the CAP, which chiefly has concerned the major producer countries (i.e., Ireland, France, Germany and Italy).

The pork subsector was distinguished in 1993 by an overall increase in production after the consistent hike in prices of 1992. This trend has given rise to a production surplus which has brought about a 30 % drop in prices. The biggest producers were Denmark (+3.8 %), France (+3.2 %), Belgium and

Luxembourg (+2.8 %). The self-sufficiency rate in 1993 was equal to 104 %.

The production of sheep meat and goat, according to Ismea estimates, went up by about 1.3 %. This can be attributed to increases in the output of the United Kingdom, Ireland and Spain.

Finally, the production of poultry in the EU is around 7 million tonnes. 70 % is made up of chickens. There are increases in production in most member countries, e.g. 5 % in the Netherlands, 3.9 % in Italy, 3.2 % in Germany, 1.4 % in United Kingdom and 1 % in France.

**Recent trends**

In constant prices, the 1984-1992 period produced stable growth in the entire sector (+3.65 %). This ended, however, in 1993. Particularly significant are the growth patterns relating to foreign trade which have shown very high export values (on average 4.39 % up to 1992) with peaks in 1993 reaching

7 % and imports distinguished by an unsteady pattern and much lower values (see Table 3).

Until 1990, production in the meat sector showed a pattern in line with that of the manufacturing industry. Since 1991, the gap between the two has widened, with a general stagnation in the manufacturing industry and a growth in that of meat.

With regard to employment levels, up through 1990 there was strong growth in the meat sector while figures tended to shrink in the manufacturing industry. The number of persons employed began to fall in 1992, however, levelling off in 1993 at 431 018, a figure slightly lower than that recorded in 1989. The recorded drop touched figures much lower than those in the manufacturing industry, once again underlining the anti-cyclical nature of the food industry.

Labour costs grew steadily up to 1992. Thereafter, they peaked and returned to 1991 values, while the total of input costs in the 90s was substantially similar to that of base year 1990.

**International comparison**

The EU is the world's biggest overall meat producer. Over the last 10 years, there has been a gradual increase in European production which, at current prices in 1993, was almost the same as that of the USA. The strongest growth rate, however, was recorded in Japan, which upped production over the ten-year period by nearly 70 %.

In constant prices, there has been an exceptional rise in quantities produced by the EU which, in 1984, recorded values much lower than those of the USA where variations tend to be far less extreme, albeit against a pattern of constant growth. With regard to Japan, an unstable trend has determined a production flow in 1993 comparable to that of 1984 (see Figure 5).

The sector has been affected by the structural decline of production in the former Soviet Union and the East European countries, following the depletion of state subsidies, the increased cost of production inputs and the scarcity of feed. This trend has been countered by the strong expansion of production in China, thanks to a soaring domestic demand and the development of intensive animal farming systems which have improved herds through the use of better-quality feeds, among other things.

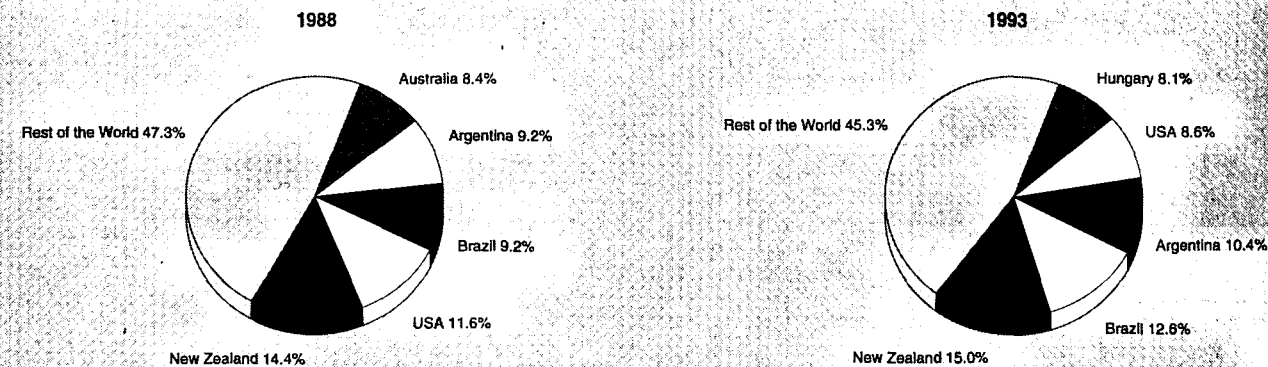

In 1993, 185 million tonnes of meat were produced, with an increase of only 0.5 % over the previous year. According to FAO sources, this pattern can be attributed to the spreading of epizootic diseases and the high cost of animal fodder.

Beef stocks at the end of 1993 equalled around 460 thousand tonnes, a considerable drop compared to the previous year (-45 %). This was caused by a heavy fall in production, sustained consumption patterns and strong export flows to third countries. Consequently, prices increased steeply by about 16 %.

The pattern of beef production over the ten-year period showed particularly high values from 1984 to 1987 following the slaughtering of numerous animals in accordance with milk quotas; and again in 1990 following the reunification of Germany, which led to an increase of around 4.4 %.

While the USA plays the lead role in the beef and poultry sectors, China is way ahead in the sheep meat and goat sector, which has been concentrated in Asia since the start of the 80s. The EU is the second biggest producer of pork, after China; the second most important producer of poultry and beef, after the USA; and the third biggest producer of sheep meat and goat, after Asia and Africa.

### Foreign trade

The balance of trade in the meat sector was in the red for almost the entire ten-year period under consideration. Positive results were achieved only in 1991 and 1993. The 1993 result is above all tied to the exceptional increase in the value of exports (+12.5 %) and a steep fall in imports, especially in France, Italy, Spain and Greece. Germany, on the other hand, upped its imports from outside the EU. It is important to point out that about 81 % of exports and 79 % of imports occur between the countries of the EU, thereby making foreign trade outside the area less significant. Export figures have, in fact, dropped slightly while there has been a gradual 'closure' against the imports of foreign products, driven out by the strong growth in production recorded in the EU (see Figure 8).

In the pork subsector, the fall in prices recorded in 1993 persuaded the Community to authorise the subsidised export of 30 000 tonnes to Russia. Meanwhile, the level of EU beef exports remained unchanged between 1992 and 1993, while imports increased.

In the sheep meat and goat subsector, in 1993, the occurrence of diseases like foot and mouth disease in the East European countries led to import restrictions. Meanwhile, the drop in production in New Zealand affected the Community market by favouring the exports of the United Kingdom and Ireland.

The poultry subsector, while having recorded a by-volume increase of about 14 %, still had difficulty extending its export markets due to the strong competitiveness of US and Brazilian products and the greater degree of self-sufficiency of the non-industrialised countries.

Exports from the US have at times been subsidised by amounts double that of the EU restitution. 40 % of European meat exports go to Japan, the USA and the EFTA countries. In 1993 there was a general reduction of trade with these countries in favour of Russia, which has a market share equal to 12 %, greater than that of the USA and EFTA, and second only to Japan. This same trend involved Poland, where imports from Europe increased considerably, though the figure reached was not particularly high (around 3 %). As a consequence of trade sanctions imposed following the Gulf War, Europe's meat exports to Iraq plummeted by 90 % from 153.9 million ECU in 1988 to 13.1 million ECU in 1993.

In 1988, the meat sector did not show any specific concentration in terms of source of imports. Apart from New Zealand (15 %) and Brazil (12.6 %) which are major partners, we find Argentina (10.6 %) and the USA (8.6 %), to which must be added Hungary, Australia and the EFTA countries, all of which have similar shares of around 8 %. From a geographic viewpoint, it is right to say that every continent except Asia contributes about equally to European imports. In 1993, greater importance was acquired by Brazil, while the USA and Australia considerably reduced their flow of trade.

## MARKET FORCES

### Demand

Generally speaking, there was an increase in the demand for products in all sectors, with a greater service component, particularly for pre-packaged and pre-cooked products. Two examples are the growing demand for pre-processed foods (spiced meats and pre-cooked vegetables, meat pieces, mince-meat - especially pork and beef, etc.) and for cuts of fresh meat presented on polystyrene or cardboard trays.

The demand for beef is affected by the supply of fish, cheese and pasta, especially in the Mediterranean countries; and poultry, which has an image that is more in line with the demand for food freshness and hygiene. The image of beef has been damaged somewhat by the widespread diseases affecting cattle and by the negative opinion of consumers towards the use of hormones in animal feeding. The consumption of canned beef is dropping, although that is of minor importance.

The demand for pork is directed in particular to deli meats - mainly Parma ham and salami - eaten as snacks or as a substitute for other meat products during main meals. In this case too, the spread of diseases - e.g. swine fever, which hit

Source: Eurostat

pig farms in Flanders in 1990 - strengthens consumer belief that pork is not very healthy.

The demand for poultry is favourably sustained not only by its image as lighter and lower in fat than red meat, but also because it is cheaper. The fastest expanding subsectors are those of turkey, roast chicken, either pre-cut or found in pre-processed foods. On more advanced markets, like that of France, there is a big demand for certified-label products, such as the label rouge, guaranteeing the respect of particular poultry farming and slaughtering techniques, such as the type of feed, life span of the poultry and percentage of various feeds used, etc.

The demand for sheep meat and goat is concentrated in those EU countries where it is traditionally eaten during main meals, e.g. the United Kingdom and Greece.

#### Supply and competition

The EU is, taken as a whole, the world's second biggest producer of beef, pork and poultry, after the USA. In the sheep meat and goat sector, China is well in the lead, as was mentioned above. The EU is the second biggest producer of pork (taken on its own) after China, the second biggest producer of poultry and beef after the USA and the third biggest producer of sheep meat and goat after Asia and Africa.

The work productivity index underwent stable growth between 1984 and 1993 with greater variations in the 1990s. In these years, levels of employment dropped as did the unit cost of labour. This pattern was followed by a fall of the gross operating rate, however, which was tied to a drop in the value added in production (see Table 5).

Currently, the retreat of foot and mouth disease, now only present in Italy, could favour greater competitiveness and enable the EU to once more be a part of the zero-risk group of countries. As it stands now, no-risk areas like the USA and Japan tend to refuse imports from the EU.

#### Production process

The biggest innovations in production processes concern the increase in the shelf life of fresh products, particularly the greater availability of products in modified atmospheres and the introduction and spreading of technologies for the production of pre-packaged and pre-cooked meats. In the beef subsector, production costs are greater than those in the USA and South American countries which have raised the technological level of their plants considerably over the last few years.

## INDUSTRY STRUCTURE

### Companies

The meat sector comprises a high number of large companies, as well as numerous small and medium-sized enterprises. The production structure is fragmented, even though Community regulations relating to new agricultural policies and the level of concentration achieved by large and modern distribution networks have given rise to a level of concentration in the sector that is among the highest ever to have occurred within the entire agricultural sector. In Italy, the phenomenon of productive reorganisation essentially involved large enterprises and the animal slaughtering subsector.

Especially in the beef subsector, there has been a gradual increase in value added in production aimed at large distribution networks, due to the integration of cutting and packing services into butchering companies. Such 'extensions', made possible by improvements in cold storage, have given added importance to companies' supply and transport services, considering the short shelf life of the product (five days). Likewise, storage technologies, such as those in modified atmospheres enabling shelf life to be extended, are becoming more significant.

The poultry subsector, characterised by high economies of scale in production, presents an industrial structure comprising numerous large enterprises in most EU countries. These companies have a totally integrated structure upstream of the processing stage, ordinarily using automated systems.

The pork subsector shows important differences in terms of industrial structure depending on the categories considered. In particular, ham production is characterised by small production units, with a large number of people still employed in the manufacturing process. In these subsectors, scale economies are substantially limited and the process of concentration of production takes place at subsequent stages, particularly during seasoning. Conversely, a greater concentration of production takes place in other subsectors where there is a higher possibility of process industrialisation, e.g. wurst, Bologna sausage and boiled ham.

The major enterprises at the European level operating in the meat sector belong to highly-diversified, multinational companies like Unilever and Nestlé; to enterprises prevalently concentrated in the sector like Hillsdown Holdings (4 828 million ECU in 1993), Booker (4 580 million ECU in 1993), BP Nutrition (3 129 million ECU in 1993), Cremonini (1 780 million ECU in 1993); and finally, firms operating exclusively

in the sector like Sudfleisch (2 033 million ECU in 1992), Nordfleisch (2 000 million ECU in 1992), Socopa (1 890 million ECU in 1993) and Moskel (1 750 million ECU in 1992). Concentration levels within the sector are generally low. In particular, the first six companies specialised in the production and processing of meat retain 19.6 % of the overall market, while multinationals Unilever and Nestlé cover about 10 % of the delicatessen market.

About 50 % of the animals slaughtered in 1992 in the EU were pigs raised mainly in Germany, Holland and Denmark. 26 % were cattle, with production concentrated chiefly in Germany, France and Italy. Finally, 22 % were poultry, slaughtered mainly in France and Italy (see Table 7). In 1993, the biggest producers (value-wise) of meat in the EU were France, Italy and Germany.

The per capita consumption of meat in 1992 was an average 94 kg, of which about half was pork, about one-quarter beef, a fifth poultry and the remainder sheep meat. The biggest consumers of meat are France, Denmark, Belgium, Luxembourg and Spain: France has the highest per capita consumption of beef, Denmark of pork, Spain of poultry, while Belgium and Luxembourg have a particularly high per capita consumption of meat of all kinds.

- **Cattle:** The consumption of beef by volume declined constantly between 1988-1993 in most EU countries (notably in the UK: -15 %), except for Portugal, Denmark and Greece where consumption rose by about 10 %. 53 % of beef consumption was concentrated in Italy, France and Germany, while the biggest per capita consumption was in Italy and the countries of northern Europe (Source: Euromonitor).
- **Pigs:** The consumption by volume of pork declined constantly throughout the EU until 1992, while in 1993 there was an approximate 1 % growth compared to the previous year. Exceptions were Spain and Portugal, where consumption continued to fall. About 50 % of consumption is concentrated in France, Germany, Italy and the United Kingdom, though the biggest per capita figures are to be found in Denmark with about 67 kg, Belgium with 50 kg and Ireland with 35 kg.
- **Sheep and goats:** The consumption of sheep meat and goat in the 1988-1993 five-year period failed to show a uniform pattern within the EU. In fact, though there was an overall drop equal to about 13 %, contributed to by the United Kingdom and Spain, in all the other countries there was a considerable increase, especially in Italy (+13 %) and Germany (+28 %). The biggest per capita consumption is to be found in Greece, with about 15 kg.
- **Poultry:** Over the five-year period considered, the consumption of poultry showed the strongest growth at around 4.8 % and reached 19 kg per capita in the EU, varying from 23 kg in Ireland and Spain and about 12 kg in Germany.

### Strategies

The meat sector is a mature market in most countries of the EU. The strategies adopted by enterprises in the various subsectors aim at differentiating and determining supply - according to the production process, the product and/or its region of origin - the elements on which to base the process of differentiation. In particular, reference is made to ISO standards, to labels as indicators of process differentiation, to PGIs as indicators of origin and to new products, such as flavoured deli meat or meat with a low fat content, etc.

Such strategies are determined by the degree of market development and by the food consumption patterns which distinguish the market. Some difficulty exists with regard to the introduction of labels certifying farming methods in those countries whose markets for beef are more advanced in terms of consumption.

**Table 9: Meat  
Production specialisation (1)**

(ratio)	1984	1993

Portugal	0.48	0.74
United Kingdom	1.04	0.98

(1) Ratio of production in the sector compared to manufacturing industry for each country, divided by the same ratio for the EU. Estimates.  
Source: DEBA

The most sophisticated differentiation strategies concern the pork meat trade subsector, which is also that with the greatest value added. In those countries where the meat market has reached an advanced stage, like France, the enhancement of the area of origin plays an important role, as is indicated by the popularity of Souchon d'Auvergne. Product differentiation also involves the introduction of deli meat for different stages of a meal, such as round salami for hors d'oeuvres and short and dry salami for sandwiches. Finally, there is the production of sausage products made from goat, wild boar or flavoured with walnuts and chanterelles; and vintage pork meat or products with a low fat content.

In the poultry subsector, company strategies are essentially based on the certification of quality. This, to guarantee that recognised farming methods have been used, e.g. during the production of pre-processed dishes where the poultry is combined with other foods.

The sector has been among the most active in terms of acquisitions with 31 such operations in 1993 and 15 in 1994. Acquisitions were prevalently made by UK, French and US companies and showed - excepting those made by US firms - a tendency to strengthen positions consolidated within respective domestic markets.

### Impact of the Single Market

The impact of the creation of the Single Market has been positive. It favoured international trade by liberalising the movement of persons and goods, increasing also competition inside the market. In relation to the meat sector, the creation of the Single Market also had a positive effect, mainly on small and medium firms by reducing financing and administrative burdens and by stimulating investment. Unfortunately, internal barriers still remain, due to the lack of fiscal harmonisation, and to differences within countries in the implementation of adopted legislation.

The harmonisation of legislation especially referring to production standards and product composition with the USA is a priority for the industry.

### REGIONAL DISTRIBUTION

Meat production shows different regional concentrations within the EU depending on the type of animal being reared. With regard to cattle, production is concentrated in Brittany and the regions of southern Germany like Bavaria and Niedersachsen. The Netherlands, Denmark and the plains of northern Germany and Emilia Romagna are pig farming centres;

while poultry is produced mainly in southern Lombardy, Veneto and western France. Finally, the central regions of Spain, the whole of Greece, Sardinia and parts of Wales and Scotland are sheep and goat herding centres.

### ENVIRONMENT

Environmental problems related to the meat sector chiefly involve territorial concentration. This problem is particularly keen in Emilia Romagna, Italy, where there is also the difficulty of the disposal of pig waste which pollutes the deep underground strata. On a more positive note, the disposal of industrial by-products is facilitated through the large and well developed industry which processes them for the manufacturer of fertilisers and animal feeds.

### REGULATIONS

#### Beef

The beef sector is regulated by EEC Regulation 805/68 - which has been amended several times over the years - and by EEC Regulation 125/93.

Every year, the Community intervenes in the operation of the market by setting the intervention price and the orientation price, taking into account the growth prospects of production and consumption as well as the situation of the milk and dairy products market. As part of the CAP reform, the intervention price was reduced by 5 % beginning in July of 1993.

The measures adopted with the McSharry reform have affected the intervention and financial incentive systems. With regard to the intervention system, the general criteria (normal regime) provide for intervention when the mean Community market price is less than 84 % of the intervention price or the mean domestic price is less than 80 % of the intervention price of each country. With the reform of the CAP, new limits have been introduced for intervention as part of the normal regime, set at 750 thousand tonnes for 1993 and 650 thousand tonnes for 1994. Furthermore, safety measures operate when the Community market price drops below 78 % of the intervention price and when the market price is less than 60 % of the intervention price of a Member State or of a region (the previous threshold was 72 %).

The incentive system also has been adapted to the new situation brought about by the CAP reform and included in the body of regulations of the Common Market Organisation (CMO). In this framework, incentives go to:

- compensate for the drop in income due to the fall of prices threshold (special incentive - awarded on the basis of a limited regional ceiling and incentive for lactating cows);
- balance the market during the course of the year (seasonal adjustment incentive awarded for animals slaughtered between 1 January and 30 April, if in the Member State the animals slaughtered in the September-November period exceed 40 % of the yearly total);
- encourage extensivisation; and
- reduce meat production in favour of milk production (incentive for conversion or, alternatively, participation in intervention for light carcasses).

The CAP reform also contains a programme for the promotion and sale of quality beef (Regulation 2067/92). This focus on quality, along with the protection of human health, led to Directive 93/43, a horizontal directive setting general rules of hygiene for food products and methods for controlling the observance of such regulations. This directive has widened the areas covered by previous sectoral regulations (e.g. Regulations 91/497 and 92/05 for the meat sector) forcing food companies (and others) to adopt HACCP (Hazard Analysis and Critical Control Points) methods for the control of all

processes - from preparation to sale - and recommending the adoption of quality manuals and EN 29 000 quality standards.

### Sheep meat and goat

The common market in this sector is standardised by Regulation 3013/89. Each year, the Council sets a single base price for fresh and chilled sheep meat for the entire Community. This price takes into account seasonal market variations.

For sheep meat and goat, the CAP reform restricts, according to the producer's sheep stock of reference, the number of sheep a farmer can raise and still have the right to incentives. This limit corresponds to the number of sheep a farmer can breed and still benefit from the incentive in the best of years between 1989 and 1991, but with a maximum of 1 000 sheep in less favoured areas and 500 sheep in other areas. Above this limit, only 50 % of the incentive is paid.

### Effects of the GATT agreement on the meat sector

- **Exports:** An overall restriction of Community exports is expected, with the criteria of a 36 % reduction in export subsidy expenditure and a 21 % reduction in the volume of subsidised exports. In the year 2000, the maximum quantity of subsidised exports will equal 817 thousand tonnes for beef, 389 thousand tonnes for pork and 291 thousand tonnes for poultry. The bilateral agreement between the USA and the EU allowing for a gradual reduction of the volume of subsidised exports, permits larger subsidised exports over the implementation period, taking the 1991/92 levels as the base, instead of those in 1986/90. Consequently, the Community will be able to recover 362 thousand tonnes of beef, 253 thousand tonnes of poultry and 16 thousand tonnes of eggs.
- **Access to the market:** The agreement provides for a minimum market access equal to 3 % of average domestic consumption in the first year of the implementation period and up to 5 % by the end of the implementation period. In any event, the impact of market access measures will be minor, partly because current EU imports exceed the limits set by the agreement, except for pork, imports of which will need to double. Reduced tariff access quotas will be opened for a total of 75 thousand tonnes, of which 39 thousand will relate to loins, boned loins and boned hams. The current 7 % tax on fresh, chilled and frozen pig's liver will be abolished by 2000. Furthermore, as different types of meat can be recorded in the calculation of the minimum access quota (as opposed to the single customs items as provided for in the Dunkel document), imports can be planned with greater flexibility.
- **Support:** Compensatory aid to income provided for by the CAP for cattle and sheep is not subject to the support reduction measures laid down by the GATT agreement.
- **Health and plant health measures:** Two criteria laid down by the agreement are of particular interest to the meat sector. The "principle of equivalence" states that if the health measures of a supplier country guarantee health protection levels required by the buyer country, these should be accepted even if they are formally different from internal measures. The second criterion concerns the status of the "area free from disease". Traditionally understood to mean a country or geographic area, it finds a more flexible interpretation in the GATT agreement, which provides that an area within a region where there are epidemics or outbreaks may continue to export its products if it can offer proof of being free of contagion.

## OUTLOOK

Over the next few years, competitiveness between enterprises is expected to become more intense due to the substantial lack of opportunity to expand and consolidate European exports to south-east Asian markets, which will be served to an ever greater degree by the USA and New Zealand.

Meanwhile, on the domestic market, Community measures regarding the control of the production and distribution processes will inevitably affect cottage and small enterprises. Moreover, increased concentration in the distribution sector and a drop in consumption levels will tend to erode profit margins of producers.

Forecasts therefore envisage an increase in the process of concentration under way in the sector, the adoption of more sophisticated differentiation strategies and the growing tendency to prefer greater value-added products.

# Dairy products

## NACE 413

The production of milk by volume has dropped following a Community policy aimed at the overall restriction of production surpluses in Europe. EU consumption of milk and cream is stable, while that of butter continues to drop while that of yoghurt and cheeses is rising.

In such a context, enterprises are strengthening their respective positions on domestic markets through a process of takeovers, particularly on the German market, in order to gain access to East European countries. Such a process is continuing despite the high degree of concentration existing in most sectors already.

The coming into effect of Community regulations aimed at developing procedures to control critical stages in the production process will help to change the structure and organisation of the sector.

### INDUSTRY PROFILE

#### Description of the sector

The dairy sector includes activities of milk thermo treatment for alimentary use - e.g. pasteurised and UHT milk (both powdered and condensed) - and the processing of milk into by-products. The latter are used as both intermediate processed products (casein) and end products like cream, butter, yoghurt and cheeses. Ice cream made from milk is dealt with in a separate chapter, together with chocolate, cocoa and sweets.

The dairy industry is among the major agri-foodstuff sectors in all European economies. In fact, it represents about 13 % of the overall food budget on average. The highest figures relate to the United Kingdom and Germany with 16 %, while the lowest figures are to be found in Spain and Portugal with around 11 %.

Although consumer patterns within the EU still differ significantly, the most consumed dairy product remains milk, followed by cheese, yoghurt and (albeit to a decreasing extent) butter.

The distribution of production activities in the dairy sector and the levels of self-sufficiency of the Member States have been significantly shaped by the strict regulations enforced within the sector since 1984, when milk quotas were introduced. The list of structurally 'deficient' countries includes the United Kingdom, Italy, Spain and Greece, while the other EU countries are fully self-sufficient.

#### Recent trends

The 1984-93 period witnessed a steady growth in production and consumption at current prices. On the other hand, exports and the trade balance show a more uncertain pattern, with a 20 % drop in exports and an almost 26 % drop in the trade balance in 1986. These drops were somewhat less steep in 1990 (16 % exports, 18.7 % trade balance). Employment figures in the sector shrunk from 281 000 in 1984 to 246 000 in 1993.

Fresh milk-based products (including milk) within the EU make up about 84.5 % of overall production in the sector. These are followed in order of importance by cheese and butter. Total production is sufficient to completely meet the internal needs of the EU and therefore the market share of imports is modest (at around 1 %). Only the demand for drinking milk is slightly greater than the EU production capacity. The demand from abroad met by internal production is equal to almost 6 %, a share which has been shrinking since 1984.

Figure 1: Dairy products  
Value added in comparison with related Industries, 1993

Source: DEBA

Exported products are full cream and skimmed powdered milk, cheeses, condensed milk and butter.

Altogether the dairy industry is marked by a high value added, only slightly less than that of the meat sector and considerably more than that of fruit and vegetables and soft drinks. The countries with the highest value added are France, Germany, Italy and the United Kingdom.

At steady prices, average growth rates for the dairy sector have been positive with regard to production and internal requirements, while exports have gradually continued to shrink. In 1992/93, such variations increased, and while internal production and consumption grew by about 3 %, exports dropped by 3.58 % and imports went up by 5.16 %.

At steady prices, dairy production between 1984-90 showed growth rates lower than those of the manufacturing industry. Subsequently, both sectors were marked by irregular growth patterns. Employment figures in the dairy industry have been on an almost constant decrease over the last 10 years, in keeping with a similar trend in the manufacturing industry.

**Figure 3: Dairy products**  
Production and employment compared to EU total manufacturing industry

1994 are Eurostat estimates.  
Source: DEBA

Following are the consumption figures for the subsectors of the dairy industry in the EU (Source: Euromonitor):

- Milk: in many countries of the EU, milk consumption dwindled through 1993. The biggest drop was in Belgium (-6%). Germany was an exception, and consumption actually increased (+5%) as it did in Greece (+2%). Ireland recorded the biggest per capita consumption, with 147 litres/year followed by Denmark with 112 litres/year and the United Kingdom with 103 litres/year. The countries with the lowest per capita consumption were Greece and Germany with around 50 litres.
- Cheeses: cheeses represent the main item of expenditure for dairy products in Europe. The biggest consumers in terms of volume are France, Germany, Italy and the United Kingdom which together accounted for more than 70% of overall consumption in 1993. From 1988 to 1993, there was an overall growth in cheese consumption which, again in terms of volume, was greater in Denmark and France.

- Butter: between 1988-93, there was a definite drop in butter consumption in many EU countries. Average figures hovered around 10% over the five-year period, the biggest drop being in Denmark (52%). An exception was Germany, which showed a rise of 4% and Portugal, where there was a 140% increase. About 83% of butter consumption is concentrated in four countries (Germany, France, Belgium and the United Kingdom), of which Germany alone accounts for 43%. These countries also have the biggest per capita consumption. In 1993, there were no variations in consumption levels, apart from Germany, where there was a large increase equal to 6% in volume.
- Yoghurt: the consumption of yoghurt jumped considerably over the 1988-93 period in all EU countries. The biggest rises were in Italy (55.8%), Spain (32.6%) and the United Kingdom (29.7%). Conversely, the smallest increase was recorded in Ireland (8.33%). The countries that consume the largest volumes of yoghurt are France, Germany and

Destination of EU exports**

Source: Eurostat

Spain, while the biggest per capita consumers are The Netherlands (21.5 kg), France (19 kg) and Denmark (16.2 kg). Spain, France and Germany also accounted for 58.28 % of overall volumes consumed in 1993. During 1993, these figures maintained the growth patterns recorded for the five-year period in most of the EU countries, except for The Netherlands, where there was a slight drop of 1.2 %, and in Denmark, Luxembourg and Greece, where figures remained unchanged compared to the previous year.

#### International comparison

The EU was the world's largest producer and exporter of dairy products at current prices between 1984-93, despite an 8 % drop in production levels between 1990-93. The EU provides the international market with about 58 % of its cheeses, 57 % of its powdered milk and 31 % of its butter.

The former Soviet Union makes roughly a 19 % overall contribution to world production, while the USA contributes 15 %. These figures represent a significant drop compared to 1984.

Between 1990-93, there was a general increase in production in the United States, Australia, New Zealand and the developing countries, especially those of Asia. Japan also underwent growth, but to a lesser extent than the other countries under

consideration, despite the fact that in 1984 its production rose by about 60 %.

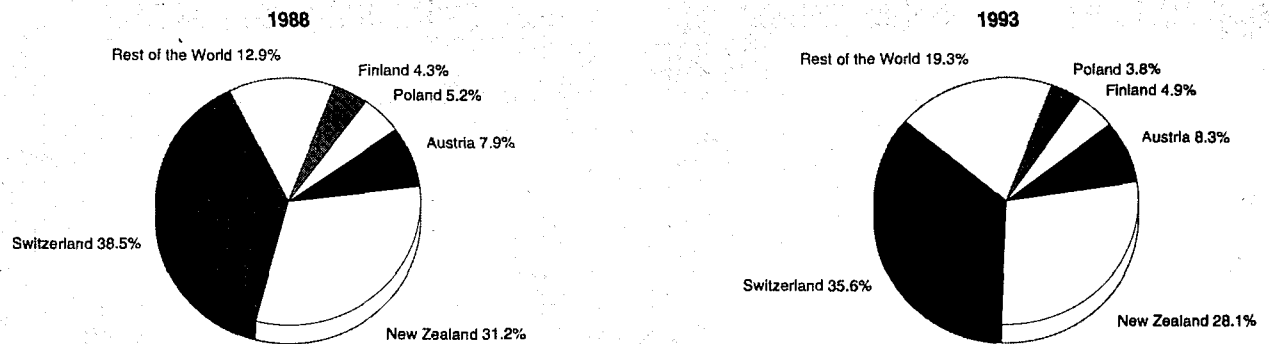

At steady prices, the EU recorded growth throughout the period, with stronger variations in the years 1988 and 1991. The USA recorded particularly strong growth up to 1988, after which figures tended to level off, while growth patterns in Japan were stable.

In the EU, there was a strong increase in the production of cheese from full cream milk (7.6 %) in 1992. This trend was greatly amplified in the USA where the rise touched 20.5 %, while there was a sharp and general drop in East European production caused by the precarious economic situation in those countries. On the other hand, the production of butter in the EU fell by about 19 %, while the drop in the former Soviet Union was not as sharp. The only increases in production were recorded in Australia and New Zealand.

#### Foreign trade

The balance of trade of the EU with regard to dairy products remained generally favourable for the entire 1984-93 period, though the trend was not stable. The ratio of exports to imports, which remained extremely high, showed a slight drop until 1991, proof that variations in import figures were larger than

Source: DEBA, Eurostat

variations in export figures. The only exception was 1992, when there was a substantial stagnation in imports and a strong growth of exports. The terms of trade index for 1990 shows that the prices of exports are more or less equal to those of imports. This situation worsened during the 1986-88 period when a tendency for import prices to rise was contrasted by a decrease in export prices.

In 1988, the main trading partners for the EU were the United States and EFTA countries; Saudi Arabia and Algeria, with equal shares, are the main players in the Middle East and North Africa. Combined, the USA and EFTA countries took 18 % of total EU exports in 1993, while Algeria and Saudi Arabia took 12 %. In 1993, there were no particularly significant changes to these figures, although EFTA's share grew to 8.5 % and there was an increased contribution from the USA. Alongside these trading partners, Mexico acquired growing importance with a share of 4.6 %. As far as the Arab countries are concerned, it should be emphasised that, while in 1988 Iraq took 4 % of European exports for a value at current prices of 67.3 million ECU, in 1993 this figure had dropped drastically to 0.7 million ECU at current prices. The overall share of the Arab countries underwent a slight increase, however, while the overall share of the countries of North Africa shrank by 3 %.

Around 49 % of imports come from EFTA countries. Switzerland has a 35.6 % share followed at a distance by Austria and Finland. Another European partner is Poland with a very small 4 % share. Among non-European countries, New Zealand plays a lead role with 28 % of EU imports. 1993 also saw a rise in imports from Eastern Europe (outside Russia and Poland), especially from Lithuania, Ukraine, the Czech Republic, Bulgaria, Hungary and Romania.

Generally speaking, the degree of penetration of imports did not undergo any noticeable change between 1984-93, remaining steady at around 1 %. Exports dropped, except for the period between 1987-90, due to the more aggressive policies adopted by rival countries and a reduction in production levels due to the Community policy for the restriction of surpluses.

## MARKET FORCES

### Demand

Dairy products are used primarily for human consumption. An exception is powdered milk, which is also used for cattle rearing. All the segments considered relate to a saturated final market, looking to marketing instruments for product differentiation and the progressive increase of market segmentation. In line with this trend, the products are distinguished by the ongoing growth of services as emphasised by the introduction and development of fast foods. Since the early 1990s, consumers have tended to prefer low-fat products and fresh foods, which has led to their dissemination in all segments of the sector.

Milk is considered a dietary staple in all EU countries. It is used at breakfast mixed with tea, coffee and cereals, and is consequently tied to the consumption patterns of these products. It is also consumed on its own as a beverage and thus feels the competition of mineral waters, fruit juices and soft drinks. Over recent years, the increasing consumption of alternative drinks and the drop in the consumption of tea have caused a further drop in the consumption of milk. The popularity of low-fat diets has resulted in milk being used in place of cream during cooking. Since early in this decade, the fastest growing segments are those of milks containing flavourings and nutritional additives.

The demand for butter, though used in different ways in accordance with the different eating habits in the EU countries, has fallen sharply as a result of the tendency to prefer 'lighter' products over animal fats. Subsequently, butter is being replaced by oil, above all in the southern EU countries, and also by margarine. In some areas, mixed-fat products are also used.

Cheeses are primary foodstuffs in France and in Italy, where there is a strong consumption tradition. In other countries, they are more commonly eaten as snacks and are not usually

Source: DEBA

alternatives to meat for main meals. Apart from Spain, there has been an increase in the consumption of fresh and low-calorie cheeses to which must be added dessert cheeses (intended for children) and green-mould cheeses.

The demand for yoghurt is tied in most EU countries to the consumption of desserts at different times of the day. In the southern areas of the EU, this demand very much follows a seasonal pattern, given the abundance of fruit during the summer and a greater consumption of ice cream year round. Among the products taken into consideration, yoghurt presents the highest degree of differentiation and the fastest growing segments concern products for children, bio yoghurt, Greek yoghurt (mainly in the United Kingdom), low-calorie yoghurt and liquid yoghurt (for drinking).

### Supply and competition

The EU is the world leader in all subsectors of the dairy business. This position was validated with regard to cow, sheep and goat milk for human consumption in 1993, though production had dropped compared to 1992. A drop has also occurred in the production of North and Central America, though to a much lesser extent. Certain countries in Asia, Oceania and Africa have recorded increases.

The labour productivity index has continued to grow steadily, with particularly significant increases between 1985-89 and 1992-93. Unit labour costs also tended to increase between 1985 and 1989, whereas a sudden drop was recorded between 1992-93. Meanwhile, the gross operating rate fell after 1989 following a reduction in production value added. Likewise, overall production costs are dropping, as are the number of employees in the sector as a result of the introduction of labour-saving technologies. Though the biggest producer of milk, the EU is distinguished by a high cost of raw material, which is above the level of costs in the USA, Australia and New Zealand. The use of the Bovine Somatophyn hormone in the USA - forbidden in the EU - will enable that country to further reduce its overall production cost of raw material.

The butter segment has seen a substantial fall in exports due to the steep drop in demand in the major traditional markets. The cheese subsector has recorded the regular growth of fresh products and increased its exports of cream cheese between 1992-93 by about 11 %. Finally, the yoghurt subsector recorded a drop in consumption at EU level for the first time in ten years.

There is an affirmed trend towards a progressive erosion of profit margins in the dairy industry within the EU. This is due to the high concentration achieved by modern organised distribution in the management of dairy products and by the competition - triggered after the application of Community policies aimed at reducing production surpluses - among companies in the raw material supply stage.

The market share of dairy products which involve the most advanced forms of distribution varies according to the buying habits of consumers, the degree of development of such forms and the types of products considered. Such advanced distribution is more common in Northern Europe, e.g. in The Netherlands, where 86 % of dairy sales were managed by these forms of distribution in 1992, while in Spain and Italy this figure dropped to 65 % and 49 % respectively. There has been a strong rise in the sale of dairy products through discount stores, which detain a share around 63 % in Germany.

Milk, butter and yoghurt are the chief products purchased through modern distribution networks. In 1992, milk retailed through supermarkets represented 86 % of the total in The Netherlands, 72 % in Spain and 50 % in Italy. An exception to this trend was the United Kingdom where 58 % of milk is delivered directly to the home. This figure, which in 1988 touched 73 %, has fallen sharply due to the lower retail price of milk purchased through advanced distribution set-ups. Dis-

tributor brands of dairy products are also on the rise, though growth rates differ between the various Member States. In particular, the market share is higher for products which are more difficult to differentiate, e.g. UHT milk and butter. In 1992, this figure touched 85 % in Germany, 28 % in France and 13 % in The Netherlands in 1992.

### Production process

The dairy sector is distinguished by the presence of companies of different size, starting with the small cottage industries producing cheese only, to the large multinationals with high production outputs and fully-automated production cycles. Consequently, production levels vary significantly depending on the type of company.

Compared to past years, intensive capital production techniques have been adopted in every subsector in order to cut costs and provide greater standards of product hygiene. An exception is cheese production, above all the controlled denomination of origin type, made prevalently by small and medium-sized enterprises.

The consumer trend towards a greater consumption of fresh products has stimulated the introduction of milk processing techniques able to increase the storage life of pasteurised milk up to 15 days (e.g. in France). Finally, developments in the production of fresh products have elevated the importance of the supply and transport stages within both production and distribution enterprises.

## INDUSTRY STRUCTURE

### Companies

The dairy industry comprises a group of multinational enterprises which exist alongside numerous small and medium-sized firms with regional marketing areas. The introduction of the milk quota system has brought about strong competition between milk processing companies in the raw material supply stage. This situation has triggered a process of mergers and take-overs which has strongly curtailed the number of enterprises in the subsector, to the detriment of the smaller firms that had not adopted a differentiation strategy aimed at achieving a position in a niche market or an alignment in terms of prices with the large groups.

From 1982 to 1991, the number of dairy enterprises dropped by about one-third, although there is a significant difference between the levels of fragmentation of the EU countries. The situation goes from that of Italy with, 2 400 enterprises having

a turnover of 12 billion ECU in 1992, to those of Germany (315 enterprises and overall turnover of around 15.6 billion ECU) and France (998 enterprises and 16 billion ECU). The Netherlands has 24 enterprises, the United Kingdom 670 and Spain has around 600.

In terms of employment in 1993, jobs in the industry were mainly concentrated in France, Germany, Italy and the United Kingdom. Besides the actual weight of the countries considered in terms of production in the sector, this situation stems from a bigger concentration in the countries of northern Europe of such products as powdered milk. In the livestock rearing subsector, the number of dairy cows fell between 1983-93 with more substantial variations in Belgium, The Netherlands, Italy and France.

In terms of processing, the biggest producers are Germany, France and the United Kingdom: the first two show extremely high production levels for all types of products in the subsector, while the third specialises in the production of fresh milk-based products and drinking milk. Of considerable importance is the production of condensed milk, full cream powdered milk, butter and cheese in The Netherlands, of drinking milk in Spain and of cheese in Italy.

However, very few enterprises present a market extension equal to that of the EU. Among the top ten European groups is a large majority of French and Dutch companies, confirming the predominance of France and the Netherlands in the sector, while German firms are absent, despite the fact that Germany is the biggest producer of milk in the EU. The first 10 European firms offer a range of different products and have a strong presence on the market in all the major segments (milk for human consumption, butter, cream, yoghurt and cheeses). The leading companies at the European level are:

- Yoghurt: Danone, Yoplait, Muller, Zott, Milram, Northern Food, Unigate, MD Food;
- Cheeses: Campina Melkunie, Kraft, Coberco, Friesland Frico Domo, Entremont, Besnier, MD Food; and
- Milk: Campina Melkunie, Dairy Crest, Unigate, Waterford, Parmalat, MD Food.

The individual subsectors show high concentration levels, except in the fresh milk market, where Dairy Crest has a 5.6 % share, Northern Food 4.2 % and Sodial 2.3 %. With regard to powdered milk, however, Nestlé, France Lait and HL Food have a 60-65 % share.

**Table 9: Dairy products

Source: Eurostat

Elsewhere, examples of concentration can easily be found. For example, Danone has a 35-40 % share of the yoghurt sector. And, Kraft (Philip Morris) has a 17 % share of the cheese market while Danone had an approximate 30 % share of the fresh cheese market in 1992.

### Strategies

Companies confirmed the trend through 1993 towards an increase in the combination of activities through takeovers and commercial and production alliances. This trend has slowed down compared to previous years due to the general recession, which kindled uncertainty in international investors.

In Europe, takeovers were generally concentrated within respective domestic markets in 1993. This pattern can be explained by a desire on the part of medium-sized firms to strengthen their positions in relation to large distribution networks. A case in point is Italy, where takeovers in 1993 were concentrated in the domestic market following the abolition of the so-called 'white areas' which led to the purchase of central dairies by large groups, thus consolidating and increasing their market share of fresh and UHT milk.

Another trend is the takeover of German companies or of firms with a consolidated share of the German market. Examples of such takeovers were those of Unicolait (30 % turnover on the German market) and Sudmilch by Campina Melkunie. The German market is of fundamental importance, not only because of its size, but also because of its potential as a launch pad for penetration into the East European markets.

The differentiation of products in the diverse subsectors has characterised the strategies of European dairy companies. In the milk subsector, one can see a greater distribution of flavoured milks, nutritionally enriched and either partially or fully skimmed. In terms of consumption, niche markets have been established for biological milk.

In the cheese subsector, companies have pursued a differentiation strategy based on the production of typical varieties, recalling aspects tied to tradition, and of green-mould low-calorie cheeses and dessert cheeses. Meanwhile, aspects of differentiation in the yoghurt subsector have involved packing (i.e. in terms of quantities offered), flavours, consistency, caloric and nutritional value and, finally, modes of consumption. Niches for biological products have been established as well in this subsector as well.

The attention given at various levels towards the production of quality foods has convinced many companies to certify

their production processes in accordance with the ISO 9000 standard. This trend chiefly has involved greater value-added production lines.

### Impact of the Single Market

The impact of the creation of the Single Market on the dairy products sector has been positive, increasing competition inside the market and favouring international trade. Harmonisation on labelling, product definition and product composition is, however, still not completed. Higher distribution costs have, however, resulted from the approval of the packaging regulations. Among the dairy subsectors, the cheeses are more penalised, since the cheeses market is very fragmented. In fact, the hygiene framework regulation affects the small and artisanal cheese producers.

### REGIONAL DISTRIBUTION

Within the Community it is possible to pinpoint areas where dairy production is the most concentrated. In particular, reference is made to Spain (Catalonia, Castille and Galicia); Italy (Lombardy, Veneto and Emilia Romagna), though there is a progressive tendency for activities to spread to the southern regions in that country; the United Kingdom (the West Country, Shropshire, Cheshire and Lancashire); France (lower Brittany, Normandy and the Loire Valley); and Germany (Bavaria and Württemberg). Belgium, The Netherlands and Luxembourg present a uniform distribution of activities throughout their territories, while Greece and Portugal show no particular concentrations.

### ENVIRONMENT

From an agricultural perspective, the main environmental problems affecting the dairy industry relate to the pollution of water beds by animal farming. As far as the processing industry is concerned, the biggest problems stem from the disposal of packing and recycling of used containers. In Germany, a country particularly attentive to environmental problems, milk is sold in recyclable polycarbonate bottles.

### REGULATIONS

The basic regulation concerning the designations of dairy products in the context of market organisation is Regulation 804/68. The market is regulated by fixing the indicative price of milk and the intervention price of butter, skimmed powdered milk

and certain types of cheese. Furthermore, the threshold prices of certain products are fixed each year, in order to guarantee that the prices of imported dairy products are placed at a level corresponding to the indicative price.

Aid measures are provided for public storage (butter and powdered milk) and for private storage (butter, prime-quality

skimmed powdered milk and some types of cheese), as well as to support the use of milk to feed animals, making casein from skimmed milk and fats from butter.

The main decisions involving the dairy industry taken as part of the CAP reform include:

- for the milk sector, the major changes already introduced into the CMO with Regulations 3950/92 and 536/93 have been confirmed; and the extension of the quota system is provided for up to the year 2000, with a reduction of global guaranteed quantities equal to 1 % in both 1993/94 and 1994/95;
- a 5 % reduction of the intervention price of butter split over the years 1993/94 and 1994/95; and
- the abolition (effective 1 April 1993) of the co-responsibility levy, a payment previously made by producers and used to fund promotional activities, market development and the development of new products.

With regard to hygiene and quality standards, enterprises in the sector are affected by the development of procedures for the control of critical stages of all processes, from production to distribution, provided for by horizontal regulations, Directive 93/43.

The milk sector has been affected further by a vertical Directive concerning hygiene and quality standards, Directive 92/46, with an implementation date of 1 January 1994. This Directive lays down the health rules for the production and distribution of raw-milk, heat-treated milk and milk-based products (some temporary exceptions are contained in Directive 92/47). Also, through Regulation 323/93, some Member States have been exempted from the minimum fat content in drinking milk.

Finally, a proposal has been presented to amend Directive 92/46 as regards the following aspects:

- temperatures for raw milk, according to the species of animal concerned;
- rules on equipment in treatment and processing establishments; and
- hygiene and standardisation requirements for the production of heat-treated drinking milk and milk-based products.

## OUTLOOK

The process of concentration in the sector will continue and competition will sharpen within the EU, caused by a drop in production and consumption coupled with the concentration in the distribution sector, which will provoke the adoption of more sophisticated differentiation strategies. The number of acquisitions and mergers will also rise, aimed at the consolidation of domestic market shares and expansion into new high-potential areas.

Furthermore, the coming into effect of regulations directed towards the harmonisation of norms relating to the processing and marketing stages of production will help to change the structure of the sector within the Community, penalising those operators who are not prepared to improve.

The industry is represented at the EU level by: European Dairy Association (EDA). Address: Rue des Deux Eglises 7, B-1040 Brussels; tel: (32 2) 230 1010; fax: (32 2) 230 2440.

# Fruit and vegetable processing and preserving

## NACE 414

The fruit and vegetable processing and preserving sector showed a positive trend throughout the 1984-93 ten-year period, with demand boosted by health trends and strongly tied to consumption patterns. Most jellies, jams and marmalades are manufactured in the countries of northern Europe, with Germany in the lead, while canned fruits are more important in the Mediterranean countries and canned vegetables in France, Spain, Belgium, Netherlands and Italy. The trade balance remained in the red for the entire decade, with a slight improvement in 1991. The major importers into the EU are the less-developed countries (Brazil, Turkey, Israel), and the USA.

From a structural viewpoint, the sector is characterised by a high fragmentation and most firms are of small size. Labour is still a fundamental factor for vegetable processing, if nothing else because few innovations have been introduced into the subsector. The average firms size doesn't allow the exploitation of scale economies. The degree of competition is very high inside the market especially within small and medium enterprises, because of extra EU imports which are characterised by lower labour costs. Import production quality is quite often low even if they are more competitive in terms of price.

### INDUSTRY PROFILE

#### Description of the sector

This sector includes all activities related to the processing of fruit and vegetables and their preservation. The main product categories are tomato, peach, pears and fruit salads, jams and marmalades, pickled vegetables and in oil, fruit juices and nectars. Frozen vegetables and fruits are dealt with in the chapter on deep-frozen foods.

#### Recent trends

The processed and preserved fruit and vegetable sector is one of the food sectors to have followed a positive trend over the 1984-93 decade. The situation of production at current prices, despite fluctuations over the last three years, appears closely related to consumption patterns which, given the big swing towards health diets and vegetarian foods, have seen an increase in demand both within and outside the EU. Employment figures failed to follow a similar pattern and, despite alternate phases, these fell by 7.2 % between 1983 and 1994.

In 1993, Germany accounted for 22 % of all fruit and vegetable processing and preserving within the EU, with a workforce of 21 200; France and Italy followed with a 20 % share and a workforce of 17 000 and 20 000 respectively. Spain is the country with the highest number of workers in the sector (25 580), while its production share is equal to 8 % of the EU total.

The value added produced by the fruit and vegetable processing and preserving sector in 1993 was slightly less than that recorded in the soft drinks sector and roughly half that generated by the bread and dairy products sectors.

Despite the fact that fruit and vegetables are traditional products of southern Europe, their processing involves, in a significantly differentiated manner, all the countries of the EU. The number one producer of fruit preserves is Spain which has a share equal to around 22 % of total EU production;

Figure 1: Fruit and vegetable processing and preserving Value added in comparison with related industries, 1993

Source: DEBA

France, Greece and Italy follow with shares between 17 % and 20 %. France, with a share of about 48 %, is the number one producer of vegetable preserves (excluding baked beans) followed by the Netherlands and Belgium, which has a share of around 17 %. In the jam, jelly, marmalade and maroon pure sector, Germany leads the way with approx. 31 %, followed by France with 25 %. Greece, despite a drop in quantities produced in 1993, remains European leader with regard to the production of canned fruits, in particular peaches. Italy leads the way in tomato processing within the EU and is the second in the world after the USA. In 1993, Italy processed 56 % of the tomatoes utilised by EU industry.

Dividing the sector up into main production segments, we can observe, for instance, how marmalades, jellies, etc., are almost exclusively restricted to Northern Europe, especially Germany, while with regard to canned fruits and vegetables, the Mediterranean countries play important role. In both segments, France is among the leaders, and geographically speaking too, this country occupies a central position. Thanks to the greater earning power of the more elaborate products such

**Figure 3: Fruit and vegetable processing and preserving  
Production and employment compared to EU total manufacturing industry**

1994 are Eurostat estimates.  
Source: DEBA

as marmalades, Germany tops the value added gradings for EU countries, followed by France, while Italy and the United Kingdom are on the same level.

While all indicators, measured in real terms, show a positive growth rate between 1984 and 1993, there has been a recent tendency for internal and external Community demand (imports), and production to drop. At the same time, there has been a significant rise in exports.

Production in the sector rose until 1991, following substantially the general trend for the manufacturing sector as a whole. After 1991, there was a downswing, though the processed and preserved fruit and vegetable sector was affected later than others and less seriously than the manufacturing sector as a whole.

A comparison of employment figures between the two sectors shows how the annual drop in the number of workers in the fruit and vegetable processing and preserving sector was, between 1984-89, higher than that recorded for the manufacturing

industry as a whole, while, in the period 1989-93, the number of workers who left the manufacturing industry as a whole was greater than that of the fruit and vegetable processing and preserving industry.

In 1993, in the tomato segment, there was a general increase in quantities produced inside the EU, except for France (-4.5 %). In Spain production went up 22 %, in Greece 13 % and in Portugal 12 %. Within the EU, the production of raw materials used for making tomato purée went up by 7 %, while that for peeled tomatoes rose by 23 % and that for other processings by 4.5 %.

**International comparison**

The production pattern of the sector being examined becomes more interesting when compared with that of the major production countries, in competition on world markets. While in 1984, US production, in terms of value, was over double that of Europe, and over three times that of Japan, in 1994,

**Figure 4: Fruit and vegetable processing and preserving  
International comparison of production in current prices**

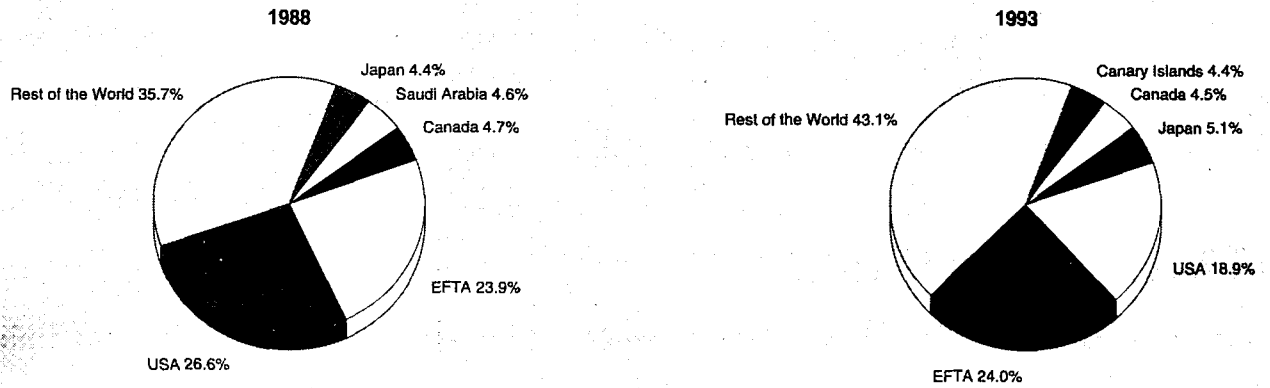

Source: DEBA

**Figure 5: Fruit and vegetable processing and preserving  
International comparison of production in constant prices**

Source: DEBA

**Figure 6: Fruit and vegetable processing and preserving  
Destination of EU exports**

Source: Eurostat

this situation changed, with a slight drop in production value for the USA compared to a 50 % growth in the EU and a 100 % growth in Japan.

The turnover indexes at constant prices reveal that the situation described above was realised through an increase in production which, in Europe, was concentrated between 1986 and 1987 and between 1989 and 1991, and in Japan between 1990 and 1992. It should be furthermore stressed that the loss of ground on the part of the USA compared to Japan and Europe centred more on the value of production than on the quantity produced, as is shown by the production indexes at constant prices.

It must be added as well, that in the canned-fruit segment, there was a considerable fall, in 1993, in the world production of canned fruit (peaches, pears and fruit salad), which went from 1 230 000 tonnes to 1 030 000 tonnes, with a drop of 16.3 % compared to 1992. This drop was caused mainly by a fall in production within the Community area (-23 %), which represents 65 % of world production, and was different for pears (-20 %), peaches (-16 %) and fruit salad (-9 %). In the countries outside the EU, production of canned fruits remained stable.

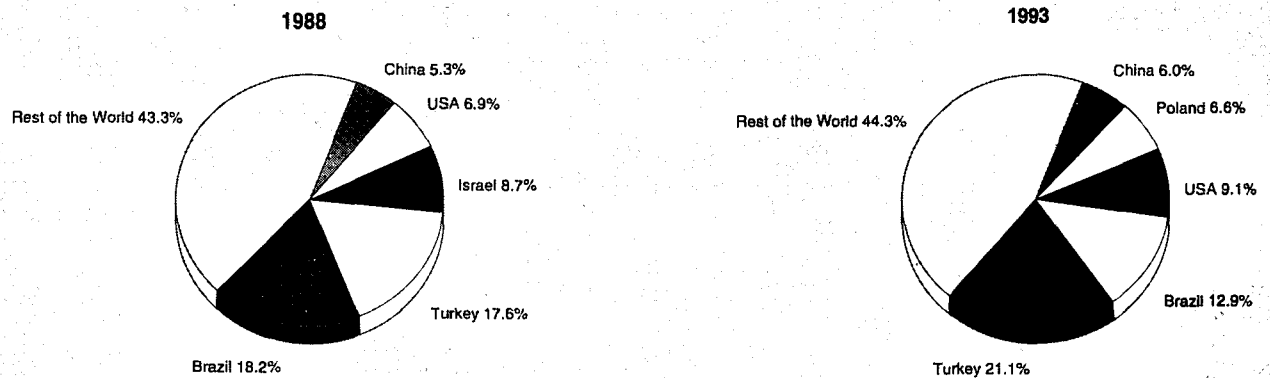

### Foreign trade

The trade balance of the Community remains in the red as regards trade of processed and preserved fruit and vegetables by about 8 % approx. of its own needs. During the course of the decade in fact, this adverse trade balance has steadily worsened due, above all, to a bigger growth of imports over exports outside the EU. Since 1991, the growth in exports, the reduction in imports and the improvement in the terms of trade have helped to reduce the trade deficit.

A closer look at the European exports by individual country and/or area of destination in value shows, after 1988, significant changes. The USA, in 1988 the main country of destination of European processed and preserved fruit and vegetable exports has reduced its share by 10 %. The leading export destination is currently the EFTA countries which, in fact, have merely maintained their 1988 share. Exports to Canada and other countries of the world have increased, while Saudi Arabia's share is no longer significant.

A similar comparison involving European imports shows the number one fruit and vegetable supplier to the EU to be Turkey which has ousted Brazil. This latter country's share dropped

by 5.9 %. US exports have also undergone consistent growth while Israel's have lost ground.

A structural analysis of trade outside the EU can be completed by considering the fact that Community exports have dropped, in value, in relation to production, and the same goes for imports in relation to consumption.

## MARKET FORCES

### Demand

The fruit and vegetable preserves sector includes tomato based products, vegetable preserves and canned vegetables. The consumption market of these products has reached maturity. Canned vegetables, and above all preserved fruits are permanently affected by the high consumption levels of fresh products and, in the first case, by the expansion of frozen products. With regard to tomato-based products, over the last decade, traditional products (peeled tomatoes and tomato concentrate) are in competition with more innovative products (pulp and purée). In the jam and marmalade sector, consumption is tied to breakfast and between-meal snacks, and the biggest growth rates have affected products with a strong 'natural' image.

Germany, with 50 litres per head is the biggest consumer of fruit juices, followed by the Netherlands (22 litres) and the United Kingdom (19 litres). France is the EU country with

the strongest growth rate. The reason for this is to be found in the aggressive marketing strategies employed over recent years, despite the fact that there has been no product innovation. The EU's favourite flavour is orange. Despite the differences between the various countries in terms of consumption occasions, the demand for juices is rising. This is particularly true with regard to 100 % products made from squeezed fruits rich in liquids and which are often also used to make long drinks and cocktails. The most important points so far as strengthening demand is concerned are purity and the health aspect. In the case of all juices, nutritional value is very important too, and consequently the possibility of these products having a real food function for the consumer. Generally speaking, there has been a strong demand in the baby foods sector. Nectars are produced essentially in Italy.

The overall demand for products in oil and pickled products, as well as other specialities, tends towards traditional products and, to a great extent, depends on the request for hors d'oeuvres and occasional between-meal snacks. Opportunities for the expansion of demand, which in many EU countries has reached a mature stage, are also tied to the increase in the number of occasions for eating these products and to de-seasonalisation. This is the road being followed by side dishes (vegetables) and pasta sauces.

### Supply and competition

In terms of production costs, the processing of fruit and vegetable products is achieved more economically in developing countries or in countries like those of North Africa and Turkey, etc., because of lower costs associated to labour factor, and often, in the case of many products, the production of little differentiated producer goods tends to concentrate in these countries. The pressure imposed by fresh or processed vegetables from third countries (Eastern Europe, China, South America; chiefly countries with weak currencies) is expected to increase. The observance of new Community regulations concerning packaging will oblige companies to review marketing and distribution strategies and, unless they comply with such regulations, these companies will be considerably penalised, above all in trade between countries of the EU.

Generally speaking, the contractual position of farmers/growers serving the processing industry looks weak within the EU, even in the few areas where these are organised into groups; this is due in part to the strong pressure on prices from third country imports, but also to future surpluses in the supply of vegetables grown for the fresh-produce market. In the fruit preserve market, the amount of fruit imported from Eastern Europe is rising, to the detriment of EU products.

### Production process

Levels of technology affecting production processes within the sector are rising. In particular, the optimisation of processing cycles aims to keep down production costs, while proc-

(1) Estimates.  
Source: DEBA

ess innovation aims to improve product quality standards, a critical success factor in all segments. In the field of tomato-based products, an important innovation was the introduction of mechanical harvesting, while other important future developments will involve research and selection of tomato varieties more suitable for the industry, in particular in relation to new derived products.

In the whole of the vegetable preserve sector, manual produce sorting operations are slow and highly labour intensive. Over recent years, innovative systems based on automatic high speed sorters or on optical sorting systems have become popular, drastically reducing the need for manual labour. The industrial processing of tomatoes can rely on consolidated technologies which have developed and improved over the years thanks to a number of factors like product innovation, aimed at offering final consumers better quality products and a higher service content and companies greater value added, and process innovation, aimed at reducing costs and energy consumption and perfecting the various treatments, especially heat treatment.

For both vegetable preserves and fruit preserves, the opportunities for product innovation are more restricted compared to those for tomato-based products and are mainly based on an expansion of product range. There has been little or no process innovation and this has been limited principally to management of production lines. The incidence of manual operations remains high, especially so far as medium-small enterprises are concerned, and with particular regard to sorting and cleaning. Work phases differ according to the product involved, though they all have a common basic structure. Particularly interesting product innovation has affected the processing cycle of dry legumes, with the introduction of a rapid legume rehydration process. Due to the high investment costs involved, still in the study stage is the adoption of a process for stabilising food products through the use of high pressures to eliminate the degradation resulting from heat treatment.

From a technological viewpoint, the production process for the preparation of jams and marmalades is fairly simple and does not permit obtaining significant production scale economies nor does it generate technological barriers at entry. The innovations introduced into the sector principally concern the adoption of control systems which increase the reliability and the reproduction capacity of those parameters which have a greater effect on product quality.

An innovation in the enzymatic inactivation of vegetables and fruit from which are obtained concentrated juices and purées is the use of hard vacuum which better protects the thermolabile compounds and colour, and offers advantages both in terms of the organoleptic characteristics of products and the reduction of broken grains, at equal drained weight.

In the field of the production of fruit in syrup or water, technological innovations have swung towards shorter production times, as well as better management of factories. Sorting and weighing are becoming particularly important factors in this field too. Depending on the type of fruit being treated, filling can be done manually and in an orderly manner (in the case of glass jars and for more prestigious product lines) or in a disorderly manner with the aid of high-speed machinery.

The fruit juice production process adopts different technologies for pulpy nectars and for 100 % juices. The former are produced starting with non-concentrated fruit cremogenates stored in large sterile tanks and, during production, are mixed with water and sugar to obtain fruit nectars. Like fruit juices, fruit nectars are made using two technologies and two different packagings: hot filling in bottles and cold filling in cartons. Cold filling gives better results compared to hot filling, but storing of products for medium-long periods is better in bottles than in cartons.

The production process of products in oil and pickled products starts with fresh products or pickled semi-worked products. There is a substantial reliance on foreign products especially when the quality/price ratio is good, as in the case of mushrooms and olives. Unlike other subsectors of the preserved product sector, e.g., canned vegetables, this subsector has undergone considerable innovation over recent years as is shown by the introduction of modified-atmosphere preservation which, together with improved product quality, represents a major success factor.

## INDUSTRY STRUCTURE

### Companies

The fruit and vegetable processing and preserving subsector is a very fragmented market, being characterised, on the average, by small and only few medium firms. Most of the small ones operate at a regional level as sub-producers for bigger companies. Only some of them and of medium sized firms occupy highly-specialised market niches. The very diversified multinational companies, operating on international markets are a minority. The main European enterprises in the fruit juice subsector are Stule (D), Dittmeyer (D), Wesergold/Riha (D), Hero (CH). In the vegetable preserves subsector Granini (D), Gerber Foods (UK), Conservé Italia (I), Bonduelle (F), Cecab d'Aucy (F), Heinz (USA) and Grand Metropolitan (UK) play a leading role. In the jam and marmalade subsector the major firms are: Hero (CH), Danone (F), Franz Zentis (D), May Holding (D), Chivers Brothers (UK).

### Strategies

In all the sub-sectors firms strategies are aimed at the reduction of production costs which broadly differ within EU countries (ex within Greece and Germany) and are higher in Europe than in extra EU competitors partly because of lower costs associated to labour. That is the main strategy pursued especially by small firms which cannot exploit scales or scope economies. Many of them produce for bigger companies or for big distribution chains. Some of them, as far as it concerns tomatoes and fruit, usually import concentrated juices from extra EU countries. Only few firms in fruit and vegetable processing and preserving subsector has adopted product diversification policies and, at the same time, has introduced new products, for example ready-to-use sauces, in line with the recent trends expressed by the market. Rare are the firms

interested in ISO 9000 standards certification. Packaging too is playing an increasingly important role in product marketing.

The subsector of products in oil and pickled products allows major diversification policies ever for small sized firms, granting higher profit margins. Diversification was attained with the introduction for instance of sauces for pasta and rice, and vegetables. In 1993, within the fruit and vegetable processing and preserving sector, there were eleven acquisitions. Of these, four were carried out by French companies and six by UK companies. Of the six acquisitions carried out by UK companies, four involved companies outside the EU (USA, Hungary and Brazil). In 1994, the number of acquisitions by EU companies amounted to seven, of which four were carried out by UK companies. The concentration of the distribution system has represented and continues to represent in all countries one of the major problems for food companies and, in fact, much of the movement in the industrial set-up is caused by movements in the distribution system.

### Impact of the Single Market

The impact of the creation of the Single Market on the fruit and vegetable processing and preserving sector has been positive overall. It favoured international trade and competition inside the EU market increased.

Higher distribution costs were, however, generated by the approval of the packaging regulation. The reduction of barriers to imports from third countries with lower social costs are considered a priority for the industry.

### ENVIRONMENT

The industries in the sector require large quantities of water during the production process; most of this is used during the washing and swilling stages. Packaging ecology will represent a major topic in the future and enterprises will soon have to comply with recent regulations on recycling and re-utilisation of food containers.

### REGULATIONS

The common organisation of markets in the processed fruit (and legumes) sector is regulated by Reg. 426/86, ultimately amended by Reg. no. 1569/92. The production of processed citrus fruits and bananas on the other hand is covered by the fresh fruit CMO. The current system is based on the granting of aid with the aim of ensuring an adequate income to growers of fresh produce. This aid is granted on condition that the agreements between producers and processors are concluded before the growing season and that the processors pay the minimum prices fixed by the Commission. The products forming part of this system are processed tomatoes, pears and peaches in syrup and/or juice, prunes, dried figs and currants. Support measures also exist for the processing of pineapples and raspberries. The stabilisation mechanism involves cuts in aid to production whenever guarantee thresholds are crossed.

In the case of processed tomatoes, a quota system applies: Reg. no. 668/93 establishes maximum quantities for the Community of twelve in 6 596 787 tonnes.

For other canned vegetables or packed in glass jars, neither premiums nor quotas exist; only for canned mushrooms, including those temporarily preserved, do favourable import regulations exist, while for other products, there are no restrictions on imports. The fruit juice and nectar and vegetable sector is regulated by Dir. no. 75/726, relating to the harmonisation of the laws of member states, which has been periodically updated (Dir. no. 79/168; Dir. no. 81/487; Dir. no. 89/394; Dir. 93/77). The International Fruit Juice Association - AIJN - furthermore drew up in 1990 a "Code of Use" fixing physical, chemical and microbiological standards for orange juice, grapefruit juice, apple juice and grape juice. Special measures to foster the processing of certain citrus fruits are contained in Reg. 3119/93 while measures for promoting the marketing of lemon-based processed products are contained in Reg. 3338/93.

Up until now, the fruit and vegetable sector has not been affected by the CAP reform. However, following the GATT agreements, the Commission must reform regulations so these comply with the new clauses covering international trade. The Commission intends to take advantage of this forced clean-up to improve the overall operations of the CMO. On July 27 1994, the Commission approved the wording in the communication to the European Council and Parliament concerning "The Evolution and Future of EU Policy in the Fruit and Vegetable Sector". This official document will serve as the basis for discussions concerning the new common organisation. Despite some undeniable structural imbalances, the present market organisation provides an operational framework which answers the requirements and has proved its worth. All the positive features, market orientation, decentralisation of management and grouping of supply, as well as the central role played by producers' organisations should be reinforced. Therefore the Commission is in favour of reform proposals which would consolidate the positive features of the present CMO, while simplifying it and remedying any drift or weakness observed.

### Fresh produce

Intervention prices represent one of the main Community instruments able to affect the market. About 70 % of fruit production is subject to the intervention price mechanism. The varieties where intervention involves large quantities are peaches, nectarines, apples and oranges. In the 1988/93 season, almost 90 % of fruit and vegetable withdrawals was made up of fruit.

As far as import protection is concerned, the measure with the biggest impact is that of reference prices, which however only covers 20 % of fresh vegetables and main varieties of cultivated fruits.

Export refunds are only important for tomatoes, oranges, apples and some varieties of nuts. These are useful for counterbalancing part of the negative impact of currency devaluation in numerous third countries. In the banana sector, the common organisation of the market has been recently established, through Reg. no. 404/93

## OUTLOOK

Many factors bear favourably on the demand for products in the sector, and consequently the trends under way will continue: the health trends, the practicality of preserved fruit and vegetable-based products, the importance of large distribution networks. Import penetration is going to increase at least in volume, because of the higher competitiveness of third countries productions characterised by weak currencies and lower labour costs.

Furthermore, compliance with recent Community regulations on packaging will call for the reviewing of marketing and distribution strategies, keyed to a greater degree of recycling and the modification of currently used materials. The reform of Common Market Organisation will be the most important issue affecting next years' market structure.

# Processing of fishery products

NACE 415

Seafood consumption in the EU has shown a dramatic expansion over the last ten years. However, this expansion slowed down over the last two years due to the adverse economic conditions which affected the Union. The EU industry developed under the influence of large powerful agro-food companies. Since the supply of raw material of certain popular species by the EU fishing fleet does not satisfactorily meet industry requirements, large amounts of processed seafood are purchased in third countries, widening the negative balance of international trade. The market segment which shows the fastest growth is that of fish-based prepared dishes, matching the changing social habits of EU consumers.

## INDUSTRY PROFILE

### Description of the sector

Output of the fish and seafood processing industry can be divided into five major categories:

- frozen fish products (excluding whole fish), e.g. frozen fish fillets, which are partly processed items using basic raw seafood material, which can be either further processed into prepared dishes or consumed in that form (about 83 % of frozen fish fillets is imported from outside the EU);
- dried, salted and smoked fish, e.g. smoked salmon, salted cod, consumed without any further industrial processing;
- prepared or preserved fish, e.g. tuna cans, prepared dishes, surimi, which are basically value-added ready-to-eat items;
- aquatic invertebrates, frozen, dried or salted, e.g. cuttlefish fillets, frozen mussels, which can be either further processed into prepared dishes or sold to consumers in that form; and
- crustaceans, molluscs and other aquatic invertebrates, prepared or preserved, e.g. crab cans, shellfish salads, which are ready-to-eat items.

The fish processing sector is a rather concentrated industry with 75 % of the products being manufactured in five Member States: Germany, the UK, Spain, France and Denmark. This group accounts for 80 % of total EU value added, with the German fish processing industry showing the highest value added in 1993 with 23 %. The production of prepared or preserved fish dominates in most EU countries with the exception of Greece where smoked or salted seafood products (e.g. salted anchovies) are the main manufactured items, and Ireland and the Netherlands which both produce mainly frozen fish fillets.

### Recent trends

Apparent consumption of processed fishery products has shown a dramatic increase over the past ten years reaching 11.2 million ECU in 1993 compared to 6.4 million ECU in 1984. EU production has also experienced a significant increase of 59 %, although it has not kept pace with consumption. Thus, market operators have had to seek supply in extra-EU countries to meet expanding consumer demand as the 1984-93 average annual growth rate (8.5 %) of extra-EU imports demonstrates. Meanwhile, extra-EU exports have remained fairly stable averaging 2.1 % per year. Most end-products manufactured by the industry are sold on the EU market. Consequently, the trade balance deteriorated sharply over the 1984-93 period reaching a deficit of over 2.2 billion

Figure 1: Processing of fishery products  
Value added in comparison with related industries, 1993

Source: DEBA

ECU with an export/import ratio of 26 %. In terms of employment, the fish processing sector shows primarily a decreasing trend over the past ten years, except for an upswing in 1988 and 1989.

Since 1991, most EU Member States have experienced adverse economic conditions and the development of the fish processing industry has been hampered by the drop in consumer demand. The ascending trend observed in apparent consumption since 1984 has levelled off since 1991 (the 1991-92 percentage change posted a negative figure while previous annual growth rates were over 6 %). This decreasing trend was confirmed over 1992 and 1993. In terms of external trade, the industry recovered during 1993 with extra-EU exports reaching an all time high after a marked depression in 1992. Concurrently, extra-EU imports confirmed the decreasing trend initiated in 1992.

Employment figures in 1993 indicate that the number of employees in the industry has decreased (11 600 jobs lost since 1989) as a consequence of the difficulties of smaller firms

Source: DEBA

having to compete on this rapidly evolving market, and of the industry strategy to realise economies of scale through mergers and take-overs.

**International comparison**

Figure 4 indicates that whilst the EU is doing better than the USA in terms of production of processed fishery products, it still lags far behind Japan. Japan, populated by the equivalent of one-third of the total EU population, is the world's biggest seafood market. Domestic demand for fishery products in Japan has expanded dramatically over the last few years, with consumption currently reaching more than 65 kg per capita per year, whilst EU consumption stands at 15 kg per capita. Changing social habits have boosted the emergence of prepared/ready-to-cook fish products, which now supplement, to a certain extent, traditional dishes based on whole fresh fish products.

The countries of the ASEAN, led mostly by Thailand and the Philippines, emerge now amongst the top world producers

of processed fishery products. These countries take advantage of modern processing units manned by inexpensive manpower to manufacture high quality products at low prices on the world market.

**Foreign trade**

The ratio of exports/imports (26 % in 1993) shows that the EU is a net importer of processed fishery products. Few of the EU fishery landings are used by the fish processing industry because they are too costly, mostly directed towards the fresh market, and do not meet the industry needs of constant sources of calibrated supply of raw material throughout the year. In 1993 the two major imported items, in tonnes, were aquatic invertebrates, frozen, dried or salted (40 % of total extra-EU imports) and prepared or preserved fish (35 %) which are both lacking in the EU landings and more expensive when available than similar products purchased from third countries. These products are basically semi-processed items used by manufacturers as supply to the industry which further proc-

**Figure 4: Processing of fishery products

Destination of EU exports**

Source: Eurostat

esses them into value-added items. Extra-EU exports are dominated by prepared and preserved fish (59 % of total extra-EU exports) and by semi-processed materials imported from third countries and re-exported after repackaging under a European brand.

The negative external trade balance is therefore structural and the situation is not expected to improve in the future. The EU fishery sector suffers from severe resource depletion and more non-EU countries are able to supply processed seafood products at EU quality standards and at attractive prices. An analysis of the sector shows that the trade balance improved slightly in 1993, but this was mostly due to a decrease in EU domestic consumption of fishery products. Consumer preferences have shifted towards cheaper meat products like poultry, for example.

The main suppliers of processed fishery products are Iceland and Norway (21.7 % of EU imports in 1993) which supply mostly frozen fillets of white fish (mainly cod, haddock, and saithe) and salted or smoked fish (smoked salmon from Norway). They are followed by Thailand (8.0 %), USA (5.7 %) and Morocco (5.0 %) for which the seafood canning industry is healthy and expanding, and countries like Argentina and other Asian countries which offer large quantities of processed

fish and shellfish (mostly cultured shrimps). The share of the other large seafood market (Japan) remains low in the EU supply (1.0 % in 1992).

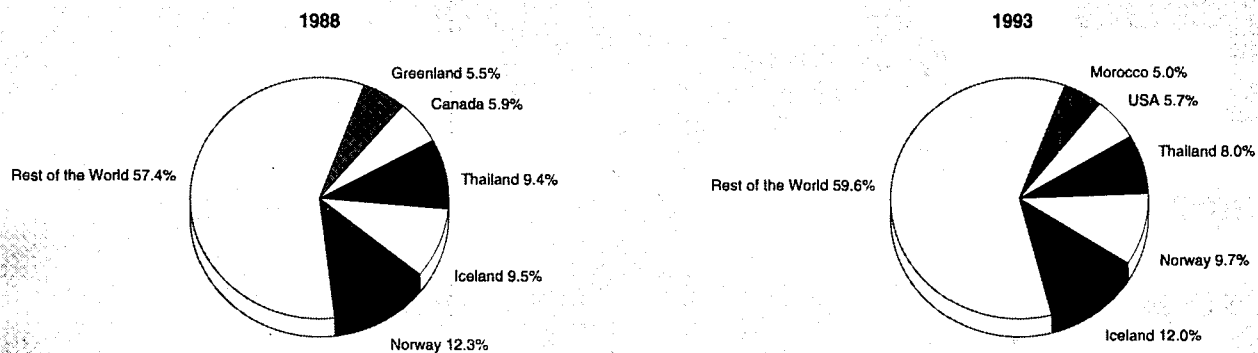

Individual EU Member States export their production of processed fishery products primarily to other EU countries. The main extra-EU clients are the EFTA countries (27.3 % of EU exports in 1993) which purchase ready-to-eat dishes and canned fish. The shares for the USA and Japan as destinations of EU exports (8.5 % and 9.5 %, respectively in 1993) are higher than their shares of EU imports.

## MARKET FORCES

### Demand

Demand for fishery products has grown dramatically over the past ten years due to a growing public awareness of the importance of fish as part of a healthy diet. In addition, the emergence of processed seafood has provided an alternative to the consumption of fresh fish, traditionally viewed in Northern Europe as a smelly product that is bothersome to prepare. This, combined with other factors relating to changing social patterns, has boosted the consumption of processed items, which rose from an average of 6.7 kg/head in 1983 to 9.8

kg/head in 1991 in the EU (65 % of the average consumption of fishery products). However, the economic crisis which affected EU Member States over the last two years slackened this ascending trend, but an increase in consumption is anticipated to resume when the economy recovers.

The market for fish-based ready-to-eat meals is the most rapidly growing market in the EU, with the exception of Greece and Portugal where the purchasing power of customers is low. Reasons for this expanding market include: changing social factors, such as the growing number of working women, greater leisure time, more fragmented mealtimes within households, and the growing number of households with one or few members. The need for simple and ready-to-cook meals has consequently increased. The catering sector is also increasingly adding prepared or semi-prepared ready meals to their menus to meet client tastes and allow for savings in time, manpower and investment in kitchen equipment. Some giant agro-food firms such as Unilever (UK/NL) and Nestlé (CH) dominate this market segment and use their advertising power to attract more consumers.

The consumption of canned fish is on an increasing trend throughout the EU thanks to the marketing efforts of the leading firms which have adopted product differentiation policies through high quality standards and the introduction onto the markets of new forms of products such as tuna-based salads and elaborated mackerel-based preparations.

Lastly, the EU market for surimi seems to offer good prospects. It was estimated at 34 000 tonnes in 1990 and is expected to grow to 50 000 tonnes in 1994. France and Spain clearly appear as the leading markets in Europe for these products. Other major markets include the UK and Italy. The German market for this product is small as there is no traditional consumption of crustaceans in this country.

### Supply and competition

International competition in the EU processed seafood market is very tough. More developing countries are now capable of supplying quality products at low prices, dragging the EU industry into a restructuring phase. Since the EU industry cannot compete in terms of labour and other running costs, a great amount of research has been conducted to release alternative products of high quality standards, meeting EU customer requirements.

The EU industry has had to restructure through mergers and take-overs in order to allow for economies of scale and vertical and horizontal integration. As a result, whilst the EU industry was characterised by a large number of independent small-scale units in 1984, the processing industry now includes an increasing number of large agro-food firms or financial holdings with large financial resources. This policy has produced positive results on labour productivity of the sector.

Two of the most significant competitive variables for the processing industry are raw material availability and cost. Over the last three years, the average price of cod and haddock, which are widely used in the preparation of fish-based ready meals, rose by as much as 40 % due to a shortage in production (e.g. average price of imported cod rose from 1.06 ECU/kg in 1989 to 1.50 ECU/kg in 1992). This forced the industry to look for cheaper alternative species. As a result, only the most powerful firms with the financial and technical strength to test and promote new products (for instance based on Alaskan pollack or New Zealand hoki) were able to remain competitive in this market segment.

To secure sources of supply, the leading EU processing companies have increasingly set up joint-ventures in third countries, where resources are presumed abundant. This is, in particular, the case for Groupe Adrien (F) and Pescanova S.A. (E) in South America and Africa, and Pêche et Froid (F) and Compagnie Saupiquet (F) in West Africa and the Indian Ocean. Concurrently, the Community has signed 28 fishing agreements, principally with Scandinavian, North and South American, African and Baltic countries, enabling EU-registered vessels to operate outside Community waters.

In conjunction with the increase of the price of raw materials, the major producing firms have had to tighten their profit margins to remain competitive. Consequently, the 1992-93 period has witnessed a marked decrease of gross operating rates within the industry.

### Production process

Production processes of fishery products are now characterised by a certain degree of automation. Although research still focuses on the definition of new processing machines to save manpower, a great amount of work is being devoted to extending the shelf-life and quality of the end-products.

The Individual Quick Freezing (IQF) process is now an established preservation technique which allows the processor to supply the customer with frozen seafood in small, ready-to-cook quantities instead of solid blocks which had to be cut or thawed prior to packaging or use. The benefits of IQF have led many companies to invest in this process, despite the high initial costs and the need for skilled staff. Another broad principle to extend shelf-life, by up to three weeks without freezing, is to apply temperature treatment after packing the raw material. This is done by using both vacuum packs and microwave pasteurisation. This technique is more economical as it entails energy savings with shorter time required for temperature treatment. Many processing plants throughout the EU are already using this means of conservation. Products preserved in this way are also much more convenient for consumers to microwave than frozen meals.

Intense product development has been taking place in the packaging industry. Notably, plastics have been developed with special properties such as thermal resistance, reducing the use of traditional aluminium containers.

### INDUSTRY STRUCTURE

#### Companies

A study carried out by the DGXIV of the EU Commission indicated that there were about 2 300 companies active in the fish processing sector in 1991. More than 55 % of them are concentrated in Italy, France, and Spain where the number of small-scale units remains high. Another 29 % of EU processing companies are located in the United Kingdom, Denmark and Germany. The number of employees in the processing of fishery products industry decreased by 8 % during the 1984-88 period, increased by 9.8 % between 1988 and 1989 and has steadily decreased since reaching 80 300 in 1993. Although no precise figures are available on the size of the firms, the survey of the European Commission indicated that the average number of employees per firm decreased from 50 in 1983 to 38 in 1991.

### Strategies

Motivated by the dramatic expansion of the EU market for processed seafood products, the two multinationals Nestlé and Unilever have performed mergers and take-overs to gather in their groups the most efficient fish processing enterprises. These two groups have, however, two different strategies: Unilever heavily invests in its subsidiaries, mostly located in the United Kingdom and Germany without conducting take-overs, while Nestlé performs buyouts of competitive enterprises dominating some promising market segments, especially in France. Besides these two leading agro-food groups, some holdings like United Biscuits (UK), Hillsdown Holdings (UK), Albert Fisher (UK), RT Holding Artlal (B), and IFM-Bongrain (F) have invested in the fish processing sector through take-overs of existing companies.

In 1992-93, these major agro-food groups slowed down their expansion strategies though. The new strategy has been to keep the subsidiaries in a healthy economic condition rather than to further increase the size of the groups. As a consequence, internal restructuring has led to shut downs or sale of non-profitable units, and suppression of jobs.

### Impact of the Single Market

The processing of fishery products' sector includes a wide range of products, so the impact of the creation of the Single Market differs across sub-sectors. In global terms, the effects of the Single Market were positive for consumer protection, thanks to the implementation of more severe hygiene measures and higher trade intensity. Another effect has been increased competition, even if the free movement of goods has created unfavourable circumstances for small and medium sized enterprises. Other problems are linked to the lack of harmonisation in the implementation of adopted legislation and to differences in customers' tastes.

The next priorities for the industry are the low sanitary inspection of the shellfishery products from third countries, especially from the Far East, and the agreement between the EU and Morocco in the sardines sector.

### ENVIRONMENT

Fishing has an undeniable impact on the environment. The most obvious illustration may be a decline in the actual level of fish stocks. Knowledge of changes in fishery stocks is the best gauge of the state of the marine population. Research into the impact of fishing on food chains is still at an early stage. But, increased efforts are being made not only to understand how and to what extent these human activities disturb the balance in the marine environment, but also to design and encourage the adoption of more selective fishing techniques.

The continued expansion of intensive aquaculture projects has also had an impact on the environment. The concentration of fish in a limited space and their intensive feeding can lead to substantial discharges into the surrounding waters. Even the escape of farmed fish, perhaps not indigenous to the area, can drastically upset the local ecological balance.

One of the main environmental issues related to the fish processing industry is connected with the occasional death of dolphins caught in tuna fishing operations. In 1990, the USA declared an embargo on raw tuna suspected to have been fished in association with dolphins. This embargo concerned primarily South American countries (particularly Mexico, Venezuela) whose vessels fish tuna swimming in association with dolphins in the Eastern Pacific. This led to a boycott of tuna cans manufactured in France, Italy and Spain, as these countries were buying raw material from South America. The embargo was lifted in 1992 for France when the French canning industry undertook to buy dolphin-safe tuna, with Spain and Italy only recently following. A secondary effect of this em-

bargo was that all the tuna that the South American countries could not sell to the USA was placed on the world market. Consequently, prices of raw materials on the international markets plunged steeply, drawing the EU tuna fleet into a major crisis from which it is only now slowly recovering.

## REGULATIONS

The two key regulations for the fishery product processing sector are:

- Council Directive N° 91/493/CEE of 22 July 1991 laying down the health conditions for the placing on the market of fishery products, completed by Council Directive 92/48/CEE of 16 June 1992 on the health conditions onboard certain fishing vessels. This key regulation harmonises practices within the EU and requires the hygiene standards of all establishments, where fishery products are prepared, processed, chilled, frozen, packaged or stored, to be approved by a competent authority. This Directive also applies to processing units of third countries exporting products to the EU to guarantee the safety of imported products at levels matching those of EU products.
- Council Regulation (CEE) N° 3759/92 of 17 December 1992 on the common organisation of the market in fishery and aquaculture products. This regulation focuses on marketing standards, producer's organisations, and prices of the products with special reference to the EU canning industry.

There are about 50 other regulations on: the name of the species to be used, import quotas, and minimum prices of imported raw material, which do not all specifically concern fishery products, but the larger food products sector. In 1994, the DGXIV of the EU Commission published an useful vademecum of EU regulations of interest for the economic operators of the fishery and aquaculture processing sector (ISSN 92-826-7860-1).

## OUTLOOK

The EU processing industry is suffering somewhat from the recession in which the EU has stepped into over the last two years. Globally, fish consumption is expected to further increase over the 1994-98 period and the industry should follow accordingly. Imports are expected to increase as EU waters will continue to deplete, propelling the industry to purchase raw materials in third countries. As exports will not show significant progress, due to the structural deficit of the EU in seafood products, the trade balance deficit will widen.

# Deep-frozen products

NACE 412.21, 414.1, 415.1

*Deep frozen foods have shown a very positive market trend, thanks to ready-prepared foods. Traditional products, though achieving the highest consumption levels, are distinguished by lower growth rates.*

*The biggest production in the various market segments is achieved by those countries with a high degree of specialisation in the corresponding fresh product sector, while traditional importing countries account for the highest consumption. From a structural viewpoint, the market is fairly concentrated to of a small group of multinational companies, but own-label sales are important as well. The remaining share is split up between numerous small or medium-sized firms.*

## INDUSTRY PROFILE

### Description of the sector

The deep-frozen food sector includes various products which have undergone a low-temperature preservation process. Such products include vegetables, meat, fish or pre-cooked and subsequently deep-frozen foods, including pizzas. The first are the traditional products of the sector, distinguished by a demand which has reached a stage of maturity, intended to substitute fresh products and to be used when and wherever the latter are not available. The second represent a newer segment with good development prospects, thanks to the high quality of deep-frozen foods as a result of improvements in deep-freezing techniques and changes in eating habits. These products have a greater service content than other frozen foods and replace equivalent fresh products, not so much because of seasonal variations, but rather because they represent elaborate products which can be prepared quickly. Such products have boosted value added in the sector in terms of services provided, among the highest in the entire food industry.

### Recent trends

Over the last ten years, the sector has undergone substantial growth, above that recorded for the manufacturing industry as a whole. In fact, while the latter grew by little more than 1 % in 1993, the former increased by about 3 %. Traditional products like deep-frozen vegetables or meat, except poultry, showed a slowdown in growth. On the other hand, more innovative foods (e.g. pre-cooked) are the prime movers of the sector (as well as frozen fish), though consumption levels

are below those of other products. The biggest growth was recorded in 1990, when there was a 6 % increase by volume.

In terms of value, the growth rate was higher, except in 1992 when there was a drop of approximately 2 % caused by a reduction of profit margins in countries like the United Kingdom, Spain, Portugal and Italy. In 1993, the cost of deep-frozen foods was the highest in Portugal and Italy due in part to fragmented distribution and supply.

The major producers in the sector in 1993 were the United Kingdom and Germany, with over 1 000 tonnes per year. These were followed by France, Spain, Italy and the Netherlands with smaller quantities. Generally speaking, the biggest production occurred in the segments of deep-frozen vegetables, potato-based products and deep-frozen meat. The production levels reached per market segment relate to the degree of specialisation achieved by the different countries and, in some instances, reflect the major deficiencies found on domestic markets. In the first case, the major producers are also important exporters, e.g. France, Germany and the United Kingdom for potato-based deep-frozen products, and Spain for deep-frozen meat and fish. In the second case, there is a tendency to import fresh products which are subsequently deep-frozen. For example, Germany and the United Kingdom make up for their cold climates - which do not favour fresh vegetables - by a high production level of deep-frozen products.

In the deep-frozen, oven-bake product segment (e.g. ready-made foods), the major producers are France and Germany. This, thanks to their well-developed sales and distribution structures.

### International comparison

Deep-frozen products are found in greater quantities on more developed food markets with advanced product distribution and management structures. In this regard, the USA is one of the most important producer and consumer countries in the world. There are many reasons for this. First and foremost is the wide extension of the market, which many years ago ensured the consolidation of the sector. Per capita consumption in the USA touches 50 kg against an average of 25-30 kg in Europe. Secondly, the development of particular forms of distribution on the one hand and the increase of microwave and freezers in the home on the other, have given a significant boost to the sector. In Japan, changes in family lifestyles resulting from an increasing proportion of women going outside of the home to work, have provoked an increase in the consumption of ready-prepared and frozen foods.

## Foreign trade

The EFTA countries, particularly the Scandinavian countries supply frozen fish. Significant foreign demand for deep-frozen products in 1988 came from Japan and the Middle East. While the USA also represented a good trading partner at that time, over recent years its share of EU imports has halved. Meanwhile, the role of Russia in this sector has become more significant.

Export flows have shown alternate patterns. From 1988 to 1993 there was an overall growth of 3 %. The steepest drops were recorded in 1989 and 1991: in the former due to a considerable fall in meat exports, while in the latter, the drop was generalised, but more significant for fish. In 1993, the highest export levels were touched by meat, followed at a distance by fish. As regards imports, the biggest growth rates were recorded up until 1990, after which the trend inverted

**Table 5: Deep-frozen products**

and there was a downswing. The major imports in 1993 were fish and meat, though values were rather different.

## MARKET FORCES

### Demand

In 1993, the products most in demand were deep-frozen vegetables, potato-based products and meat, although the fastest growing markets, starting in 1989, were those of frozen fish and ready-prepared foods.

Within the EU, the biggest consumers (by volume) of deep-frozen foods are Germany and the United Kingdom, with quantities around 1.5 million tonnes per year, followed by France, Spain, Italy and the Netherlands. Per capita consumption shows a completely different picture, with Denmark in the lead with 34 kg, followed by Ireland, 26 kg, the United Kingdom, 24 kg and Germany, 21 kg. Spain and Italy have per capita consumption rates among the lowest in the EU.

The reasons for the success of deep-frozen foods are tied to the fact that they are practical and easy to use, i.e. they are a time-saving and always-available reserve; and the choice is vast at any time of the year. They are also very good value for money and have a high service content. Besides being eaten at main meals, deep-frozen products are also becoming

popular as snacks; this is especially true of deep-frozen oven-baked products and pizzas.

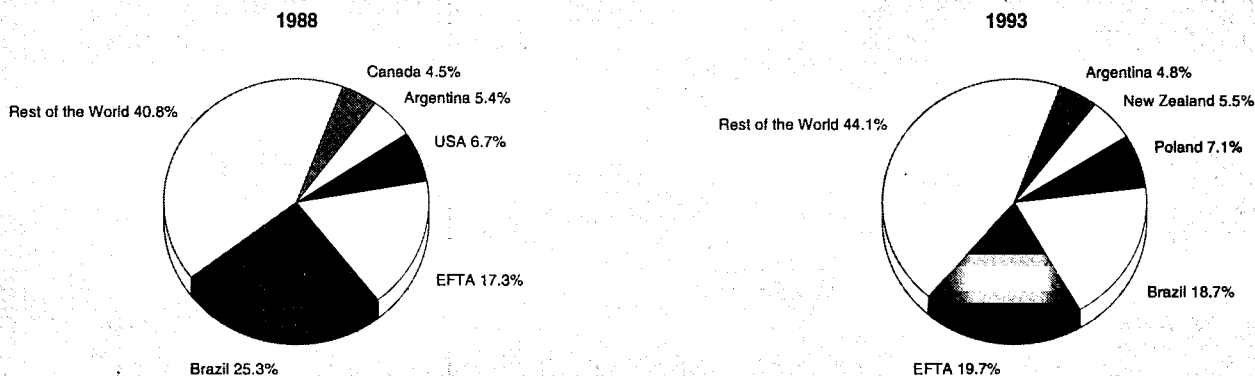

The distribution channels through which these products reach the consumer are numerous: large organised distribution networks, catering, discount stores, freezer centres and even home delivery. Organised distribution is a good vehicle for frozen products, inasmuch as it presents the best structures for the preservation of frozen foods, without interrupting the cold chain.

Because people have less time to spend in the kitchen, the demand for collective catering has risen and this has helped to boost the demand for deep-frozen products, in all segments. In some countries like Germany, France and Italy, home deliveries have increased considerably - thanks to the greater service content - with a consequent increase of prices.

In northern Europe, freezer centres are fairly common. These are retail outlets specialising in the distribution of foods preserved using cold techniques, where the variety is usually wider. Such specialisation often results in sales being completed by particular services such as home delivery.

The demand for deep-frozen products varies according to the country considered. In Spain for example, there is a clear consumer preference for unbranded products and this is a considerable obstacle to brand-name products. A weak link

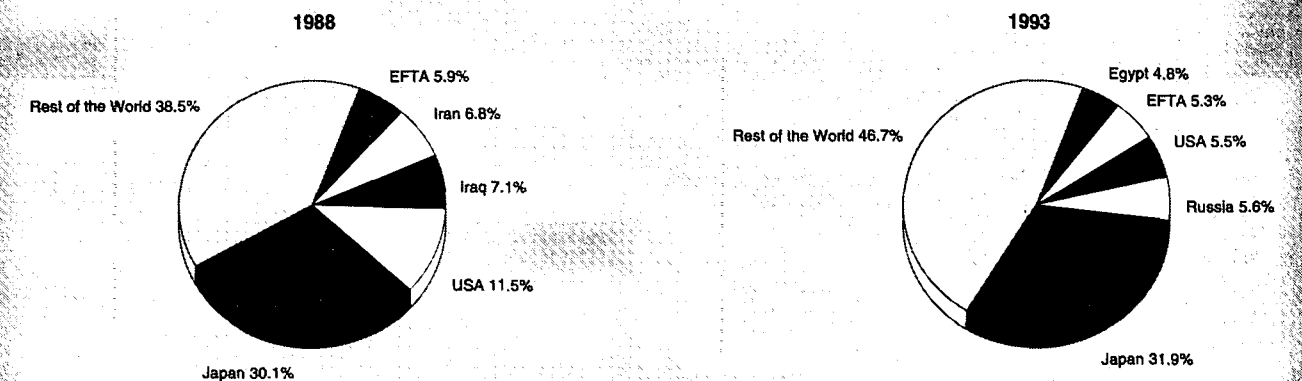

**Figure 1: Frozen-food products**  
**Origin of EU imports**

Source: Eurostat

**Figure 2: Frozen-food products  
Destination of EU exports**

Source: Eurostat

in the local system is supply and transport, which are still insufficient to manage deep-frozen products, despite the fact that this country is a major importer of such commodities.

The fastest growing segment in Denmark is ready-prepared food, above all chicken and pasta-based products. As far as deep-frozen meat is concerned, there is a progressive loss of demand compared to preserved meat, while the demand for vacuum-packed meat continues to increase.

In the United Kingdom, the deep-frozen food market continues to expand especially in relation to hamburgers and savoury cakes. The fastest growing sectors are high-quality vegetables and potato-based products.

#### Supply and competition

The deep-frozen food sector is still developing, and there is plenty of room for further expansion of supply as is evidenced by global annual investments of around 100 billion USD in structures for managing deep-frozen food within organised distribution networks. This figure is ten times greater than that for low-temperature treated commodities. The competitiveness of the industry is chiefly tied to the products which are deep-frozen particularly meat, fruit, vegetables and fish.

For many years the management of deep-frozen products represented an important entry barrier. In Germany and France, reorganisation and optimisation of this industrial cost were achieved, taking it out of the production chain. Additionally, computerised logistic systems integrated with other production and planning functions were developed. In some cases, however, the taking over of logistics by distribution has resulted in the appearance of new producers.

#### Production process

Freezing and deep-freezing are based on the same principle: turning water into ice so that bacteria cannot live and reproduce on the raw food product. The two processes are different, however. Freezing means achieving low temperatures slowly, so the ice crystals reach such proportions as to damage the preserved food cells and when defrosted, together with the ice, proteins, sugars and vitamins, which are removed. Through deep-freezing, low temperatures are achieved, but quickly, so the ice crystals are smaller and do not damage the food cells. Technological development in the sector is inclined towards the achievement of high-quality.

### INDUSTRY STRUCTURE

#### Companies

The industrial structure is characterised on the one hand by a number of multinational companies which cover about 70 % of the European market and operate at the same time in various other business markets. On the other hand, European production is fragmented into numerous small and medium-sized organisations with regional markets. France has the biggest number of producers (around 400). In 1992, there were about 90 in Germany, 135 in Spain, 90 in Denmark, 65 in Italy, and around 130 in the United Kingdom. Belgium has the smallest number of manufacturers (only about 15).

The Spanish deep-frozen food industry employed about 11 000 workers. Businesses are small or medium-sized, with an average of 96 employees. The production of deep-frozen foods is not yet very concentrated, with the top ten companies controlling about 45 % of the market. The five major foreign companies cover 15 % of the market.

The main multinational company is Unilever (UK, NL), which is the undisputed leader in nearly all subsectors, with over 50 % of the market in Italy, France, Spain and

Belgium. The second largest multinational company in terms of market share is Nestlé (CH), especially in the UK.

Other companies operating in the deep-frozen food sector at the international level and specialised productions in certain subsectors are Bonduelle (F), Cecab d'Aucy (F) and Grand Metropolitan (UK), which mainly operate in the vegetable subsector; and McCain (USA) which operates in the potato and potato-based product subsector. Dr. Oetker (D), Ross Food (United Biscuits UK) and Panzalin (F) - recently established through the joint venture between Danone and St.Louis - specialise in ready-prepared foods.

Two firms specialising in home delivery, which have been operating for some time in Germany and the Netherlands, are Bo\*Frost and Eismann.

### Strategies

17 acquisitions took place in the sector from 1993-94. These were promoted by large European groups. The growth strategy of these companies focuses on the consolidation of their market shares in the fastest growing segments, on higher service content and also on area markets with good development prospects, e.g. Spain and Italy, where consumption levels are below the Community average, but considerable growth is forecasted. This tendency to expand has spurred many medium-sized firms to establish co-productions or joint ventures with the aim of acquiring and expanding know-how, exploiting commercial and industrial synergies and widening the range of deep-frozen products, from vegetables to meat, and from fish to ready-prepared products. This phenomenon is particularly significant in France and the United Kingdom where there is a larger number of medium-sized firms.

Small companies adopt promotional or third parties' account policies. The large companies, on the other hand, revert to strategies based on product innovation, above all in the ready-prepared food subsector, through high market segmentation. Particular focus is put on regional specialities, ethnic cuisine and diet foods. A further element of segmentation is represented by packaging through the introduction of individually wrapped portions, as an effective response to the demand from more "promising" target consumers, i.e. youngsters and singles.

### Impact of the Single Market

The creation of the Single Market had a globally positive impact on this sector. However, while the common legislation is already accepted almost uniformly by all Member States, there are still some barriers regarding the monitoring of temperatures in means of transport, warehousing and storage of quick-frozen foodstuffs and the definition of procedures and methods of analysis for official controls. Other problems are linked to a lack of clear definitions, which gives problems to apply QUID (quantitative ingredient declaration).

The next priorities are to achieve more uniformity on the labelling and packaging standards, in particular with respect to the average weights and the indication of the preserving temperature. One also needs to reach agreement on the exact definition of deep-frozen products across the Member States.

### ENVIRONMENT

Manufacturers and planners must try to keep down energy consumption and thereby safeguarding the environment. Plant technologies must solve their effluent problem, which plays

a role in the destruction of the ozone layer. The harmful properties of CFCs represent a brake which must be taken into careful consideration.

---

## OUTLOOK

---

The future of the deep-frozen food sector will be characterised in general by less significant or in any event different growth rates for the various market segments, with the ready-prepared food and snack subsectors showing the highest growth rates.

From the point of view of industry's structure, the process of concentration by multinational companies will continue and focus on major-growth markets. Cost optimisation and the attainment of competitive advantages will be particularly important objectives for medium-sized firms.

# Grain milling

## NACE 416

In terms of production, the milling industry has been fully independent for some years and is distinguished by a high level of finished-product stocks. In this way, the EU is able not only to meet internal demand, which has reached a wide-spread degree of stability, but also demand from abroad, which is much more lively. This continues to produce less need for foreign supplies (and a degree of production plant utilisation below maximum levels). Demand has reached the saturation point, which entails a restructuring process, consisting of: the closing down of small mills, which had become inefficient; the concentration of large industries, able to compete on the international level; and the integration with the industries in downstream sectors, in order to keep production costs low. Finally, almost all companies in the sector tend towards high-quality products, by means of production technologies which utilise selected grain mixtures.

### INDUSTRY PROFILE

#### Description of the sector

The milling industry comprises substantially homogeneous products, obtained by processing cereals. These can be divided up into the production of semolina, flour (wheat and corn, common and durum, rice) and bran; rusk manufacture; the hulling and grading of seeds and grains, especially of maize; and the manufacture of biological products, which represent a niche market. The milling industry is linked upstream with primary production and, at the same time, downstream, with the pasta-manufacturing sector and the bread-making and confectionery industries. Therefore, the products often represent commodities, and there is a very small margin of product differentiation, as the production process is highly standardised and has a low value added compared to other manufacturing industries. Among the Member States, the United Kingdom has the highest level of value added, immediately followed by France and Italy. Germany and Spain, on the other hand, present substantially similar and not particularly high levels.

#### Recent trends

In 1992/93, there was a significant drop in internal demand at current prices, and consequently in production, bringing the values of these indicators back down to approximately those recorded in 1985. Conversely, the foreign trade indicators, in particular of imports, rose considerably. Employment figures declined during the entire 1984-1993 period, with steeper drops in 1987/88 and 1991/92, as manual labour was in part replaced by less labour-intensive modern production technologies, as a result of the industrial restructuring of the sector.

The major indicators in the sector do not point to a particularly brilliant situation. The reasons for this are: a strong market production output capacity on significant finished-product and raw material surpluses, in particular of wheat; and a saturated internal demand, due on the one hand to a downward swing in the pasta industry since 1992 and to a growth in the bread-making and confectionery industry smaller than that of the previous year on the other. The biggest drops concerned durum wheat flour, while common wheat flour production remained stable. In the case of flours made from other cereals, the situation is rather different. Starting in 1992, there has been a strong downward swing in the production of soya flours, due to a considerable drop in cultivated areas. This has benefited maize production, though this product is distinguished by heavy imports from third countries.

Figure 1: Grain milling  
Value added in comparison with related industries, 1993

Source: DEBA

The production pattern, at constant prices, is fairly stable compared to that of the manufacturing industry, with a more substantial increase from 1988-1989 and a downward swing in the 1990s. Mean variations relating to foreign trade indicators are the most interesting: in 1984-89, imports fell by 34 %, with a drop of 80 % in 1988/89 alone. Conversely, between 1992-93 there was a big increase (around 10 %). Exports also fell during the 1984/89 period, but variations were less extreme. On the other hand, from 1989-93 there was a moderate growth, especially during the 1991/92 period. A variety of factors made 1989 a crucial year. In the first place, there was the considerable increase in import prices from 1987 to 1989 caused by the bad harvests in the major cereal growing countries. Secondly, internal demand was not particularly lively, so the need to look for greater supplies in third countries was discouraged.

The milling industry shows a greater production of common wheat flours in northern Europe, while southern Europe also produces durum wheat flour. The biggest producers in the

1994 are Eurostat estimates.  
Source: DEBA

Community in 1993 were France and Italy with virtually the same quantities, followed by the United Kingdom, Spain and Germany. Only France and Germany have contributed meaningfully to growth, while in Spain and Italy there has been a big downward swing. In Spain corn crops were smaller and of lower quality due to bad weather conditions. Italy cut export quantities, in particular to the former Soviet Union and Algeria not so much due to a fall in the demand from abroad as to internal provisions which froze insurance cover on credits to various countries. Compared to the other Member States, the excellent performances of Belgium and the Netherlands should be taken into consideration. In fact, these countries - though not in a position to produce particularly high volumes - have proved themselves capable of strong growth in the short term.

**International comparison**

Global production of flours did not change much between 1984 and 1993. The EU was the world's biggest producer of processed cereals, both in 1984 and in 1993, followed by the

USA and Canada. The deflationary patterns of the EU and the USA tended to be constant and quite similar, while in Japan there was a downward trend.

Maize and wheat-based products are mainly concentrated in the USA, wheat-based products in the EU, rice and minor cereal-based products in Asia and soya-based products in South America.

The trade of processed cereals throughout the world appears stable compared to the previous year, excepting the impressive growth of demand for flour in the USA. Anyway, a fall is expected due to the greater independence of some Asian countries in terms of production, coupled with the overall drop in demand, especially in the former Soviet Union (due to the ongoing economic and social changes there). The production of minor cereals and rice, of which China and India are the top producers and boast the highest crop yields, continues to increase. Since 1992, soya flour imports from Argentina and Brazil have been rising.

**Foreign trade**

The EU's flow of trade is marked by the clear predominance of exports over imports. The former go above all to the countries of North Africa, which took 40 % of the total in 1988. These are followed by the EFTA countries, where production potential is very low due to the lack of raw material, Cameroon and Syria. In 1993, the share of the North African countries rose considerably as the production levels in Algeria dropped sharply because of bad weather conditions. Also on the upgrade are flows towards the Middle East, with Syria as the biggest buyer.

In 1988, 35 % of EU imports came from the USA, followed by Thailand, Surinam, Uruguay, and India. In 1993, imports plummeted, despite the significant increase of quantities from Thailand, especially of processed rice, and the slight downswing of the USA caused by bad weather conditions. At that time, the main trading partners were completely different: in place of Uruguay, Surinam and India, we find Egypt, the EFTA countries and Australia.

During the 1984-93 period, the trade balance of the EU, at current prices, not only remained in the black, but actually tended to improve as well. The turning point, which occurred in 1989, after a period in which both imports and exports dropped at the same rate, can be attributed to the steep fall

**Figure 4: Grain milling**  
International comparison of production in current prices

Source: DEBA

**Figure 5: Grain milling**  
International comparison of production in constant prices

**Demand**

Market needs, principally of secondary processing food industries, shape the activities of the milling industry both in terms of quality and quantity. With regard to quality, requests made by final processors affect supply policies concerning raw materials which have to respond to certain chemical-protein parameters. With regard to quantity, the pattern of the demand for flour-based products affects the degree of exploitation of production plants which tends to reach an optimum level in order to keep production costs down as much as possible. The optimisation of the exploitation rate of the production plants is the result of planning, whereby there is a regular flow of raw material over time. Purchasing policies therefore represent an important and critical factor not only in terms of quality standards, but also with respect to the productive efficiency of the sector.

Durum and common wheat flour represent a primary input for the pasta industry; and common wheat flour is also used for bread-making (on an industrial and non-industrial scale) and in the confectionery industry. In the countries of northern Europe, this latter type of flour is used mostly by local pasta producers who exploit production techniques to obtain a product able to substitute for durum wheat pasta. Alongside this particular use of flour, there is also direct retailing, though this represents a very small share of the overall supply. Flour for domestic use is, in fact, in the maturity stage of its life cycle and demand for this product does not seem likely to pick up. This is explained by the fact that current eating habits prevalently favour pre-prepared products or products which require little preparation, which can be used more frequently. The demand for flour in the pasta and bread-making sectors in 1993 was higher in Belgium, Denmark, Spain and Italy. The share of flour for the confectionery industry was more or less the same in all countries, except Italy, where it was higher. Denmark and Germany consumed the largest amounts of flour for direct retailing.

While traditional flours are passing through a substantially stable period, the market has expanded for low-residue or completely biological flours. In fact, products of biological origin, riding the wave of recent health trends in food consumption, have gained in popularity in some northern countries, where they represent an already consolidated market niche. The demand for organic products has waned over the last few years in the United Kingdom, whereas in the Medi-

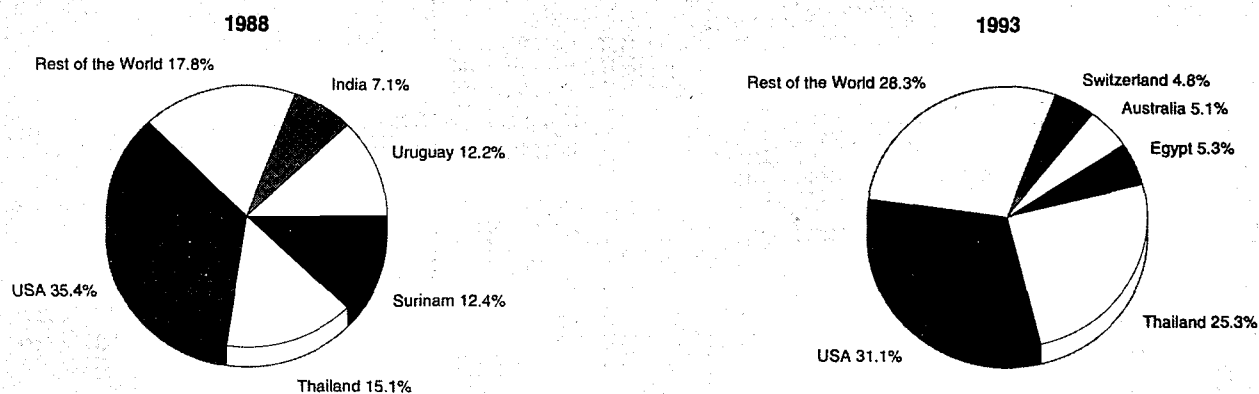

in imports. The export/import ratio thus went from 2.31 in 1988 to 12.81 in 1989 and consistently increased up to 1993, with a peak at 20 % in 1992. The countries most significantly behind this jump are Germany, France and the United Kingdom, while Italy shows the strongest counter-trend.

The internal market of the EU is chiefly dominated by Germany, France and the United Kingdom, and to a lesser extent by Belgium and The Netherlands. In particular, France exports the most to the other countries of the EU - which received similar shares from Germany - and to third countries, thanks to the generally high production levels of common wheat flours. This means that France, after winning the internal EU market, has sought new outlets abroad. Italy, and to a lesser degree, Spain, export considerable quantities to third countries as well. The terms of trade index reveals a very similar pattern to that of the trade balance and shows a recovery in 1989 due to a bigger increase in export prices over import prices.

Destination of EU exports

**Figure 7: Grain milling  
Origin of EU imports**

Source: Eurostat

terreanean countries they are just beginning to spread. Health recommendations throughout Europe also have encouraged the greater consumption of bread.

### Supply and competition

The labour productivity index underwent substantial growth between 1984-1993, though production and employment figures tended to drop. This means that labour is not a marginal component of the production process, despite the large reductions in employment levels of the milling industry through the 1980s. In fact, there was a greater introduction of new production technologies and employment of capital assets during the 1980s, while over recent years things have levelled off. Production costs are fairly steady and very near the base year 1990 values. The biggest item of expenditure remains raw materials, though labour costs rose during the entire 1984/93 period with the most significant increases occurring in the 1990s.

The grain milling industry is distinguished by a strong fragmentation of supply, located principally in the major producing countries. A case in point is the bread-making industry, which is split up into a high number of smaller bakeries.

### Production process

Technological innovation in the sector involves the computerisation of the production process, through which it is possible to obtain a better quality product. Flours are obtained from a mixture of selected grains and treated at high-temperatures

during the drying phase. The automation of the production process results in the greater specialisation of the work force (with the subsequent higher labour costs), as the work chiefly involves the control of the production cycle.

The production process of biological flour is not much different from that of other flours in the processing stage: the biggest differences appear during storing. Storage time must be as short as possible because the raw materials are free of additives or preservatives.

Thanks to technological innovation in the sector, production capacity has increased, but the degree of plant utilisation, particularly with regard to common wheat flours, has not yet reached maximum levels. In France and Germany it varies between 70-80 %, in Italy it is around 60 % and in Spain it only touches about 40 %.

## INDUSTRY STRUCTURE

### Companies

The number of milling companies in the EU has dropped steeply over the last decade - especially in the early 1980s - in Germany, France, Italy and, to a lesser extent, in Spain. Currently, a large number of small milling companies exist, chiefly in the major producer countries (i.e. Italy, France), but also in Spain and Greece, where average production quantities were not more than 10 thousand tonnes in 1992. The

**Figure 8: Grain milling  
Trade intensities**

Source: DEBA

large companies are situated in France, the United Kingdom, The Netherlands, Belgium and Denmark. The average production figures per mills are respectively 51 thousand tonnes in the United Kingdom, 28 thousand tonnes in The Netherlands, and 20 thousand tonnes in Belgium and Denmark, but only 6 thousand tonnes in France. Between 1991 and 1992, a 25 % growth was recorded in the average production figures per mill in Belgium. In the first group of countries very old traditions exist involving a fairly fragmented industrial structure, e.g. in France just less than half the milling companies in existence produced less than 10 thousand quintals of flour in 1991. In the second group on the other hand, a greater industrial concentration exists because of a larger number of high-technology production units.

Product specialisation ratios, calculated both in 1984 and 1993, were fairly high. In 1984, Portugal and Greece achieved the highest values, followed at some distance by Spain, Ireland, Italy and Denmark. In 1993 Greece achieved the greatest product specialisation of them all.

The major milling companies per country are: for Belgium, Ceres-Bruxelles-Gent N.V. and Molens van Deinze; for Ger-

many, Kampffmeyer Muhlen GmbH Hamburg, Wehrhahn-Muhlen OGH Düsseldorf and BM Bakermuhlen AG Mannheim; for France, Moulins Soufflet, Grands Moulins de Paris (GMP) and Euromill; for Luxembourg, Muller Frères and Nonnemillen; for The Netherlands, Meneba and Ranks Meel B.V.; for Portugal, National, Companhia Industrial de Transformação de Cereais and Germen, Moagem de Cereais; and, finally, for the United Kingdom, Allied Mills Ltd, Rank Hovis Ltd and Spillers Milling Ltd.

### Strategies

To recover competitiveness, producers are focusing on quality control and on minimising production costs. The former concerns all the stages of the production process, from storage to processing, right up to marketing. The latter is implemented above all through technological innovation, the closing down of small plants and raw material purchasing policies.

As in many other sectors of the manufacturing industry, policies are being adopted in the grain milling industry for the certification of the production process in conformity with ISO standards. Quality certification represents a further instrument to increase the competitiveness of enterprises. Quality certification is widespread throughout much of Europe, so that most of the mills in the United Kingdom and many in Germany are certified. In Italy, the first milling company to adopt production quality certification was Molino Seragni SpA, a firm capable of an output of 1 800 quintals a day (located in Lombardy), and in France Moulins Soufflet and Intermeunerie.

The location of plants also has strategic importance in relation to both upstream and downstream sectors. Plants are very often situated in raw material production areas, to keep down transport costs as much as possible; and near processing industries, especially pasta industries, with which a process of integration is under way (e.g. the pasta industry in Italy).

Besides this greater integration with industries downstream of the milling sector, policies of industrial concentration should be considered which, through mergers and acquisitions, lead to the creation of giant and multinational companies, engaged primarily in foreign trade. In 1994, in France one merger went ahead: that of Moulins Soufflet with Française de Meunière. Finally, in 1994, the United Kingdom Golsin Investment acquired Maria Mayor Gil of Spain.

### Impact of the Single Market

The impact of the creation of the Single Market on grain milling sector has been overall positive, even if small. It affected in particular the free movement of goods, and most of all stimulated consumer protection. The limited nature of

**Table 6: Grain milling

Source: DEBA

the impact is due to two factors. Firstly, the sector is characterised by a low international trade intensity. In fact, transportation and distribution of flour is very expensive, so grain processing take place regionally. Secondly, the sector had already been deeply influenced by the reform of the Community Agricultural Policy.

The harmonisation of legislation on additives which still represents an internal barrier to trade, is a priority for the industry.

### REGIONAL DISTRIBUTION

Traditional durum wheat growing regions are located in Italy, Spain, the United Kingdom, Portugal and Greece, while common wheat growing regions are in France and Germany.

In Italy, the highest concentration of common wheat and relative processing is in the Po Valley regions, while durum wheat is prevalent in the south. Rice processing industries are to be found chiefly in Piedmont while maize processing is mainly located in northern Italy.

In Spain, the major flour producing regions are Castilla y Leon, Andalusia, Murcia, La Roija, Castilla-La Mancha, Extremadura and Navarra. In Portugal, the big mills are located near the centre of consumption and near the coast, whereas common and durum wheat are produced in the interior.

In Germany, the main cereal producing regions are in the west (Bayern and Niedersachsen) and in the east (Mecklenburg-Vorpommern). Meanwhile, the main flour producing regions are near to the centre of consumption: Nordrhein-Westfalen and Niedersachsen/Bremen in the west, and Berlin and Brandenburg in the east.

The largest French plants are situated in Ile-de-France, while the regions with the highest number of plants are the Loire Valley, Brittany, Midi-Pyrénées and Rhône-Alpes. In the United Kingdom, the largest concentration of mills is to be

found in the port areas of England, while in Belgium the region with the biggest concentration is Flanders.

### ENVIRONMENT

In the past, large quantities of water were used to wash cereals during the production process. This environmental problem has been remedied by the use of pneumatic washing systems, which require smaller quantities of water. Consequently, no serious environmental problems related to the grain milling industry exist at the present time.

### REGULATIONS

In the cereal sector, the CMO (Common Market Organisation) came into force in June, 1967 and is controlled by Regulation 1766/92, which fixes prices, measures of intervention and measures relating to cereals, oleaginous and protein products of the McSharry plan. This reform came into force on 1 June, 1993; its main aim is to reduce the difference between Community prices of cereals and world prices, while supporting farmers through compensatory payments and stabilisation measures.

The cereals sector is influenced by the GATT Agreement, and particularly by the measures adopted with the Blair House agreement between the EU and the USA. Focal points are: measures relating to market access, domestic intervention, the setting of tariffs and export. Export subsidy expenditures are to be reduced by 36 % and the volume of subsidised exports by 21 % over the implementation period, using the years 1986/90 as a base. In this framework, direct compensatory payments introduced by the 1992 CAP reform are not included.

### OUTLOOK

With regard to supply, the forecast for future years shows that objectives of production cost reduction and product quality differentiation will guide strategic policies within the grain milling industry. Technological levels will be maintained more or less, and the process of industrial restructuring will slow down, though the possibility still exists that a number of production units will be closed down and the trend toward concentration will continue.

On the demand side, future growth in the sector will depend on food consumption trends in neighbouring sectors. The drop in bread consumption, despite increases in amounts produced at the industrial level, and the increased consumption of other flour-based products will be the chief factors likely to bring about the most important changes. However, given the stability of most indicators in these sectors, no particularly significant variations are envisaged.

Written by: NOMISMA

The industry is represented at the EU level by: Groupement des Associations Meunières des Pays de la CE (GAM). Address: Avenue des Gaulois 9 (ECCO), B-1040 Brussels; tel: (32 2) 736 5354; fax: (32 2) 732 3427.

# Industrial baking

## NACE 419

The baking industry has achieved substantial stability in terms of consumption, and a saturation of internal demand could present itself in the future. In fact, the demand for bread appears stagnant. Health considerations prevail which boost the market for wholemeal and biological products. The industry is increasing its degree of concentration in terms of production, mirroring the strategy taken in distribution. Companies are expanding through acquisition strategies, and the preferred sales channel is through modern, organised distribution networks. In this context, innovations relating to technology, products and packaging as well as marketing policies (notably advertising policies) acquire an ever greater importance.

### INDUSTRY PROFILE

#### Description of the sector

The industrial baking sector processes semi-finished products from other sectors of the food industry and turns out products for the final market. Besides bread and bread substitutes, these include biscuits, confectionery and other sweets.

Such products can be categorised in part by the occasions at which they are eaten: bread substitutes, e.g. crackers, rusks, breadsticks and toasting bread, which are eaten during main meals; biscuits and cereals, eaten at breakfast; industrial confectionery, still subject to only occasional consumption; and cakes, eaten on holidays and special occasions.

This sector has expanded in several directions. The development of bread substitutes is favoured by a drop in bread consumption and by the organoleptic and storage characteristics of such products. Breakfast products have undergone considerable expansion, especially cereals, which are now becoming popular in Southern Europe.

The economic clout of the sector, expressed in terms of added value, is one of the biggest of the entire European food industry. Germany offers the greatest contribution to value added and to the growth of the sector, as it is in a position to boost both production and employment. This country is followed in order of importance by the United Kingdom, Spain and France.

The main indicators in the sector went up between 1984 and 1993. During 1993-94, however, the growth rate slowed down a little. Internal demand is almost completely covered by internal production. In fact, the percentage of imports with respect to total demand was only 1 % in 1993, and there is consequently a tendency to export European products abroad. Unlike many other industries in the food sector, employment levels continued to rise between 1984 and 1993, going from 411 to 449 thousand.

#### Recent trends

The growth rates of principal indicators at constant prices are for the most part positive. Supply and demand are growing at the same speed and the pattern of foreign trade indicators is also positive. There was a considerable increase in demand from abroad which reached its apex in 1993 when the export share of total production was over 3 %, with a contemporaneous slide in the growth pattern of imports.

The anti-cyclical trend of the sector is underscored not only by the pattern of the main indicators, but also by a comparison with the manufacturing industry as a whole. Up to 1990, the production pattern in the bread sector was in line with that

Figure 1: Industrial baking  
Value added in comparison with related industries, 1993

Source: DEBA

of the manufacturing industry as a whole: whereas the latter appears to have reached a certain degree of stability, the former continues to grow. Employment in the baking industry showed an almost exponential growth from 1985 to 1990, then, having reached an apex in 1991, there was a fall, but at a slower rate than that which affected the manufacturing industry in general. 1991 consequently appears to be a pivotal year, and the beginning of a less brilliant period for the industrial baking industry.

The strongest - yet still only moderate - growth in biscuit manufacturing over recent years occurred in France, Italy and the Netherlands, while the remaining EU countries showed a tendency to slow down their production. Of particular interest is the trend in France towards a rise in the price of bread, while in the United Kingdom and Portugal bread prices are going down. In the biscuit sector, there is a tendency for prices to rise in nearly all countries, especially Greece, while exceptions are found in the United Kingdom and the Netherlands. Price sensibility is particularly high in relation to

biscuit consumption. The recession, along with a drop in purchasing power, has made consumers more attentive to their choice of goods, which is shifting towards the lowest-cost products.

**International comparison**

The major world producers in the 1984-93 period were the USA, followed by the EU and Japan. While the former maintained production values at current prices, the EU and Japan increased production considerably, thereby narrowing the gap with respect to the USA. This is explained by the fact that EU efforts have been directed towards achieving substantial independence in terms of production, and boosting exports in order to increase its share of world markets. In fact, even at constant prices, the EU experienced extraordinary growth which continued until 1991, after which the trend was interrupted and figures remained fairly stable up to 1993. Japan, despite its development performance, took a fairly 'closed-shop' attitude towards foreign imports, and showed extremely

low export figures. Therefore, the country manufactures prevalently for its domestic market, which is not very big, as bread is considered an 'exotic' product. Conversely, the USA significantly boosted its exports, as well as its industrial expansion process, towards both Europe and third countries. In fact, the USA market leader, RJR Nabisco, is involved in a series of acquisitions of factories in extremely diverse locations. Among the major world exporters are the EFTA countries, which mainly trade breakfast confectionery products and cereals.

**Foreign trade**

During the 1984-93 period, extra-EU imports more than doubled in volume terms, despite the fact that import penetration remained at marginal levels. Exports followed a similar pattern, but their percentage variation since 1984 was smaller. Starting in 1988, the trend inverted, with a growth of imports greater than that of exports.

**Figure 4: Industrial baking**  
International comparison of production in current prices

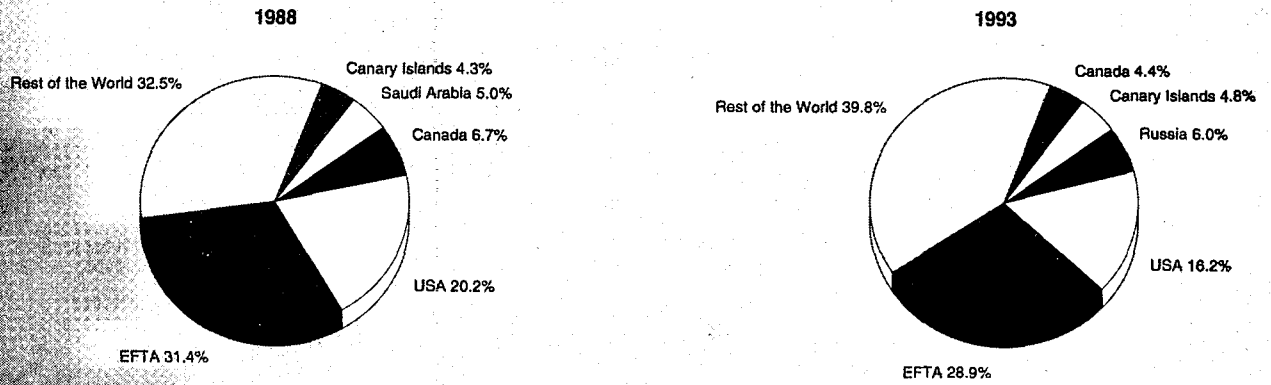

Source: DEBA

**Figure 5: Industrial baking**  
International comparison of production in constant prices

Source: DEBA

**Figure 6: Industrial baking  
Destination of EU exports**

Source: Eurostat

The trade balance was generally positive for the entire 1984-93 period. The main partners of the EU as far as exports are concerned have traditionally been the ex-EFTA countries, the USA and Canada, joined in 1993 by Russia. On the import side, the ex-EFTA countries represent the major EU partners, with an 84 % share in 1988 and an almost 73 % share in 1993.

With regard to trade within the EU, there has been a strong growth of both imports and exports (155 % and 149 % respectively), sustained mostly by the countries with the strongest economies. Many of the major producers have large import shares, often larger than their capacity to export. A typical example is France, which over recent years has reached an import share of around 22 %, the largest of all EU countries. Germany and the United Kingdom are also big importers. Among the main exporters is the Netherlands (with a share similar to that of Germany), which is much less dependent on foreign production.

## MARKET FORCES

### Demand

The biggest consumers of bread in terms of quantity are the Germans, with 5.2 tonnes, followed by the Italians and the French, with approximately 3.5 tonnes apiece. Relatively speaking, the United Kingdom and Spain have experienced the biggest drops over the five-year period, while there was an upswing in the demand for bread in Germany after 1990.

A preference for black bread exists in Northern Europe, and it is gaining in popularity in the south, where the demand for white bread has always prevailed. There are also significant differences in terms of bread use among Member States. The health concerns which have dominated food consumption over recent years have boosted the demand for biological bread. The distribution of freshly baked bread takes place above all through traditional channels, while industrial bread passes through the large distribution networks.

The market for bread substitutes like rusks and crackers is profiting from the drop in bread consumption. The advantages of such markets are: distribution through both large and traditional channels; innovation of packaging with individually

wrapped products offering greater freshness; and more occasions for consumption.

Among breakfast products, cereals are those which show the strongest growth, above all in countries like Spain (+242 %), Belgium (+149 %), Italy (+140 %) and France (+133 %), where consumption always has been fairly low. The market differentials which have contributed to this change in demand are high organoleptic qualities, a wide assortment and health considerations. For these reasons, the niche market for biological confectionery products has met with considerable success which is expected to continue into the future.

With regard to biscuits, the biggest consumption in 1993 was in the United Kingdom with 656 thousand tonnes, followed by Italy and France with 570 and 402 thousand tonnes respectively. The fastest growing markets in the sector are those of Germany and Belgium, thanks to diversification towards wholemeal biscuits and confectionery. Dry biscuits, on the other hand, have reached an advanced stage of maturity in all member countries, and this trend is not likely to change.

Further regional differences exist for biscuit consumption in terms of use and traditional eating habits: in Southern Europe, biscuits are eaten mainly at breakfast, while in the north they are eaten as a snack. The demand for confectionery products

is linked to typically regional products, distributed in part by supermarkets.

The market for mid-afternoon snacks is now showing some initial signs of slowing down. This can be attributed to a number of causes: economic recession, the consolidation of the market in a stage of maturity, adverse demographic trends and an increase in competition from products like yoghurt, ice cream and chocolate snacks. There is essentially one reason for consumer preference of these products: a nutritional need met by high-energy and quality products, keeping in line with the latest fitness trends.

Confectionery products which represent a highly specialised niche market (e.g. Christmas cakes) have shown positive patterns, due to a tendency towards product innovation which allows for much variety.

### Supply and competition

Labour productivity grew regularly over the entire period, as did the cost of labour per unit. The use of capital assets in processing was fairly consistent, and did not lead to a replacement or reduction of the work force, which remains an important production factor. The EU enjoys considerable productive independence, and consequently does not face a great deal of extra-EU competition.

Generally speaking, the sector shows a phenomenon of cannibalisation, inasmuch as, through diversification, new products have reached the market, in competition with each other (e.g. biscuits against confectionery, confectionery against mid-afternoon snacks, etc.).

Strong diversification exists on the bread market (e.g. durum wheat bread produced in certain areas of Southern Europe) and includes product innovation, with many products being of a regional nature. In the bread baking sector, efforts are centred on increasing the service content.

In the breakfast cereal market, which is distinguished by high value added, there is strong competition based on high product innovation and considerable segmentation. Such diversification policies have kept prices high for some time now. The introduction of new brands some years ago, in competition with the American leader Kellogg's, brought about a drop in margins.

In the industrial confectionery sector, strong scale economies exist during the manufacturing and marketing stages as well

as important entry barriers tied to high innovation and communication investments.

### Production process

In order to maintain constant quality standards in terms of flavour and thickness, production processes of bread substitutes and biscuits have been fully automated and subjected to scale economies. Furthermore, to ensure hygienic standards of production, manual labour is reduced to a minimum. The introduction of computerised production lines also has permitted lower production times which translate into greater flexibility, speed of response to market demands and product freshness. Packaging plays an important role, acting as a protective barrier to prevent product deterioration from dampness. For this purpose, one of the latest breakthroughs for bread and bread substitutes is modified atmosphere packaging.

## INDUSTRY STRUCTURE

### Companies

The highest turnovers in the sector are in Germany, the United Kingdom, the Netherlands and France. From 1992 to 1993, turnovers rose slightly, while the number of people employed in the sector remained substantially stable. Only in Germany did this figure go up, and Germany is the country employing the highest number of workers in the sector. The Netherlands and the United Kingdom have fairly different turnover levels, as well as profoundly different production structures. The former has a turnover of 1 683 million ECU and high productivity, due to large facilities. The latter is distinguished by lower productivity, with a turnover of 3 387 million ECU and a work force of 44 500.

The highest production specialisation both in 1984 and 1993 was in Spain, where bread consumption is fairly high and where that of confectionery products is going up. This country is followed at a considerable distance by the Netherlands and Greece, which have similar values.

The structure of the sector is rather diversified in relation to product segments. The bread baking industry is still fairly fragmented with many small bakeries able to serve local areas. In some countries (e.g. Italy), this situation is caused by regulations which forbid the sale of products not baked in industrial ovens. In Germany and France on the other hand, it is possible to market unfrozen bread baked in distribution centres. This situation has permitted the expansion of the industry and the reduction of transportation costs, which have a big bearing

on the final cost of bread which is not otherwise expensive to manufacture.

The biscuit and bread substitute industries are in the hands of multinational companies and medium-sized firms operating at the national level. The breakfast cereals industry is strongly concentrated into both European and non-European multinationals.

Among the biggest multinational companies are: Unilever, Nestlé, Danone and Barilla in the confectionery sector; Barilla and Danone also operate in the bread substitute sector. In France, the principal firms in the confectionery sector are Danone, Patisserie St-Honoré; in the United Kingdom, the main companies are Unilever, United Biscuits and Allied-Lyons. In Italy, where concentration levels are fairly high despite the strong presence of local bakeries, the biggest company is Barilla. Finally, in Germany, the largest producers are Balhsen, Convent and Piasten for biscuits. In the breakfast cereals sector the European leader is the American firm, Kellogg's. In the bakery sector, the French leader is Jacquet and in the United Kingdom it is Rugenberger.

### Strategies

The growth of industrial baking companies occurs mainly through mergers and acquisitions. In 1993, thirty acquisitions took place which emphasise the strategies aimed at consolidation on the EU market and an ever greater expansion towards third countries. The high number of acquisitions in the United Kingdom can be attributed to a gradual process of industrial concentration by multinational companies.

The multinational companies in the sector, which often operate in several business markets, take advantage of a series of competitive factors like production know-how; new and completely automatic transport systems which permit just-in-time (JIT) distribution and thereby increase product freshness at retail outlets; and massive investments in communication and advertising.

Big efforts have been made to revitalise the biscuit sector through production differentiation policies based on high market segmentation and a wider range of goods on the market, in order to increase opportunities for consumption. At the same time, the presence of high scale economies in production has induced companies to manufacture under distributor brands in order to continue to promote production volumes.

In the industrial confectionery sector, companies have tried to favour greater penetration of products among families through modern distribution and the use of packaging which

makes consumption easier. In the biscuits segment, the principal innovations concern packaging, through individually wrapped products.

Manufacturers of cakes for holidays or special occasions are trying to escape from the seasonal nature of their products and to extend their product ranges to increase sales. Thus, they are tending towards diversification into related segments. The smaller companies, on the other hand, achieve better efficiency through subcontracting. The bread substitute sector also is distinguished by strong product innovation, while the bread-baking sector is less marked by product diversification.

### Impact of the Single Market

While the free movement of persons is not very important for the bakery sector (because the business is mainly concentrated at national level), the free movement of goods had a great impact, increasing trade, favouring product internationalisation, especially for fine bakery, and widening the range of products at disposal for consumer.

The general degree of competition inside the EU market increased due to a rise in import penetration characterised also by cheap products of low quality.

Too high sugar cost is perceived, especially for the fine bakery sector, as a constraint to competition inside the market. The reform of the sugar Common Market Organisation (CMO) and the reduction of export tariffs in non-EU countries are thus seen as the next priorities for the industry.

### ENVIRONMENT

The main environmental problems of the industrial baking sector relate to the extensive use of packaging which contributes to the increase of solid urban wastes that are not easy to recycle. In this regard, companies will be subject to strict regulations concerning the composition of packaging materials, aimed at favouring recycling.

### OUTLOOK

The industrial baking sector is nearing saturation of internal demand and consequently consumption in the main segments will tend to increase only marginally, if at all. Consequently, possible adjustments to the market situation are restricted to the ongoing product innovation to stimulate the curiosity of the buyer, communication, greater segmentation and the quest for new and unexplored markets and consumption opportunities.

Companies will therefore continue to grow not only in the EU, but also through acquisitions of factories in third countries. Competition within the EU is therefore likely to sharpen. The most lively markets will remain those of wholemeal products and breakfast cereals, as these are seen as extremely healthy and highly nutritional, and of biscuits and mid-afternoon snacks. For the latter, the polarisation between premium price products and distributor brand products will gain importance.

# Sugar

## NACE 420

Consumption figures for the sector are fairly stable within the EU, while production, in spite of slight fluctuations caused by weather conditions, is tending to increase as is reflected by the degree of self-sufficiency of the EU which, in 1993, reached 111 %. As far as production structures are concerned, the sugar industry comprises 84 companies operating generally on highly concentrated domestic markets. The approval of the GATT treaty provides for a reduction of 21 % of volume and 36 % of export subsidies by 2000 (based on the 1986-90 reference period).

### INDUSTRY PROFILE

#### Description of the sector

Around the world, sugar is made from sugar cane in tropical regions and regions south of the tropics, while sugar beet is the chief source of sugar in the temperate zones. The EU produces sugar almost exclusively from the processing of sugar beet. (Small areas of land planted with cane sugar exist only in the south of Spain).

The EU sugar industry is engaged in the production and refining of sugar (NACE 420). More specifically, this involves the extraction, purification and crystallisation of the sugar juice from sugar beet and molasses, as well as the refining of cane sugar. Also included in this sector is the manufacture of candied fruits. Additionally, the sugar industry is related to the production of ethyl alcohol, which is discussed in more detail in the chapter on alcohol and spirits.

France, Germany and Italy are the biggest sugar producers in the EU. In 1993, they accounted for about 65 % of the production of white sugar. The main indicators relating to the sugar sector show a fairly stable internal demand, though insufficient to guarantee the absorption of achieved production.

Due to a strictly regulated quota system, the EU has a surplus equal to only 11 %. This difference is exported to third countries under the quota regulation system. The quantity of sugar produced beyond the quota must be exported to third country at the world price.

Apparent consumption indicates substantial stability, though variations do exist between the years taken into consideration. Sugar production, on the other hand, is affected by weather conditions throughout the year. The surface of cultivated hectares can be adapted to the level of stocks.

1992 was a particularly good year, with the production of about 16 million tonnes of white sugar. In terms of exports, the largest volumes of trade occurred in the period 1984-1987, when the peak value of the decade was reached. This was followed by a slight downswing, though figures still tended to grow.

#### Recent trends

The area of land planted with sugar beet increased only slightly between 1984 and 1993, while the production of sugar has been increasing steadily since 1987. During the 1992/93 season, cultivated areas equalled 1 983 thousand hectares, with a drop of 6 % compared to 1984 figures. Of particular interest was the drop in Spain, which fell to 37 %. This can be attributed to the progressive adjustment of Community quotas.

The average growth rate of sugar production in the EU was approximately 1.2 % in the 1985-90 period. Production yields vary considerably between the EU countries, ranging from the average yield of 10 000 tonnes per hectare in France to figures of just under 6 000 tonnes in Italy, Spain and Ireland. The particularly efficient French beet-growing sector makes this country the top European producer of sugar, despite the fact that, since unification, Germany has the biggest cultivated land area. Big variations also exist within each Member State.

#### International comparison

The EU is the world's biggest producer of sugar. It is followed by India, China and Thailand. In Asia, most of the sugar produced is consumed on the domestic market, making this geographic area the biggest consumer of sugar. Then come Brazil, Mexico and Cuba. In Brazil, a greater balance exists between exports and domestic consumption, while Mexico and Cuba are more export-oriented.

Finally, the heaviest demand, after Asia and Europe, exists in the countries of the former Soviet Union. Currently, about two-thirds of the sugar produced in the world is made from sugar cane, while the remainder, which is on the upgrade, is made from sugar beet.

The biggest producers of cane sugar are, in order of importance: India, Brazil, Cuba, Mexico, Australia and the United States. Meanwhile, the major producers of sugar beet are the EU, the former Soviet Union countries, the United States and China (80 % of production).

On the global market, the 1993 season showed a gap between supply and demand equal to 300 000 tonnes. The 1994 season seemed to duplicate this situation. The reasons for this can be found in the drop in production in high-potential areas such as India, China, South Africa, Thailand and Cuba, due to adverse weather conditions. An exception to this pattern is Cuba, where the drop in production stems from the economic and social crisis existing in that country.

The EU shows a counter-trend, and in 1993 production actually increased. However, world prices should increase only slightly, considering that, for the time being, supply is guaranteed by stocks accumulated in previous years. The world price of sugar had remained fairly low on all world markets in 1992 also.

#### Foreign trade

The major importing countries of EU sugar are the OPEC countries, the EFTA countries and countries of the former Soviet Union. It is important to point out that the Community imports 1.3 million tonnes of sugar every year from Africa,

the Caribbean and the Pacific (ACP); from the overseas countries and territories (PTOM); and from India. And, it is forced to export a similar quantity of white sugar produced within the Community, the proceeds of which are taken charge of by the European Agricultural Guidance and Guarantee Fund (EAGGF). Over the last few years there has been a growing trend towards the transport of refined sugar to developing countries without local refineries.

## MARKET FORCES

### Demand

The demand for sugar inside the EU comes mainly from the food, chemical, pharmaceutical and animal feed industries. Over recent decades, the search has been intensified for other alternative uses of sugar, as the demand for sugar has been affected by the popularity of low-calorie sweeteners.

With regard to the food industry, sugar is prevalently used to make fruit juices, candy, chocolate, syrups, soft drinks,

jams and marmalades. The pulp of the sugar beet and molasses, a by-product of the sugar industry, goes to make animal feed. Molasses is also employed in the distillation, fermentation and production of citric acid.

Within the EU, about 30 % of production goes for direct retailing, though big differences do exist between the various countries considered. In particular, the figure goes from 44 % in Italy and 47 % in Portugal to 15 % in Holland.

### Supply and competition

The EU has the biggest production yields (7.5 tonnes/ha) compared to the USA (6 tonnes/ha) and the former Soviet Union (2.5-3 tonnes/ha). Within the EU, there are significant differences in terms of competitiveness between producers. In north-west Europe for instance, weather conditions enable using sugar beet varieties, giving higher yields and big energy savings during processing.

### Production process

Sugar processing involves the extraction, purification and crystallisation of juice. The production process is seasonal, concentrated in a period of three months - from August to October in Italy (45 to 80 days) and from September to December in Northern Europe (70-113 days in Holland, France, Germany, up to 114 days in the United Kingdom). Over the last 20 years, the concentration of activities in a dwindling number of plants has given rise to improvements in production efficiency and allowed the tripling of production per plant at the Community level. Significant improvements also have been recorded in terms of sugar beet yields per hectare, though differences still exist in terms of quality of raw materials, harvesting season and processing across Europe.

### INDUSTRY STRUCTURE

#### Companies

The sugar industry is strongly concentrated within individual domestic markets. Generally speaking, these markets are made up of a couple of large companies and a series of enterprises having only one production facility. In 1992, the top six Euro-

pean producers covered about 50 % of the EEC quotas, with peaks of 54 % for the top three producers in France and 83 %, again for the first three producers, in Italy (ISI and Eridania have been considered on an aggregate basis).

In Germany, one company, Sudzucker, controls about 40 % of German production and 75 % of Belgian production. Currently, there are 183 sugar refineries operating inside the Community, which belong to 84 sugar manufacturing companies. Following the closure of plants and acquisitions on the part of competitors, virtual production monopolies exist in the smaller countries. This is the case of Ireland, Denmark and Greece. In the United Kingdom and Holland, the entire domestic market is controlled by two companies. The high concentration in the sector is mainly attributed to the high economies of scale in the production and storage of sugar.

The number of sugar processing facilities has been on the downgrade for the entire 1982-93 period. The biggest drops have affected Italy, which has reduced the number of plants by about 50 %, Belgium (48 %), Holland (40 %) and Ireland (50 %). It is important to highlight the significant restructuring process under way in Germany, begun after 1990 with the annexation of the former DDR.

These cutbacks involved sugar refineries with production outputs below 5 000 tonnes of beet per day, while the number of larger plants (above 12 000 tonnes) increased. Differences between the various countries are significant: in Holland four plants out of six exceed this size, while in Italy, Denmark, Greece, Ireland, Spain and the United Kingdom, no refineries larger than this exist.

### Strategies

The strategies adopted by the enterprises in the sector aim at achieving greater production efficiency through the concentration of activities in a smaller number of plants; the selection of more qualified varieties of raw materials (especially in the countries of Southern Europe); the improvement of production quality through the introduction of ISO 9002 quality certification mechanisms; the search for lower energy-consumption; and environmentally safe production processes. The high economies of scale in the production of sugar are also leading to a gradual increase of concentrations through the acquisition of enterprises in the sector operating on the same domestic market and also on that of Eastern Europe. In 1994, four operations were successfully brought to a conclusion, mainly by French firms allied with other European enterprises. Little differentiation exists between the products made by the major enterprises in the sector, particularly raw cane sugar.

### Impact of the Single Market

The creation of the Single Market had almost no impact on the sugar sector.

The very limited nature of the impact is due to two factors. Sugar is a basic raw material which is used as an input by many other sectors, but the trade intensity of the sector is

very low. In fact most of the EU countries are self sufficient producers and sugar firms are mostly concentrated on domestic markets. On the other hand, the European sugar industry has already been regulated by a Common Market Organisation since 1968.

Finally, the sector is highly concentrated, not only on domestic markets, but also at European level. The market structure is substantially oligopolistic and, since the beginning of the nineties, no relevant changes in competition has been observed.

### REGIONAL DISTRIBUTION

The consumption of sugar in the EU was fairly stable between 1982-1993 at around 11.8 million tonnes; the EU share of world consumption did not vary much either, remaining at around 11 %. The biggest consumers are the United Kingdom, Germany, France and Italy, all with pretty uniform levels.

The main destinations of the products of the sugar-manufacturing industry are industry and direct retailing. The industrial sectors which use sugar and its by-products are the chemical industry, the food industry and the animal feed industry. The highest volumes of sugar employed in the food industry in 1992/93 were to be found in Germany, France and Italy. With regard to direct retailing figures, over the 1982-93 decade, the highest per capita consumption was recorded in Belgium and Denmark, with 47 kg, followed by Holland and Ireland with 39 kg and 38 kg respectively. The EU average per capita consumption remains on the whole fairly stable at around 33 kg, with minimum levels of 31 kg recorded in 1992/93.

It should be emphasised that France and Italy produce mainly for intermediate industrial uses of sugar, while Germany and the United Kingdom produce mainly to meet the demand for

sugar for direct retailing. Currently, the major enterprises, operating prevalently on the single domestic markets, are: Eridania Beghin-Say (936 million ECU in 1992 and 10 % of the European market), Tate and Lyle Sugars (650 million ECU in 1992 and 7 % of the market), Sudzucker, British Sugar (1 023 million ECU in 1992, 11 % of the EU market), Danisco, Ebro, Hellenic Sugar (208 million ECU and 2 % of the EU market) and Général Sucrière (973 million ECU in 1992 and about 10 % of the EU market).

## ENVIRONMENT

The sugar-manufacturing industry is actively seeking solutions to the considerable environmental problems related to it. These involve: the emission of fumes into the atmosphere, the reduction and recycling of solid waste (earth and calciums), and the reduction and treatment of industrial waste (industrial water). The noise level of plants is also taken into account. Altogether, the environmental measures taken by the European sugar industry have decreased the level of polluting emissions by 30 % in the last 10 years.

## REGULATIONS

The common organisation of markets in the sugar sector came into force in 1968. Sugar production is regulated by a quota

system, to guarantee the price and placing of limited quantities corresponding to quotas A and B. Quotas A and B represent the quantity of sugar, fixed for each Member State, which can be sold directly to companies of the Community and/or worldwide. All production above this quantity, C quota, cannot be marketed in the EU, but must be exported, without returns, on the world market.

However, a measure is envisaged to soften the effects of annual variations in production. This allows for the possibility to carry over a quantity of B or C sugar - up to 20 % of the production of quota A - to the quota A production of the subsequent year, keeping the sugar stored for 12 months.

Since the 1986/87 season, sugar producers bear the entire responsibility of financing the placement of exports, through production contribution from growers (60 %) and manufacturers (40 %) as listed below:

- a basic tax of 2 % on the intervention price for A and B sugar quotas;
- a tax of 37.5 % on the intervention price for B sugar quotas; and
- a complementary levy, to be paid if needed.

Each year, the Community fixes two categories of prices: that for sugar beet and that for sugar. For the former, the

base price is fixed as well as the minimum price for sugar beet to be processed into sugar A and B. For sugar, it fixes the indicative price for white sugar (indicatively 5 % above the intervention price); the intervention price for white sugar for deficient areas (currently Spain, Italy, Portugal, United Kingdom and Ireland) and for raw sugar; and finally, the threshold price for white sugar, raw sugar and molasses, to guarantee preference for the Community product.

For the sugar produced in Spain and Portugal, the realignment of prices was implemented beginning on 1 June, 1992 and 1 January 1993 respectively. These provide for transitory measures to support adjustment.

Emphasis should be placed on the adoption of Regulation 133/94, whereby the Council, besides regulating the 1993/94 season, introduced provisions concerning inulin syrup, a sweetener extracted from chicory, produced above all in Northern France, the Netherlands and Belgium. This sweetener, an alternative to sugar and isoglucose in some confectionery sectors, results in a lower consumption of sugar or isoglucose in the Community, with the consequent effects on the quantities of sugar for export at the expense of Community producers.

The coming into force of the GATT agreement for the sugar sector is expected for July 1, 1995. The accord mainly will affect exports, which have to be reduced by 21 % in terms of quantities or/and by 36 % in terms of value of global refunds, compared to the average quantities exported during the 1986-90 period. Thus, the implementation of the GATT agreement could lead to a slight reduction of the A and B quotas.

---

## OUTLOOK

---

An increase of research efforts to find lower energy-consuming production technologies, thereby reducing production costs, is expected. For the same reason, an intensification is expected of acquisitions, especially of enterprises operating on respective domestic markets and on those of Eastern Europe. Further, an increase is expected in competition on Community markets following the drop in exports after the approval of the GATT treaty. Finally, an intensification of efforts to find alternative uses for sugar and its by-products in the detergent, pharmaceutical, chlorine and paint industries, etc., is anticipated.

# Cocoa, sugar confectionery and ice cream

## NACE 421

Industry globalisation and concentration continues to be the dominating trend in the cocoa, sugar confectionery and ice cream industry. In Europe most production is concentrated around a handful of major multinationals which supply a wide range of products. The most important sector is that of cocoa-based products, thanks to changes in eating habits favouring snacking, while the traditional seasonal nature of cocoa-based products and ice creams is tending to disappear, as these become associated with multiple-use functions. If the current trends towards healthy eating continues, they will, generally speaking, have a strong impact on the industry in the future.

### INDUSTRY PROFILE

#### Description of the sector

The cocoa, sugar confectionery and ice cream industry comprises a wide range of products showing steady growth in the international market as well as generally high margins. Cocoa includes final products derived from the processing of chocolate such as chocolate bars, pralines and boxed assortments. Sugar confectionery includes sweets like chewing gum, pastilles, jellies, nougats and toffees. Finally, ice cream, for which different regulations defining content exist within the EU, includes products manufactured from milk, butter or cream, which may or may not contain vegetable fats or oils, depending on the country where it is made.

The industry has a value added of 7 434 million ECU, most of which is contributed by Germany, the United Kingdom and France. The larger markets absorb most cocoa-based products, which represent over 70 % of the sweets sold in the United Kingdom and 60 % in France.

#### Recent trends

The main economic indicators show a growth in production and consumption in real terms concentrated between 1987 and 1991, with a fluctuation in the two subsequent years. A substantial stabilising of growth is projected for the coming years. The balance of payment figures were positive for the entire decade under consideration with a faster growth rate between 1988-90 and 1991-93. This pattern was sustained by a large increase in exports over recent years and by a contemporaneous drop in imports in value terms. Employment figures dropped on the whole, particularly since 1986.

As far as sugar confectionery products and cocoa-based products are concerned, Spain and Germany experienced the biggest consumption growth rates between 1988 and 1994, while there was a fall in the United Kingdom and overall stability in Italy and France. France also showed a big increase in the consumption of ice cream, which augmented its market share in value terms by 50-60 % in most EU countries except Italy, the United Kingdom and Greece.

Production growth rates, which are not particularly strong overall, show a drop between 1992-93. This decline was steepest for apparent consumption, which was negative at that time. A small growth in production can be attributed to exports outside the EU which grew over the period by 21 %. Between 1984 and 1993, the importance of exports for the balance of

Figure 1: Cocoa, sugar confectionery and ice-cream Value added in comparison with related Industries, 1993

Source: DEBA

trade increased considerably and is currently three times the value of imports.

#### International comparison

At current prices, the EU is the number one producer of cocoa-based products, sugar confectionery and ice cream in front of the USA and Japan. Between 1984-93, the USA experienced a drop in production value due to a gradual fall in prices, a pattern not experienced in the EU or Japan. In fact, these countries are distinguished by a strong growth rate which has caused production to double in Japan and to increase by about 68 % in the EU. Conversely, Japan experienced a drop in imported products in 1993 equal to 6.4 %.

#### Foreign trade

The industry is mainly concentrated on the European market. Nonetheless, foreign trade is also significant, as is evidenced by the level of imports, which is around 2.5-3 %, and exports, which reached around 6-8 %.

Source: DEBA

In 1988, exports outside the EU went prevalently to the EFTA countries, the USA, Canada, Japan and the Canary Islands. Since then, the evolution of export structures has led to a reduction in the shares of the USA and the EFTA countries and the emergence of Russia and Poland.

Meanwhile, imports in 1988 chiefly came from the EFTA countries, the major African cocoa-growing countries and Brazil. From 1988 to 1994 there was a consolidation of imports from the EFTA countries, a reduction of those from the Ivory Coast and Ghana and the appearance of Malaysia and the USA.

In 1993, cocoa production fell to levels substantially below those of the early 1990s, causing a general increase in world prices. This situation essentially was advantageous to the 13 major producer countries which account for 90 % of cocoa production. Among the most important are the Ivory Coast, Brazil, Ghana and Malaysia.

## MARKET FORCES

### Demand

The industry as a whole shows extremely diversified consumption habits within the EU. Despite this, the consumption of sugar confectionary and cocoa products has, in general, gone up over the years following the big changes taking place in eating habits throughout the EU. In particular, shifting meal patterns have created trends in eating such as snacking and 'grazing', which have increased confectionary and cocoa product sales. The cocoa-based product market is also strongly affected by seasonal variations, with higher sales rates during the winter months and major holidays (Christmas and Easter).

In the sugar confectionary segment, chewing-gum consumption is higher in France and Italy than in the United Kingdom and Germany, where a higher proportion of caramel and toffee is eaten. The markets which have recently evidenced the biggest growth rates are made up of products with reduced sugar

**Figure 4: Cocoa, sugar confectionary and ice-cream

Destination of EU exports**

Source: Eurostat

content, based on artificial sweeteners. This trend predominates especially in the gum market.

Ice cream is very much a seasonal product in many EU countries, though in more advanced consumption markets (e.g. France) ice cream is being promoted as a dessert to be eaten at the end of meals all the year round.

General trends in EU food consumption in the north and south underline the peculiarities of the demand in the sector, which is concentrated in terms of apparent consumption in Germany (7 458 million ECU in 1993) and the United Kingdom (5 253 million ECU in 1993). Taking a closer look, and considering per capita consumption for individual sectors, we notice that consumption is generally higher in the northern countries of the EU. For example, the per capita consumption of chocolate is between 6.4 and 8.2 kg a year in Germany, the Netherlands, the United Kingdom, Ireland, Belgium and Denmark, while it is below 2 kg in Italy and Spain.

Sugar confectionery presents the same characteristics, with France, Italy and Spain having a per capita consumption equal to about half (2.2-2.8 kg) that of the northern countries of the EU. The range of the per capita consumption in the ice cream segment goes from 13 litres per year in Sweden to 5.7 litres per year in France.

### Supply and competition

The industry of cocoa, sugar confectionery and ice cream shows a progressive increase in productivity within the sector, with growth rates superior to those affecting labour costs. Over the years, there also has been a drop in total unitary costs with a consequent increase of the gross operating rate. In fact, from 1984, this indicator went up without interruption until 1990, and after a drop in the two following years, returned to 1990 values in 1993.

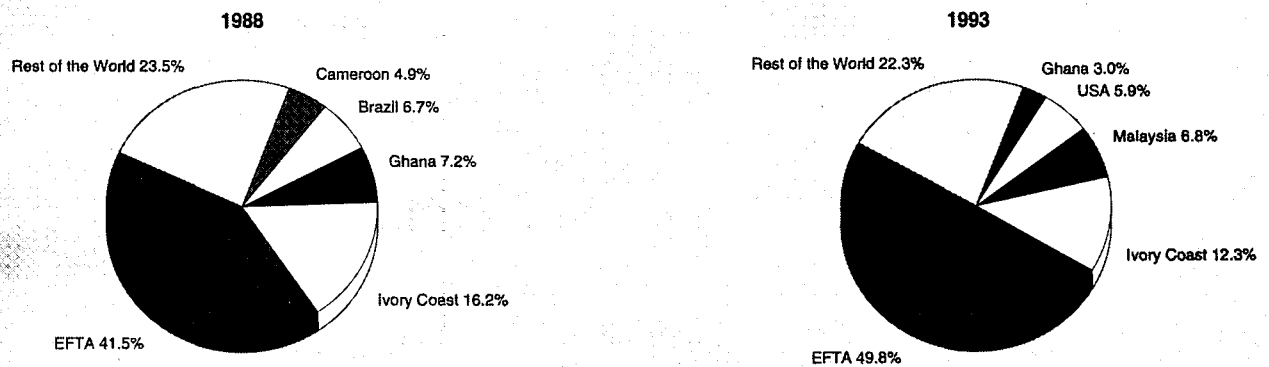

### INDUSTRY STRUCTURE

#### Companies

Cocoa, sugar confectionery and ice cream is an industry distinguished by high concentration of a handful of multinationals. In this market, the presence of small enterprises is tied to the existence of market niches relating to seasonal and/or holiday products.

In the segment of cocoa-based products, there is a high degree of concentration in the United Kingdom where, in 1992, 83 % of the market was controlled by three companies (Cadbury, Nestlé and Mars). On other EU markets, market shares held by major multinationals tend to be lower, as is evidenced in

Italy where, in 1992, the top three companies (Nestlé, Ferrero, Jacob Suchard) held 60-65 % of the market of chocolate bars. In France, Cadbury, Nestlé and Jacob Suchard cover about 60 % of the chocolate market. The situation is different in Germany, where about 35 % of chocolate blocks and bars are marketed under distributor brands.

The sugar confectionery sector shows a much higher degree of fragmentation, and a larger role is played by smaller, local manufacturers, often operating in specific niche markets. The highest levels of concentration are to be found in Italy, where the top three companies cover about 50 % of the market. In France and the United Kingdom, the market shares of the top three manufacturers in 1992 amounted to 55 % and 45 % respectively. In Spain and Germany, these figures are considerably lower (approximately 30 %). The most important companies operating in the sector are Wrigley (USA), Nestlé (CH), Cadbury (UK), Jacob Suchard (CH) and Mars (USA), which together control about 35 % of the EU market.

Finally, the ice cream sector also shows high levels of concentration. Unilever and Nestlé are the leading multinationals in the sector, covering about 55-60 % of the market in the major consumer countries.

## Strategies

The industry was characterised by a high number of acquisitions during the 1993-94 period: 28 operations took place involving mainly multinational companies, which aimed at widening markets towards the East European countries and consolidating positions already won on domestic markets.

The high degree of concentration of distribution circuits which distinguishes European markets has increased the purchasing power of retailers so that margins in these countries average

between 8-12 % compared with the USA, where a fragmented structure allows for higher margins of 15-16 %. These discrepancies in margins have ensured that most USA multinationals have been more contented to concentrate their activities in domestic markets, while EU multinationals have been interested in acquisitions and commercial agreements in the USA. Looking at things from a growth perspective, no trend towards greater or less specialisation within the EU can be

seen, though the variations of indices for Greece (+62 %), Denmark (+40 %) and Italy (+31 %) seem significant.

To promote growth in the cocoa market, manufacturers have introduced single and mini portions and emphasised their high nutritional value. Also evident in this market is the availability of increasingly more sophisticated confectionery, as manufacturers seek to differentiate their products and gain value added on basic lines. At the same time, competition has brought prices down in many markets. This trend was particularly strong in 1993, when along with competitive pressure, there was a drop in the purchasing power of consumers in many EU countries, which highlighted the importance of price to

purchasing decisions and the increase in the price of cocoa on the international market.

The industry on the whole is distinguished by a high rate of product innovation as is shown by the presence in the United Kingdom of a very low concentration of brands, in contrast with the generally large market shares controlled by the major multinationals. In the ice cream segment, the strategies adopted to promote sales are based on a growing segmentation of markets, anxious to meet the preferences of children, families and singles alike.

### Impact of the Single Market

The creation of the Single Market had a globally positive impact on the cocoa, sugar confectionery and ice creams sectors. In particular it stimulated trade intensity and has increased competition inside the market. Also mergers and takeovers activities has been more intense after the implementation of the Single Market.

However, internal barriers still remain. In particular they are linked to a lack of common interpretation of the labelling and packaging legislation. The high sugar cost is also perceived as a heavy constraint to competition.

External barriers are linked to high tariffs on EU exports. The reform of the sugar Common Market Organisation (CMO) and the reduction of tariffs on EU exports are priorities for the industry.

### REGULATIONS

The basic directive which lays down the rules and definitions for cocoa and chocolate products (i.e. their composition and manufacturing specifications and the names which shall be used in trade) is Directive 73/241. This directive is the subject of a draft proposal within the framework of the revision and rationalisation of the vertical directives initiated at the summit meeting held in Edinburgh in December 1992, with the aim of limiting the texts of the directives to the elements essential for the free movement of goods in the EU.

Directive 93/102 on food labelling for categories of additives affects the sector inasmuch as it removes the need for the qualifier 'artificial' to accompany the term 'sweetener'. Trade in products in conformity with the directive is to be ensured by January 1, 1995; prohibition of trade in products not in conformity will apply as of June 30, 1996.

With regard to the ice cream sector, a European Code of Practice was agreed to by the industrial manufactures in 1991, in order to maintain fair competition and to ensure circulation of the products. Mention also should be made of Directive 91/238, already implemented in all Member States, which provides for the exemption from the lot marketing of individual portions of ice cream, and also Directive 89/395, which exempts ice cream products from the date marking.

### OUTLOOK

A general increase is expected in the consumption of cocoa products, sugar confectionery and ice cream over forthcoming years in most EU countries. The products which will show the greatest growth rates are those with a low-calorie content and high nutritional value. An increase of acquisitions is expected, aimed mainly at consolidating positions on single domestic markets and finding new market outlets.

# Compound feed

## NACE 422

In the compound feed sector, industrial production rose slightly in 1993 with a tendency for production and apparent consumption at current prices to level off at previous year values, while exports underwent a significant upswing. In the sector of animal feed for livestock farms, price-based competition ate away at the profit margins of companies; in some weaker-currency countries, profitability was also affected by the cost of raw materials. With regard to pet food, the picture is different: though percentage-wise it counts for only a small share of the total sector by volume, it represents about 17 % of the total value. It is a very attractive segment then, dominated by just a few large multinational companies and with strong barriers to entry.

### INDUSTRY PROFILE

#### Description of the sector

This sector's activities include the production of compound feed for livestock farms, such as feed for poultry, pigs, dairy animals, meat cattle and other animals (horses, rabbits, fish, sheep and goats), as well as the pet food subsector, which makes products for domestic animals. The final products in the animal feed subsector are complete feeds (including milk-substitute feeds for calves), and complementary feeds, such as integrators and premixes (i.e. a combination of vitamins, mineral salts and amino acids which can be mixed with cereals and grains), while the pet food subsector is divided into dry and wet feeds.

The major producers of compound feed in the EU are France and Germany, which are also the principal producers of meat. Spain and the Netherlands are the main producers of pig feed, milk-substitutes and dry pet food.

#### Recent trends

In 1993, apparent consumption and production at current prices stabilised at around the previous year's figures, continuing a levelling-off trend, which has seen only slight fluctuations since 1990. In the 1984-90 period, patterns were fairly differentiated. In fact, in 1986 internal indicators dropped compared to previous years, while between 1986 and 1989, there was an upswing - with peaks of 9 % in 1989 - which stopped in 1990.

The trade balance shows an initial downswing phase up to 1987, followed by a two-year period of slight growth and a strong growth trend starting in 1991, with the 1993 balance exceeding that of 1984. Exports thus rose while employment figures dropped by 2.3 %.

The Member States which contribute most to the value added in the EU are France, Germany and the United Kingdom.

In 1993, there was a 2.7 % increase in industrial compound feed production compared to the previous year. Pig feed grew at rates above that of the sector as a whole (4.1 %), while there was a 2.0 % increase for cattle feed and an increase of less than 1 % for poultry feed. Pet food also grew in line with the average for the sector.

There were significant differences in production growth rates between the different countries. The major producer (France) grew by 6.7 %, while some of the minor producers underwent even stronger growth (with a peak of 11.7 % for Ireland). Spain was the only country which presented a significant fall, equal to 4.0 % (Source: FEFAC)

Figure 1: Compound feed  
Value added in comparison with related industries, 1993

Source: DEBA

The 1984-89 period was marked by average real annual growth rates of production and apparent consumption equal respectively to 3.6 % and 3.9 %. In that same period, a high average real annual growth rate affected imports from countries outside the EU (9.35 %) while there was a drop with regard to exports to countries outside the EU (-2.19 %).

The 1989-1993 period showed average growth rates of production and consumption equal to around 1 %, while exports and imports grew by 9.43 % and 3.84 % respectively, much different from those recorded in the 1984-89 period. Generally speaking, average growth rates of production and apparent consumption and exports to countries outside the EU during the entire 1984-93 period showed very similar figures, near 2.6 %. With regard to imports from countries outside the EU on the other hand, the average growth rate equalled 6.9 %.

Starting in 1986, production of compound feed at constant prices showed a positive growth trend (except for 1991). Compared with the trend shown for the entire manufacturing industry, growth in the animal feed sector is higher overall, excepting the 1985-86 and 1990-91 periods.

Source: FEFAC

**Figure 3: Compound feed**  
**Production and employment compared to EU total manufacturing industry**

1994 are Eurostat estimates.  
 Source: DEBA

Looking at employment patterns in the two sectors we have the following picture: from 1984 to 1986, the fall in the compound feed sector was greater than that of the manufacturing industry as a whole; from 1986 to 1988, there was a growth in the compound feed sector and a drop in the manufacturing industry; from 1988 to 1990, growth was recorded in both sectors; and from 1990 to 1994, there was a drop in the employment rate in both sectors, although it was greater for the manufacturing industry.

**International comparison**

In an international comparison of production at current prices, the EU confirmed its lead role and, at the same time had shown improved figures over 1984 by 1993. On the other hand, the USA and Japan underwent a slight drop in production in 1993 compared to 1984.

An analysis of production at constant prices shows a substantially similar pattern for the EU and the USA, while the

trend in Japan was considerably different. Both the EU and the USA, though each experiencing consistent growth overall, vied for and won the lead role in different years over this period. The EU had a slightly stronger growth rate compared to that of the USA in 1984, in 1988-89 and in 1992. Meanwhile, Japan experienced a steep drop in its growth rate between 1984 and 1987 - from 150.6 to 96.9 - and a slight upswing from 1987 to 1989, after which the growth rate fell gradually.

**Foreign trade**

The balance of trade figures were active from 1984-93; after a drop in exports greater than that in imports in 1990, the 1991-93 period was marked by the strong growth of exports over imports. The export/import ratio underscores this trend, passing from 1.18 in 1990 to 1.74 in 1993, thus approaching the ratio recorded in 1984.

In 1993, almost one-half of European exports of animal feed went to the former EFTA countries, Libya, the USA, Poland

**Figure 4: Compound feed**  
**International comparison of production in current prices**

Source: DEBA

**Figure 5: Compound feed**  
**International comparison of production in constant prices**

Source: DEBA

**Figure 6: Compound feed  
Destination of EU exports**

Source: Eurostat

and Thailand. Compared to 1988 there was an eight per cent drop in exports to the EFTA countries in 1993 and a slight increase in Libya's (1.5 %), enough to allow it to surpass the USA. The rest of the world's share also went up.

As far as imports are concerned, there was a radical geographic swing as regards EU trading partners. In 1988, more than a third of EU imports came from Chile, but in 1993, the importance of this country fell drastically, to under 10 %. Thus, in 1993, the USA took the lead, with more than one-third of all EU imports. Other countries which have increased their shares were the EFTA countries, Peru and Thailand (which, along with other Asian countries, e.g. China and Indonesia, supplies manioc).

The export/production ratio showed a decline from 1984 to 1987, after which the trend reversed. Maximum growth was recorded in 1993 (4 %). Generally speaking, the import/consumption ratio presents a slight growth trend, interrupted by levelling-off years in 1987, 1990-91 and 1993.

## MARKET FORCES

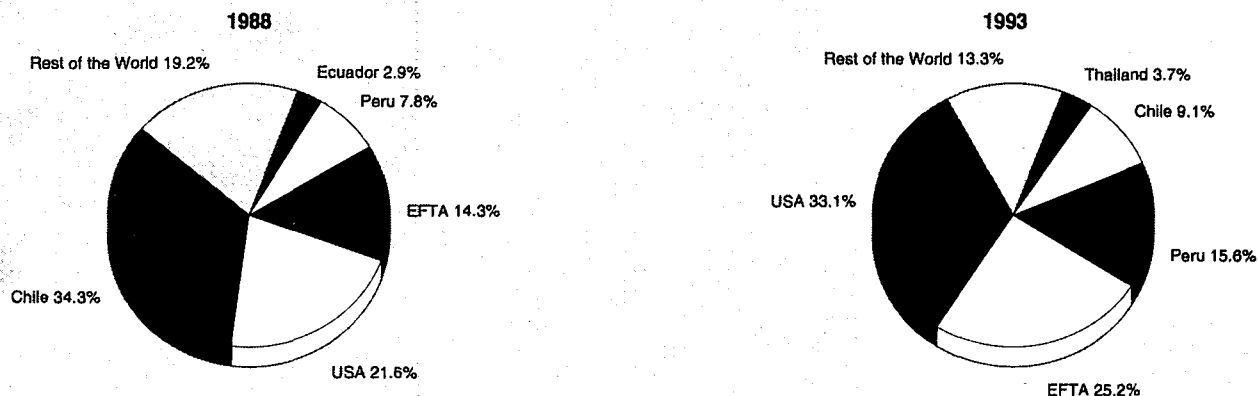

### Demand

Demand in the compound feed sector has fallen off slightly, continuing a trend which has been underway for some years now. The drop in the cattle sector, also affected by production limitation measures such as the Common Agricultural Policy (CAP), was not offset by increases in the pig and poultry feed sectors.

Active on a final market which is rather sensitive to price, the compound feed industry is extremely keen on the use of cost-advantage raw materials. In some cases, however, in order to maintain competitiveness, the industry has to partially internalise raw material price increases, acting as a deflationary factor. A case in point is Italy, a country where, despite a hike in the price of fodder grains (particularly maize) of around 13 % (1993 compared to 1992), the prices of industrially-manufactured compound feed increased by 8-9 %.

The principal raw materials employed are cereals, which represent 30 % of consumption, cakes and meals (25 %) and the by-products of the food industry (15 %). The biggest cereal consumers are Spain and Italy. The Netherlands, although

among the major producers of compound feed, uses relatively little, as manioc is preferred.

With regard to the pet food sector, demand is sensitive not only to price but also to perceived quality and brand name. The rise in social importance of pets makes this sector particularly interesting. On the major European markets (the United Kingdom, France, Germany and Italy), there was a 19 % volume increase and a 28 % value increase over the 1988-1993 period. Significant increases in demand could occur on national markets, e.g. Italy, where the penetration rate of pet food is still far below the European average.

### Supply and competition

The EU is the number one producer of animal feed, followed by the USA (at current prices). In 1993, compound feed production in the EU amounted to 115 011 million tonnes, of which 36 % was pig feed, 30 % cattle feed and 28 % poultry feed.

Pet food production accounts for about 3 % of compound feed production. What makes this segment particularly important is that the value of pet food production accounts for about 17 % of the overall value.

The labour productivity index underwent stable growth from 1984 to 1993, with the exception of 1991, when there was no variation. Labour costs also show a steady upswing, excepting 1992 and 1993. The gross operating rate went up

**Table 7: Compound feed

slightly from 1984 to 1989, with a steep fall in the subsequent two-year period, and an upswing in the 1992-93 period.

## INDUSTRY STRUCTURE

### Companies

The animal feed sector for livestock farms is highly fragmented, with very few large companies and numerous small-capacity firms located in the areas with large concentrations of farms, so as to keep transportation costs low. Such fragmentation can be exemplified by the fact that the leader firms (e.g. Provimi-Group Béghin Say and the French group Cargill) have a market share of several percentage points.

There were 4 157 production facilities in the EU in 1993, about 1 % less than the previous year. Italy is the country with the least-intensive concentration of production structures. In fact, this country has 25 % of all EU facilities, while production volume equals 11 % of the EU total. Greater concentration rates are to be found in other major producer countries, in particular the Netherlands, France and Germany.

The pet food sector is concentrated into just a few multinational firms: Mars (I), Quaker (UK) and Nestlé (CH), flanked by a number of domestic leaders like Dalgety (UK). To stay competitive, these companies invest heavily in R&D, communication and marketing policies. The size of a company is also important for acquiring contractual leverage with respect to large distribution groups. In addition, firms special-

ising in animal feed for livestock farms and food enterprises process 'wastes' to achieve diversification of production and get onto the pet food market also exist on some of the domestic markets.

### Strategies

Competition in the field of animal feed for livestock farms is very strong, and this tends to have a big effect on price, making producer profit margins precarious. For this reason, the firms with greater product development resources seek a differentiation strategy, e.g. specialising in integrators and pre-mixes (the segment of the animal feed industry with the highest value added), or by innovation through high-protein content products, such as animal-based meals.

Competitive factors for pet food are product innovation and marketing strategies, a large product range to satisfy specialised target and niche markets, and the ability to exploit sales-channel synergies between food and pet food.

The compound feed sector does not appear particularly dynamic in terms of acquisitions and mergers. There were four major acquisitions in 1993 and seven in 1994. Dalgety (UK) is the only group to have made more than one acquisition. With rare exceptions, acquisitions in the sector always have been performed by EU firms.

The countries most specialised in the production of food for animals are Portugal and the Netherlands, where production ratios in compound feed as compared to the manufacturing

Source: DEBA

industry in 1993 were equal to 2.82 and 2.80 respectively. Spain follows with 2.16, while Ireland, Belgium and France have ratios between 1.43 and 1.15. All the other EU countries have ratios below 1.

A comparison between figures expressed by the individual countries in 1984 and 1993 shows that ratios have grown only in Greece, Spain, France and Ireland. All the other countries - except Italy, which remained stagnant - had 1993 ratios below those of 1984.

### Impact of the Single Market

The impact of the creation of the Single Market on the compound feed sector, has been overall positive, but small. Firstly, the sector is mainly regulated by the Common Agricultural Policy (CAP) and secondly the sector is characterised by a low trade intensity. Transport and distribution are indeed very expensive, so production takes place regionally.

The Single Market only had a limited impact on input costs and on the geographical distribution of production plants, which continue to be concentrated in very rural areas, close to raw material production or to ports.

The remaining internal barriers are linked to phytosanitary and veterinary legislation's that differ across countries. The next priorities for the industry are related to the CAP reform and the GATT agreement, and to the harmonisation of phytosanitary and veterinary legislations.

### ENVIRONMENT

The animal feed industry can be considered a low environmental impact activity, given both the small quantity of waste to be disposed of, and the scarcity of harmful fumes released into the atmosphere, for which simple and effective technical solutions are available. Furthermore, the industry offers a positive contribution to the environment through the recycling of a significant quantity of residue materials from other production cycles of the food industry.

### REGULATIONS

The Community has regulated several aspects of the sector, with the aim of harmonising the legislation among the Member States in relation to the marketing of compound feeds (Directive 90/44), hygiene standards (Directive 92/117), Community test methods for the official control of animal feeds (Directive 93/117) and the composition of feeds (Directives 90/167, 91/357, 92/97 and 93/113).

More specifically, some of the directives mentioned concern:

- Directive 92/117: deals with specific zoonosis protection measures and the fight against zoonotic agents in animals and in products of animal origin to avoid outbreaks of infection and food poisoning. It sets the conditions for collecting data on zoonosis and zoonotic agents and provides for controls on poultry feed to identify contamination sources of salmonella in poultry and to establish procedures to secure the adoption of correct manufacturing practices.
- Directive 90/167 establishes the provisions for the preparation, marketing and utilisation of animal feeds medicated in the Community.
- Directive 93/74 regulates dietetic animal feeds - compound feeds for animals which, due to their particular composition or special manufacturing procedures, are different from other standard feeds and medicated feeds and are thus presented as products with specific nutritional requirements.

Finally, the presence of bovine spongiform encephalopathy (B.S.E.) has sparked a discussion among Community organisations on whether it might not be a good idea to prohibit the use of meals of animal origin for feeding cattle, as well as strengthen precautions for their preparation and use.

### OUTLOOK

Demand is expected to remain stable over the next few years, especially considering the strong pressures on the zootechnical sector both on international and domestic markets. Export patterns recorded in 1993 can represent an opportunity for EU firms. Also advantageous to the sector could be the drop in prices of various raw materials, as provided for by the reform of the CAP, especially as regards the cereals sector which provides the principal raw materials used to make compound feed.

To recover profitability, firms could also pursue differentiation strategies and specialise in greater value added products like integrators and mixes, thereby improving product quality. Given the nature of compound feed as a commodity, however, product differentiation remains a niche strategy.

The pet food sector presents attractive growth prospects, especially in those countries where the rate of penetration is still below the European average. The strong competition keyed to winning over consumers and the particularly aggressive marketing strategies of the large distribution chains play in favour of the big market leader groups and an increased level of concentration in the sector.

Written by: NOMISMA

The industry is represented at the EU level by: European Feed Manufacturers Federation (FEFAC). Address: Rue de la Loi 223, B-1040 Brussels; tel: (32 2) 230 8715; fax: (32 2) 230 5722.

# Miscellaneous food products

## NACE 417, 423

The pasta sector has shown a slower growth trend which particularly affected dry pasta, although there has been an ongoing concentration in the hands of large multinational companies, as well as considerable expansion abroad. The internationalisation and industrial concentration is a strategic goal for other food products of the industry as well.

### INDUSTRY PROFILE

#### Description of the sector

The miscellaneous food sector comprises pasta (NACE 417) and products like coffee, tea, vinegar and other dressings, dietetic sweeteners, baby foods and cake mixes (NACE 423). These products differ in terms of market demand, supply, industrial structures and market strategies.

#### Recent trends

All in all, the economic importance of the sector in terms of value added can be compared to that of more important industries like meat and industrial baking. These values can be traced back to products having a high degree of differentiation, distinguished by extremely different and often complex processing systems.

The geographic distribution of production and value added of the pasta subsector in 1993 was strongly concentrated in Italy which accounts for about two-thirds of total world production. This country is followed by France, Germany and the United Kingdom. With regard to other products, Germany tops the list followed at a distance by France, Spain and Italy.

#### Pasta

In 1993, a stagnating demand was accompanied by a fall in the total supply. The bigger producers, which find an alternative to the internal markets outside the EU and which had increased export levels already, have intensified their inter-

Figure 1: Miscellaneous food products  
Value added in comparison with related industries, 1993

(2) NACE 423.  
Source: DEBA

nationalisation process. In 1993, however, after a period of exceptional growth, exports began to show signs of abating.

With respect to employment figures, there was a downswing during the entire 1984-93 period, which reflected the pattern of the EU manufacturing industry as a whole. The pasta market is on the upswing, thanks to an increased demand for fresh and filled pastas which are very popular in France and Germany. Spain and Greece on the other hand, are slow growth markets in terms of volume.

#### Other products

The main indicators relating to miscellaneous foods besides pasta are all extremely positive, thanks to both a domestic and foreign demand which bolster production and employment throughout the sector. For the entire 1984-93 period, the manufacture of these products followed a pattern of strong growth

Source: Eurostat

which had a positive effect on employment. In fact, these increased by 21 % up to 1992, after which there was a drop.

The EU imports coffee and tea, which are then processed in Europe, mainly for EU consumption. The EU imports about 1.8 million tonnes of green coffee, which represents approximately 40 % of world production. A structural feature of the coffee sector is the wide fluctuation of market prices due to shock waves which hit supply, tied to weather conditions, which often determine steep falls in production. As regards tea, only about 45 % of the world tea production is exported by tea producing countries. The EU imports 24 % of the available products, i.e. about 270 thousand tonnes, of which 175 thousand tonnes go to the United Kingdom.

The total production of vinegar appears stable. Alongside the countries which are increasing their production levels (including The Netherlands, which has tripled its production volume), there are others where production is dropping. The biggest producer of vinegar in the EU in 1993 was Germany, followed by France, the United Kingdom and Italy.

### International comparison

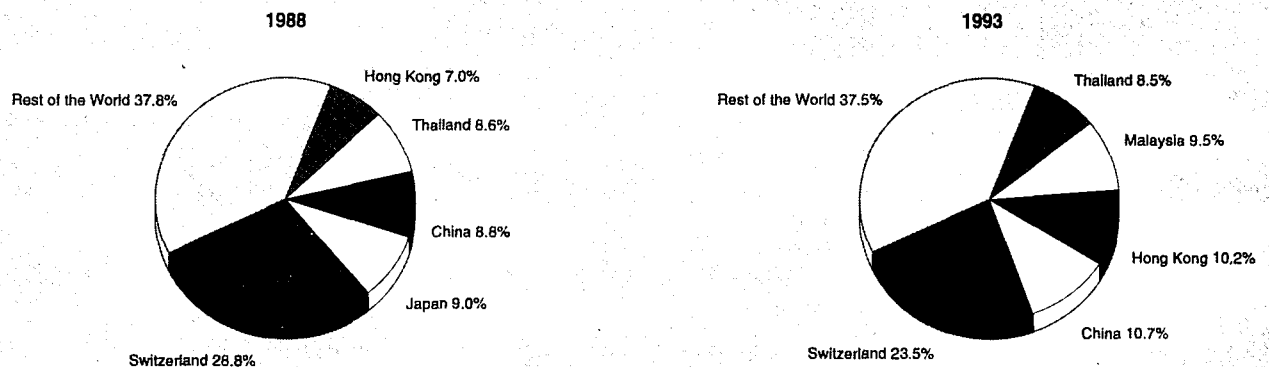

#### Pasta

The biggest producer of pasta in the world is the EU. In 1993, Italy produced about 2.5 million tonnes of pasta, mainly for export. Other important world producers are France and the USA. The South of Italy has the biggest per capita consumption at around 40 kg per year. Consumption levels in many countries outside the Community also have touched high levels. Venezuela has a per capita consumption of 12 kg followed by Switzerland and the USA with 9 kg each and 7 kg in the former Soviet Union.

#### Other products

Green coffee is produced chiefly in developing countries and is exported to the industrialised ones. The biggest world supplier is Brazil, followed by Colombia, which together grow 45 % of total world exports. Recently, African and Asian producers have gained in importance. Among these, Indonesia ranks third in world production. Yet another important growing area is Central America (e.g. Mexico and Guatemala). Since 1991, exports of ICO (International Coffee Organisation) countries have touched an annual average of 75 million 60 kg bags (equal to 45 million quintals). The most important va-

ieties are Arabica, which accounts for 75 % of world production, and Robusta, with a stronger flavour and a higher caffeine content. The first is grown above all in Central America (Colombia and Brazil), but also Kenya and India; the second comes from other parts of Africa and Indonesia. Importer countries are above all Western Europe and the USA, but over the last thirty years, the demand from developing countries has increased, touching 30 % of apparent world consumption. The top world producer of tea is India with 745 thousand tonnes, followed by China, Sri Lanka and Kenya.

### Foreign trade

#### Pasta

Foreign trade in the pasta subsector was on the upswing for the entire decade under consideration. In particular, figures showed a progressively improving trade balance and a bigger growth of exports over imports, as evidenced by the exports to imports ratio which peaked in 1992 without significant changes in price levels. 1993, on the other hand, was an anomalous year, inasmuch as the value of exports dropped slightly, due to a sudden fall in prices (with a fall in the terms of trade index which hit rock bottom) and a drop in the quantity of traded goods. In fact, the economic crisis which hit the EU caused a reduction in traded quantities due to greater price discrimination by consumers. Producers responded by cutting profit margins and prices.

Among Member States, the major importers are Germany, France and the United Kingdom, attracted by pasta made in Italy, which has a reputation for good quality. It should be noted, however, that the United Kingdom, like The Netherlands, has a bigger share of imports from third countries, especially rice from Asia. Alongside Italy, Belgium and France are the countries with the highest and still growing export

figures, while Spain and Greece reveal a substantial 'closed shop' attitude. In Italy, pasta is made only from durum wheat, because of laws which prevent the production of common wheat pasta, though imports of it are allowed. In France and Belgium, pasta is chiefly made from common wheat.

#### Other products

An active balance of trade exists for other food products in this category as well. In fact, over the 1984-93 period, figures went up more than five-fold: exports followed the same pattern as imports but reached higher levels. In 1987, the export/import ratio, having exceeded the value of 2, underwent a slight slowdown. Roasted coffee imports continued to rise, despite a certain amount of stability with regard to demand. The major importers of the EU were Germany, Italy and France.

EU tea imports followed a fluctuating pattern, but generally tended to fall. From 1992 to 1993, however, there was a slight growth. Numerous countries are cutting back tea imports including Belgium, The Netherlands, Greece and the United Kingdom. The biggest share of tea imports goes to the United Kingdom (70 %), while the rest was distributed between the other countries, including Germany, France and Ireland.

## MARKET FORCES

### Demand

#### Pasta

The extensive pasta market in the EU - which is made up of pasta of all kinds - can be attributed to the fact that the market perceives this product as inexpensive, quick to prepare and nutritional. The internal demand for pasta, after a lengthy period of fairly sustained growth, not only in terms of value but also in terms of volume, began to fall in 1991 due to the fact that a saturation point had been reached in many major European markets. This was particularly true for dry pasta, while niche products like fresh pasta, filled pasta and pre-packed, ready-to-eat pasta dishes continued to increase their market share, all the while representing a segment of limited size. European consumers consider fresh Italian pasta to be of superior quality, recognise its different regional characteristics and find it appetising and practical to use, both in terms of its packaging and preparation. Other newly-emerging market niches are aromatic pastas, biological pastas and those made from low-residue flours. The latter are especially popular in Germany.

#### Other products

In nearly all of Europe, with the exception of the United Kingdom which is a traditionally tea drinking country, coffee is the most popular hot beverage, and its consumption in the EU for the most part appears stable, with a slight tendency

to fall. Espresso coffee, a typical Italian drink, has gained in popularity and has found a market in other European countries.

The lack of uniformity of demand for coffee in the EU stems from the fact that drinking habits are fairly different from one country to another. In Italy, coffee is more of an after-meal drink and a quick "pick-me-up," and the quantities used to make espresso are quite small. In the countries of Northern Europe coffee is consumed in relatively large quantities both during and in between meals. Soluble coffee is consumed mostly in the UK, where it has a market share of 91 %,

compared to 26 % in France and 7 % in Germany (Source: EUCA). While the largest consumption of coffee is recorded in these countries, Italy tops the list in terms of the number of cups consumed.

In the United Kingdom, the traditional demand for tea mentioned above is showing signs of saturation and drinking patterns for this beverage have been on the downswing over recent years. The consumption of herb- or fruit-based teas, as well as cold tea, is expanding. In fact, this trend can be seen throughout Europe.

Finally, data for vinegar consumption can be added. The biggest consumers of vinegar are the Belgians, with 2 litres per person, followed by Germany and France, while all the other countries are more or less on the same level.

**Supply and competition****Pasta**

The labour productivity index of the pasta sector since 1989 has remained fairly stable. Figures also remained stable with regard to overall costs and labour costs, showing a substantial balance in the production process.

Both marketing and distribution reflect the growing levels of concentration affecting the sector. Products are being made more and more for global markets and sales are directed through modern distribution networks of supermarkets.

Italian durum wheat pasta has lost its top position on the EU market in terms of competitiveness due to technological innovations introduced by the producers of common wheat pasta

in Northern Europe. This latter variety is now quite similar to durum wheat pasta in terms of its physical and organoleptic characteristics, although it is less expensive.

Furthermore, European pasta has had difficulty penetrating the US market following the USA/EEC agreement of 1987, which is effective until July 1995. Under this agreement, exports to the USA which exceed a threshold of 50 % are subject

**Figure 5: Miscellaneous food products**  
**Destination of EU exports - Other food products (1)**

 Source: Eurostat

to repayment cuts. This decision penalises medium-size European producers with less well-known brand names the most.

**Other products**

The labour productivity index shows a strong growth trend, in line with the particularly successful performance of the sector. Unit costs of production are moving in the opposite direction, starting with high values which stabilise more or less on the level of the base year. The cost of labour, meanwhile, shows a linear growth trend for the entire period under consideration.

**Production process**

**Pasta**

Generally speaking, production processes are directed towards the exploitation of scale economies which focus on greater cost efficiency. The common wheat pasta manufacturers employ technologies based on high temperatures which gelatinise the product, thereby making it withstand cooking better. Such technologies are employed less frequently by manufacturers of durum wheat pasta which, thanks to a high gluten content, does not require this type of treatment.

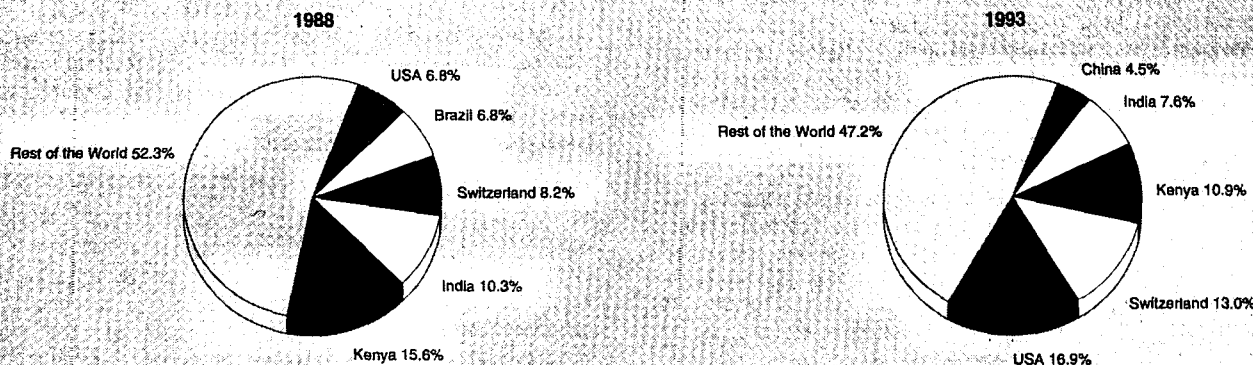

With regard to production costs of pasta, it is the production process which bears down the heaviest. For rice on the other hand, the production process is fairly simple and it is the raw materials themselves which have the biggest impact on cost.

**Other products**

The processing of coffee (roasting, de-caffeination, solubilisation) is a complex process and involves numerous controls during production. Controls on the physical characteristics of the raw materials are fairly important as they lead to the manufacture of blends of different varieties to achieve quality, flavour and consistent aroma over time. To obtain soluble coffee powder and caffeine-free coffee, various technologies exist.

Tea processing includes flavouring, blending and packing. Tea is also extracted to prepare instant tea powders which are sold as such or used for ready-to-drink teas, which can also be made from tea leaves by infusion, this infusion then being canned, bottled and tetra-packed.

## INDUSTRY STRUCTURE

### Companies

The greatest production specialisation is achieved in Greece and Spain, followed by Germany, Italy and France. Greece has the highest degree of production specialisation for both pasta and other products. Italy has a high degree of specialisation for pasta, but not so much for other products, while the other countries have a reasonably high degree of specialisation for both pasta and other products.

### Pasta

The industrial structure of the sector in the EU has, over the last few years, undergone a process of greater rationalisation which has led to the closure of numerous facilities in France, Germany and Italy, where there are now 10, 25 and 170 production facilities respectively. The average production per facility in 1991 was 288 thousand tonnes in France, 13 thousand tonnes in Italy, 10 thousand tonnes in Germany and about 7 thousand tonnes in Spain.

The principal companies in the sector are: Danone (F), the multinational leader on the French market with the Panzani brand which recently acquired the second most important Italian pasta brand; Agnesi (I); Ranks Hovis McDougall, (UK multinational), Nestlé (CH) and Barilla (I), with numerous facilities spread across France, Spain, Greece, as well as Japan and Eastern Europe (Poland).

### Other products

In many countries, a restructuring process of the coffee industry is under way by means of a decisive push towards concentration which leads to the creation of a handful of market leader brands. Among Europe's leading coffee brands are Jacob, belonging to the Suchard group, and Nescafé, belonging to the Nestlé group. In the tea sector, the Anglo-Dutch multinational Unilever has recently gone into the ready-to-drink tea business as a competitor of Nestlé.

The number of vinegar manufacturing facilities is tending to drop, especially in Germany and France. The largest facilities are in The Netherlands and the United Kingdom, with production capacities equal to 120 thousand hl and 156 thousand hl respectively.

### Strategies

#### Pasta

The process of internationalisation currently affecting the sector involves not only the EU but also Eastern Europe, Japan

and the USA and is promoted by the major companies, most of which have become big multinationals. As a reaction to the drop in consumption, pasta producers (above all in France and Italy), have begun manufacturing under distributor brands and focusing on the quality of the production process. Many companies require ISO 9002 certification or PGI (Protected Geographic Indication), recognised by the EU.

### Other products

In 1993, 19 acquisitions were concluded primarily in France and the United Kingdom, revealing the strategic aim of consolidating leadership at the national level and strengthening the concentration process.

In the coffee industry, apart from the major multinational companies, a small number of other relatively large companies exist alongside smaller enterprises. The degree of concentration varies with respect to the different segments: the soluble coffee segment is very concentrated while the espresso coffee segment is more fragmented. The major groups tend towards a wide diversification and large investments in advertising in order to create a strong market image. The smaller companies, on the other hand, are more intent on keeping down production costs. Furthermore, the coffee industry is distinguished by its careful attention to quality aspects during the production process, which has caused some enterprises in the sector to request ISO guarantee certificates. Due to a certain stability of domestic consumption, the enterprises in this sector are intensifying their internationalisation policies through acquisitions and trade agreements.

Meanwhile, the tea industry, in order to liven up the market, is tending towards greater product differentiation. Efforts are also being directed towards the creation of products to compete with soft drinks where there has been an important upswing in consumption. In particular, traditional tea manufacturers have entered into joint ventures or even acquired mineral water companies to manufacture ready-made cold tea.

### Impact of the Single Market

The creation of the single market had an overall positive impact for most products of the miscellaneous industry. Low effects were instead recorded for coffee as blendings significantly differ from country to country because of customers' different tastes. For the other products, the free movement of good, favouring international trade, generated the most relevant impact.

The remaining internal barriers are related to the lack of legislation on products definition. This represents a priority for the industry.

---

## OUTLOOK

---

### Pasta

Consumption is continuing to slow down, especially that of dry pasta where there is a saturation of demand. The production of fresh and frozen pasta has focused more and more on product innovation, and this should be the prime mover of the sector. The tendency towards greater concentration should play an active role and will lead to the creation of national brands through large investments in advertising.

### Other products

The coffee market is stable and only minor growth is expected, with the market for espresso coffee and speciality coffees growing. The tendency in the future will be towards greater internationalisation and concentration in the industry.

The tea market will continue to decline throughout Europe, although there will be greater product differentiation with the supply of flavoured teas, caffeine-free teas and ready-to-drink teas. The latter will increase their penetration on the soft-drinks market.

# Alcohol and spirits

## NACE 424

The sector is distinguished by a general drop in consumption, even though some domestic markets, particularly Germany and Spain, are expanding. Exports are growing, above all towards the Asian and East European countries, while the EU imports mainly from the USA and the Caribbean.

The two divisions making up the sector, spirits and ethyl alcohol, have diverse characteristics. The industrial structure of the spirits subsector is highly concentrated, with large multinational groups operating on the world market and competing through differentiation strategies, product innovation and investments and acquisitions to extend brand portfolios and distribution networks. Ethyl alcohol, on the other hand, is more of a commodity, with medium-sized enterprises and diversified market outlets such as the food, pharmaceutical, cosmetic and chemical industries.

### INDUSTRY PROFILE

#### Description of the sector

The sector comprises two categories of products: spirit drinks and ethyl alcohol. The spirit drinks industry receives its raw materials directly from the agricultural sector and uses them to manufacture the major types of alcoholic drinks: whisky, rum, vodka, gin, brandy, cognac and other drinks that are not wine-based, i.e. punch and cocktails, liqueurs, bitters and grappa (a typical Italian product) and pastis/anisette (French spirits). The main producers of spirit drinks are the United Kingdom, France and Germany.

Ethyl alcohol is made from the processing of various agricultural products such as beets, wine and fruit or other vegetable products (cereals, potatoes, etc.). It is not only used in the food industry (neutral alcohol), but also in the pharmaceutical and cosmetic industries, as well as for the production of solvents (raw alcohol). In some countries outside Europe (e.g. Brazil and other South American countries), the ethyl alcohol made from cane sugar is, to a great extent, used as fuel for motor vehicles. In the USA too, ethyl alcohol is used as a fuel to a much greater extent than in Europe, where this application is still at a much more experimental stage. Now developments are made possible under the set-aside policy of the EU

#### Recent trends

The main indicators are distinguished by considerable fluctuations. After a period of overall stability, there was a significant growth in both production and apparent consumption at current prices, as well as in the foreign trade indicators (extra-EU exports and trade balance) from 1989 to 1991. Subsequently, this trend inverted, however, and apparent consumption and production began to decline with -7 % and -3.4 % respectively (1993 compared to 1992). At the same time, the foreign trade indicators continued to rise with an increase in extra-EU exports of over 9 %.

With regard to employment, we find a steeply falling trend which does not look likely to stop in the near future. Figures dropped from 62 thousand in 1984 to 43 thousand in 1993. There are many reasons for this fall, such as a drop in outputs, technological improvements in areas such as bottling, and the numerous mergers and acquisitions which have taken place in the sector and which have brought about a more rational organisation of work forces not directly involved in production.

In terms of value added, compared to related industries, the spirits sector is more or less on the same level as the wine

Figure 1: Alcohol and spirits  
Value added in comparison with related industries, 1993

Source: DEBA

sector and below that of soft drinks and beer. The country which contributes most to the aggregate value added of the EU is France, followed by the United Kingdom, Germany, Spain and Italy.

At constant prices, apparent consumption and production show rather significant fluctuations. Apparent consumption appears to be dropping, and this trend was accentuated in 1992/93 (-8.7 %). Internal production slowed down at a more gradual pace, with a drop of over 4 % in 1992/93.

Demand, however, varies among the different European countries. Considering only the principal markets in the 1989/93 period, there was a steep drop in the United Kingdom and Italy (20 % and 11 % by volume respectively), while in Spain demand increased by 27 % and in France by 6 %. For this period, it is impossible to make a comparison with Germany, where the market expanded considerably after unification, and now represents one-third of EU consumption (by volume). The EU country with the highest per capita consumption in

1993 was Greece, followed by Spain and Germany (Source: Consumer Europe).

Although the internal market is not particularly lively, demand from abroad absorbs all surplus production and showed a growth of over 10 % in 1992/93. As evidence of the surplus phase recently experienced by the sector, and as an expression of the typically European production specialisation, the imports from third countries have, over the last year, gone down by 1 % compared to the mean growth rate of nearly 6 % during the 1984/93 period.

Up to 1987, production in the spirits industry underwent a counter-trend compared to the manufacturing industry as a whole: while the latter expanded, the former contracted. Starting in 1989, however, the alcohol and spirits industry began to show a pattern very similar to that of the manufacturing industry as a whole. From 1984 to 1989, the sector also showed a different trend than the manufacturing industry in terms of employment figures. Again, both underwent a substantially negative trend thereafter.

**Figure 3: Alcohol and spirits**  
**Production and employment compared to EU total manufacturing industry**

1994 are Eurostat estimates.  
 Source: DEBA

**International comparison**

The biggest and undisputed world producer of alcohol and spirits (at current prices) is the EU. This was true for both 1984 and 1993. In 1993, Japan's production was roughly half that of the EU, while the USA accounted for a very small share, with a production one-fifth of that of the EU.

A comparison of production at constant prices between the EU, USA and Japan shows Japan as having the steepest drop in production. In the five years between 1989-93, the average annual growth rate was -5 % against a rate of 1.8 % in the USA and 0.3 % in the EU.

**Foreign trade**

The balance of trade figures remained positive for the entire decade under consideration, and in 1993, the EU played the role of world leader in terms of production and exports. In 1993, exports represented 29 % of total production, while imports accounted for only 4 %.

EU exports go chiefly to the USA and Japan. While exports to Asia - in particular to Japan and Hong Kong - went up compared to 1988, those to the USA dropped steeply, going from one-third to about one-fifth of the total. Of growing importance are the East European markets, in particular Russia.

As far as exports of the different types of drinks are concerned, whisky provides the largest volume (from the UK and Ireland) followed by Cognac (from France). More than half of the total imports to the EU come from North and Central America.

Imports to the EU tend to concentrate around North and Central America, areas which supply over half the total. As far as the USA is concerned, the situation represents a mirror image of that of exports; imports from the USA have gone up by about 11 % compared to 1988.

## MARKET FORCES

### Demand

The demand for spirit drinks is affected by the variety of lifestyles and national drinking habits within the EU. In fact, the healthier lifestyles, numerous anti-alcohol campaigns and high product taxation in the Member States have all contributed to the drop in demand. Two good examples of the latter are Spain and the United Kingdom. In Spain, demand has jumped considerably since the country joined the EU and removed its trade and tariff restrictions, while in the United Kingdom a steep drop in consumption can be attributed to high taxation and restrictive policies towards businesses selling alcoholic beverages.

### Supply and competition

As seen above, the EU is the major world producer of spirit drinks, with Japan and the USA falling behind. With regard to ethyl alcohol on the other hand, the EU takes a back seat to the large quantities manufactured by South and Central America. Furthermore, it must be emphasised that US customs

duties make European products uncompetitive. The USA has a preferential trading agreement with the countries of the Caribbean and Central America for the processing of alcohol to be used as fuel. The Caribbean also receives most of the EU production of ethyl alcohol which is supported by intervention organisations.

Labour productivity in the alcohol and spirits industry was stable from 1991 to 1993, while the unitary cost of labour and production went up. The drop in the gross operating rate is can be attributed in part to the waning development of innovative production techniques, compared to the levels reached in the years prior to 1989.

**Production process**

The production of spirit drinks is based on the fermentation and distillation of agricultural products. For some products (such as whisky, brandy and cognac) this is followed by an ageing process ("maturation").

If it is possible to speak of innovation in a sector where techniques tend to be consolidated, it is primarily in the context of building plants with greater production capacities. As far as distilleries manufacturing ethyl alcohol are concerned, improvements in the production process are sought above all to reduce the cost of cleaning up effluents - in order to comply with the regulations for safeguarding the environment.

**INDUSTRY STRUCTURE**

**Companies**

The spirits industry is split into a number of large groups operating on the international market and small firms with niche positions (e.g. grappa manufacturers in Italy). The main European groups are: Grand Metropolitan (UK) which, with 10 of the 100 leading spirit drink brands, is the fourth largest European group in the food industry; Allied Domecq, producer of fortified wine, whisky and spirits, which has a large share of the second biggest world market for whisky consumption (i.e. Japan, where the group has established a joint venture with Suntory); Guinness (UK), the major British company for whisky and gin (and the seventh group in the European food industry); Pernod Richard (F) has the leading position in the very large pastis market and is also an important manufacturer of whisky (and soft drinks), with a large share of the continental European market: it owns the number one spirit drinks distribution network; Remy-Cointreau (F), producer of cognac, champagne, liqueurs and spirits, one of the major groups at the world level, with a presence in 200 countries; and Martini & Rossi (I), specialised in the production of vermouth and spumante wine.

The ethyl alcohol sector comprises numerous medium-sized firms, prevalently active on their own domestic markets. An example is Germany, a country with a high number of small distilleries manufacturing only raw alcohol, since the distilling and marketing of neutral alcohol remains a state monopoly. In addition, it must be remembered that in the ethyl alcohol sector, sugar manufacturers also have a strong presence. For example, Ferruzzi is the number one operator in Italy and the second in France (figures refer to the end of 1992).

The EU leader in terms of production specialisation is France, which has strengthened its position considerably since 1984. This is due to the fact that one of the most important products in the sector, cognac, is manufactured in the country, where the necessary high-quality grapes are grown. The United Kingdom is the second country, above all thanks to its production of whisky. The UK had the lead position in 1984, but has considerably decreased its specialisation since then, along with Italy and Portugal. All the other countries intensified their specialisation between 1984 and 1993.

**Strategies**

Key factors affecting the success of the spirit drink companies on the world market are: the provision of a wide range of branded products to meet an extremely fragmentary demand in terms of consumer preferences; and the ability to penetrate high-potential markets, e.g. by introducing traditional spirits from other countries through the establishment of marketing agreements with local manufacturers (a strategy widely pursued on the Asian market).

Source: DEBA

Ethyl alcohol, on the other hand, is more of a commodity. Consequently, the main strategy is to acquire cost advantages so as to remain competitive in terms of price.

There were seven main acquisitions in the sector in 1993 and seven again in 1994. The most active groups in terms of acquisitions are in the UK, especially Grand Metropolitan and Allied-Lyons. A particularly significant acquisition was that of Pedro Domecq (the eighth world group for spirit drinks in 1992) by Allied Domecq. As a result, Allied-Lyons will become the world leader in brandy and number two in tequila, and will own 13 of the top 100 spirit brands in the world.

### Impact of the Single Market

The implementation of the Single Market had a globally positive impact on the spirit sector. In fact the harmonisation of labelling, packaging and distribution legislation increased trade intensity, and in general competition inside the market has risen.

The remaining internal barriers are linked to different advertising legislation across Member States, to different taxation regimes, to the lack of common technical standards and to different levels of excise taxes. The next priorities for the external market are the negotiation of extra EU export condition as the definition of more restricted technical standard and the reduction of export duties. On the domestic front the harmonisation of advertising towards a more relaxed legislation and the harmonisation of excise levels are priorities for the industry.

The effect of the implementation of the Single Market on the alcohol industry has been positive but small. Trade intensity in this market segment is relatively low, and the market has already been deeply influenced by wine CMO. The breakdown of barriers to extra-EU trade is a priority for the industry.

### REGULATIONS

Community regulation policies in the sector go in two directions: on the one hand, they aim at promoting free trade; on the other, they promote good health by restricting the consumption of alcohol.

Article 37 of the Maastricht Treaty provides for the suppression of exclusive rights relating to the import, export and wholesale marketing of alcoholic products. Furthermore, the European Court of Justice has ruled on several occasions that the presence of monopolies in the trade of alcoholic products undermines the spirit of the Maastricht Treaty.

The promotion of health is implemented by two instruments: harmonisation policies - directed towards creating minimum European standards in taxation, advertising and alcohol abuse suppression; and monitoring policies, including health-related educational seminars and campaigns.

With regard to advertising, safety and sales, the legislation of the Member States is still somewhat diversified. Nonetheless, two legislative tendencies can be seen: strong regulation in Northern Europe and weaker or virtually no regulation in Southern Europe. With regard to commercial communication instruments, the strictest limits are imposed on radio and television (although television advertising continues to show an

erratic pattern), while there are more lenient limits for the printed press. Self-regulation codes are converging towards common standards in the EU countries.

Community regulations require the setting of rates at an above-average level, to make alcoholic drinks more expensive. For example, Directive 92/77 provides for a minimum VAT rate of 15 %. The matter of excises involves two aspects: harmonisation of duties on alcohol and alcoholic drinks, and the convergence of these charges. Directive 92/93 provides for an excise on beer, wine and other alcoholic drinks, on intermediate products and also on ethyl alcohol. Moreover, this directive determines the different application modalities of the manufacturers taxation fee referring to the definition contained in the Common Customs Tariff and to the proportion of determined substances relating to the total volume. In addition, reduced rates are provided for some products with a low alcohol content. Directive 92/84 provides for the harmonisation of the production charges for wine, beer and other alcoholic products.

Basic provisions for spirit drinks, and the definitions of the different categories of spirit drinks are laid down in Regulations 1576/89 and 1014/90, respectively. These have been amended several times, most recently by Regulation 3458/92, which was implemented on January 1, 1993).

Finally, it should be remembered that ethyl alcohol is regulated by the provisions of the Common Market Organisation of the wine industry, specifically by the regime of support distillation and obligatory distillation. In these cases, if the distillers have recognised the minimum price for wine producers, they are granted aid for storing the alcohol produced or, in the case of obligatory distillation, they are offered the opportunity to deliver production to the intervention organisations.

---

## OUTLOOK

---

In the alcohol and spirits sector, a slight downswing in apparent consumption is forecast over the next few years, though patterns could differ on the various domestic markets. Conversely, given the opening up of previously closed markets, exports are expected to rise. These are already sustained today by the lead role of the EU on the world market.

Furthermore, these groups are pursuing a strategy of growth onto rapidly expanding markets, especially those of the more economically advanced Asian countries and the East European countries. The aim is to increase market penetration through marketing agreements with local companies.

On the internal market, growth through acquisitions is aimed at enlarging product portfolios and strengthening distribution networks. This trend also leads to a more rational organisation of company structures which, together with a fall in outputs, contributes to the ongoing fall in employment figures in the sector.

While product diversification and the ability to develop new marketing strategies are feasible possibilities for the spirit drink companies as a means of contrasting those factors which negatively affect demand (i.e. high taxation, campaigns to restrict consumption, healthy lifestyles), the firms manufacturing ethyl alcohol are obliged to pursue strategies aimed at keeping down costs, in order to remain competitive in terms of price.

# Wine

## NACE 425

The overall per capita consumption of wine has tended to drop over the years within the EU. On the other hand, there is a growing uniformity of eating habits in the north and south of the EU which has led to a greater demand for wine in the traditionally non-wine drinking countries like Belgium and Denmark. The penetration of imports is increasing and eating into market shares in the United Kingdom and the Netherlands.

### INDUSTRY PROFILE

#### Description of the sector

The sector includes the production of wine and other alcoholic drinks made from grapes, the manufacturing of cider and alcoholic beverages made from other fermented fruits.

The biggest producers of wine-based drinks in the EU are Italy (in terms of volume, though the average quality is not high), France, Spain and Germany. Since 1984, there has been an overall drop in production of wine following Community initiatives to minimise production surpluses. Currently, such production surplus goes for distillation, which to a large extent is paid for by the EU. The biggest percentage of wine for distillation comes from Italy with a 24 % share. The countries with the biggest per capita consumption are France, Italy, Spain, Portugal and Greece.

#### Recent trends

The production and consumption of wine at current prices dropped between 1992 and 1993. Such a pattern seems to have followed trends in the market. In recent years, there has been an increase in prices compared to the steep production drop in physical terms, in part related to economic inflation and to a greater extent tied to a swing in demand towards high-value products.

The trade balance in the sector shows a tendency to worsen throughout the period under consideration, with a substantial improvement between 1992 and 1993 thanks to a drop in average unitary production prices.

Employment too has been negatively affected by the situation of the sector, with a loss of around 5 000 jobs over the decade. The biggest drops occurred between 1987 and 1988, after which there was a partial recovery, followed by a continued drop in figures.

The wine-based product sector had a value added of around 2 656 million ECU in 1993, substantially lower than that recorded in related sectors, e.g. soft drinks and beer.

France remains the EU country with the most important wine industry in terms of value added, even though this position appears seriously threatened by the up-and-coming Spain. In fact, the latter has similar commercial and production policies to those of France, especially in relation to its policies concerning high-quality wines, which have caused a sharpening of competition between the two countries. Though the number one producer in the EU, Italy generally pursues price and product policies different from the others, as is shown by the low value added associated with its product. Since 1986 (following the methanol wine scandal), Italian wine producers have focused on the production of table wine.

Over the last decade, real apparent consumption and production growth rates went up, especially in 1993 and 1994. This upswing also affected exports, which had gone down by around 9 % between 1984 and 1989, but which rose by 19 % between

Figure 1: Wine  
Value added in comparison with related industries, 1993

Source: DEBA

1992/93, following a pattern which can be considered exceptional considering the trend which characterised the early 1990s. The growth rate of imports also rose both considerably and steadily.

The production of wine by volume within the EU for 1993 was around 197 million hl (+23 % compared to the previous year). The only country which did not show a growth was Portugal, while all the others, showed increases varying from 53 % for France to 15 % for Italy and 14 % for Spain, despite the heavy rainfall. Such increases also affected production of the highest quality wines (i.e. VQPRD wines), which went from 50 million hl to 62 million hl, thus expanding surpluses which, in 1992, were around 52 million hl. (The usual gap between production and consumption levels is about 32 million hl).

The positive and anti-cyclical pattern of wine production, measured at constant prices, failed to compensate for a continuing drop in the number of people employed in the sector. After a negative peak recorded in 1988, employment figures underwent a substantial upswing between 1989 and 1991,

after which they followed the general downswing trend of the economy as a whole.

### International comparison

The EU is classified as the major wine producer worldwide, with 60 % of world production and 55 % of consumption, in front of the countries of the former Soviet Union, Argentina, the USA and Eastern Europe.

At the global level, 1993 production was estimated at 261.6 million hl, with a drop of about 12.5 % compared to 1992. This drop was particularly heavy in the USA where it touched 7.7 %, while in all other areas average falls were around 3-5 %.

At the international level, between 1984 and 1993 there was an increase in production at constant prices in the EU and the USA. Japan on the other hand showed a gradual drop in production over the period, except between 1991 and 1992, when there was a slight increase.

**Figure 4: Wine  
International comparison of production in constant prices**

Source: DEBA

Canada, Australia, New Zealand, Chile and Morocco are the new competitors on the international market, which have come on strong over the last few years.

### Foreign trade

The export pattern to countries outside the EU shows negative growth for the entire decade under consideration. Despite this, there was a noticeable improvement from 1992 to 1993. Conversely, imports, on the downswing until 1986, increased thereafter. This trend appears to still be going strong. The gap between exports and imports has narrowed substantially over the decade. While the export-import ratio is less than half of what it was in 1984, it is still high at around 13.

In 1993, EU exports went mainly to the USA, Switzerland, Russia and Japan. Since 1988, the share of the USA, Canada and Switzerland has shrunk considerably, while the level of exports to Japan rose. Russia has been an important market since 1993, and its significance is growing.

As regards imports, EU suppliers have changed substantially since 1988. In fact, Australia and the USA have increased their market shares dramatically, while the former Soviet Union, which used to make up more than 30 %, has practically disappeared.

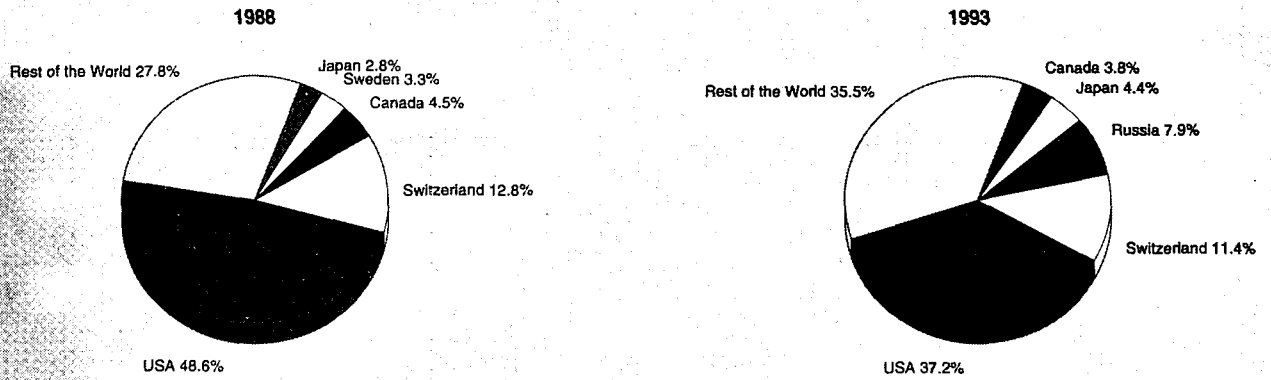

Despite the above trends, imports onto the EU market remain marginal at less than 1 %, while the quantities exported are high compared to overall production.

## MARKET FORCES

### Demand

The consumption of wine has dropped since the early 1970s, as consumer eating and drinking habits have changed. In particular, the increase in average wages and of white-collar workers has fostered the demand for high-quality products. Like all traditional products, wine has followed this pattern. Countries like Italy and France underwent a steep drop in gross per capita consumption between 1989 and 1993 and this has affected the Community as a whole. It should be said, however, that if wine and alcoholic drinks in general are no longer in fashion, the merging of northern and southern European eating habits has brought about a somewhat greater consumption of wine in countries such as Denmark and Belgium where, until only a few years ago, wine was not as popular.

**Figure 5: Wine  
Destination of EU exports**

Source: Eurostat

Alongside such trends is the greater attention on the part of consumers for health which has led to a swing towards lower-alcohol content products like wine-based drinks. Wine is habitually drunk during meals only in the countries of southern Europe (including the southern region of France), while in the northern countries it is more of a luxury commodity, beer being preferred.

#### Supply and competition

Beginning in the mid 1980s, the European wine-making industry lost in competitiveness, with internal and foreign market shares being eaten into by the USA and other countries such as Chile, South Africa and Australia. All of these countries have adopted particularly aggressive marketing policies.

A case in point is the USA, which, thanks to the huge funds provided by the federal government for the upgrading of US wine products abroad, set up extremely effective sales and marketing policy organisations whereby American wine producers have managed to penetrate not only the Canadian and Mexican markets, but also that of the EU, namely the United Kingdom and the Netherlands.

## INDUSTRY STRUCTURE

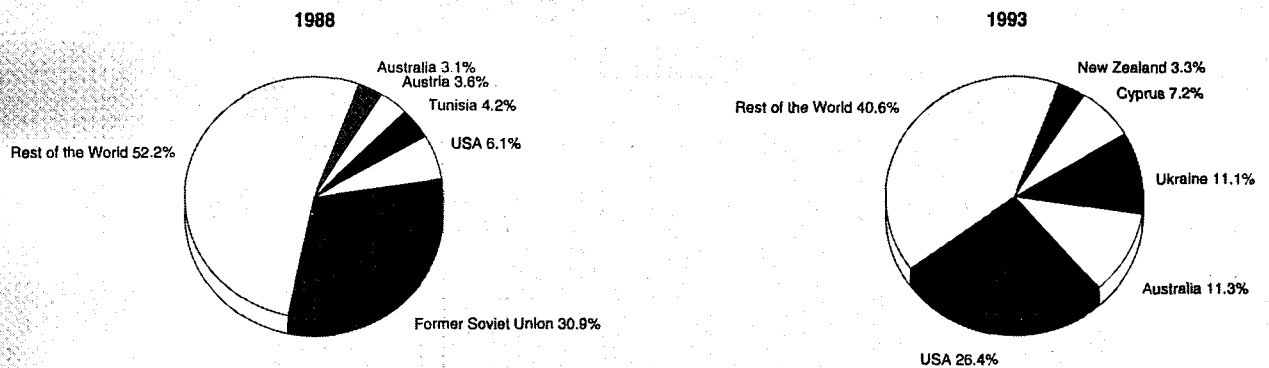

### Companies

The wine industry is still distinguished by a highly fragmented situation in terms of production which varies from country to country. For instance, market fragmentation is more evident in Italy compared to France, Spain and Germany.

Many cooperatives operate in the wine sector, making up 65-70 % of the table wine market in France (35-40 % of the choice wine market and about 35 % of the champagne market). In Italy, cooperatives are responsible for 40 % of the wine sold on the domestic market. These are located mostly in the south, and produce blended wines, stopped must or concentrates used in other regions to blend local wines.

The companies making up the sector are mainly small-sized firms tied to multinationals in the spirits sector which have added wine to their product range, and other independent firms. The main companies are Pernod Ricard (F), LVMH (F), Allied Lyons (UK), Grand Metropolitan (UK) and Martini & Rossi (I). In the multinational bracket, major companies are: Antinori (I), Gancia (I), Castel (F) and Lagedar (F).

## Strategies

The strategies adopted by companies in the sector vary according to the different types of production. Generally speaking, there is considerable attention paid towards meeting market requirements, particularly by producers of Beaujolais nouveau, wine with low alcohol content and spumante.

Producers of medium-quality wine have adopted strategies of keeping costs down as much as possible while widening the market niches for the wines they produce. An example of this is the "Tetra Pak," designed to promote consumption outside the home (e.g. for travelling).

Different again are the strategies adopted by high-quality wine producers. In this case attempts are made to differentiate production and increase market segments, qualifying production through Controlled Denomination of Origin and VQPRD labels, or through the adoption of company brand name enhancement policies. Companies are also trying to widen their product ranges to include white, red and rosé wines.

Of great importance are the strategies directed towards external growth, exemplified by the 22 acquisition deals completed between 1993 and 1994. These involved mainly French com-

panies and were directed towards expanding domestic market shares.

With regard to the levels of specialisation in the wine sector between the different EU countries, it should be pointed out that though Italy, France and Spain effectively possess levels of specialisation above the average, it is also true that it is becoming even more important in those countries with poorer manufacturing industries like Greece and Portugal.

Furthermore, the specialisation levels are higher or lower from country to country for completely different reasons. French production centres on high-quality wines and therefore has increased its degree of specialisation. Meanwhile, the specialisation patterns recorded in Greece and Portugal can be attributed to a general reorganisation of respective manufacturing industries.

## Impact of the Single Market

The impact of the creation of the Single Market on the sector of wine has been overall positive, stimulating in particular international trade and consumer protection.

Source: DEBA, Eurostat

Nevertheless it is perceived to have increased administrative and production costs for small and medium sized firms because of the approval of packaging regulations.

The legislation with respect to advertising, which deeply differs within EU countries and fiscal harmonisation, is considered to be the main remaining internal barrier. On the export side, the reform of the Common Market Organisation and international trade negotiations with USA, Chile, South Africa, Canada and New Zealand are considered priorities for the industry.

## REGIONAL DISTRIBUTION

The wine industry is widely distributed throughout the EU. However, certain areas can be identified which are particularly active in the sector. These are the regions of Valencia, Extremadura and Castilla de la Mancha in Spain; Languedoc-Roussillon, Provence, the French Riviera, Champagne, Alsace, the Pyrénées and Bordelais in France; the Peloponnese and Aegean islands in Greece; western Ribatejo in Portugal; Emilia-Romagna, Veneto, Trentino, Tuscany and Puglia in Italy; and finally, Rheinland, Moselle, Franconia and Württemberg in Germany.

imported from a non-member country. In accordance with the Uruguay Round, the Community has agreed not to fix a reference price (starting on 1 July 1995) and to replace this system with a tariff equivalent. The reference price system for grape must, on the other hand, will be replaced by tariff equivalents to be reduced by 20 % during the course of the six-year implementation period.

Other effects of the GATT concern:

- for NC 2204 code products (fresh grape wine, including alcohol-enriched wines) and NC 2205 code products (vermouths and other wines made from fresh grapes and using plants and aromatic substances) no specific protection measures are provided; an exception is grape must for which an entry price is fixed; and
- the elimination of refunds for grape must starting at end-1993.

Of particular interest for the wine-making sector is the agreement relating to intellectual property rights in trade (ADPIC). This agreement contains an article on the protection of geographic indications, which prevents the utilisation of any labelling or packaging which could create confusion for the consumer as to the actual place of origin of the product.

With regard to the individual segments of the sector, Regulation 122/1994 has been adopted. This specifies the application procedures of Regulation 1601/91, relating to the definition, designation and presentation of aromatised wines, of wine-based aromatised drinks and of aromatised wine-based cocktails.

## OUTLOOK

In the years to come, a drop in wine consumption is expected which will hit the market for higher-alcohol content wines and red wines in particular. Furthermore, marketing strategies will become more consequential as will the upgrading of brands, especially company brands.

Competition will sharpen within the sector, mainly because of the appearance of aggressive competitors which primarily will hurt medium-quality production. This situation will bring about greater concentration on the market through acquisitions of companies operating on domestic markets.

Written by: NOMISMA

The industry is represented at the EU level by: *Comité de la Communauté économique européenne des industries et de commerce des vins (COMITE VINS)*. Address: Rond Point Schuman 9, Bte 4, B-1040 Brussels; tel: (32 2) 230 9970; fax: 230 4323.

## ENVIRONMENT

The sector's main impact on the environment comes from the use of high amounts of pesticides during grape growing. Recently, however, the spread of integral/organic cultivation methods have helped to reduce the environmental pollutants created by the sector.

Wine sold in bottles involves the problem of recycling the glass. To eliminate this problem, some companies have promoted the sale of wine in cardboard "briks."

## REGULATIONS

Beginning with Regulation 24/62, common market organisation of the wine industry was gradually established. The basic regulation in the sector is Regulation 822/82, which was subsequently amended by Regulation 1756/92.

The Community is essentially inclined towards a reduction of production considering that intervention measures are no longer sustainable due to their heavy costs. In conformity with the decisions of the Council adopted in February 1988, a packet of stabilisation measures has been adopted, hinging on the abandonment of wine-growing areas and the strengthening of compulsory distillation, measures which have been accompanied by a drop in the support price of surplus wine. The aim of these measures is to decrease the EU production potential between 1988 and 1996 by 40 million hl.

The impact of these measures, however, would seem to have little affect on the reduction of the structural surplus of the Community, considering that yields have increased on average by half a hectolitre per year per hectare despite the fact that 250 thousand hectares of vineyards were uprooted between 1988 and 1993. This has sparked a review of Community policies, starting with the document presented by René Steichen in June 1993, behind which lies the principle of directing Community resources towards the prevention of surplus formation, rather than towards getting rid of it.

As far as price regulations are concerned, each year the Council fixes a target price for each type of table wine and an intervention price, while the Commission fixes the representative price (average production price for each type of wine) and the reference price, which aims at protecting Community olive growers by fixing a minimum price at which wine may be

# Brewing and malting

## NACE 427

In 1993, 1 611 breweries were operating throughout the Community. These employed 139 000 workers and produced 289 319 million hectolitres (hl) of beer. Germany, with 1 281 breweries, a workforce of 60 000 and a production of 115 000 million hl is the major EU producer and, with 138.5 litres per capita, against the 85 litres EU average, is also the biggest consumer. Over the last decade, employment figures for this sector dropped consistently. Taxes on general alcohol production play an important role in the sector. The beer market also has been affected by the economic recession, with a drop in volume of around 4 %.

### INDUSTRY PROFILE

#### Description of the sector

The beer brewing sector includes the processing of hops, maize and barley to make biological beer, exotic beer, light beer, non-alcoholic beer, normal beer, special beer and double-malt beer. These product types are further categorised by colour (pale, red and dark), while in terms of packaging, they are divided into draught beer, bottled beer with returnable bottles, bottled beer with non-returnable bottles and canned beer. Along with the brewing of beer, the sector also includes the processing of malt, used as an ingredient in some types of beer and employed as an input for other food industries, especially the confectionery, spirits and liqueur industries. In 1993, Community malt production reached 6 436 000 tonnes. Imports (960 000 tonnes) were considerably below exports (2 530 000 tonnes).

Most EU-produced malt (4 223 000 tonnes) was used to make beer. Germany (1 841 million of tonnes in 1992), the UK (1 434 million of tonnes) and France (1 263 million of tonnes) were the major producers, followed by Belgium and The Netherlands. Germany, France, the UK, Denmark and The Netherlands have shown a slight increase in production since 1989, while Italy and Spain strongly reduced their production. Beer malt (97 %) and malt whisky (3 %) are the main categories of malt production.

The beer-making process is fairly complex and requires big capital assets. The value added in the brewing industry is very high compared to related industries and is the highest in Germany, followed at some distance by the UK. The other countries have a much lower value added. The value added of the malting sector, on the other hand, is very low, and malt represents 80 % of the sale price. Although the malting production process is not complex, it too requires big capital assets.

#### Recent trends

A look at the main indicators of the sector first of all shows a rise in production, up from 19 604 million ECU in 1984 to an estimated 25 972 million ECU in 1994, with an ongoing annual growth rate. In 1992, there was a slight drop in consumption, but demand recovered immediately in the following year. Counter to growth in production and consumption has been the ongoing drop in employment figures, down from 164.5 thousand in 1984 to 123.9 thousand in 1994. Exports, except for the 1986-88 period showed a positive annual trend in 1989, thus contributing to an improvement in the already positive trade balance.

The value added produced by the brewing and malting sector is equal to 5.2 times that of the value added of the grain milling industry, 3.3 times that of wine and 1.7 times that of

Figure 1: Brewing and malting  
Value added in comparison with related industries, 1993

Source: DEBA

soft drinks. Germany is the country that contributes the most to the level of EU value added (40.5 %), followed by the UK (20.5 %), Spain (11.8 %), the Netherlands (8.9 %) and France (8 %).

At constant prices, growth rates - excepting those of foreign trade - are distinguished by substantially modest, when not negative, variations, which intensified between 1992 and 1993. Export and import levels, on the other hand, have undergone considerable growth variations, though the latter slowed down suddenly between 1992 and 1993. At constant prices, production patterns in the EU were fairly stable up to 1990, unlike those of the manufacturing industry as a whole. Since 1990, EU production in the brewery sector has begun to fall, while the manufacturing industry rose and then stabilised for the most part, excepting 1993.

Employment figures continued to fall throughout the period without showing any signs of recovery. In the 1984-91 period, the drop in the number of jobs in the brewery sector contrasted with a fairly stable situation in the manufacturing industry

as a whole. This decline, in spite of the fairly stable demand for beer and an equally stable production, is due to an increased use of technologies in the production process and to a general process of concentration of enterprises producing advantageous scale economies.

Over the last decade, different local and national drinking traditions have tended to overlap, or at any rate to affect one another. Countries strongly tied to a wine-drinking culture, and traditionally strong producers and consumers of wine (e.g. Spain) shifted to beer, which is becoming more popular throughout the Mediterranean. At the same time, countries that were at one time almost exclusively beer-drinking have witnessed a growing demand for wine. This is the case, for example, of Ireland, Germany, the Netherlands, Denmark and the Scandinavian countries. It should not be forgotten, however, that in each country the importance of traditional drinks is still strong: wine in the Mediterranean countries, beer in Central and Northern Europe, spirits in the North and in some areas of Eastern Europe.

**International comparison**

In 1993, the biggest world producer (in value) of beer was the EU, followed by Japan, while the USA not only lost its position on the world market but showed a tendency to reduce its production capacity compared to 1984. An analysis of the evolution of production at constant prices shows an increase in EU production, though very slight, up to 1990. This was followed by a three-year downswing. The USA, on the other hand, enjoyed considerable growth from 1984 to 1990 and then levelled off over the 1990-93 period. The biggest fluctuations were experienced by Japan over two separate periods: the first, from 1984 to 1988, shows annual growth rates, except for 1987, of between 3.2 % and 10.9 %; in the 1990-92 period, the annual growth rates were between 1.4 % and 5.1 %. In 1989 and 1993 there was a fall in production of 5.6 % and 7.9 % respectively compared to the previous years.

### Foreign trade

The balance of trade figures in the sector, positive through the decade, show a slight drop between 1986 and 1988; and a recovery starting in 1989 with a growth rate from 15.6 % in 1988/89 to 1.5 % in 1990/91. Behind this trade balance growth are, above all, exports to countries outside the EU, the value of which, excepting 1986-1988, grew over the decade at a rate between 2.3 % and 15.5 %. Imports at current prices also grew during the course of the decade, though hardly as much as exports, going from 39.7 million ECU in 1984 to 108.8 million ECU in 1993. In 1991 alone there was an annual growth rate of 64.1 %. The export/import ratio also fell during the decade, down from 24.4 in 1984 to 9.7 in 1991. It then rose slightly in subsequent years until it touched a value of 11.6 in 1993, indicating that variations in imports were greater than those of exports.

Most brewing and malting exports went to the USA, though this country's share of exports fell by more than 10 % since 1988. Switzerland's share of exports also dropped. The second most important importer of brewing and malting products from the EU in 1993 was Japan which, compared with 1988, increased its share. Russia also joined the group of major im-

porting countries, with a 3.7 % share in 1993, just out in front of the Canary Islands, which also had increased their share compared to 1988. The most export-oriented country is Ireland; in fact the volume of beer for export is just less than half that produced there. The other countries of the north and north-west - like Luxembourg, The Netherlands, Belgium and Denmark - have high foreign market shares. Germany, on the other hand, accounts for a fairly small share of foreign markets because most of the beer produced goes to meet its domestic demand. Finally, Spain, France and Italy import more beer than they export. These are the less typical brewing regions and domestic demand is met chiefly by foreign imports.

In 1993, the main countries of origin of EU imports were the Czech Republic, Mexico, the USA, Austria and China. In 1988, the former Czechoslovakia accounted for 28.5 % of EU imports, followed by Austria (13.2 %), USA (11.7 %), Australia (11.6 %) and Finland (5.9 %). A comparison between the two periods shows a growth in imports from Mexico and a drop in imports from Austria. The USA, on the other hand, slightly increased its import share.

The degree of penetration of exports shows a downswing up to 1988, dropping from 4.94 % to 3.81 %. Starting in 1989,

United Kingdom	95	30 200	54 881	4 582	2 100	100.2

(1) 1992 figures for imports and exports.  
Source: CBMC

this trend reversed, recovering in 1993 the same positions shown in 1984. The import/consumption ratio, though having doubled over the decade, shows a minimum growth of around 0.2 %, going from 0.2 % in 1984 to 0.4 % in 1993.

In the malt sector, France is the main export country, exporting 80 % of its production to extra-EU and EU countries. Belgium and Denmark, which produce only one-half as much as the French, export more than 65 % of their production. The main malting import countries are Germany, The Netherlands and Italy. The Netherlands imports 50 % of their capacity of production, while Italy's malting imports percentage is higher.

## MARKET FORCES

### Demand

In recent years, there has been a general tendency for consumers to move towards lower alcohol-content drinks and, above all, to soft drinks. This process has been enhanced by the recession, which has contributed to the 4 % drop in volume. Increased consumer concern about the potential health hazards of excess alcohol consumption and general fitness conscientiousness have stimulated the demand for non-alcoholic beers - especially on the part of women - as well as for biological beers, made from raw materials cultivated without the use of pesticides and fertilisers.

'Exotic' beers are also gaining in popularity, e.g. Latin-American beers. Some pass off this particular increase in demand as a fad, caused by more widespread travel and the growing number of Tex-Mex restaurants. However, the growth of imports from Mexico shows that this is not the case. The big seller, when speaking of 'exotic' beer, is 'Corona' made by Cerveceria Modelo and popular today in 68 countries, including Mexico, where the Corona phenomenon also has grown regularly over the last 15-20 years. Between 1984 and 1986, the Corona brand took the USA by storm and today it ranks second among imported beers.

Climate also has a great impact on consumption patterns. Beer is very much a seasonal drink, especially in the Mediterranean countries. For example, in the summer of '94, temperatures throughout Europe were higher than normal and beer consumption rocketed.

The biggest per capita consumption is to be found in the main producer or exporting countries. Alongside Germany, with almost 139 litres per head in 1993, come Denmark (126 litres), Ireland (123 litres), Belgium (107 litres), Luxembourg

(103.8 litres) and the UK (100 litres). Italy, with 25.1 litres, is the EU country recording the lowest consumption of beer.

### Supply and competition

Labour productivity did not increase much during the 90s. Rather, it remained substantially stable at base year values, with the labour and production index falling steadily at constant prices. The brewing industry is distinguished by the strong utilisation of fixed assets, which increased notably in the 1980s.

The production costs presented a higher growth rate starting in 1990. One of the most significant cost items was labour, as the labour cost index indicates.

### Production process

Beer is a drink made from barley or other cereals obtained through alcoholic fermentation of a watery concoction of malt, barley or other cereals, mixed with aromatic substances (e.g. hops) and also carbon dioxide. The sector benefits from important economies of scale, both in the production process and in distribution.

The beer brewing sector comprises companies of various sizes, starting with the small firms which meet local demand right up to the large multinationals with their direct productions and licensed productions, the latter granted to other companies in other countries. Therefore, productivity levels vary considerably depending on the type and size of manufacturers.

## INDUSTRY STRUCTURE

### Companies

In 1993, the Community counted 1 611 independent beer brewing companies. Germany, the biggest manufacturer, followed at a distance by the UK, had 1 281 brewing companies. Of these, the top 52 made over 60 % of the overall production and 860 only 3.5 %.

France, with the same number of breweries as Spain and more or less the same production volume, is distinguished by high capital investment in the work cycle, with a workforce half the size of Spain. In 1993, total production of the 16 Dutch breweries equalled 20 431 thousand hl, while the 102 Belgian breweries produced 14 700 thousand hl.

The largest number of malt processing facilities is in Germany (97); these include the main independent factories to be found in the sector. The United Kingdom also has a fairly high

**Table 6: Brewing and malting Maltings, 1993**

(units)	B	DK	D	F	IRL	I	NL	UK	Total
Independent	4	3	68	6	5	3	2	10	101

Total	6	5	97	7	8	3	3	20	149

Source: EUROMALT

number of malt processing facilities: 20 facilities of which 10 are independent. It should be noted that the overall number of facilities dropped between 1991 and 1993, due to the closure of independent firms, while the number of those associated with breweries remained substantially stable. 86 % of malt processing facilities have a low production capacity (below 10 thousand tonnes), while 24 % have a production capacity of over 50 thousand tonnes. In Germany, small facilities predominate (83 % of German facilities have a production capacity below 40 thousand tonnes) and contribute only 20 % to total production. Conversely, the United Kingdom is distinguished by high-capacity plants (45 % of facilities have a production capacity of over 50 thousand tonnes) and account for 91 % of total production.

Over recent decades, there has been a generalised process of productive concentration, through mergers and acquisitions. Thus, beer brewing has been concentrated into large multinationals. In some countries such as the Netherlands, Portugal, Ireland and Greece, medium-sized industries prevail, while in France, and above all Germany, many low-capacity firms operate.

Similarly, in the malt processing sector, there is a general trend towards concentration (from 170 companies in 1989, to 97 in 1993), aimed at the growth of the production capacity of each individual facility, thereby enabling the achievement of strong scale economies. In fact, out of a total 49 malt processing enterprises within the EU, the top 21 have a production capacity equal to 2/3 of the total. In France, Malteurop and Soufflet are the main malting companies; Saplo and Malt Italia are the major ones in Italy.

Source: DEBA

## Strategies

Within the sector, there has been a generalised process of concentration favoured by the possibility of achieving scale economies and amortising the cost of the factories and equipment. Over the last decade, through a series of acquisitions on the part of a number of European giants, the European market has become concentrated in the hands of large industrial groups. In 1993, 18 acquisitions took place worldwide. Of these, 11 were accomplished by industrial enterprises and groups belonging to the EU; five of those were conducted by British companies and four by Dutch companies. The number of acquisitions went up in 1994 with 21 operations worldwide, of which 12 were promoted by EU enterprises. The German Brau & Brunner and the Dutch Heineken completed four acquisitions each. Five operations carried out by European groups involved East European breweries and demonstrate the great interest for these new markets. It should be remembered, however, that in some countries (e.g. Poland), strict regulations are being introduced to penalise beer consumption.

The growth of hard discount distribution chains and increased consumer concern for prices have convinced beer manufacturers to review their brand and promotion policies. Promotion and advertising are important strategic levers for the marketing of beer.

In 1993, the types of containers used within the Community for the sale of beer were returnable bottles (48.4 %), draught beer (34.9 %), non-returnable bottles (10.1 %) and cans (6.6 %). The consumption of draught beer is prevalent in Ireland (83.1 %), the United Kingdom (68.5 %) and Luxembourg (48.4 %), while returnable bottled beer is prevalent in Denmark (92.3 %), Germany (78 %), Greece (76 %), the Netherlands (63.9 %) and Portugal (54.9 %). Non-returnable bottles are used mainly in France (57.7 %) and Italy (56 %). Some 'precious' containers are also used, e.g. ceramics, for top-quality beer. In this case, a lever-top often enables the bottle to be re-closed.

Two main marketing channels are used by brewers: the 'long channel' (company, agent, sales outlet or bar/café) and the 'short channel' (from the industry directly to the retailer). Direct sale is prevalently done through the large chains, which possess a centralised purchasing structure. Finally, there is the phenomenon of specialised 'brand' outlets, where a particular brand of beer is highlighted. In this case, the breweries supply managers with orders and advice on how to run the premises.

Over the last few years, breweries have attempted to reorganise supply and transport - because the place of production is often distant from that of consumption - and to improve transport packaging, in order to reduce breakage and keep retail prices down or increase profit margins.

The strategies adopted by European breweries in general are the following: first-price strategies, which offer small profits but permit the amortisation of the heavy investments required by breweries; strategies based on special or double-malt beers, which affect margins; strategies based on product innovation,

**Table 7: Brewing and malting**

Source: EUROMALT

especially alcohol-free beers, which are riskier, but are not subject to taxes on alcoholic drink production; and client portfolio diversification strategies throughout Europe. This last strategy is implemented through the winning of new markets within the EU and in the East European countries and is becoming indispensable, as most companies are leaders of their domestic markets and often find it difficult to expand into other countries.

#### Impact of the Single Market

The creation of the Single market had a positive impact on the brewing sector, stimulating and favouring international trade and the internationalisation of products. However, internal barriers still remain. In particular the lack of fiscal harmonisation, and in particular relevant differences in excise levels across countries reduce competition inside the market. The harmonisation of excises is a priority for the industry.

The effects of the creation of the Single Market on the malting sector was in general positive, but small. Trade intensity in the sector is very low and production takes place regionally, near the breweries company. One of the next priorities for the malting industry is the new CAP, which reduced the production of raw material in the European Union. Consequently, malting firms are constrained to import from third countries the barley malt, often at higher prices.

#### ENVIRONMENT

The main problems tied to the production of beer are linked to the disposal of packaging, which now is partially reused during production, thereby providing considerable energy savings. Furthermore, over the last few years, there has been a considerable savings of water used during the production process. Other problems concern the disposal of yeast generated during brewing and of fumes discharged into the atmosphere.

EU Directive 94/62 has introduced a series of measures concerning the recovery and recycling of food packaging. These measures will result in important benefits for the environment inasmuch as they will oblige companies to adopt adequate packaging and change supply and transport organisation within the sector in order to facilitate and expand the recovery and recycling of packaging. Germany, Denmark and France have begun to implement this policy already.

#### REGULATIONS

Community policies in the sector regulate two different aspects. On the one hand, they promote a marketing logic based on free trade; on the other, they promote healthy lifestyles by restricting the consumption of alcohol.

The promotion of the health is implemented by harmonisation policies directed towards creating minimum European standards in taxation, advertising and abuse control; and monitoring

policies, developed through educational campaigns to inform the public about health issues.

With regard to advertising, safety and sales, the legislation of the Member States is still somewhat diversified. With respect to taxation, Community action requires the homogeneity of rates at a high level, in such a way as to render alcoholic drinks more expensive: for example, Directive 92/77 provides for a minimum VAT rate of 15 %.

The matter of excises involves two aspects: harmonisation of these charge structures on alcohol and alcoholic drinks on the one hand, and the convergence of such charges for the same products on the other. Directive 92/93 provides for the

application of an excise on beer (in addition to wine and other alcoholic products). Directive 92/84 provides for the harmonisation of the production charge percentages for wine, beer and other alcoholic products.

Within the EU, the lack of fiscal harmonisation in relation to the excises of the different countries creates trade distortions between the EU countries. In fact, especially with regard to neighbouring countries, there is active trade along frontiers caused specifically by the different excises existing in the different countries. At the same time, the excises in the beer sector make the product less competitive in terms of price

Source: DEBA

compared to substitute drinks like wine, soft drinks and mineral waters, which are not subject to this type of duty.

Finally, EEC Directive 88/136 on the packaging of liquids indicates the standards of packaging used for liquids. They are: 25, 33, 50 and 75 cl. This standard is optional; the manufacturer can use either the capacities in use in his own country or those fixed by the EU. In the second case, if the measurements are not identical, the 'e' mark is applied.

## OUTLOOK

Prospects for the sector, in the medium term, are for a general growth and concentration of beer manufacturing enterprises. Mergers and acquisitions will be directed towards new markets like the East European countries. Concentration in the sector, which facilitates the achievement of important scale economies, will continue to lower the employment level over the years to come. Diversification of beer will continue, with growth rates greater than those for non-alcoholic beer. The demand for non-alcoholic and light beers and, at the same time, for special and double-malt beers look ready to expand. There should also be a greater consumption of beer in the Mediterranean countries. There will be a general tendency to keep costs down by concentrating production facilities so as to obtain scale economies, as well as better supply and transport organisation and sales prices.

# Soft drinks and mineral waters

NACE 428

The consumption of soft drinks went up through the 1980s thanks to a greater attention on the part of consumers health and physical fitness which fostered the demand for low-calorie soft drinks containing sweeteners in place of sugar and, at the same time, a general swing of preference from more to less alcoholic drinks and, above all to non-alcoholic beverages. Table mineral water has, over the last ten years, virtually become a 'must'. French, Italian and German firms share the continental mineral water market.

## INDUSTRY PROFILE

### Description of the sector

The sector comprises soft drinks which are generally carbonated and prepared with water, sugar (excepting diet and light varieties), fruit juices, fruit extracts and/or other flavourings. Production in the sector is not concentrated in any specific area or country of the EU.

There are various ways to classify the products making up the sector. Among the principal types are fruit-based beverages (e.g. orangeade, lemonade and grapefruit), those with special formulas (colas, tonic waters, etc.), those named from plants (chinotto) and finally, diet drinks. The latter include low-calorie drinks on the one hand, and saline-integrated drinks on the other. A special category is that of tea-based drinks, which are becoming particularly important (some with fruit added). The consumption of such beverages has risen sharply over the last five years.

The value added produced by the soft drinks and mineral water sector is twice that of the wine sector, while it is 71 % of the cocoa, chocolate and sugar confectionery sector and 60 % of the brewing and malting sector.

An assessment of the size of the sector in the various EU countries, in terms of value added, shows Germany in the lead, followed by the United Kingdom and France. Such a classification hides a more complex situation, but one that is already visible if the soft drinks and mineral water sectors are taken separately. In both, production capacity depends directly on domestic consumption rates. Such a statement justifies the position of Germany, considering this is the EU country with the highest number of inhabitants and with a per capita consumption among the highest. In fact, both the consumption per capita of soft drinks and mineral water equals 88 litres and underscores eating habits which are much different to those of other EU countries. The United Kingdom, for instance, shows how the domestic soft drinks sector is consistent in terms of domestic consumption, production and number of employed, while the production of mineral waters goes mainly for export. The opposite is true in Italy which, though covering the domestic demand for soft drinks, is undoubtedly specialised in the production of mineral waters.

The biggest producers of soft drinks are Germany (6 670 million litres), the United Kingdom (4 123 million litres), Spain (2 756 million litres), Italy (2 625 million litres) and the Netherlands (1 012 million litres). Germany and Belgium, with 86 litres per person, are the countries with the highest consumption figures, while Portugal, with 36.3 litres per person, is the country where consumption is the lowest.

The biggest producers of mineral water are Italy (6 650 million litres), Germany (6 300 million litres) and France (5 406 mil-

Figure 1: Soft drinks, mineral waters  
Value added in comparison with related Industries, 1993

Source: DEBA

lion litres). Spain follows, with 2 001 million litres. With regard to per capita consumption, Italy is in the lead (118 litres) followed by Belgium (106 litres), Germany (92 litres), France (81 litres) and Spain (50 litres). The other countries have a per capita consumption of between 7 and 29 litres. France is the biggest exporter (185 million ECU) and, at the same time, the country with the best trade balance (178 million ECU) (the Netherlands, the United Kingdom and Italy come next). Germany also has fairly high export figures (72.3 million ECU) followed by the Netherlands (58.5 million ECU).

### Recent trends

Over the last decade, production at current prices has more than doubled, going from 8 767 million ECU in 1984 to 18 792 million ECU in 1994 with an annual growth rate of between the 3.6 % of 1991 and the 21.4 % of 1989 (excepting 1993, where a slight decrease was recorded). Apparent consumption shows a slightly higher annual growth rate compared to those recorded for production, but in 1993 there was a drop of 1.5 % compared to the previous year. The value of exports

Source: DEBA

at current prices also doubled, recording in 1989 and 1991 annual growth rates equal to 25.2 % and 23.6 % respectively, thereby consolidating the trade balance which went from 211.4 million ECU in 1984 to 358.6 million ECU in 1993. Employment figures went up from 1985 to 1991, with annual rates between 0.4 % and 4.6 %. Starting in 1992, there was an annual drop of around 3.5 %, which brought the number of employees in the sector back down to 1984 levels.

The consumption of soft drinks most definitely went up during the 1980s. The fitness craze, which provoked a fall in the consumption of alcoholic drinks, at the same time pushed up the consumption of soft drinks and mineral waters. EU production managed to cover internal consumption and also generated a surplus which went completely for export and rose steeply. Between 1984 and 1993, the increase, measured at constant prices, was over 54 % in terms of production, while the value added in the sector underwent a more restricted growth of 22 % going (at 1990 constant prices) from 3 976 million ECU in 1984 to 4 880 million ECU in 1994. The

smaller growth in the sector in terms of value added can be explained in part by the drop in the number of persons employed in the sector, caused by the recession of the early 1990s, which was not followed by an improvement of gross operating margins.

During the 1984-90 period there was a bigger growth of the 1990-base production index in the soft drinks and mineral waters sector than in the manufacturing industry as a whole and, since then, this index has remained practically unchanged, while that of the entire manufacturing industry shows a slightly fluctuating rate around the base-year figure. The production pattern between 1992 and 1994 has strongly affected employment levels in the sector, which appear aligned to those of the manufacturing industry in general. The 1990-base index in relation to the number of employees in the soft drinks and mineral water sector was lower than that of the manufacturing industry during the 1984-94 period. Three separate stages can be highlighted: first, a period of substantial stability from 1985 to 1987; this is followed by a period of growth to 1990,

**Figure 4: Soft drinks, mineral waters  
International comparison of production in current prices**

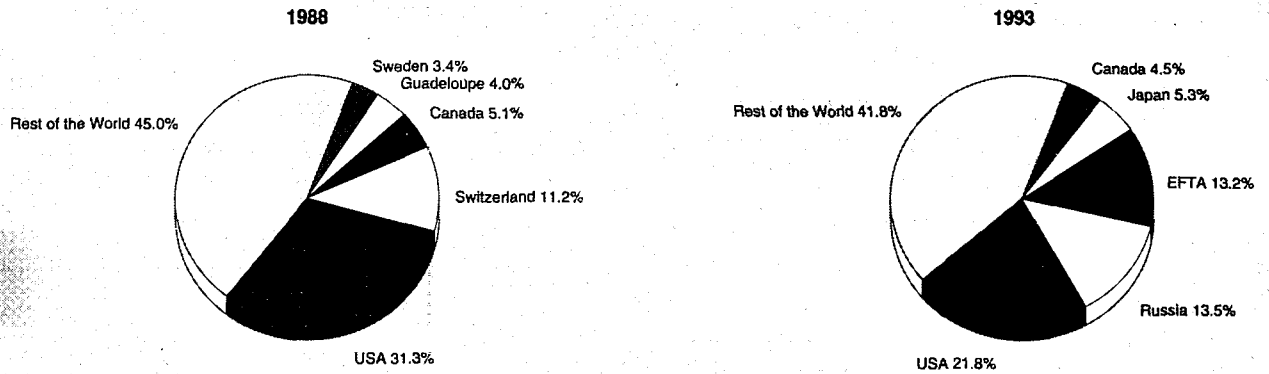

Source: DEBA

**Figure 6: Soft drinks, mineral waters  
Destination of EU exports**

Source: Eurostat

after which there is a sharp fall, with annual variations around 3.5 % - slightly lower than those recorded in the manufacturing industry as a whole. This steep drop in jobs brought the number of employed in the industry in 1993 to the same levels as 1984.

#### International comparison

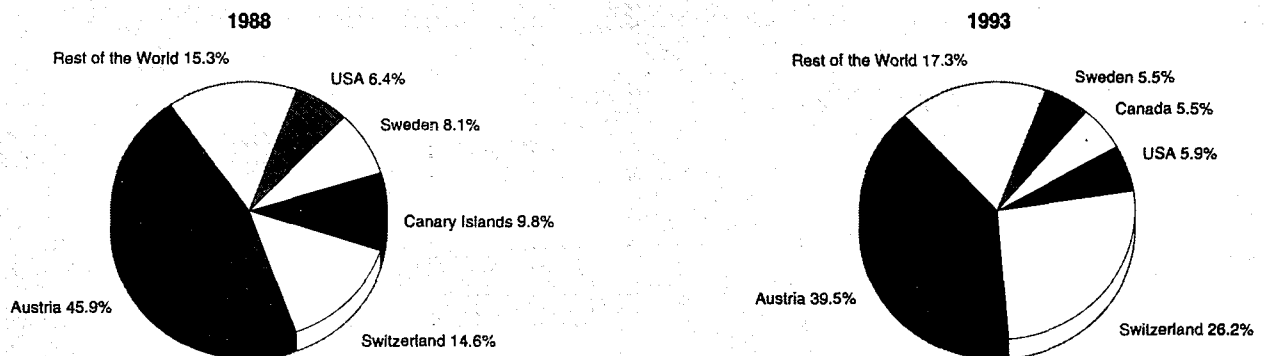

The considerable increase in value at current prices of soft drinks and mineral water production recorded in the 1980s has changed the strength of the EU, USA and Japan. In 1984, European production was around one-third that of the US, while in 1993, the situation was much closer between the two areas. And, although Japan also shows an impressive growth over the period, has not bridged the pre-existing gap with the USA to the same extent. The increased production levels are interesting considering the shrinking employment figures in the sector. And, while production indices of the EU and Japan at constant prices show a general, somewhat parallel upswing in the sector until 1990, patterns thereafter diverge, with a continuing rise in Japanese production and a levelling off of Community production.

#### Foreign trade

A look at imports and exports shows that the sector produces chiefly for domestic markets. The self-sufficiency in terms of EU production is reflected by the level of exports which increased throughout the 1980s, rising almost 90 % between 1984 and 1993. The trade balance, though remaining largely active, must take account of the growth in imports which more than doubled (increasing by 65 %), showing a greater inclination to import as is shown by the export/import ratio which, from 1984 to 1993 went from 9.26 to 4.94. The percentage variations in the 1990 base terms of trade index illustrate a situation marked by an almost regular fluctuations between good and bad years. Finally, in the 1991-93 period the terms of trade index showed an overall drop equal to 16.7 %.

Exports to countries outside the EU changed between 1988 and 1993, with Russia and the EFTA countries taking a larger share. Japan's share also grew while Switzerland, which in 1988 imported 11.2 % of EU exports, drastically reduced this figure in 1993. On the import side, there are no important changes, excepting the increase in Switzerland's share (from 14.6 % in 1988 to over 26.2 % in 1993) and the 6.4 % drop in Austria's share. The structural data which emerge are in and of themselves interesting. In fact, as supplies are con-

Source: DEBA

centrated in Austria and Switzerland, the sector there is strongly subjected to localised trade.

Generally speaking, the degree of penetration of imports has undergone a slight increase, going from 0.3 in 1984 to 0.5 in 1994, with an overall growth of 66 % (7 % in 1992 and around 19 % in 1993). The export/production ratio went down in the 1984-90 period, and in 1991 and 1993 recovered to reached the same level recorded in 1985.

## MARKET FORCES

### Demand

Nearly all soft drinks follow a seasonal pattern, with consumption varying between hot months and cold months depending on the type of drink and its use function. The demand for soft drinks and mineral waters is strong throughout the EU and growth is more than proportional compared to the drop in demand for alcoholic drinks. As a result, the per capita consumption of soft drinks within the EU has gone from 44 litres in 1982 to 66 litres in 1993.

Within the total consumption of soft drinks, that of colas is prevalent throughout the EU, with levels between 41 % (France) and 56 % (Greece). Exceptions are Portugal and Italy, where the consumption of fruit juice drinks is prevalent, with respective shares of 47 % and 32.4 %. Fruit juice consumption is also high in the Netherlands, Spain and France, where it touches around 30 %.

On the basis of per capita consumption of soft drinks, Germany leads (86 litres per person), followed by Belgium (85.6), Ire-

land (77), the United Kingdom, the Netherlands and Spain (73), Portugal, with a per capita consumption of 36.3 litres is the back runner. With regard to mineral waters, Italy tops the list (112 litres) followed by Belgium (106 litres), Germany (92 litres) and France (81 litres). Portugal, the Netherlands, Ireland and the United Kingdom have a per capita consumption between 7 and 29 litres.

The general upswing in consumption has occurred not only as a consequence of the fitness craze, but also in response to the deterioration of the quality of tap water. There also has been a general tendency over the last few years for consumer preferences to shift from alcoholic beverages to drinks with low levels of alcohol (or even none), hence the move towards soft drinks. The economic recession has accelerated this trend. The number of teetotalers is also going up, especially among women. Attention to health and physical fitness also has boosted demand for low-calorie drinks, containing artificial sweeteners instead of sugar and salt integrators. The consumption of diet and light soft drinks reached 30 % in the United Kingdom and 33 % in the USA, while the mean European figure is around 9-10 %. The introduction of products with dietetic/light characteristics has helped to alter the competitive balance of corresponding conventional drinks. In fact, light soft drinks occupy areas which once belonged to regular soft drinks and mineral water.

### Supply and competition

Though the drop in employment figures in the sector has improved productivity, it has not been able to prevent the further reduction of the gross operating margin, which had already been undergoing a negative trend since 1987, as a result of the progressive increase of production costs. Starting in 1988, the gross operating margin was reduced at an annual rate between 0.7 % and 7.1 %. The expansion of the hard discount distribution chains and greater consumer concern for prices have spurred soft drink manufacturers to review their brand and promotion strategies. Promotion and advertising are strategically important levers for the marketing of soft drinks and mineral waters.

Within the sector, it is difficult to make comparisons at the international level in relation to the competitiveness of different product systems, due to the high influence of transport costs on retail prices which create big problems of competitiveness in the case of extra-EU exports. The consumption of mineral water, due to high transport costs, is essentially tied to domestic markets.

In 1993, the most utilised packaging for soft drinks in the EU was non-returnable plastic, especially in Italy (64.7 %), but also in other countries, e.g. Ireland (56 %), the United Kingdom (51 %), Spain (43.9 %) and Belgium (43.4 %). In Germany and Portugal, returnable glass/plastic is preferred (respectively 76.7 % and 53.1 %). Metal packaging accounts for a modest share and is most popular in the United Kingdom (30.4 %). Other types of packaging (cardboard, non-returnable glass and pre/post mix) do not account for more than 10 % of the packaging used by the Member States. Two principal marketing channels are used by soft drink manufacturers: the

'long channel' (company, agent, sales outlet or bar/cafe) and the 'short channel' (direct from manufacturer to retailer). Direct retail is most prevalent where large distribution chains are involved.

### Production process

Production in the sector is not restricted to any particular area or country. In the case of mineral waters, the geographic location of the companies depends on the existence of springs.

One factor which has undoubtedly stimulated the soft drink market is the evolution of packaging, through the use of plastic containers, especially those of the PET type. The trend towards the replacement of glass with plastic materials has been very strong within the entire drinks sector. However, the pace at

which this replacement has gone on, as well as the methods used, have differed greatly from one segment to another. In the soft drinks sector, as in that of mineral waters, the swing towards PVC first and PET next has been strong. While the share occupied by metal cans has remained steady in the soft drinks sector, the use of glass has dropped steeply. Used in both the soft drinks and the mineral waters segments, PET has a high resistance to the pressure of carbon dioxide and better chemical inertia than its predecessor, PVC. Just like glass, PET can be re-closed and is transparent. A possible threat to the use of this material could come from increased legislation on plastic packaging.

## INDUSTRY STRUCTURE

### Companies

A look at the evolution of the production specialisation index over the 1984-93 period shows that Greece is the only country whose index has risen, going from 2.08 to 3.66, while Belgium showed the biggest fall, going from 1.11 to 0.75. The data available for the other countries shows minimum fluctuations.

In the soft drinks sector, the level of concentration is very high and is tied to the existence of just a few large multinationals (Coca-Cola, Pepsi-Cola, Cadbury and Schweppes). In the mineral water sector on the other hand, three types of company stand out: regional, national and supranational.

French, Italian and German firms share the continental mineral water market. First on the list are the two French giants Perrier and Evian, followed at a distance by Vittel (F), Volvic (F), and four Italian firms: Sangemini-Ferrarelle, San Pellegrino, San Benedetto and Crippa & Berger Levissima.

### Strategies

In the soft drinks sector, where the areas of taste and consumption are well outlined and now widely consolidated, in-

Source: Nomisma

novation concerns marketing more than the products themselves.

The unitary value, weight and volume of the products contribute to storage and transport costs far above those of other consumer goods. Consequently, the market areas for the individual production facilities are somewhat limited.

Mineral waters can be distributed regionally, nationally and internationally, depending on the size of the firm, the customers' perception of intrinsic and extrinsic qualities, etc. The mineral waters which go for export (e.g. Perrier and San Pellegrino) are those with the greatest value added and which are the most diversified, destined for the medium-high income consumer segments.

Investments in advertising take up a substantial share of the total costs borne by the manufacturers. Marketing and product communication strategies have contributed heavily to the sector's success. These are based on carefully studied placing and focus on specific functions and uses, the widening of the product range and the efficient distribution policies of the larger companies, which have permitted a diffuse presence

of products in various businesses and sales outlets. The globalisation of tastes on an international scale has also helped to push up sales. Finally, the gradual pollution of ground water has forced consumers to turn to mineral waters and soft drinks, and the arrival of products on the mass market has considerably enlarged the potential consumer base.

In 1993, 17 mergers and acquisitions took place, of which 11 involved multinational groups of the EU, especially from the British (5 operations) and French groups (4 operations). The phenomenon has slowed down due to the recession of recent years. In 1994, there were 14 mergers and acquisitions, of which only 4 involved European groups.

#### Impact of the Single Market

The impact of the creation of the Single market on the soft drinks and mineral water sector has been globally positive, increasing firms' efficiency at satisfying consumer demand satisfaction and dismantling barriers to intra-EU trade, as the regulations on additives had been before harmonisation. Moreover it favoured international trade thanks to the abolition's

of controls at internal frontiers. Higher costs were, however, generated by the approval of the packaging regulation.

The harmonisation of VAT within European Countries, the prevention of new national barriers connected to the environmental issue and the creation of a single EU currency are the main priorities for the industry.

---

## ENVIRONMENT

---

The widespread use of PET and PVC for packaging made the disposal of these plastic containers more acute and leads the sector to waste closely with consumers, distributors and local authorities to set-up environmentally-friendly packaging systems.

---

## REGULATIONS

---

The basic directive regulating the exploitation and marketing of mineral waters is Directive 80/777. A draft proposal of this directive has been done in which the European mineral waters industry has asked for its revision and the update of certain technical provisions to it. As part of the discussions under way, the Commission declared its willingness to regulate spring and mineral waters separately (such an approach is contained in document III/5502/93 - Rev.2).

EU Directive 94/62, which has introduced a series of measures concerning the recovery and recycling of food packaging, will oblige companies to adopt adequate packaging and change supply and transport organisation within the sector in order to facilitate and expand the collection and recycling of packaging.

---

## OUTLOOK

---

The gradual shift in consumer tastes from alcoholic to soft drinks will positively affect the growth of consumption in this sector. In particular, greater attention to health and fitness will increase the popularity of light and sports drinks. Similarly, the gradual deterioration of ground water sources will push up the consumption of mineral water. Such growth in the sector will favour concentration and stimulate more acquisitions.

Written by: NOMISMA

The industry is represented at the EU level by: Union of Soft Drink Associations (UNESDA). Address: Boulevard Louis Schmidt 35, Bte 14, B-1040 Brussels; tel: (32 2) 735 3749; fax: (32 2) 732 5102.

# Tobacco

## NACE 429

The tobacco industry has a high value added concentrated mainly in the processing stage of production. The consumption of cigarettes began to drop in many EU countries in 1992 and 1993. Production, which for many types of tobacco does not respond to market requirements, will fall in the future due to the lowering of the ceiling set by the Community. This is likely to provoke a rise in unemployment - particularly in the Mediterranean growing areas - given the labour-intensity of tobacco manufacture.

### INDUSTRY PROFILE

#### Description of the sector

The industry comprises the growing and processing of tobacco to make cigars, cigarillos, cigarettes and other products like pipe tobacco, chewing tobacco, cut tobacco for cigarettes and agglomerated sheets (NACE 429). The main types of tobacco grown in the EU are: Flue Cured (e.g. Virginia), Light Air cured (e.g. Burley), Dark Air cured (e.g. Paraguay), Fire cured (e.g. Kentucky), Sun cured (e.g. Herzegovina), Basmal, Katerini and Kaba Koulak classic.

Altogether, the EU accounts for 9 % of world production. In the EU, the main producers are Italy with 45 % of overall production, Greece with 32 %, Spain with 11 %, and, to a lesser extent, France and Germany.

The tobacco industry has a high value added, equal to 44 669 million ECU, far above that of related sectors like mineral water and soft drinks, beer, cocoa-based products, sweets and ice cream, which already are considered to be in the high-margin bracket. The countries of the EU which most strongly contribute to this value added are the United Kingdom, Germany and Spain.

With regard to processing, the biggest EU labour forces are in Germany, The Netherlands and the United Kingdom, while Italy, Spain and Greece have the highest work forces engaged in cultivating tobacco.

#### Recent trends

At current prices, apparent consumption rose until 1990 and then levelled off; production levels followed a similar trend. Exports also went up, while the trade balance fluctuated.

1992 shows a drop in tobacco production of around 11 %, caused by the reform of the Common Agricultural Policy (CAP), which resulted in a shrinkage of cultivated land area, and also by the prolonged drought in Greece (Europe's second largest producer), where tobacco yield fell by around 24 %.

Average real annual growth rates for production and apparent consumption have been substantially stagnating over the decade; the sudden increase between 1989-1993 was mainly caused by the reunification of Germany.

Extra-EU exports have been growing since 1989, after dropping between 1984-89. In fact, levels between 1992-93 increased by 8.16 %. Extra-EU imports showed a similar dynamic even though the 1989-93 increase was at 21.12 % and 1992-93 showed a drop of 13.23 %.

#### International comparison

The USA, though with production levels far above those of the EU (728 801 tonnes in 1993 as compared to 179 430 tonnes) has a production value at current prices substantially below those of the EU (24 564 million ECU as opposed to

Figure 1: Tobacco  
Production in comparison with related industries, 1993

39 671 million ECU). This situation persisted through the 1984-93 period.

The pattern of EU production at constant prices showed an ongoing increase with strong variations in 1993. Prices in Japan and the USA on the other hand, were less stable; and while the former underwent a slight upswing until 1992, the latter recorded a fall. This trend can be attributed to drops in cultivated land area and in yield per hectare. In 1993, such drops had a particularly significant affect on Flue Cured and Burley crops.

Similarly, economic and social problems between 1992-93 caused production to drop in Cuba by around 50 %. Conversely, strong growth was recorded in the East European countries, especially Poland and Romania which practically doubled their tobacco production in only two years.

#### Foreign trade

In 1988, EU exports went mainly to the Middle East (about 17 %) and south-east Asia (14 %). By 1993, the EU's export

partners had changed radically, with the Far East's share almost doubling and the appearance of Russia. Exports to the USA are expected to drop considerably over the next few years, though in any case they are not particularly significant. The further drop will reflect regulations whereby 75 % of tobacco used to make certain cigarettes must be of domestic origin, and the fact that the American anti-smoking laws have become even stricter.

With regard to imports, the Canary Islands supply more than half the EU's tobacco. In 1993, the market share of the Canary Islands was strengthened, while imports from the USA and Cuba decreased by around 50 %.

The penetration of imports has increased steadily over the decade, as foreign tobaccos meet the needs of the EU market better than those produced by the Member States. 45-50 % of Community imports are made of Virginia flue cured. Despite this, since 1987 there has been a sustained increase in exports as well, chiefly of dark tobaccos to the less demanding markets.

At the global level, the EU is the biggest importer of tobacco leaves and accounts for about half of all world imports, though

**Figure 4: Tobacco**  
International comparison of production in constant prices

(1) Eurostat estimates.  
Source: Eurostat, DEBA

this figure fell a little in 1993. Among the major importers are the USA, Japan and the former Soviet Union. Raw materials originate in countries with favourable climatic conditions for growing tobacco, e.g. Brazil and some African countries. In 1993, trade in tobacco leaf fell slightly, causing a drop in imports. The global trade of cigarettes on the other hand, rose in 1993: the contribution of the EU in terms of imports and exports was 24 % and 28 % respectively.

## MARKET FORCES

### Demand

Over the last 20 years, there has been an overall redirection of demand for tobacco-based products. Consumption has turned prevalently to cigarettes, while there has been a drop in the consumption of pipe tobacco, cigars, etc. From 1987 to 1992, the production of cigarettes went up, especially in Spain, Germany and The Netherlands. Meanwhile, Italy and France experienced a drop in production, and in 1993 there was a general drop in all Member States. The cigarettes which have undergone the biggest growth rates are lights and filter

cigarettes, with a preference for Virginia cured and American blend tobaccos.

As regards per capita consumption, in 1992 the biggest quantities were consumed in Greece and Spain, while the other countries show fairly uniform figures. It should be noted that in The Netherlands, despite that country's considerable increase in production, per capita consumption is low, with a significant tendency to export.

### Supply and competition

The EU is the world's fifth biggest producer of tobacco with a share of around 9 %. The major producing countries are in Asia (with an overall production of 4.8 million tonnes), specifically China, with a production of 3.5 million tonnes, India (576 000 tonnes), Indonesia (162 000 tonnes) and the Philippines (114 000 tonnes). These are followed by the USA (887 000 tonnes), South America (820 000 tonnes) - including Brazil (600 000 tonnes) and Argentina (107 000 tonnes) - and finally, the former Soviet Union (245 000 tonnes). During

Source: DEBA

recent decades, there has been a progressive increase in the production of tobacco in the developing countries (i.e. Asia and South America), which have lower labour costs - a factor accounting for about 35-40 % of overall costs - and more favourable weather conditions.

Community production is more focused on oriental tobaccos which, though the demand for these at the world level is on the upswing, have high production costs compared to those of other producer countries. Bigger problems affect the six other types of tobacco produced in the EU (Flue Cured, Light Air Cured, Burley, Dark Air Cured, Fire Cured, Classical Oriental and Oriental Filler), which, for the most part, are not of high enough quality to meet market requirements or do not possess sufficiently distinctive traits to distinguish them from foreign tobaccos (e.g. Burley).

### Production process

Over the last 10 years, the processing industry has concentrated its efforts on introducing innovative production processes through high technology which allows big savings of raw materials. In particular, expanded tobacco and techniques permit the re-use of dusts and shreds.

Generally speaking, consumer preference for light cigarettes has been met without altering blends. Rather, changes to the filters used and the degree of ventilation of cigarette papers and/or cigarette holders have been made. At the agricultural level, varieties of tobacco are being selected which have a low content of nicotine and tar, and are particularly outstanding in terms of flavour.

## INDUSTRY STRUCTURE

### Companies

The tobacco industry is distinguished by a high degree of concentration, with the existence of state monopolies in many EU countries and the presence of multinational companies serving global markets. During the 1991-92 period, the state monopolies of France (Seita), Spain (Tabacalera) and Italy accounted for 50-60 % of domestic markets, while the major private companies were BAT Industries, Hanson Imperial and Rothmans International (UK). Other multinational companies with significant shares of the EU market are Philip Morris, American Brand and RJR Nabisco (USA). At the agricultural level, concentration remains high with 90 % of tobacco leaf

marketing and about 40 % of processing in the hands of transnational tobacco conglomerates.

The highest degree of specialisation is found in Denmark and Greece. From 1984 to 1993, most countries maintained the relative importance of the tobacco industry to the entire economic system. An exception was the United Kingdom, where the sector declined in significance and Portugal, where a significant increase in activity was recorded.

### Strategies

The tobacco industry is distinguished by products that are essentially differentiated through marketing strategies which highlight packaging and associate cigarette smoking with a particular social status. The slowdown in cigarette consumption in most European countries has fostered a process of acquisitions directed primarily towards new markets, e.g. the East European countries where health and consumer safeguarding systems are not yet very developed. Over the 1993-94 period, ten operations were concluded, mainly by US and British multinationals.

### Impact of the Single Market

The creation of the Single Market has been globally positive, albeit small. It has affected in particular trade intensity, thanks to the reduction of controls at internal frontiers. The very limited nature of the impact is mainly due to the fact that the industry has been deeply regulated by tobacco CMO since 1970.

The reduction and the harmonisation of VAT taxation on cigarettes, the harmonisation of advertising towards a less severe legislation, and less constraining policies for smokers are priorities for the industry.

## REGULATIONS

The Common Market Organisation of tobacco became effective with Regulation 727/70, as amended by Regulation 860/92. The regulation of 1970 underwent various amendments through Regulation 2075/92, which represents the new basic regulation.

The most significant aspects distinguishing the new organisation of the sector are:

- since 1993, the Council no longer fixes an institutional price; rather, a system of financial incentives for the various categories of tobacco exists;

**Table 10: Tobacco Production specialisation (1)**

(ratio)	1984	1993

Source: DEBA

- in the raw tobacco sector, customs tariffs ensure limited protection, while the incentive system compensates for the difference between the price of Community tobacco and that of imported tobacco;
- no more repayments are called for on exports, though repayments must still be made on 1990, 1991 and 1992 harvests;
- public storage has been abolished;
- the incentive system is aimed at guaranteeing income for growers, as well as fostering market orientation; and
- a global production ceiling is fixed for the entire Community (370 thousand tonnes in 1993 and 350 thousand tonnes in 1994), split between tobacco varieties and among Member States. Passing this threshold means no longer being eligible for financial incentives for surplus production (the 'guaranteed thresholds' are contained in Regulation 2076/92, as amended by Regulation 164/94).

Procedures for the implementation of quotas in the raw tobacco sector (Regulation 3477/92) have been amended by Regulation 268/94, in consideration of the fact that guaranteed thresholds for the 1994 crop are, compared to those of 1993, higher for some varieties and lower for others.

With the aim of concentrating supply and adapting to the quality needs of the market, aid equal to 10 % of financial incentives is provided in the event of agricultural agreements being signed between a primary processing company and an association of growers, and on the condition that the agreement covers the entire production of the group of growers.

---

## OUTLOOK

---

The lowering of the overall production ceiling and market redirection policies relating to the varieties of tobacco grown in the EU will lead to greater unemployment, especially in the Mediterranean countries specialising in tobacco production. Production in the EU will furthermore have to be redirected towards tobacco crops with the greatest market demand. This situation is aggravated by the tendency towards a drop in consumption and production mainly affecting France, Spain, Germany and Denmark.

An increase in the number of acquisitions aiming at greater penetration and consolidation in new markets is expected. At the same time, European tobacco companies will have to concentrate their research on low-tar and nicotine production.

Overview

NACE 43, 44, 45

The sector can be divided into the upstream industries of textiles and leather and the downstream industries of clothing and footwear. The links between the industries are strong, with the clothing industry being the destination of about half the output of the textile industry and the footwear industry accounting for almost half the leather production.

In terms of employment, the sector is very important, with a labour force of about 2.5 million units in 1994. However, employment in the sector has declined by about 30 % during the 1984-94 period.

After the fall in production recorded for two consecutive years, in 1994 the sector's output has risen slightly, and forecasts for the medium term are encouraging. As growth in production will lag behind growth in consumption, however, the trade balance deficit for the EU textiles, clothing, footwear and leather industry is bound to increase in the medium term.

INDUSTRY PROFILE

Description of the sector

The textiles and clothing industries represent together about 86 % of total production of the sector, the footwear and leather industry accounting respectively for about 9 % and 5 %. Hence, the analysis in this overview will concentrate on textiles and clothing, whose trends affect the entire sector of textiles, clothing, leather and footwear. For details on the footwear and leather sector, the reader should refer to the specific chapters.

The textile and clothing industries cover all production processes required for the manufacture of garments, from fibre preparation to clothing finishing. The textile industry also covers the manufacture of household and technical textiles.

In 1993, the two industries employed nearly 2.4 million, which represents about 10 % of manufacturing employment in the EU. Together, they accounted for 5 % of the manufacturing industry's value added. The industry is mainly concentrated in Italy, Germany, France, and the UK.

In the future, industry will have to face a changing international environment, as 1994 has seen the final conclusion of the GATT Uruguay Round negotiations. This means that quantitative limitations on imports of textiles and clothing will be gradually phased out over a ten-year period starting in 1995. This liberalisation is expected to increase competitive pressure on EU producers, partly via a reduction in import prices.

Recent trends

Both the textile and clothing industries were badly hit by recession. Apparent consumption of textiles and clothing decreased in 1993 by 9 % in current prices, while 1994 is expected to have experienced a slight rise. Consequently, production fell by 10.2 % in 1993 in current prices, while production for the manufacturing industry as a whole fell by 4.5 %. In constant prices, production fell by 6.3 % in 1993. This reduction in production was accompanied by a fall in employment of 139 000 (5.4 %) in 1993. The two industries thus shed employment of 731 000 between 1984 and 1993, of which 492 000 in textiles and 239 000 in clothing.

The two industries had a trade deficit around 13 billion ECU between 1991 and 1993, which is expected to worsen further

Figure 1: Textiles, clothing, footwear, leather Value added in comparison with related Industries, 1993

Source: DEBA

in the next years. This deficit is mainly due to large imports of clothing and the inclusion of raw material imports. The export/import ratio for clothing was 39 in 1993, compared to a ratio of 87 for textiles. In addition, as textile imports used here include raw materials and knitwear, the export/import ratio for textiles becomes 127 in 1993 when excluding these imports.

International comparison

The EU is a much larger producer of textiles and clothing than the USA and Japan. In 1993, EU production was 43 % higher than in the USA and more than double the production in Japan. The market for textiles and clothing in terms of consumption indicates even larger differences, as EU apparent consumption in 1993 was 66 % higher than in the USA and nearly three times higher than in Japan.

Production and employment compared to EU total manufacturing industry**

1993 are DEBA estimates.  
Source: OETH, Cotance, DEBA, Eurostat

In 1993, production of textiles and clothing decreased strongly in the three trading blocks, although slightly more in the USA than in the EU and Japan. Between 1984 and 1993, apparent consumption expanded most in Japan, followed by the EU and the USA. The slow growth of apparent consumption in the USA was partly compensated by exports to third countries which have doubled between 1984 and 1993, while EU exports are 50 % higher in 1993 compared to 1984. Exports of textiles and clothing from Japan are even lower in 1993 than in 1984.

#### Foreign trade

Between 1985 and 1994, EU exports of textiles and clothing grew at an annual average rate of 4.4 % in current prices. Imports, however, expanded by an annual average of 11.3 % during the same period, which resulted in a worsening trade balance, expected to have reached a deficit of more than 14 billion ECU in 1994. This trend is mainly explained by the continuously deteriorating trade position of the clothing industry, as EU imports of clothing increased by an annual average of 11 % between 1984 and 1988 and 14 % between 1989 and 1993, against 5 % for exports between 1984 and 1993.

In 1993, about 25 % of EU consumption of clothing relied on extra-EU imports, compared to 14 % in 1984. In contrast, the textile industry has kept a higher share of EU textile consumption. In 1993, only 20 % of EU textile consumption relied on extra-EU imports (including raw materials imported by the industry itself). This difference is partly due to the fact that labour costs account for a lesser share of production costs in the textile industry and that a large share of the industry does not primarily compete on the grounds of costs but factors such as product innovation and quality, as is the case in industrial textiles.

In 1993, around 66 % of EU exports of textiles and clothing went to only 10 countries, compared to 58 % in 1988. The major foreign markets were the USA, Switzerland, Austria, Japan and Poland. Poland's high position in textile and clothing exports stems from the fact that Poland has developed into the EU's main foreign partner for the manufacture of garments on the basis of outward processing trade (OPT), as fabrics of EU origin are sent to countries like Poland, to be processed into garments for re-importation.

The main sources of EU imports of textiles and clothing in 1993 were China, Turkey, Hong Kong, India and Austria, imports from the latter mainly being man-made fibres. The importance of major suppliers has increased significantly in recent years. In 1993 the ten major countries of origin supplied 63 % of all textiles and clothing exports to the EU, compared to 46 % in 1988. Among these countries, China stands out with the highest growth rate of exports to the EU, as imports from China grew 2.6 times between 1993 and 1988.

#### MARKET FORCES

##### Demand

The EU textile and clothing industry has had to suffer decreasing market shares within the EU as well as fierce competition internationally, exacerbated by the fact that its labour costs are among the highest in the world. In 1992 and 1993, EU apparent consumption of textiles and clothing decreased in current prices, while imports continued to grow. The EU's import/consumption ratio for textiles and clothing thus continued to increase, and reached in 1993 a level of nearly 23 %.

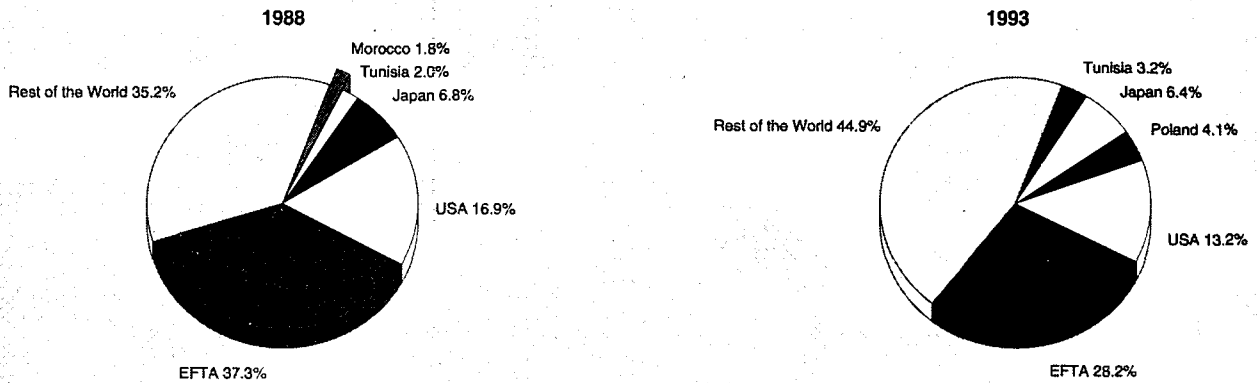

In the face of decreasing market share and the recent fall in consumption of textiles and clothing within the EU, the industry has explored ways to develop sales outside the EU. While exports of textiles and clothing expanded steadily in recent years despite the recession, the export potential of EU textiles and clothing, notably to the rapidly growing economies in Asia, has not yet been fully realised.

##### Supply and competition

Both the EU's textile and clothing industries have to compensate for the high labour cost content of their production costs in the international competitive environment. Within the textile industry, some sectors such as carpets are much less exposed to this problem, as their production is highly capital-intensive. In the clothing industry, most companies are heavily exposed to this competitive pressure, although this is less the case for high-quality products and goods which are supplied to retailers within very short delays (i.e. less than a week from order to delivery).

While a significant share of EU clothing production has already been lost to foreign competitors, clothing manufacturers are

**Figure 4 : Textiles, clothing, footwear, leather  
Destination of EU exports**

Source: Eurostat

increasingly delocalising part or all of their EU production to lower-cost countries, mainly in locations close to the EU such as Poland and Morocco. While the assembly of clothing, a very labour-intensive operation, is thus moving gradually outside the EU, fabrics tend to be mainly of EU origin. This means that the textile industry has, to date, maintained most of their customers. But this situation could change dramatically in the future if EU textile producers supplying the clothing industry were not able to safeguard these supply links against foreign competition.

#### Production process

Unlike the clothing industry, the textile industry has become a technologically advanced industry during the 1980s, through restructuring and important investment in modern machinery. Spinning, weaving and knitting processes have been highly modernised in many companies in the recent past, which has allowed them to reduce the share of labour in production costs and to increase quality and speed.

The clothing industry has not succeeded in significantly reducing the labour content of its production, as research into alternative production techniques, such as fully automated production, have not led to applicable methods of clothing production. However, modern technologies have been applied to some processes such as design and cutting. The clothing industry is at present much more influenced by innovations which do not relate directly to new production techniques, but to the organisation of production via the use of new information technologies such as EDI (electronic data interchange). These allow for the increasingly flexible organisation of production, reduced delivery times and the management of shorter production runs.

### INDUSTRY STRUCTURE

#### Companies

In terms of turnover and employment, more than three quarters of the EU textile and clothing industry is concentrated within firms employing more than 20 people. However, nearly 600 000 people are employed by small firms, of which 353 000 are in the clothing industry. The clothing industry employs an average 17 people per firm, compared to 27 for the textile industry. In the textile industry, given higher capital requirements and technological skills, the average size of firms is greater.

Among the largest textile and clothing companies in the EU, several are active in both textiles and clothing. Examples are

Coats Viyella (about 21 % of turnover is clothing), Courtaulds (50 % in clothing) and Marzotto (25 % in clothing). Other major companies, however, specialise in certain fields only, such as Beaulieu (carpets) or Triumph (underwear).

#### Strategies

In the EU clothing industry, in recent years a growing number of companies have adapted their organisation of production to concepts such as quick response, just-in-time and lean production. The number of collections has expanded from two per year in the past to up to six collections today for some articles. This implies that order times have shortened on average, which partly favours manufacturers closely located to the market.

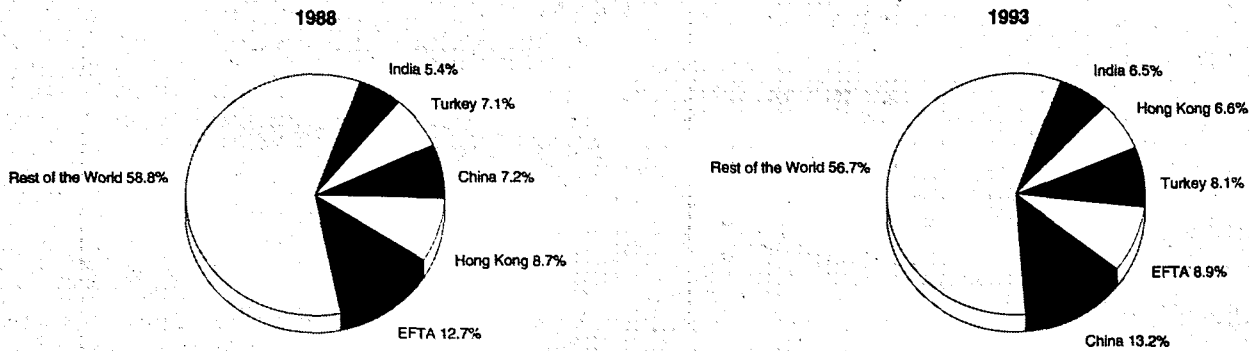

The time required to produce a garment is conditioned not only by the organisation of clothing production, but also by the delivery in due time of the fabric, and yarn. In the extreme, quick response to clothing orders implies high reactivity from the whole textile pipeline. Therefore, the strategies followed by clothing producers also imply adjustments by the textile industry.

The clothing industry also increasingly uses delocalised production in lower-cost countries as a response to decreasing market shares and strong price competition from lower-cost countries, mainly in Asia. Again, the textile industry as the principal supplier has to adjust to these policies in order to maintain its customer base.

#### Impact of the Single Market

The Internal Market programme has been globally positive for the sector so far. Free movement of goods has been the most important issue for the sector. On one hand side, the abolition of national import quotas increased the market share of low cost producing countries. However, on the other side, the abolition of controls at internal frontiers has reduced delays and transport costs, which has allowed the EU clothing companies to specialise in higher quality and fashion-led segment of the market, where consumer demand is more dynamic. Other positive effects of the common market are coming from the Community trade mark, the opening of public procurement markets, the support policy to SMEs and the training and education programmes. However, the legislation on environmental protection should take more into account the ability of EU companies to achieve ever increasing standards. The main priorities for the future are the elimination of the national non-tariff barriers to goods trade, most of them having been recently adopted for purposes of consumer protection, an ac-

celerated fiscal harmonisation (more particularly, the harmonisation of the VAT regimes), an accelerated harmonisation of monetary policies in order to avoid exchange rates fluctuations, and a fairer competitive environment not only within the EU but also in relation to extra-EU trade.

## REGIONAL DISTRIBUTION

The textile industry is located in a relatively small number of regions, with a heavy population of workers. The clothing industry is more widely spread, in relatively smaller pockets of employment.

When the two industries are considered together, a number of regions stand out for their heavy concentration of employment. Employing more than 150 000 workers are Lombardia (I) and Cataluna (E). Employing between 100 000 and 150 000 are four regions - Veneto (I), Bayern and Nordrhein-Westfalen (D), and Norte (P).

There are eight regions employing between 50 000 and 100 000, three each in Italy and France, one in Germany and one in the UK. There are fourteen regions employing between 25 000 and 50 000.

The figures are more significant when looked at as a proportion of all industrial employment in a region. Regions with over 30 % of industrial employment in textiles and clothing are Norte (P), Kentriki Makedonia (GR), Dytiki Ellada (GR), and Castilla-La Mancha (E). It is noteworthy that the last three are not included in those areas with the heaviest absolute level of employment.

Regions with 20-30 % in textile and clothing employment, as a proportion of industrial employment, are nine in number, including two in Portugal and two in Greece. Two further Greek regions have textile and clothing employment of 15-20 %. It is evident that in Greece and Portugal, two of the EU's least prosperous Member States, regional dependence on the textile and clothing industries is of considerable importance.

## ENVIRONMENT

The manufacture of textiles poses greater problems for the environment than the manufacture of clothing. There is heavy use of energy in man-made fibres, and many cleaning processes with natural fibres (as well as the use of pesticides etc. in their growth). The danger of pollution in water - used widely for many textile processes - has been countered by EU and national regulations (which affect industry generally) on effluents discharged to water.

Clothing manufacture raises fewer environmental problems. Here however the question of the final disposal of garments raises difficulties for synthetic fabrics, because these are not biodegradable, unlike fabrics made from natural and cellulosic fibres.

There are heavy costs involved in improving environmental standards. The EU Commission has estimated that environmental costs in dyeing and finishing account for between 3.5 % and 9.2 % of total costs, depending on the Member State involved.

## REGULATIONS

The Uruguay Round of multilateral trade negotiations was successfully concluded in December 1993 and the Final Act signed at the Marrakech Ministerial meeting in April 1994. In the area of textiles and clothing, the object of the negotiation was to secure the eventual integration of the textiles and clothing sector - where much of the trade is currently subject to bilateral quotas negotiated under the Multifibre Arrangement (MFA) - into the GATT, on the basis of strengthened GATT rules and disciplines.

Integration of the sector into the GATT will be in four phases. The first started on 1 January 1995. The second will be on 1 January 1998, and the third on 1 January 2002. During this process, products will be progressively integrated into the GATT, i.e. bilateral restrictions on imports into the EU of different groups of products will be phased out. All products will be integrated into the GATT by all members after 10 years, i.e. on 1 January 2005. The Uruguay Round Final Act, apart from the agreement on textiles and clothing, also contains protocols and agreements some of which are of major importance to textiles and clothing under the aspect of strengthening GATT rules and disciplines, as a basis for the integration of the textile and clothing sectors into the GATT.

In this framework, the European Commission prepares the modification of regulations regarding the implementation of the Agreement on Textiles and Clothing (ATC) of the Uruguay Round. In particular, this refers to the product coverage, the integration of products into the GATT in the 3 stages described above, the new safeguard clause and the new administrative arrangements with partner countries.

For textile imports from third countries not covered by bilateral agreements or other arrangements, a regulation has been approved which establishes a new autonomous regime for these imports, including Community quotas for non-MFA products for China, North Korea and the Republics of former Yugoslavia. Legislation has also been passed on different aspects regarding textile imports from China, in particular the implementation of a new bilateral agreement on imports of products made of silk, ramie, linen and other vegetable fibres (in preparation) and the adjustment of existing quotas in order to compensate fraudulent imports.

In connection with the MFA and the related bilateral trade agreements, a textile anti-fraud initiative (TAFI) for the detection of anomalous imports, launched by the European Commission, is currently in progress. This initiative aims at preventing certain economic operators from subverting the intentions of the MFA agreements.

In 1991, The European Commission also launched an export promotion scheme (EXPROM), which seeks to develop new markets outside the EU, including those for EU textile and clothing products, by investigating the potential of new markets and supporting exploratory missions and trade fairs. A further major objective is to promote a clearly defined European image for the products concerned in third markets.

The establishment of OPT quotas at EU level from 1st January 1993, as part of the Single Market process, required the elimination of disparities in the interpretation of OPT regulation 636/82 between Member States. The Council of the EU has adopted in December 1994 a new regulation (3036/94) establishing economic OPT arrangements for certain textile and clothing products. According to the new regulation, OPT authorisations can only be granted to EU manufacturers of similar products as the compensating ones, and for a total quantity of compensating products with a value of the processing carried out in third countries no higher than 50 % of the value of the applicant's Community production.

The European Commission currently prepares legislation to take into account the enlargement of the EU to Austria, Finland and Sweden, in particular the adaptation of existing EU12 quotas, after conclusion of negotiations with all textile exporting countries which have concluded a bilateral textile agreement with the Community.

The European Commission continues its efforts regarding the RETEX initiative, which has been defined for the period 1993-1997. This initiative aims at a diversification of economic activities in those regions which are strongly dependent on the textile and clothing industries. RETEX mainly focuses on 'soft' measures, i.e. on the improvement of know-how within firms, co-operation between firms in the same region or sector, and the use of new technologies to improve quality. A specific initiative has been taken by the European Commission and the Council regarding the textile and clothing industry in Portugal, which has been identified as a vital sector for this economy, notably in terms of employment and exports.

The European Commission is currently exploring ways to support initiatives regarding subcontracting activities in the textile and clothing sectors in the EU, as these activities have been recognised as an essential feature of the industry.

The textile and clothing sector is also concerned by the European Commission's initiative in favour of SMEs, among other sectors of activity. This initiative is aiming to help SMEs, particularly in regions covered by Objective 1 of the Structural Funds, to adapt to the conditions of the Single Market and to improve their international competitiveness. Other horizontal initiatives, also applying to textiles and clothing, have been developed by the European Commission to help SMEs, among which are programmes such as INTERPRISE, EUROPARTENARIAT, BC-NET or the Euro Info Centres (EIC).

In the area of research and development, the textile and clothing sectors are active in the framework of the new Brite-Euram III programme launched by the European Commission. The global objective of this programme is to help reinforcing the competitiveness of the European industry by developing targeted technological research and development actions on priority industrial objectives. In previous versions of this programme, the textile and clothing sectors already achieved much success and were one of only two sectors to have been invited to coordinate their research as part of a targeted programme under the Brite-Euram.

Source: DEBA

The European Commission has also taken an initiative regarding training. The LEONARDO DA VINCI vocational training programme will support and complement actions in member states to improve the quality of training policy and practice and its capacity to find new ways of learning, including in textiles and clothing.

In the course of 1995, the European Commission will publish a practical guide on programmes and measures of support open to the EU textile and clothing industries.

## OUTLOOK

Both the textile and clothing industries of the EU have been badly hit by the recent recession. In 1993, by far the worst year, textile and clothing production was 10 % lower than in 1992 in current prices and employment was reduced by nearly 140 000.

Improving economic conditions have already started to bring some relief to textiles and clothing in 1994. Production increased again in current prices, although by a mere 0.9 % compared to 1993. This upturn is forecasted to improve slightly further in the following years with an annual average growth rate of about 2 % between 1994 and 1997, in current prices. Apparent consumption is expected to increase slightly more, by an annual average of 2.6 %. The difference in growth would be made up largely by increased imports.

# Textiles

## NACE 43

The textile industry, as defined by NACE 43, covers the preparation, spinning, weaving and knitting of a number of natural (wool, cotton, silk, linen, flax, ramie, jute) and man-made fibres (synthetic or cellulosic). It also covers the process of textile finishing and the manufacture of carpets. The textile industry accounted for 3.1 % of value added generated by EU manufacturing industry in 1993, with employment of nearly 1.3 million people.

Production in the textile industry has been falling since 1991 and even decreased by 10 % in 1993, in current prices. Apparent consumption of textiles followed a similar trend as extra-EU imports and exports only changed slightly in recent years. In constant prices, apparent consumption fell by 5.5 % in 1993. Employment was reduced accordingly, of which 90 000 in 1993 alone.

The largest export markets are developed countries, of which the USA and Switzerland, although a growing portion of textiles are exported to Eastern Europe and the Mediterranean rim, for subsequent processing into clothing for re-import into the EU (known as outward processing trade). Imports of textiles (including raw materials and knitted products) come increasingly from a limited number of third countries, as Turkey, China and India nearly doubled their import share to the EU between 1988 and 1993, to account for one-third of EU textile imports. When excluding raw materials and knitted products, major suppliers of textile products to the EU in 1993 were Switzerland, India and Austria.

A large share of the EU textile industry is concentrated at a regional level. As a supplier to the clothing industry, the industry has had to adjust to production and marketing strategies such as quick-response and just-in-time as these are increasingly adopted by clothing producers and distributors. The development of outward processing and sourcing strategies also represents a major challenge for textile producers to maintain the use of EU-produced textiles in garments assembled outside the EU.

As the EU economy emerges from recession, prospects for the textile industry as a whole improve. Estimates for 1994 indicate that production rose again by 4 % in current prices, a trend which is projected to continue at least until 1997. Prospects are, however, not equally positive for all segments of the industry. Much depends on the health of the EU's clothing industry, which itself has been depressed.

### INDUSTRY PROFILE

#### Description of the sector

The textile industry, as defined by NACE 43, covers the preparation, spinning, weaving and knitting of a number of natural (wool, cotton, silk, linen, flax, ramie, jute) and man-made fibres (synthetic or cellulosic). It also covers the process of textile finishing and the manufacture of carpets. The industry produces intermediate products such as woven fabrics for the clothing industry and industrial textiles, as well as final products such as household textiles and knitwear.

The textile industry accounted for 3.1 % of value added generated by EU manufacturing industry in 1993. Although employment decreased strongly in recent years, the industry employed nearly 1.3 million people in 1993. The industry is largely concentrated in the larger EU member states. Italy, Germany, France and the UK accounted for nearly 80 % of EU textile production in 1993. Italy alone, the biggest producer, generated 32 %.

**Figure 1: Textiles**  
Value added in comparison with related industries, 1993 (1)

(1) Data is for enterprises with 20 or more employees.  
Source: DEBA

#### Recent trends

Production in the textile industry has fallen since 1991. Between 1984 and 1989, in real terms, it expanded at an average annual rate of 2.1 %. Production started to decrease slightly in 1991 and has declined increasingly since then. In 1993, it fell by 10 %, in current prices. Production in constant prices fell by nearly 6 % in 1994. This trend has to be placed in the context of the general economic recession and preliminary figures for 1994 indicate a reversal of this trend as production has increased again by 4 % in current terms.

Apparent consumption followed a similar trend to production as extra-EU imports and exports have changed only slightly in recent years. Thus, 1993 stands out as a very difficult year for the EU textile industry with a fall in apparent consumption of 5.5 % in real terms.

As output in the textile industry has fallen, employment has also declined. The textile industry has undergone a process of restructuring in recent years in order to reduce costs and

Source: DEBA

increase productivity. Between 1988 and 1993, the EU textile industry raised its productivity by 17 %, in constant prices. This has contributed to important reductions in employment, reinforced by the effects of the economic recession towards the end of this period. The industry lost nearly 500 000 jobs between 1984 and 1993 (28 %), of which 90 000 were lost in 1993 alone (6.6 %). Estimates indicate that a further 70 000 job losses occurred in 1994.

The EU trade balance in textiles (including raw materials) reached a trough in 1991, when the deficit amounted to nearly 3 billion ECU. Since then, the trade balance has improved steadily and is estimated to have reached a deficit of around 2 billion ECU in 1994.

**International comparison**

Compared to other major trading blocks, EU textile production was 84 % higher than in Japan and 13 % higher than in the USA in 1993. Between 1984 and 1993 textile production in current prices increased most strongly in the EU (15 %), fol-

lowed by Japan (13 %), while production in the USA only increased by 7 %. These evolutions, expressed in constant prices, indicate the strongest volume reductions in the USA, followed by Japan and the EU.

The EU had the highest apparent consumption of textiles in 1993, 12 % more than in the USA and double that in Japan. However, apparent consumption expanded most in Japan between 1984 and 1993 (20 %), followed by the EU (18 %) and the USA (6 %).

Among the three trading blocks, the EU exported three times more textile products than the USA or Japan in 1993. Export growth was, however, highest in the USA at 66 %, over the ten years from 1984 to 1993, followed by the EU (42 %). In Japan, exports to third countries actually decreased by 16 % during the same period.

**Foreign trade**

Extra-EU exports and imports of textiles both expanded between 1985 and 1994, although imports grew faster than exports. This trend translated into a larger trade deficit since 1990. The EU textile industry has to import most of its raw materials (wool, cotton, silk, etc.). The data shown in the tables also includes knitted clothing. The exclusion of these trade flows shows that the EU textile industry has a trade surplus in manufactured textile trade. In 1993, the trade balance in EU exports and imports of textiles (excluding fibres and knitwear) amounted to a surplus of 3.1 billion ECU.

Although EU textile imports grew more than exports for most of the period between 1985 and 1994, this pattern started to change in 1992 as exports began to grow faster than imports. Between 1992 and 1994, EU textile exports increased by roughly 18 %, compared to 10 % for imports. Accordingly, the export/import ratio has improved.

The largest export markets for EU textiles are the USA, Austria and Switzerland with export shares between 9 % and 11 % in 1993. They are followed by Poland, Japan, Tunisia and Morocco. Apart from Japan, these three export markets draw their importance from outward processing trade. EU companies export textiles to these countries to be processed into garments which are then re-imported into the EU. Between 1988 and 1993, the major ten export destinations for the EU took an increasing share of the overall textile exports, from 51 % in 1988 to 64 % in 1993.

**Figure 4: Textiles**  
International comparison of production in current prices

Source: OETH, DEBA

**Figure 5: Textiles**  
International comparison of production in constant prices

Source: DEBA

Imports of textiles are even much more concentrated, as the ten major countries of origin for EU textile imports represent 70 % of all textile imports in 1993. Main countries of origin are Turkey, China, Austria and India. Between 1988 and 1993, Turkey, China and India nearly doubled their import share to the EU, to account for one-third of EU textile imports in 1993.

## MARKET FORCES

### Demand

The textile industry has had to face decreasing consumption in several end-markets in recent years. Apparent consumption of clothing, which accounts for about half of textile end-use (followed by technical and other textiles, household textiles and carpets), decreased by nearly 6 % in volume terms during 1992-93. EU consumption of household textiles and floor coverings contracted by 1.3 % in volume between 1992 and 1993.

These trends are compounded by the fact that in recent years the share of household expenditure on clothing has tended to decrease slightly, combined with the worsening balance of trade in clothing and depressed general economic conditions.

As a supplier to the clothing industry, the EU textile industry has had to adjust to production and marketing strategies such as quick-response and just-in-time as these are increasingly adopted by clothing producers and distributors. The development of outward processing and sourcing strategies also represents a major challenge for textile producers to maintain the use of EU-produced textiles in garments assembled outside the EU.

About one-fifth of textile production consists of technical and other textiles (including non-woven goods). These textiles include carbon, glass, aramid and other special fibres, in addition to conventional textile fibres. The products go into such high-tech uses as defence equipment, high-speed trains, aircraft and racing cars, as well as leisure products such as mountain bikes, tennis racquets and golf clubs. Technical textiles are often divided into industrial textiles, transportation, geotextiles, technical apparel, medical and leisure textiles. The demand for technical textiles are not only determined by demand, but also by the development of new applications and uses on the supply-side.

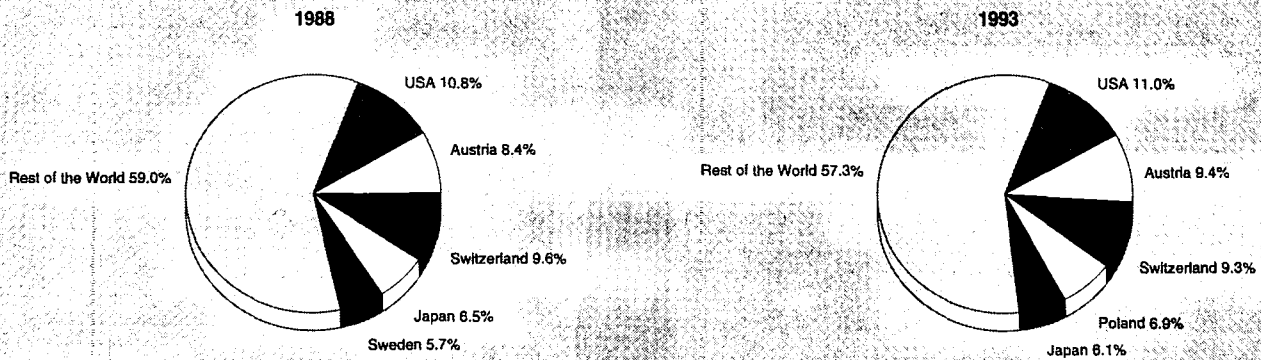

The consumption of technical textiles is part of intermediate consumption of textiles by service and non-service industries. This includes textiles consumed by non-service industries such as pharmaceuticals, electronics or furniture as well as service industries such as hotels or retail services. This consumption has been recently estimated for the first time and represented a market of 26.6 billion ECU at the EU level in 1993 (Report on Consumption and Distribution commissioned by the OETH in the framework of its prospective scenarios on textiles and clothing).

### Supply and competition

The textile industry is relatively capital-intensive compared to the clothing industry. The labour content in manufacturing costs, however, varies strongly between different products. While the share of labour costs in the spinning of cotton yarn accounts for about one-third of total manufacturing costs in the EU, in the production of carpets this share is below 10 %. Labour cost differences around the world are therefore of differing relevance to the competitiveness of the different segments of the textile industry.

After several years of sustained growth, the value of investment in the EU textile industry has shown a steep fall in recent years. Investment decreased by an annual average of nearly 6 % between 1990 and 1993, in current prices. In 1993, investment was at its lowest since 1988. Overcapacity in the highly capital-intensive short-staple sector of the textile in-

Source: DEBA

dustry, at a time of recession, has been among the main reasons for the fall. The biggest cuts in capacity have occurred in the cotton industry, which is one of the most modern sectors in the EU, but suffers from overcapacity worldwide.

While the industry reduced investment into new machinery and shed employment in recent years, it succeeded in rising labour productivity continuously between 1984 and 1993 by more than a third.

### Production process

In the spinning and weaving processes, the quantity of installed textile machinery and its geographical location worldwide have changed significantly in recent years. In the past twenty years (1973-93), the EU spinning industry reduced the number of spindles installed by 14 %, while the number of open-end rotors increased from 24 000 in 1973 to 506 000 in 1993. In terms of production capacity these trends are even more relevant, as open-end rotors are judged to be 5 times more productive than spindle machinery. Worldwide, the EU textile industry only accounts for 6.4 % of open-end rotors, as the bulk of capacity is to be found in Asia, Eastern Europe and the USA. Open-end rotors are, however, relatively less important in the EU than in other regions as they are mainly used for fibres other than wool. The EU is one of the largest wool producers in the world.

In weaving machinery, the EU textile industry mainly uses shuttleless looms (65 % of all looms in 1993). These are the most modern machinery used in the weaving process. The

number of looms installed in the EU has decreased in recent years, while in Asia, capacity has expanded strongly. Asia now accounts for 35 % of shuttleless looms and 74 % of shuttle looms worldwide, compared to 10 % and 2 % respectively in the EU.

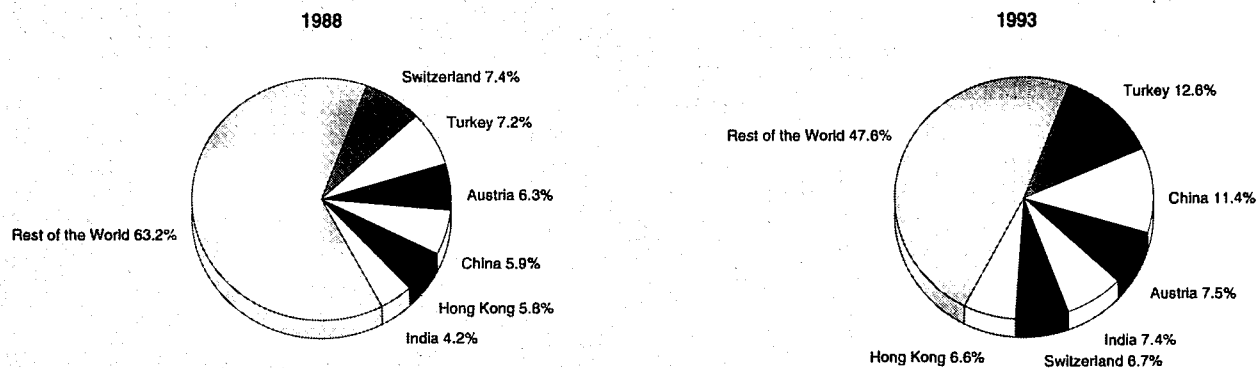

## INDUSTRY STRUCTURE

### Companies

In 1993, the EU textile industry was made up of nearly 47 000 firms, of which 72 % were firms with less than 20 employees. These smaller firms employed 18 % of the total workforce (233 000 employees) and generated 15 % of total turnover. From the early 1980s, small textile firms increased their share of both employment and turnover in all major EU countries. In the case of employment, this pattern is explained by the fact that the reduction in employment has been greater in larger companies. Smaller firms in the textile industry reduced their employment by 14 % between 1988 and 1993 compared to 18 % for larger firms. Over the same period, the number of smaller firms fell by 9 %, compared to 11 % for larger firms.

In terms of turnover, the ten largest textile companies account for about 11 % of the EU textile industry's total turnover in 1993. The five largest companies alone account for 8 % of the total (Coats Viyella, Beaulieu, DMC, Marzotto, and Chargeurs). Among these, Coats Viyella and Marzotto also produce clothing products.

## Strategies

Textile companies in the EU have reduced investment continuously over recent years, while extensive technological modernisation took place in the past. In 1993, investment was 18 % lower than in 1990, when investment was at its peak. Among member states, Italian companies generated 27 % of total EU textile investment, followed by German, French and UK firms (respectively 18 % and 13 % for the two latter). In terms of investment per head, major investment efforts were made by Dutch, Belgian and German firms, while firms in the Southern EU member states indicate the lowest levels.

The strategies of EU textile firms are determined by various objectives depending on their place in the so-called textile pipeline. Producers of cotton yarn do not operate in the same competitive environment as producers of knitwear, for example. Their strategies will also differ according to company size and location within the EU. However, textile companies tend to specialise in a limited number of production processes, relying partly on subcontracting in some segments of the industry. A growing number of EU textile companies will also have to determine strategies capable of safeguarding their position as suppliers to an increasingly delocalised EU clothing industry. These strategies result in a change of organisation and methods to encourage globalisation and flexibility.

## Impact of the Single Market

The textiles sector was already very open to trade before the Internal Market programme was launched. So, the latter has not changed the degree of competition in the market. The recent overcapacity problems in the sector reflect the fact that intra-EU trade increased during the eighties and that the beginning of the nineties was characterised by a recession. The abolition of national import quotas has nevertheless reduced the competitiveness of EU companies with respect to non-EU competitors.

The sector is mainly composed of small and medium-sized firms, and the European market has remained fragmented due

to cultural and linguistic differences, and to differences in consumer preferences. So, there has not been volume effects from the Internal Market. Main issues for the EU textiles companies include an environment protection legislation which takes into account the specificities of SMEs, an extension of the training and the education programmes available to EU textiles companies, the abolition of the national non-tariffs barriers to trade, a simplification and an acceleration of the mutual recognition of rules on procedures of conformity certification and a level-playing field for of competition both within the EU and with respect to third country producers.

## REGIONAL DISTRIBUTION

A large share of the EU textile industry is concentrated at a regional level. Regional industries in textiles are generally organised around specific product groups (knitwear, technical textiles, and the like), and present significant degrees of local subcontracting.

The main textile regions of the EU can be classified by size of employment. According to Comitextil data, the largest regions, those employing 100 000 or more, are Lombardia (I), Cataluna (E) and Norte (P). The next largest textile regions, employing between 50 000 and 100 000, are both in Germany - Baden-Württemberg and Nordrhein-Westfalen. The five largest regions represent nearly 30 % of total EU employment in textiles.

## ENVIRONMENT

The textile industry uses natural fibres, as well as man-made fibres (cellulosic and synthetic). Wood pulp is the basic element in producing cellulosic fibres, while synthetic fibres are produced from oil derivatives (the main synthetic fibres are polyamide, acrylics, and polyester). The production process therefore uses natural resources - water, land, animals, wood pulp, and oil.

Trade Intensities (1)**

(1) Trade data includes some raw materials and knitwear.  
Source: OETH, DEBA

The production of textiles requires considerable volumes of water - in the production of fibres, in processing fibres and in fabric finishing, among which dyeing and finishing require the most water.

During processing wool has to be cleaned and degreased and cotton has to be washed. Chemical applications are used in the processing of both man-made and natural fibres, to obtain easy-care properties, fast colour, stain and crease resistance, handle, flame retardancy etc. Dyes may sometimes cause unnatural colouring of streams and rivers, although this is more of an aesthetic problem than an environmental one.

Then there are the environmental problems, common to all consumer products, connected with packaging. And once the textile product is in the hands of consumers, repeated laundering consumes much energy and detergent, and gives rise to a great deal of water-borne effluent.

Final disposal is another problem. Products made from natural fibres, and also from cellulose, biodegrade effectively. However, polyester, nylon, polypropylene and acrylics are persistent, yet account for 65 % of total fibre usage in textiles.

The growing level of pollutants in the environment, including those connected with the textile industry, are being increasingly controlled by legislative control on discharges to water, air emissions and waste production, by active regulatory bodies on national and EU levels. There has for example been much EU legislation on emissions to water, and this has affected the textile industry, with its heavy water usage.

The Fifth Framework Programme for the Environment, proposed by the EU Commission in 1992, encompasses all environmental issues manufacturer and users will have to integrate into their strategy in the future.

According to Comitextil, the industry is responding positively to the different aspects of this framework programme, in particular the voluntary eco-auditing scheme which it sees as the key to continuing the reduction of the environmental impact of textile manufacturing over and above legislative requirements. Fully integrating environmental considerations into the general management of the fifty thousand or more small plants that make up the European textile sector, is the major environmental challenge facing this industry.

## OUTLOOK

The textile industry had to experience falling apparent consumption during 1992 and 1993, in the context of a general economic recession. While production rose during the 1980s, it started to fall slightly in current prices in 1991 and decreased strongly in 1992 and 1993.

As the EU economy emerges from recession, prospects for the textile industry as a whole improve. Estimates for 1994 indicate that production rose again by 4 % in current prices, a trend which is projected to continue at least until 1997. Production is forecasted to increase by an annual average of 3.7 % in current prices during that period. In comparison, apparent consumption should increase by an annual rate of about 3.6 %, with extra-EU exports expanding at a rate of 3.8 %. Thus, imports are expected to increase less than exports (by an annual rate of about 2.2 %), which will result in an improvement of the trade balance.

Prospects are, however, not equally positive for all segments of the textile industry. The EU knitting industry will have to face continuing competition from lower-cost countries outside the EU, reinforced by the gradual liberalisation of textile and clothing trade. The growing delocalisation of EU clothing production mainly to locations close to the EU will also pose a threat to textile manufacturers who are traditional suppliers to the EU clothing industry. Textile production with a relatively high content of labour (as in the low to medium quality production of fabrics) is expected to experience decreasing market shares as competition from lower-priced imports continues.

# Clothing

## NACE 453

The clothing industry, as defined by NACE 453, covers the manufacture of garments and clothing accessories, but does not include the manufacture of knitwear. Many of the industry's inputs are supplied by the textile industry, 55 % of which are based on man-made fibres, 45 % on natural fibres such as cotton, wool and silk.

The industry is an important employer. It employs 1.1 million people, 5.2 % of total EU manufacturing employment. It also generates 1.8 % of manufacturing industry value added. Clothing production and employment, however, have been declining in recent years. The volume of production fell by 20 % between 1990 and 1994. Employment has fallen by 16 % over the same period.

EU clothing manufactures have faced, on the one hand, weak levels of domestic demand for their output and, on the other hand, increasingly fierce competition from producers in low-wage countries. The industry has a substantial balance of trade deficit amounting to over 12 billion ECU in 1994, over four times its level in 1984.

Clothing exports have also increased in recent years, but at a more gradual pace than imports. The main export markets for EU producers are other developed countries. Internal trade in clothing between member states is also significant. Another important feature of the industry has been the growing practice of Outward Processing Trade (OPT), whereby more labour-intensive processes are transferred to lower-cost countries close to the EU borders.

The outlook for the industry is expected to improve on the performance of the last two years, although production volume and employment are likely to continue to fall, but at more modest rates, as domestic demand strengthens with economic recovery. Much will depend on the effects of the phasing out of the Multi-Fibre Agreement (MFA), which was agreed upon in the Uruguay Round of the GATT. This is likely to intensify competition in the world clothing market. EU firms may be forced to increase their moves towards improved quality, new fibres, flexible production and quick response to defend their market share.

### INDUSTRY PROFILE

#### Description of the sector

The clothing industry covers the manufacture of garments and clothing accessories. It does not include the production of knitwear which, for statistical purposes, is included in textiles. The industry is closely linked to the textile industry which supplies the bulk of its inputs. The EU's production of apparel is based 55 % on man-made fibres and 45 % on natural fibres such as cotton, wool and silk.

The production of clothing involves a number of different stages: design (styling, prototyping, the choice of collections); development (the sourcing of fabric, making of patterns, planning of cutting); and manufacture (cutting, sewing, pressing, finishing).

The industry's products can be classified in a number of ways, for example, into men's, women's and children's wear, into outerwear and underwear, or into low, medium or high quality wear.

The clothing industry has remained relatively labour intensive. It employed 1.1 million people in 1993, 5.2 % of EU manufacturing employment. In 1993 the clothing industry's value added was 15.7 billion ECU, 1.8 % of total value added by EU manufacturing industry. This was generated mainly by

Figure 1: Clothing Value added in comparison with related industries, 1993 (1)

(1) Data is for enterprises with 20 or more employees only.  
Source: DEBA

the four largest producing countries - Italy (22 %), Germany (21 %), France (18 %) and the UK (17 %).

#### Recent trends

The volume of EU clothing production has fallen steadily from a peak in 1986. The decline appeared to accelerate in 1993 and 1994 bringing the volume of production to 20 % below its 1990 level. This is a different trend to that followed by the value of production measured in current prices, which rose gradually to a peak in 1992 before falling in 1993. The difference between the two trends can be explained in part by the fact that the production figures are derived from turnover, which can include production subcontracted outside the EU, and in part by improvements in the quality of EU production, which is not fully reflected in the price index used as a deflator.

In current price terms, production rose until 1992 before falling in 1993 and 1994. Apparent consumption also fell in the last two years, but grew more strongly in the period to 1992 as rising imports replaced EU production.

**Figure 3: Clothing Production and employment compared to EU total manufacturing industry**

EU trade in clothing, already in deficit in 1984, moved further into deficit by 1991 as the growth in imports exceeded growth in exports. Over this period the deficit increased by four times, before falling in 1992 and widening once again in 1993 and 1994.

There have been significant job losses in the EU clothing industry over recent years. Between 1984 and 1994 around 300 000 jobs were lost - a fall of 23 %. It is estimated that 70 000 jobs were lost to the industry in 1994 alone. This has been the result, not only of the loss of production in the face foreign competition and the general economic recession, but also to gradual improvements in productivity.

**International comparison**

Of the three main trading blocks - the EU, the USA and Japan - the EU is by far the largest clothing producer. Its production, in 1993, was greater than that of the USA and Japan combined. The EU is also the most important exporter. The EU's clothing exports to third countries in 1993 were

1.7 times those from the USA and 13 times those from Japan. However, the USA exported a greater proportion of its production.

Measured in constant prices, production in the EU and Japan increased gradually between 1984 and 1992, but in 1993 fell to below its 1990 level. In the USA, in contrast, production fell between 1985 and 1990 and then remained relatively stable. In current prices, production rose in both the EU and Japan between 1984 and 1993, but fell in the USA. Likewise, while apparent consumption, in current prices, grew significantly in the EU and Japan, the increase was barely perceptible in the USA.

However, the recent export performance of the USA has been much stronger than that of the EU and Japan. Exports from the USA, in current prices, increased fourfold between 1984 and 1993, compared to an increase of 67 % for the EU and a fall of 45 % for Japan. This can be partly explained by a weakening dollar during the second half of this period.

**Figure 4: Clothing International comparison of main indicators in current prices**

**Figure 5: Clothing**  
International comparison of production in constant prices

### Foreign trade

The EU has seen consistent increases in both imports and exports of clothing between 1985 and 1994, although imports have grown much faster than exports. Compared to an average annual rate of growth in exports of 4 % between 1984 and 1988 and 6 % between 1989 and 1993, imports grew at an average annual rate of between 11 % and 14 % over the same two periods, in constant prices. The result has been a widening in the trade deficit to over 10 billion ECU in 1994, over four times the level in 1985.

The EU clothing industry has faced considerable competitive pressure from lower-cost countries, mainly in the Far East, the Mediterranean rim and Eastern Europe. This has been particularly severe in the low and medium quality segments of the market. The terms of trade index, comparing the prices received for exports to those paid for imports, increased between 1985 and 1992 by 15 % before slipping slightly.

The main destination for EU clothing exports are other developed countries. The main customers are Switzerland (15.5 %), the USA (13.1 %) and Austria (12.2 %). With the

exception of Japan, these countries' share of total EU exports has fallen since 1988. As a result the share of the EU's top ten customers has fallen from 79 % to 72 %.

The major origins of EU imports of clothing are low-cost countries in the Far East, the Mediterranean rim and Eastern Europe. The principal suppliers in 1993 were China (15.3 %), Hong Kong (9.9 %) and Turkey (7.6 %). The origins of EU clothing imports are less concentrated than the destination of its exports. The ten most important suppliers accounted for 66 % in 1993. This is considerably higher than their 52.5 % share in 1988, suggesting a concentration of imports in the hands of a small number of major suppliers.

The share of many of the more important suppliers increased over this period, with the exception of Hong Kong which saw a significant fall in its share of the EU market. Much of this has been taken up by China which has seen a rapid increase in its share of EU clothing imports since 1988. This has been the result of the transfer of production away from Hong Kong to China, and other countries in the region, in response to rising wage costs.

This is similar to what has taken place in the EU, where production has shifted to neighbouring countries, such as Tunisia, Poland and Morocco. For countries such as these, production of clothing for the EU is often conducted by or on behalf of EU manufacturers. Fabrics are exported from the EU, to be made up into clothing for subsequent re-importation within the framework of Outward Processing Trade (OPT). This practice has expanded in recent years. In 1993, OPT imports of clothing accounted for 15 % of total EU imports of clothing, in tonnes.

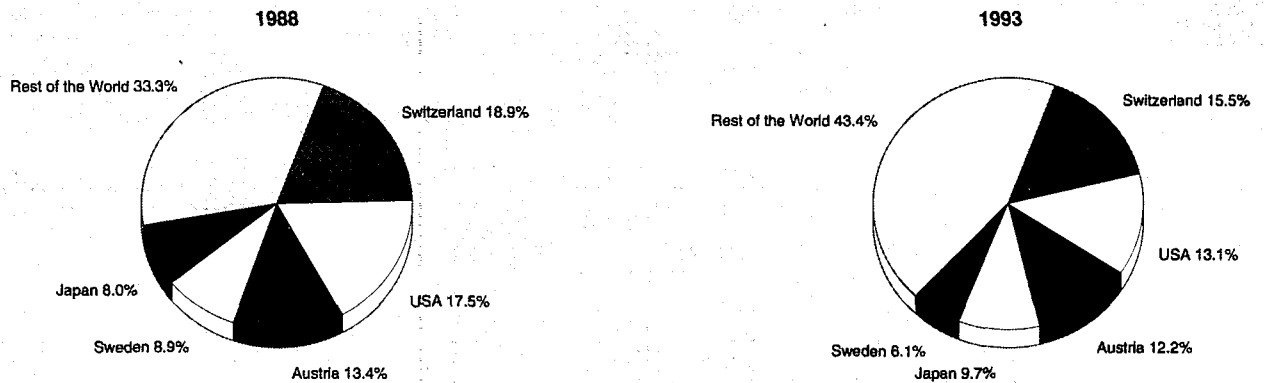

## MARKET FORCES

### Demand

The EU clothing industry has faced weakening demand conditions for much of the last decade. Consumer spending on clothing (and footwear) as a proportion of total consumer spending has fallen gradually from 8.4 % in 1980 to 7.4 % in 1993. This is still higher than in the USA and Japan where the proportions are 5.5 % and 6.5 % respectively.

Part of this decline in the share of consumer spending on clothing can be explained by the downward trend in the price of clothing relative to other consumer goods. Some of this change in relative prices is a consequence of the increase in lower priced imports. It also stems from recent changes in

**Figure 6: Clothing**  
Destination of EU exports

the structure of clothing retailing throughout much of the EU. This has seen a growing concentration of retailing in the hands of a small number of larger companies in many EU countries. As an example, the relative price of clothing has fallen further in the UK where retailing is highly concentrated, than in Italy where it remains relatively fragmented.

Over recent years, demand for clothing has required a growing number of styles and new collections each year. This has put much greater emphasis on the speed and reliability of response to orders by retailers. In addition, moves towards the maintenance of lower stocks by retailers has increased recourse to repeat orders. Because of the importance this places on speed, it is thought to favour EU production, especially by subcontractors.

### Supply and competition

The EU clothing industry is characterised by a very high level of competition. There are a number of reasons for this: firstly, EU companies face fierce competition from other countries whose low wage costs give them a considerable competitive advantage; secondly, low barriers to entry make it relatively easy for small firms to enter the industry; finally, increased price pressure has also been exerted by traders and organised retailers.

The industry has reacted to these pressures by consistently improving productivity and by seeking other ways to improve its competitiveness. Labour productivity increased by 37 % between 1984 and 1993 in comparison to an increase in unit labour costs of 4 % over the same period.

Another response by EU clothing manufacturers has been to relocate production to low-wage countries close to the EU. This has taken the form both of directly controlled production and subcontracted production. This is often conducted with the framework of Outward Processing Trade. (OPT). Fabrics of EU origin are exported to countries such as Tunisia, Poland and Morocco, to be made up into garments for subsequent re-importation into the EU. Such production may be granted more favourable tariff and quota treatment.

### Production process

The manufacture of clothing involves a number of different stages, from design to final packaging. At the design stage, the garments are styled, materials are selected, and a prototype is developed. Once collections have been defined in this way, they enter the development stage where manufacturing is prepared. This involves the making of patterns, the purchasing of materials, and the planning of cutting. The final garments are manufactured in three stages, including the cutting of the fabric, sewing and pressing.

The drive, begun in the 1980s principally by Japan, to develop totally automated garment production has largely been abandoned. Automation of fabric handling and sewing operations has proved to be more difficult than anticipated. Greater emphasis has recently been placed on design, the development

of new fabrics, and the development of new methods of working so as to achieve more rapid and flexible production.

Significant technological advances have been applied in recent years in the application of computer technology in controlling pattern layout and cutting, in improving fabric handling, the management of stocks, and in the use of Computer Aided Design (CAD) systems in the design stages. New telecommunications technology is also likely to be increasingly adopted by the industry, facilitating more direct links between retailers, designers and manufacturers.

## INDUSTRY STRUCTURE

### Companies

There were 67,400 enterprises in the clothing industry in 1993. Of these, the majority (85 %) employ less than 20 people. The remaining companies, however, are much more important in terms of employment (68.5 %) and turnover (75 %).

The existence of returns to scale in the industry is evident from the presence of a number of large companies. The largest among them, in terms of turnover, are Benetton (I), Triumph Gruppe (D), Courtaulds Textiles (UK) and Levi Strauss Europe (B).

However, a ranking on this basis must be treated with caution. Some companies such as Coats Viyella (UK) produce their own fabrics, while others such as Gruppo GFT (I) and Steilman (D) use mainly bought-in fabrics.

### Strategies

Clothing manufacturers pursue a range of different production strategies. While some companies focus on the production of a specialised, narrowly defined range of products, others have diversified into a range of activities, which can include the production of textiles.

An increasingly important aspect of clothing companies' production strategies over recent years has been the widespread growth in subcontracting. Often firms choose to subcontract certain stages of the production process to outside contractors. These can be situated locally, in other countries in the EU, or outside the EU. The choice of strategy depends on criteria such as price, quality and the need for quick response times.

The importance of subcontracting in the industry was recognised by the European Commission, who commissioned a study of subcontracting in the EU clothing industry. The study found that European subcontractors have taken advantage of the changing strategies in distribution and disinvestment by existing clothing manufacturers.

The study estimated that clothing subcontractors employed approximately 800 000 workers. Declared workers in sub-

Source: DEBA, OETH

contracting represented almost 60 % of total employment in the clothing industry. Of this number 200 000 were artisan and an estimated 150 000 were illicit workers (Estimate by Mercer Management Consulting).

Subcontracting has grown rapidly in recent years, largely because the main-contractor - subcontractor relationship confers a number of advantages for both parties. This can include the cases where a subcontractor can achieve lower unit costs, or can offer greater reactivity and flexibility, or special expertise and services; or the cases where manufacturers can increase their capacity utilisation by combining their own production with that done on a subcontracted basis.

Subcontracting can also benefit from the proximity of the subcontractor, and the ability to form long-term relationships. This has favoured the development of subcontracting in a number of regions such as the 'Sentier' in Paris and Prato in Tuscany. Here subcontractors have exploited their ability to produce runs with short lead times.

### Impact of the Single Market

The Internal Market programme has been globally positive for the sector so far. Free movement of goods has been the most important issue for the sector. On the one hand side, the abolition of national import quotas has increased the market share of non-EU countries (mainly low wage producers). On the other hand, the abolition of controls at internal frontiers has reduced delays and transport costs, which has allowed the EU clothing companies to specialise in higher quality and fashion-led segment of the market, where demand is more dynamic. Other positive effects are coming from the Community trade mark representing a guarantee to trade marks, the opening of the public procurement such as cloths supplies to public institutions (army, hospitals), the support policy to small and medium-sized firms and the training and education programmes.

However, the downward trend in employment represents a serious problem for this sector. Also, companies in this sector feel that the environmental protection legislation should take more into account the ability of EU companies to achieve ever increasing standards. Among, the priorities for the future are the elimination of national non-tariff barriers to trade, most of them having been recently adopted for purpose of consumer protection, an accelerated fiscal harmonisation (more particularly, the harmonisation of VAT regimes), an accelerated harmonisation of monetary policies in order to avoid exchange rates fluctuations and a level playing field for competition with third country producers.

## REGIONAL DISTRIBUTION

The clothing industry is relatively widely spread throughout the EU in a number of small pockets. According to Comitextil, the largest clothing producing region in the EU is Lombardia (I) with 75 000 employees, followed by Veneto (I) and Bayern (D) each with between 50 000 and 75 000.

There are a six regions with between 25 000 and 50 000 employees, four of which are in Italy. There remainder are Nordrhein-Westfalen (D), Île de France (F), Cataluna (E), Norte (P) and Greater Manchester (UK).

There are around 25 regions with 10 000 - 20 000 people employed in the clothing industry. Among these, six are in the UK, four each in Italy, Spain and France, three in Germany, and two in Portugal.

## ENVIRONMENT

While the manufacture of clothing gives rise to fewer environmental problems than the manufacture of textiles, the day-to-day use of clothing has a significant impact on the environment. The pollution caused and the energy consumed in the washing and cleaning of items of clothing can be considerable.

The recycling of clothing is commonplace, especially for woollen garments. Recycled wool does not have to be scoured and may not need dyeing, thereby saving on water and energy. The final disposal of clothing can give rise to environmental problems, since synthetic fabrics are not bio-degradable, although natural and cellulosic fabrics are.

The EU is introducing a system of 'eco-auditing', by which firms can monitor the environmental effect of their production processes. This affects all industries. Another scheme which may affect clothing is the European 'eco-labelling' scheme, whereby products whose manufacture meets certain strict environmental criteria may bear the EU eco-label logo, thereby informing the consumer of this point.

Much work has been done to analyse the full life-cycle of two pilot products - T-shirts and bed linen made from cotton or cotton/polyester blends. The process has taken longer than expected, but criteria for the pilot products are close to being finalised. It remains to seen to what extent this market instrument will contribute to reducing the environmental impact of clothing manufacture.

## OUTLOOK

The demand conditions facing the EU clothing industry are not expected to improve significantly even with recovery in the EU economy as a whole. Apparent consumption is expected to increase by a modest 5 % between 1994 and 1997, in current prices.

Production will continue to be adversely affected by foreign competition, in the form of increased imports, and sluggish demand conditions. However, it will benefit from higher exports. The fall in production, in current prices, is expected to be 3 % between 1994 and 1997. Much, however, will depend on the effects of the conclusion of the Uruguay Round of the GATT which will bring about greater competition for EU clothing markets.

Employment will suffer from the decline in production. With productivity gains expected to continue their present course, employment is anticipated to fall by over 7 % by 1997.

# Footwear

## NACE 451, 452

The EU is one of the world's largest footwear markets. Consumption increased steadily throughout the 1980s until the recession caused demand to fall. In 1993, production increased much more slowly in value terms and dropped in volume terms. A rapid growth of extra-EU imports, in both value and volume terms, outstripped modest export growth. Italy accounts for almost half of the value of EU production and over half of extra-EU exports. Increased competition from countries with cheap labour has led to the relocation of EU manufacturing facilities to third countries. The structure of distribution is changing - a number of large manufacturers are developing their own retail chains as well as factory outlets, while some of Europe's large fashion groups now have manufacturing interests in footwear. Technological developments in the industry, particularly computer-based applications, have shortened production times, thus enabling a quick response to fashion trends and the introduction of just-in-time (JIT) manufacturing. In addition, these developments have helped make shoe manufacture environmentally safer.

### INDUSTRY PROFILE

#### Description of the sector

The different types of footwear produced within the Community are classified under NACE codes 451 and 452 as follows: mass produced outdoor footwear (451.1) mass-produced indoor footwear (451.2), special types of footwear (451.3), and hand-made footwear (452). It is also common to classify footwear into broad groups by the major material of the upper - leather, synthetic, rubber, textile and other. Some of Europe's large fashion groups have an interest in the manufacture of footwear, which is sold through their own outlets.

#### Recent trends

The EU footwear industry employed approximately 288 000 workers in 1993 (including firms with less than 20 employees) according to the Confédération Européenne de l'Industrie de la Chaussure (CEC). Eurostat data, which excludes firms with less than 20 employees, estimated total employment in 1994 as 224 400 workers, a decrease of 7 % in 1993 and of almost one-third since 1984. The difference between CEC and Eurostat estimates reflects the importance of small enterprises in the footwear sector.

The industry is relatively labour-intensive. The value of production in 1994 was 16.9 billion ECU including labour costs of 3.4 billion ECU, equivalent to 20 % of production value. Total value added for the industry in 1994 was estimated as 5.1 billion ECU. Apparent consumption in 1993 was higher than production, reflecting a small deficit on extra-EU trade.

The deficit in the EU footwear trade balance in 1993 was 448 million ECU. This is only the third deficit ever to be recorded; and while larger than the 1992 figure, it is lower than that of 1991. The emergence of the trade deficit on footwear is symptomatic of the increasing vulnerability of the EU footwear industry to low-cost extra-EU producers, even though the growth of imports slowed in the early 1990s. At the same time, while production value data for the EU footwear industry points to stagnation during the 1980s there has been some recovery in recent years. This recovery has mainly reflected very strong growth in Italy, although some of this may be more apparent than real. In addition to trade data, other indicators such as volume of production, employment and value-added show a less favourable trend in the devel-

**Figure 1: Footwear**  
Value added in comparison with related industries, 1993

Source: DEBA

opment of the EU footwear industry. In particular, employment has fallen almost continuously over the last decade with particularly sharp decreases over the last three years.

Italy is Europe's major footwear producer, accounting for 42 % of the total volume of EU production in 1993. The next largest producer, Spain, accounted for 17 %. Other major producers are France (14 %), the United Kingdom (10 %) and Portugal (9 %). The only other country with somewhat significant production is Germany (5 %). EU production is dominated by production of leather footwear, 1.09 billion pairs, accounting for more than two out of every three pairs of shoes produced in the EU in 1992. The importance of different types of footwear production varies across Member States. The production of leather footwear accounted for 90 % of footwear produced in Portugal, 83 % in Germany, 69 % in Italy and 74 % in the Netherlands in 1993. Over 50 % of Belgian output is in slippers and approximately 30 % of footwear produced in the United Kingdom is synthetic- or rubber-uppered. In France, slippers account for 33 % of production while cloth uppered and synthetic uppered footwear account for 12 % and 10 % respectively.

Source: CEC

The 1980s was a difficult decade for the European footwear industry. Modest growth resumed in recent years following substantial rationalisation in the early 1990s. However, import penetration by low-cost producers remains a key feature of the sector, rising in each of the ten years to 1993. Overall, import penetration rose 29 % in value terms, in the ten years to 1993.

While production by EU companies increased in recent years, the apparent EU consumption grew more rapidly, with EU producers continuing to lose considerable market share to extra-EU imports. In the decade to 1993, the value of apparent consumption increased by 48 % in current prices, while the value of EU production over the same period rose by 22 %. There was a brief turnaround in the footwear industry in the 1988-91 period, with strong real annual average growth rates of EU production and extra-EU exports, but the onset of economic recession in 1992 reversed this trend. The rapid fall in employment in the last three years reflects both the effects of the recession and another round of rationalisation within the industry.

An analysis of trends for individual Member States indicates that the value of production in constant prices fell in most Member States in recent years and only Italy and Denmark recorded significant increases. A substantial portion of the growth in the value of production in Italy is a result of adding value - often through marketing - to finished or semi-finished shoe imports and then re-exporting them at much higher prices. This practice exists in all Member States, particularly in relation to shoe uppers. The added value is also generated by high levels of quality control, one of the keys to the "brand"

image of European footwear. Value added in constant prices fell slowly, but almost continuously, over the last decade, falling by 19 % between 1984 and 1994. Similarly, employment in firms with over 20 workers declined by 104 000 over the ten years to 1994.

The footwear industry within the EU is dominated (in value terms) by six Member States - Italy, France, Germany, the United Kingdom, Spain and Portugal. Their relative importance has declined marginally, however. Together, they accounted for 95 % of the value of EU production in 1994, compared to 96 % in 1984. However, the relative importance of Italy and Portugal increased considerably while that of the other five, particularly France and Germany, decreased. Almost all of the growth in production recorded over the 1988-92 period was in Italy, with an overall increase in the value of production in constant prices of 39 %. In contrast, Germany, France, Spain and the United Kingdom all recorded falls in the value of production in both current and constant prices over the same period.

CEC data indicates the volume of all footwear remained almost constant between 1988 and 1992, but that the quantity of non-leather footwear production decreased by 6 % to 706.7 million pairs. Most of this decrease occurred during 1992 and is reflected both in the overall fall in footwear production of 36.5 million pairs and a rise in slipper production of 9.7 million pairs.

#### International comparison

The EU is a major producer of footwear, accounting for around 10 % of global footwear production and 20 % of world footwear exports. Footwear production is, however, dominated by low-cost developing countries and newly industrialised countries (NICs), with the United States and Japan accounting for only 3 % and 4 % of world footwear production respectively. In contrast to the European experience, the footwear industry in the USA has contracted considerably over the last ten years, with the value of production in current prices falling by over one-half in the 1984-94 period. The corresponding statistic for the EU showed a growth of 27 %. Similarly, while production value in constant prices increased by 5 % over the 1984-94 period in the EU, it fell by 44 % in the USA. Production in the highly protected Japanese market, however, has risen about twice as fast as in the EU over the last ten years.

#### Foreign trade

International trade in footwear is not covered by the Multi-Fibre Arrangement (MFA), which governs trade in the textile and clothing sectors. The EU footwear sector is heavily dependent on international trade, with 26 % of EU production exported to extra-EU destinations in 1993. In current prices, extra-EU exports increased by 19 % between 1984 and 1993, while the current price value of extra-EU imports almost trebled

**Figure 3: Footwear  
Production and employment compared to EU total manufacturing industry**

1994 are DEBA estimates.  
Source: DEBA

led over the same period. By 1993, extra-EU imports accounted for 29 % of apparent consumption in the EU in value terms, compared to 21 % and 15 % in 1989 and 1984 respectively. In volume terms, import penetration was much higher at 48 %. However, some of this increase includes growth in imports of semi-finished shoes for further production.

Increasing import penetration of the internal EU market is now reflected in an overall footwear trade deficit. Traditionally, the EU has recorded a surplus in footwear trade but deficits have been recorded now since 1991.

Extra-EU imports are spread across several footwear varieties, with textile uppered footwear accounting for 32 % of the total by volume in 1993. Leather footwear accounted for a further 30 % of the volume of extra-EU imports, with slippers and synthetic-uppered footwear accounting for 17 % and 16 % respectively. In contrast, the majority of extra-EU exports were leather-uppered in two out of every three pairs in 1993.

In 1993, the EU had a trade surplus in footwear with the USA, Japan and what then constituted the EFTA countries. However, it has a large trade deficit in footwear trade with developing countries. The leading market for extra-EU exports was the EFTA countries, the other main market being the USA, although the relative importance of both has declined as the market for EU products diversified in recent years. Italy is the EU's major exporter. With the accession of Sweden, Finland and Austria in 1995, the USA will become the most important extra-EU export destination.

The majority of extra-EU imports come from developing countries, and their value has been increasing steadily. The largest growth in imports to the EU in nominal terms has come from China, which, followed by Indonesia, is the largest exporter of footwear to the EU. Germany is the largest importer of extra-EU footwear, importing 34 % of the total value of extra-EU imports in 1992. Italy, the United Kingdom and France, are also major importers in value terms.

## MARKET FORCES

### Demand

Most footwear is purchased by individual consumers. Spending on footwear tends to be cyclical, being reduced or deferred in times of recession, with a compensating upturn during economic recovery. Contract sales to major customers such as the military, or industries requiring specific work or safety footwear are important niche markets.

Footwear is seen primarily as a necessity, and a smaller proportion of income is spent on footwear as income rises. Some niches within footwear, in particular the market for trainers and certain segments of the ladies' footwear market are strongly influenced by fashion trends. In addition, demand for sports footwear has been boosted by higher levels of sports participation. Increased fashion demand has also boosted the usage of coated fabrics and textiles, rather than leather, for uppers or lining material. Reflecting the impact of the recession and the gradual ageing of the European population, the profile of the average shoe buyer is changing, with purchasers being less fashion-conscious and placing greater emphasis on quality and durability. In the sports shoe market there has been a move towards specially developed shoes for specific sports. The 15-24 age group (which is the most fashion-conscious and makes up the bulk of the most frequent purchasers) is contracting. The tendency among the upper-middle-aged, on the other hand, is to buy fewer shoes of a much higher quality.

Both volume and value figures show the largest markets for footwear in the EU to be Italy and Germany, each accounting for 26 % of the value of consumption in 1992. France (20 %) has the highest per capita consumption of footwear: 5.99 pairs per annum in 1992 compared to an EU average of 4.63 pairs.

A comparison between Member States shows significant differences in prices paid per pair - reflecting to some extent where a greater quality- and fashion-consciousness exists in Europe. The price paid per pair is highest in Italy.

Innovations in manufacturing technology have helped maintain the competitiveness of European footwear producers. While Computer Aided Design (CAD) has been available since the 1970s, it was only in the late 1980s and early 1990s that its use became widespread. An increasing use of both CAD and Computer Aided Manufacture (CAM) has allowed European manufacturers to introduce quick response and JIT manufacturing to compete with countries offering cheap labour, as well as to produce high-quality, low-volume runs to take account of fashion trends. A recent trend in CAD technology has been the development of modular systems, so that purchasers can buy only what they need, rather than investing an entire CAD package.

The importance of these technological developments for the competitiveness of EU manufacturers is closely linked to their proximity to the large European market. Footwear technology, by comparison with many industries, is relatively basic. Most technological advances are embodied in capital equipment and the machinery manufacturers readily sell their product to buyers in NICs and developing countries. The key for EU manufacturers is the utilisation of such advances to maximise their proximity to the world's most lucrative footwear market and to the footwear industry's leading fashion centres. Even these advantages are being cancelled out. Low-cost producers close to the European market in North Africa and Eastern Europe may become more important in the medium term. However, European manufacturers can now use CAD systems

to transmit new designs on-line to production facilities in low-cost countries.

### Supply and competition

The distribution of footwear traditionally has been mainly through independent retailers, but the retailing sector has become more concentrated. The importance of larger department stores and multiple retail chains has increased at the expense of independent retailers, whose relative bargaining strength has shifted as a consequence.

Some large manufacturers such as the Bata Organisation (F) and Bally (UK) also have established retail establishments in a number of European countries. Other manufacturers such as André (F), Charles Jourdan (F), Clarks (UK), Eram (F) and Salamander AG (D) also operate retail units both within their domestic markets as well as in other Member States. In addition, footwear manufacturers are becoming increasingly involved in direct selling to customers through factory outlets and second-hand stores. Manufacturers also are seeking to benefit from the trend of retailers to combine their clothing lines with accessories. Thus, more and more footwear companies are attempting to link with retailers or operate in-store concessions.

The key competitive advantages of the EU footwear manufacturers - under pressure from lower priced imports - is their timely and high-quality service, along with design, styling and other creative features. All successful EU manufacturers are committed to offering the best price, delivery performance and flexibility. In response to the ever-changing needs of the retail groups, footwear manufacturers are increasingly adopting quick response strategies, although the number of com-

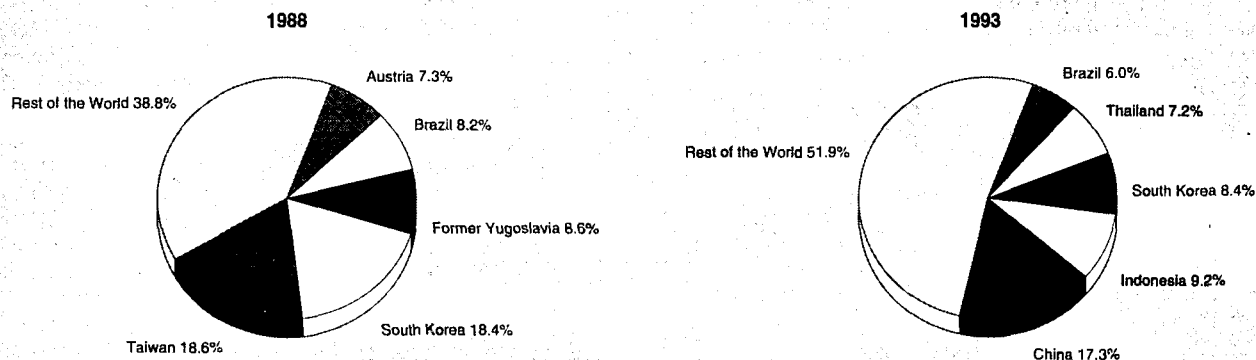

panies using them remains relatively low compared to the clothing sector. Many SMEs have adopted these strategies, for example.

A large number of firms, combined with few restrictions on extra-EU imports and barriers to intra-EU trade make the internal EU footwear market relatively competitive. Internal EU competition increased in the run-up to the completion of the Single Market in 1993, with some of the larger retail chains expanding into other EU Member States. However, the ongoing recession in major EU markets dampened the impact of the Single Market during 1993.

The removal of customs and other physical barriers to intra-EU trade has led to a reduction in transport cost and delivery time. This benefits firms who are dependent on markets in other Member States, as well as those competing on the basis of delivery performance and quick response. The approximation of VAT on footwear will not now take place until at least 1997, at which time Member States which currently have a low VAT on footwear - Ireland, Spain, Italy and Luxembourg - will experience price increases.

Imports of footwear to the EU originate mainly from countries with low labour costs, most notably China, South Korea, Indonesia, Thailand and Taiwan, although imports from other developing countries, such as Vietnam, India and Brazil, are growing. Imports from China have grown the most rapidly in recent years, but this growth will be halted by new quotas on certain types of shoes (adopted in March 1994), which are based on the average level of trade over the last three years.

**Figure 7: Footwear  
Origin of EU Imports**

Source: Eurostat

Following a complaint from the industry alleging dumping of footwear in the EU from some countries in the Far East, the Commission has recently announced the opening of enquiries into imports of specific leather shoes from China, Thailand and Indonesia and certain textile uppper shoes from China and Indonesia. Many developing countries exporting to the EU benefit from GSP (Generalised System of Preferences) regulations with around 40 % of total EU imports falling under this regime. Since January 1995 and until the end of 1998, a revised GSP will operate. The quotas and ceilings of the previous regime will be replaced by a series of duties and the new system will target preferential margins to specific country/product group combinations based on their sensitivity and specialisation. Footwear is classified as a sensitive product which implies a basic preferential duty rate of 70 % of the MFN rate for most beneficiary countries. However, those countries which are very specialist, such as South Korea, Thailand, Brazil and Indonesia, will have their preferential margin phased out during the duration of the regulation. In addition, countries such as China and South Korea, which were excluded for most footwear products under the previous regime, will remain outside the new GSP, while the least developed countries will continue to enjoy duty-free access.

Extra-EU exports are generally high-quality, leather footwear to developed countries such as the USA, Canada, Switzerland, Austria and Sweden. The volume of exports to destinations such as the USA and Canada has fallen, partially explained by the depreciation of the dollar during the latter half of the 1980s. The long-term competitiveness of the EU footwear industry will depend on its ability to continue to supply high-quality products, not only to high income countries but also to consumers in developing countries with high levels of disposable income. In common with the leather industry upstream, expansion into some extra-EU markets is blocked by high duties and tariff barriers (particularly in Japan), while restricted access to some of the raw materials necessary for higher value-added European production is also a problem.

To help improve the prospects of EU footwear firms, a budget for export promotion was voted by the European Parliament in 1993 with the aim of improving access to the markets of non-EU countries. This budget was increased by more than 65 % for 1995. This increase dovetails with the "market-opening" benefits of the Uruguay Round of the General Agreement on Tariffs and Trade (GATT). In general, while the results

of the GATT were not totally satisfactory with regard to improving access to the fast-growing markets in Asia, some progress was made, particularly in Thailand and Korea. In Japan, the most lucrative market, there is an agreement to significantly lower tariffs over an eight-year period. However, non-tariff barriers still need to be addressed by the World Trade Organisation (WTO).

The fragmented nature of the footwear industry makes it difficult for manufacturers to benefit from economies of scale. Pressure from cheap imports, coupled with increases in the cost of labour, has led to a decline in profitability in the sector. European manufactures trying to compete with cheap imports have tried to maintain their market share by expanding their existing line of products, while companies responsive to changing fashions are producing smaller production lots and recouping increased product costs through higher prices.

**Production process**

The traditional production process for footwear is a relatively simple, yet labour-intensive manufacturing process, which can be divided into a number of stages. The first stage, called "clicking", involves the cutting out and preparation of components for the upper and the sole. This is followed by "closing", when the components are stitched together to produce an "upper." The upper is then shaped and an insole and a sole are affixed. Finally, the shoe is finished by cleaning, inspecting and boxing.

Mechanised footwear production usually has been organised in a track system along which progressively assembled shoes are carried and lifted from the track by operators to perform the next stage. The introduction of the "rink" system has increased productivity and led to a significant reduction in the volume of rejects. This system involves arranging the various steps in the shoe-making process in sequence, generally in the shape of a horseshoe. Each function is the responsibility of an operator, although each operator should be capable of performing a number of tasks. Work is passed from one operator to the next, one pair at a time. The team is responsible for quality control and inspects its own work.

Footwear production within the EU is becoming more mechanised and specialised. The introduction of computer-aided design (CAD), which allows a shoe to be designed on a computer and the detail-work to be downloaded to production machines, has been one of the most important developments. CAD reduces the time span between design and production to only a few hours, thus enabling a quick response to style changes for fashion footwear. The use of CAD systems has been accompanied by computer-aided manufacture (CAM) and computer-integrated manufacture (CIM). CAD systems are increasingly being linked with computer-aided cutting systems using water jet, laser or die cutters. Operators can view a piece of leather with the use of video and computers and create shoe patterns, taking into account any blemishes on the raw material.

Labour productivity in the EU footwear industry increased steadily over the ten years to 1993, registering an overall increase of 36 %. The increase was particularly sharp in 1993. Unit labour costs have fallen slightly against a background of an overall rise in total unit costs. The need to rationalise costs to maintain competitiveness with developing countries has led larger companies in some Member States to transfer production facilities to those countries within the EU where the cost of labour is lower, including Portugal.

firms in the EU in 1993, employing an average of 20 workers, compared to 14 730 firms in 1992. More than half of these firms, 55 % to be exact, were in Italy. Major EU footwear manufacturers include Salamander AG (D), Romika & Co. KG (D), Eccolet Sko (DK), Eram (F), André (F), Clarks (UK), Church & Co (UK), Simod SpA (I) and Filanto SpA (I).

### Strategies

Available investment data on the EU footwear industry is dated, with 1989 being the latest year for which information is available for most Member States. In 1989, the value of investment in current prices for all Member States, except the Netherlands, was 295 million ECU, roughly equivalent to the levels in 1985 and 1986 in nominal terms. This was less than 2 % of the value of production and gives an indication of the low level of confidence in the future of footwear manufacturing in the EU during the second half of the 1980s.

Some of the companies which transferred their production to the lower-cost countries include the French company, Charles Jourdan, which transferred production from the Rhône valley to Spain. Eram, one of France's largest producers and distributors of footwear, operates ten plants within France along with one in Portugal and one in Spain. Likewise, many German producers have transferred their production to Portugal, as well as Austria, while the United Kingdom manufacturer Clarks has two plants in Portugal. The Danish footwear manufacturer, Eccolet, operates plants in Portugal and the former Czechoslovakia, as well as in Denmark.

Many EU producers have shifted their operations to developing countries outside of the EU, where cheaper labour can also be found. South Korea, China and Thailand are the most popular countries for sourcing, since some of the other developing countries are not yet as well-organised or reliable.

Some French manufacturers now sub-contract to Tunisia, Morocco and China. The German company Wortmann has factories which manufacture inputs in Taiwan, Hong Kong, China, Thailand and Brazil. Europe's leading sports footwear manufacturers such as Adidas and Puma also transferred substantial proportions of their production facilities to the Far East during the second half of the 1980s. This was done in order to remain competitive with their main rivals who already manufacture the majority of their footwear in the Far East. Puma closed its last German manufacturing facility during 1993. Vietnam is, however, becoming increasingly popular. Italian companies Diadora and Simod both established manufacturing facilities in China during 1994, while Ferragamo extended its operations there by opening a second boutique in Shanghai.

The import of uppers and other labour-intensive parts from low labour cost countries for assembly is also common. While this practice is less popular in Italy, it is most popular in Germany, which pioneered such outward processing in Eastern Europe. However, the trend of locating production facilities in Eastern Europe is likely to slow down, as labour costs in

these countries have been increasing and therefore any benefit to footwear manufacturers will exist only in the short term.

Conversely, some quality- and image-conscious footwear companies almost completely refrain from sourcing production in low-cost locations. While Bally's in-house production contracted rapidly during the 1980s, most of the subsequent sub-contract work is in high-cost locations with the major portion of the company's sub-contractors located in Italy. Bally's fashion studios in Milan, Paris and London cooperate closely with these sub-contractors. Some leading German retailers also source the production of their private label shoes with Italian sub-contractors.

The integration of retailing and manufacturing has been an important feature of the footwear sector over the last decade, although many footwear companies are now placing greater emphasis on the retailing aspects of their operations. France's Groupe André, for example, which has been increasing its retail presence in France and other EU markets sold Jallate, a world leader in the manufacture of safety shoes, in early 1993.

In addition, strategies both in terms of capital investment and new organisational structures place increasing emphasis on quick response, flexibility and other aspects of delivery performance. In France, Bata's computerised manufacturing system can provide customers with a coated sample in real time, and can achieve a three-day turnaround for urgent repeat orders. Similarly, Bally recently introduced a computerised merchandise information system aimed at minimising stocks, shortening order delays and improving cooperation between production units, sub-contractors and retailers.

### Impact of the Single Market

The impact of the Single Market programme on the footwear sector has been mixed. By abolishing national import quotas, the Single Market programme has contributed to a further increase in import penetration by low-cost countries. In addition, in Europe opportunities for economies of scale are rare in this sector as the EU footwear market is very fragmented. As a result, many EU producers have shifted operations to low labour cost producing countries. The imports of uppers and other labour-intensive parts from low labour cost countries for assembly is common. However, increasing use of Computer Added Design (CAD) and Computer Added Manufacture (CAM) has allowed European manufacturers to introduce quick-response and just-in-time manufacturing to compete with low-labour cost countries. This has also made possible the production of high quality low-volume runs well adapted to fashion trends. In this context, the removal of customs and other physical barriers to intra-EU trade has led to a reduction in transport cost and delivery time.

The future priorities of the sector are the elimination of the remaining national non-tariff barriers to trade, an accelerated harmonisation of monetary policies in order to avoid exchange

rates fluctuations, a legislation on environment protection which takes more into account the ability of the EU companies to achieve ever increasing environmental standards and a level-playing field for competition both within the EU and with respect to third countries.

## REGIONAL DISTRIBUTION

Much of the EU footwear industry is concentrated in specific regions in a few countries. These regions are often areas with little alternative employment to the footwear industry. The industry is the most regionally concentrated in the Iberian peninsula. In Portugal, Aveiro accounts for over half of all footwear production, while Porto and Braga account for a further 31 % and 11 %, respectively. Meanwhile, in Spain 62 % of footwear firms were located in the Valencia region in 1991.

Three Italian regions - the Marches, Tuscany and Veneto - account for almost two-thirds of the all footwear employment in Italy, and one-fifth of the total footwear employment in the EU. Similarly, over 60 % of the shoes produced in France in 1991 came from the Pays de la Loire and Aquitaine regions.

The industry can also be concentrated even further in towns and areas within regions such as Herzogenaurach and Pirmasens in Germany, and Northamptonshire in the United Kingdom. The impact of any adverse developments for the industry therefore heavily impact these specific areas of the EU.

## ENVIRONMENT

Environmental issues are more important in industries supplying the footwear industry than in the industry itself. The leather and tanning industry is a major source of raw materials to European producers. Suppliers in this sector are under pressure to use water and chemicals more carefully to reduce the level of effluents. The need to install water effluent treatment equipment to meet increasing environmental standards will lead to increased tanning costs and therefore higher supply costs for the footwear industry, although there is already sourcing of materials outside the EU.

Further problems for the industry are caused by the divergence between existing national legislation and the EU Directive on PCP (pentachlorophenol), with the maximum permitted limit set at very low levels in some Member States. The lack of standardised testing procedures exacerbates the situation. Suppliers of raw materials for non-leather footwear production

are likely to face increasing constraints from regulations on the usage of polyurethane and polyvinyl chloride (PVC).

Environmental problems with traditional materials has accelerated the search for alternatives such as fish skins. Most fish skins can be tanned and cured, are available in a greater range of colours than traditional hides and can often be both tougher and easier to clean. Another alternative is to use frog skins, which are very elastic. New man-made fibres are being developed, both as alternatives to traditional hides and as insoles and other shoe components. Their advantages would include not only comfort and general functionality, but environmental appropriateness as well. Finally, components are being produced using recycled materials, particularly insoles.

Discussions have begun regarding an eco-label for shoes. A CEN Working Group is also working on specific functional requirements for shoes. These will provide a further "quality" guide to help brand and market EU-produced shoes.

## REGULATIONS

With the arrival of the Single Market and the dismantling of border protection, the national quotas for footwear imports from some low-cost producers have become more or less redundant. Previously, national quotas could be protected through Article 115 of the Treaty of Rome. This Article helped to circumvent national import controls by routing goods through another Member State. With no physical internal border controls since January 1993, the use of this article has become very problematic and it is now being phased out.

An EU Directive concerning the labelling of the materials used in the main components of footwear for sale to the consumer was adopted by the Council in March of 1994. It will enter into force in March 1996. The Directive deals primarily with indicating the composition of footwear by either "pictograms" or text.

## OUTLOOK

The EU footwear industry faces a difficult future, although there are some encouraging factors. These include the possibility that some of the trade restrictions which EU manufacturers face on some lucrative extra-EU markets will ease following the GATT agreement. New markets for EU footwear will emerge in the increasingly prosperous Asian NICs. The mixed outcome of the GATT negotiations, however, complicates any forecast on how soon and how deeply EU companies

will penetrate these markets. Recovery in the key extra-EU markets of Japan and the USA, as well as better prospects for Member State economies from 1994, will drive growth in consumption over the next few years.

However, recovery in the EU will also lead to resumed growth of extra-EU imports of footwear from low-cost competitors. The rate of growth of sourcing production in lower-cost countries slowed in recent years, but is unlikely to end anytime soon. The industry's fundamental difficulty is that it is caught in a shift of comparative advantage in labour-intensive industries. This shift is accentuated by the fact that footwear is a basic commodity for which there is traditionally strong local demand, and also that it is a major part of the industrial sector in developing countries which are at early stages of industrialisation. Thus, as labour costs in countries such as Taiwan and South Korea rise as a result of their ongoing economic development, new locations such as Vietnam, China and Indonesia will become more important.

The full impact of the Single Market, initially dulled by the impact of the recession on consumer demand, should become more apparent as EU Member States enter a strong growth phase over the next few years. The measures taken will have increased competition within the EU and may cause a further squeeze on the margins of European manufacturers. How competitive the internal market becomes also will depend on the evolution of EU trade policies, not only in the context of the GATT but also with regard to arrangements vis-à-vis Eastern Europe. In addition to the improved access to the EU for East European footwear, easier access to Eastern Europe will make it easier for EU manufacturers to locate production facilities in these countries. Provided that political stability is maintained, the volume of extra-EU footwear imports from Eastern Europe seems likely to increase, as does the volume of imports of uppers or semi-finished inputs.

Growth in consumption is, however, expected to lag behind overall economic growth. With increasing import penetration both employment and production in the EU are expected to fall in the medium term. While the increasing use of technology will help the industry to regain its competitiveness, it will not provide the complete solution. Increased cost effectiveness will also be needed, along with a greater emphasis on marketing and satisfying the changing demands of the consumer.

# Leather tanning and finishing

NACE 441

Improved business prospects in the leather industry is bringing dynamism back to the tanning sector after several years of a depressed market situation. EU tanners optimism may be frustrated due to critical shortages in the supply of raw materials and alarmingly rising prices in hides and skins. Export orientation, fashion and quality remain the factors of strength and competitiveness for EU tanneries.

## INDUSTRY PROFILE

### Description of the sector

Tanning hides and skins is possibly one of the oldest trades of mankind. Down through history it has evolved into a modern industry blending high technology and fashion to satisfy the demanding needs of today's consumers. Production of leather consists of industrial processes where raw hides and skins are converted into a durable material which suits the requirements for the manufacture of a wide range of consumer products. Leather is thus an intermediate product resulting from the valorisation of a residue from the abattoirs and meat industry and serving as a major input for sectors such as footwear, clothing, furniture, leather goods etc.

Tanning is a relatively small and capital intensive sector which has to be considered in connection with its upstream (abattoirs, hides and skins dealers, tanning chemical and machinery suppliers) and downstream (footwear, clothing, furniture and leather goods manufacturers) counterparts in order to understand its actual economic weight. Together with those other labour intensive activities, the global EU leather industry represents an industrial sector comparable with the clothing industry in terms of production and employment. Southern EU Member States predominate in the geographical distribution of production with Italy being by far the most important leather producer accounting for 4 266 million ECU and some 60 % of total output.

### Recent trends

Leather production by volume in the EU is experiencing a continuing contraction. Today the EU leather production totals some 250 million m<sup>2</sup>, down 15 % compared to a decade ago.

The trend of relocation of traditional sectors in other regions of the world following a general pattern from north to south and from west to east has eroded much of the EU leather sector's production capacity. Mediterranean Member States have benefited from this trend during the 1970s. Their level of production rose in relative terms but they are now increasingly facing the same difficulties as their northern counterparts. Closures due to the inability to compete in an international environment where unfair trade practices proliferate, increased non productive costs for environmental protection are some of the reasons behind the contraction of the EU tanning sector.

It has lost over 1 000 production units and about 30 000 workers since 1983, a trend which is likely to continue in the future. As bulk leather production shifts more and more to NIC's and developing countries, European tanneries concentrate in producing less volume but more value in order to maintain the sector's high level in terms of turnover. Consumption of leather is dropping in the EU as an increasing number of downstream manufacturers disappear either relocating their factories in low cost countries or closing down their businesses because of the fierce and often unfair com-

Figure 1: Leather tanning and finishing  
Value added in comparison with other industries, 1993

Source: DEBA

petition from extra EU producers. The EU leather market, once the world's largest, is losing ground progressively with the emergence of new, dynamic, and exponentially growing leather consuming regions notably in Asia.

With a shrinking internal market and rising opportunities in foreign markets, EU tanners have spent considerable efforts in developing exports. The EU tanning sector's export performance has improved continuously doubling in current prices since 1983 and reaching about 1 500 million ECU.

The most recent sectoral data reflect these long term trends but also a slight recovery from the recession which depressed the leather sector since the beginning of the decade. Leather production in value reached 7 069 million ECU in 1993, an increase of 2.5 % compared to the year before. Italy, Spain, Portugal and Greece were the EU member States who performed the best with increases of 5 %, 4.5 %, 3 % and 16 % respectively.

### International comparison

The leadership of the EU in the worldwide leather industry remains unchallenged. Its traditional image of quality and reliability combined with excellence in the field of fashion secures EU tanners a privileged position in the international marketplace.

Compared to the USA and Japan, the EU appears particularly important in terms of production. It is to be noted however that Japan has managed to improve significantly its position during the last decade behind the wall of protection provided by prohibitive import tariffs (Tariff Quota system). Inversely, the USA continued to loose ground in the domestic leather production. More serious competition for EU tanners comes from India and Pakistan in Asia and Argentina and Brazil in South America. Central and Eastern European Countries (CEECs) are also emerging players. All those countries however are stemming up production on the basis of protectionism.

### Foreign trade

The EU leather industry has managed to maintain its position as the world's largest supplier of leather accounting for slightly over 50 % of total supplies. Its importance in relative terms tends however to decline in the long term with the emergence of new players notably in Asia. Whereas in 1983 Asia and Oceania contributed with 20 % to the global availability of leather, in 1992 this figure rose to 24 % and by the year 2000 it is likely to be in the range of 30-40 %. So far this region's expansion has been to the disadvantage of the American continent whose relative performance has been less positive over the years.

The development of extra EU exports since 1988 has been particularly significant with Hong Kong and South Korea. The former generally acts as a distribution centre for the markets around the Pacific Rim. Exports to China look quite promising considering this country's potential. The USA and

EFTA have remained important trade partners for the EU in the leather sector.

In extra EU imports the most striking development is the improvement of the relative share of CEECs whose leather exports to the EU have slightly eroded those of India and Pakistan.

## MARKET FORCES

### Demand

Fashion and consumer spending patterns are the main factors affecting the demand for leather in developed economies. Footwear, garments, leather goods, upholstered furniture and cars constitute the most classical outlets for this material. Their relative importance as a market for EU tanners varies from country to country. Shoe production remains however the most important client sector overall for the leather industry with a share of 50 % of the total EU production. Next follows the clothing industry with 20 %, the furniture sector with 17 % and finally the leather goods sector with 13 %.

Geographically the demand for leather shifts to the emerging economies in Asia where a wealthy middle class appreciate increasingly the appeal of leather.

### Supply and competition

Reduced slaughter due to the reform of the Common Agricultural Policy (CAP), the increase of extra-EU exports of live animals and the proliferation of protectionism in the form of export restrictions of hides and skins by an ever increasing number of trade partners is causing damaging supply shortages to the EU tanning industry. Prices of raw materials on free markets are rocketing and threaten to put EU tanners out of business.

Export restrictions of raw materials are particularly damaging unfair trade measures which artificially distort competition to the benefit of those countries tanners' implementing them. The ultimate consequence is a forced transfer of production from competitive businesses operating according to free market rules to non competitive operators which only manage to overcome their handicap through measures diverting the optimal allocation of resources. Protectionism in the leather industry of Central and Eastern European Countries (CEECs) is causing great disarray among EU tanners because the threat is so close and the impact so tangible.

## Production process

EU tanneries' competitiveness relies on a successful blend of quality and fashion achieved through the optimisation of the production processes. Product innovation generally starts in the EU where the major fashion centres anticipate the trends and the most important specialty chemical suppliers develop new techniques in cooperation with the tanning industry.

## INDUSTRY STRUCTURE

### Companies

The total number of tanneries in the EU continued to decline in 1993 leaving the sector with only 3 002 companies and 52 026 workers, a drop of 9.7 % and 9.5 % respectively compared to 1992. Since 1983 1 000 tanneries have closed down and 28 000 workers made redundant.

SMEs predominate in the tanning sector. In a recently created databank of the EU tanning industry recording the 1 000 most important companies of the sector, only 10 tanneries appear to employ more than 200 people, 28 are listed in the range of 101 to 200 employees, 82 in the range of 51 to 100, 175 provide work for 21 to 50 people and the rest has less than 20 workers. Companies are often family businesses transmitted from generation to generation and some can proudly show a centenary tradition in the industry.

The EU tanning industry databank gives also an indication of the sector's breakdown in terms of company turnover: 4 tanneries present a turnover of more than 30 million ECU; 20 tanneries are in the range of 20 to 30 million ECU; 71 tanneries are in the range of 10 to 20 million ECU; 129 tanneries are in the range of 5 to 10 million ECU; the bulk

of EU tanneries present a turnover of less than 5 million ECU.

Leading EU tanneries in different member States include: Mastrotto, David, Dal Maso, Arno, Industria Conciaria Europea SpA and Russo di Cassandrino in Italy; COSTIL Tanneries de France and Tannerie PECHDO SA in France; Curtidos CODINA and Grupo Lederval in Spain; Kon. Hulshof's Ver Fabrieken BV in the Netherlands; Swewi Svendborg A/S in Denmark; The British Leather Co Ltd in the UK; Lederfabrik Louis Schweizer GmbH & Co and Ludwig Lindgens GmbH & Co. KG in Germany.

### Strategies

Mergers and acquisitions are not common features in the EU leather industry and strategic alliances are usually developed in key foreign markets with the objective of boosting exports. Company strategies focus, among others, on certification to quality assurance systems, product innovation and improved customer service adapting constantly to the demand of the market.

### Impact of the Single Market

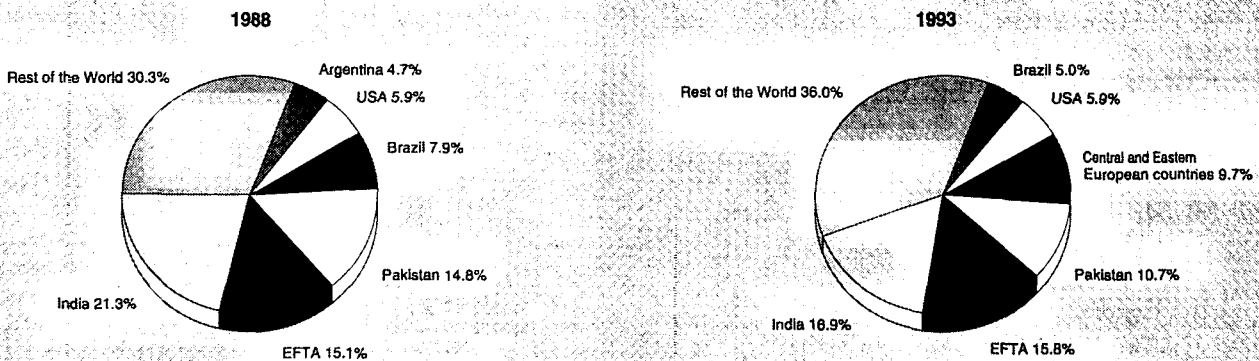

The impact of the Internal Market has been globally positive for this sector. By better defining the characteristics of leather products, the technical harmonisation represents an important measure as it allows economies of scale. However, the reality is that the domestic market is shrinking, mainly due to the fierce competition of extra-EU tanners from countries where the access to raw materials is protected. This competition has been increased with the Generalised System of Preferences,

which makes the access to the European market even easier. Moreover, there is a movement of relocalisation of the client industries to low wage countries. So the EU tanneries have to excel in quality or fashion succeeding in the market segment where price considerations are not the most important factor. Among the future priorities are the fact that environmental regulations should take more into account the ability of the industry to assume ever increasing standards, and a fairer degree of competition in the sector of leather tanning and finishing, both for intra-EU trade and with respect to non-EU producers.

### REGIONAL DISTRIBUTION

There are regions within EU member States presenting characteristic concentrations of tanneries and municipalities whose local socio economic life depends heavily on this sector's activity. Such areas are more frequent in southern European countries than in the north of Europe where the decline of the tanning industry has led to the isolation of individual tanneries and their loss of influence in generating wealth and employment. Whereas in Germany, Backnang and Müllheim are some of the remaining leather areas in this country, in Italy there are several. Tuscany is a particularly well endowed region for the leather industry. The tanning centres of Arzignano, Santa Croce sull'Arno, San Miniato, Castelfranco, Montopoli and Solofra concentrate most of Europe's sole leather production and a significant share of all the countries soft leathers. Catalonia concentrates in Vic and Igualada an important proportion of Spanish tanneries. Graulhet and Mazamet

in southern France is the traditional small skins leather area which developed historically due to the abundant supply of sheepskins imported mainly for the wool. Alcanena in southern Portugal has become more recently one of the leather centres in the EU.

## ENVIRONMENT

At present, the challenge for EU tanners consists in combining successfully quality and ecology for securing the sector's future in Europe's industrialised economies and its sustainable development. Initially forced by the regulatory pressure at all governmental levels, EU tanneries have progressively integrated the concept of environmental protection into their management strategies and have adopted consequently measures to prevent pollution rather than to apply "end of pipe" solutions. The sector's operators throughout the EU have understood that sound environmental management and the implementation of cleaner process technologies often lead to considerable savings as waste disposal costs rise. High tanning chemicals exhaustion technologies, water based coatings, enzymatic degreasing, effluent separation techniques are just a few examples of environmental technologies which are more and more widespread in the EU member States' leather sector. This proactive approach to environmental concerns has led to minimise pollution in the EU leather industry so as to reasonably expect to be excluded from the scope of proposed legislation in the field of Volatile Organic Compounds (VOC), or Integrated Pollution, Prevention and Control (IPPC). The administrative costs for the SME's of the sector possibly induced by the proposed instruments would be out of proportion to the nuisances they cause. The fact that only one residue from the leather industry, "degreasing waste containing solvents", has been retained from the European Waste Catalogue (EWC) in the list of hazardous waste, is an indication of the environmental performance of the sector. Environmental consciousness plays indeed an important role in today's EU tanneries. Waste minimisation through prevention, recycling and recovering residues for converting them in inputs to other industries are well established techniques in an increasing number of plants. These efforts could be enhanced by a more homogeneous environmental legislation in the different EU

Source: DEBA

Member States and a EU legislation encouraging a wider use of secondary raw materials.

## REGULATIONS

Only a few EU regulations apply specifically to the leather sector as it is usually covered by the complex and comprehensive set of standards governing all type of industries. Of particular interest are some technical regulations which have been recently adopted by the EU:

- the footwear labelling directive setting requirements for the use of the term "leather" and adopting officially the definition of the International Council of Tanners (ICT);
- the "balai" directive specifying the raw hides and skins needing a veterinary certificate for their circulation within the EU and setting standards for avoiding the spread of pathogens.

It is also worthwhile noting that the new EU scheme of generalised preferences (GSP) has classified the leather industry among the sensitive sectors and the most competitive beneficiaries, such as Argentina, Brazil, India and Pakistan, will be progressively excluded from the granting of preferential access to the EU internal market.

## OUTLOOK

The prospects for the future of the EU tanning industry depend mainly on the developments in the field of raw materials. This factor is of capital importance as it will determine which leather industries in the world may remain in business. With a shrinking availability of hides and skins on free markets and poor prospects for a liberalisation of supplies in those countries with abundant resources, one must forecast a further contraction of the leather production in the EU.

Written by: COTANCE

The industry is represented at the EU level by: Confederation of National Associations of Tanners and Dressers of the EC (COTANCE). Address: Rue Belliard 3, B 1040 Brussels; tel (32 2) 512 7703; fax: (32 2) 512 9157.

## Overview

### NACE 46

In 1994, total production in the wood processing industry (excluding furniture) was estimated to reach 38.1 billion ECU. The sector is highly dependent on developments in building activity and furniture production. The industry is characterised by an abundance of small and medium-sized enterprises (SMEs). Intra-EU trade is still hindered by remaining technical barriers. Over the period 1995-97, demand for goods produced by the wood processing industry is expected to grow by an average nominal rate of 5.7 % per year. With the entry of Austria, Finland and Sweden into the EU in 1995, the relative importance of the wood processing industry in the EU economy will increase considerably.

### INDUSTRY PROFILE

#### Description of the sector

The wood processing industry is divided into the following subsectors :

- sawing and first processing of wood (NACE 461);
- semi-finished wood products, such as particle board, fibre board, plywood and impregnated wood (NACE 462);
- wooden building components, such as doors, window frames and parquet flooring (NACE 463);
- wooden containers and pallets (NACE 464);
- other wood manufactures (NACE 465);
- articles of cork, articles of plaiting materials, brushes and brooms (NACE 466).

The wood processing industry is an important supplier to the building and furniture industries. In 1994, the total production value was estimated at 38.1 billion ECU and employment at around 392 000 people. The largest subsector is the wooden building components industry. At an estimated production value of 14.2 billion ECU in 1994, it represented 37 % of the total wood processing industry. Sawing and first processing of wood accounted for 15 %, semi-finished wood products for 23 %, and other wood products for 25 %. Value added amounted to 12.4 billion ECU in 1993. Germany is the biggest producer, representing nearly 40 % of total EU value added.

As the sector has a large number of SMEs, production and employment figures are considerably underestimated by most statistical sources, since these generally do not cover smaller businesses (less than 20 employees).

#### Recent trends

Between 1984 and 1993, apparent consumption of wood products increased by an average real growth rate of 1.4 % per year. Over the same period, production in constant prices increased by 25.4 % (2.5 % per year), and thereby outperformed total EU manufacturing industry which grew by 18.5 % (1.9 % per year). Extra-EU exports in current prices remained relatively stable between 1989 and 1992, but in 1993 there was again a significant increase (+8.8 %).

Employment grew by 7.1 % between 1986 and 1990, to reach a peak of 440 500. Since then, however, employment has dropped to a projected 392 100 jobs in 1994. Long-term changes in employment in the wood processing industry par-

**Figure 1: Wood processing Value added in comparison with related industries, 1993**

Source: DEBA

allel those of the EU manufacturing industry. Since production has increased more rapidly than the manufacturing industry average, this means that the wood processing industry has achieved higher productivity growth.

EU consumption and production expanded in 1987-91, but stagnated in 1992 and began to decline in 1993. In 1993, apparent consumption in current prices amounted to 43.6 billion ECU, a decrease by 1.1 % compared to 1992. Production amounted to 35.5 billion ECU in 1993, a decrease by 1.5 % compared to 1992. For 1994, production was estimated to grow by 7.4 %.

#### International comparison

In 1993, EU wood processing equalled only 58 % of US production and 84 % of Japanese production. With an average

Source: DEBA

annual real growth rate of 2.6 % over the period 1984-93, production in the EU grew slightly faster than it did in the USA (where it grew by 2.4 %), but was outperformed by the Japanese (+3.4 %). Production in the USA is evidently subject to cyclical fluctuations to a greater extent than in the EU or Japan.

**Foreign trade**

In constant prices, both extra-EU exports and extra-EU imports are following a long-term negative trend. Between 1984 and 1993, they declined at an average real annual rate of 1.9 % and 2.3 %, respectively. Although imports are decreasing faster than exports, the EU trade balance remains negative. In 1993, the deficit amounted to 8.1 billion ECU.

In current prices, extra-EU imports rose by 5.9 % per year from 1985 to 1990, declined by 5 % in 1991 but increased again by 2.6 % in both 1992 and 1993. Extra-EU exports grew rapidly in 1988-89, but then stagnated. In 1993, extra-EU exports grew by 8.8 %.

Between 1984 and 1993, the exports/imports ratio has remained relatively stable at around 20 %. The import/consumption ratio has declined, however, from 28 % in 1984 to 23.6 % in 1993. The export/production ratio fell between 1984 and 1988, but has remained stable since then at around 6 %.

In 1993, extra-EU imports mainly originated in the EFTA countries (41.8 %), the USA (11.3 %), Indonesia (5.9 %), Malaysia (5.8 %) and Canada (4.9 %). Extra-EU exports, on the other hand, mostly went to the EFTA countries (42.2 %), USA (12.2 %), Japan (4.7 %), Saudi Arabia (2.4 %) and Australia (2.0 %).

The entry of Austria, Finland and Sweden into the EU in 1995 should bring about a considerable "improvement" in the EU trade balance for wood products.

## MARKET FORCES

### Demand

Since the wood processing industry comprises a wide range of products, these products have different types of buyers, i.e. industrial or final consumers. Demand for the products of the wood processing industry largely depends on two sectors, the furniture and building industries. Since these two sectors are highly cyclical, demand for wood products is largely influenced by the evolution of general income levels and interest rates.

In 1993, the furniture industry, like most parts of the manufacturing industry, suffered considerably from the recession. On average, production of furniture in the EU declined by 2.2 % in value and by 2.8 % in volume in 1993, to reach 38.5 billion ECU. Nearly all EU countries experienced a decrease in furniture production, except for the UK, where private consumption was buoyant, and Portugal. 1993 was worse than 1992, which had already been a poor year for many furniture manufacturers. Weak demand due to a lack of consumer confidence (increasing unemployment), a stagnation or even reduction in disposable income, high interest rates and the contraction of export markets were the key factors behind this situation. Investments were scaled down and in 1992-93 almost 40 000 jobs were lost in the furniture sector (4 % of total employment). This situation did not improve considerably in 1994. Indeed, estimates for 1994 indicated a stagnation in production at the 1993 level and a further loss of around 7 000 jobs.

In the EU, the construction business cycle reached its peak in 1992, after having experienced 5 years of declining growth rates from 1988. In 1993, there was an average decrease of 2.3 % in construction activity, due to negative growth rates in almost all countries, notably -10 % in Italy and, within EFTA, -13.6 % in Sweden and -17.7 % in Finland. Among the subsectors, the most adversely affected was non-residential building (-6 %), although civil engineering declined significantly as well (-5.2 %), whereas house building grew slightly (+1.5 %). These results can be attributed to budget problems in most EU countries, but also to the difficulties in both the manufacturing and the service industries, which have significantly scaled down investments in factories and office buildings. For 1994, estimates indicated a stagnation in EU construction activity (growth at 0.1 %). However, positive

growth rates were projected for Denmark, Ireland, Portugal, Germany and the United Kingdom.

### Supply and competition

The deficit in the EU trade balance can be explained by the dependence of important subsectors on imports of hardwood and softwood timber, sawn plywood from South East Asia (especially from Indonesia) and the USA, hardboard from South America (especially Brazil) and Eastern Europe and imports of miscellaneous wood products from the countries of Central and Eastern Europe at extremely low prices. The political and economic developments in Central and Eastern Europe will continue to have significant implications as these countries have very large wood reserves and much lower labour costs than the EU-countries.

Although imports of raw materials, such as hardwood and softwood timber, are likely to continue, an improvement in the trade balance of the sector could be stimulated by way of forestry policy in the EU. An increase in the domestic supply of wood could be brought about through the use of marginal land. As there are large surpluses of agricultural products within the EU, excess agricultural land is being converted into forest. This could lead to an improvement in the trade balance for the EU wood processing industry and would also have a positive impact on the environment.

Trade flows among Member States are more important than extra-EU exports. This is partly explained by transport costs that limit trade in wood and wood products. In previous years, competition has been affected by a large number of technical barriers to trade between Member States (national standards that have already been in existence for a long time, major differences in procedures for granting technical approval, etc.). Against the backdrop of European integration, the sector will be influenced by the results of the discussions on the short-term implementation of European standards and technical reference documents. This technical integration is expected to result in increased trade between Member States. Thus, it is imperative that the industry follow the activities in the regulatory and technical field. Within the European Committee for Standardisation (CEN), eight technical committees have been created to develop standards for products in the wood processing sector:

- CEN/TC 33: doors, windows, shutters and building hardware;

- CEN/TC 38: durability of wood and derived products;
- CEN/TC 112: wood based panels;
- CEN/TC 124: timber structures;
- CEN/TC 173: brushware;
- CEN/TC 175: round and sawn timber;
- CEN/TC 207: furniture;
- CEN/TC 261: packaging.

Thanks to rationalisation and automation investments, labour productivity in the wood processing industry is rising rapidly. Between 1984 and 1993, labour productivity increased by roughly 40 %. The gross operating rate has averaged approximately 10 % in the 1990s. Profitability deteriorated in 1989-92, but improved in 1993.

## INDUSTRY STRUCTURE

### Companies

The wood processing industry (including wooden furniture) comprises around 244 000 companies, of which 94.4 % have less than 20 employees, and 5 % have between 20 and 99 employees. Companies with less than 20 employees represent 48 % of employment and 36 % of turnover. This indicates that most official industry statistics significantly underestimate the importance of the wood processing industry, as they usually do not include units that have less than 20 employees. Companies with more than 99 employees represent only 0.6 % of the total number of enterprises, but account for 32 % of total turnover and 24 % of employment. In all, the 244 000 companies in the sector employ 1.7 million people in the EU, and represent a total turnover of 123.1 billion ECU.

Since wood processing started as an artisan activity, the family structure of SMEs in the sector remains an important characteristic. The EU countries which are the most specialised in the processing of wood are Portugal (with a production specialisation ratio of 2.37), Denmark (1.69) and Spain (1.47).

### Strategies

The wood processing industry underwent a crisis in the early 1980s. During the second half of the decade there was a rapid expansion in the demand for wood products. The companies in the wood processing industry made substantial investments in order to respond to this larger demand. Since new machines normally outperform older ones, new invest-

ments resulted in a rationalisation of the production process and an improvement in efficiency and productivity. The capital intensity of the production process increased considerably over the past decade. As demand slowed down in the beginning of the 1990s, investments were focused on the introduction of new products (e.g. medium density fibre board and oriented strand board) and new production technologies. In order to stave off extra-EU competition, many SMEs have adopted a strategy of specialisation.

### Skill shortages

Due to the fast changes in production techniques, the sector is having increasing difficulties in finding properly trained staff. This implies that considerable attention will have to be paid to raising training standards in this field, to meet the need for skilled workers and qualified executives. In the context of the Eurofortech/EU-Comett programme, a training and education programme in the area of timber engineering and design known as STEP (Structural Timber Education Programme) has been developed. STEP aims at organising more than 100 Euro-wide courses, seminars and workshops on the structural use of timber. Its budget is nearly 1.5 million ECU.

### Impact of the Single Market

The impact of the Single Market on the wood processing industry varies between the different measures of the programme, as well as across the sectors of the industry. The overall effects are difficult to distinguish as they have been obscured by the impact of the recession. With increasing harmonisation, intra-EU trade has grown, as have extra-EU imports, particularly of simple, standardised products, such as pallets imported from Eastern Europe. Increasing competition has spurred mergers and acquisitions, mainly among larger companies in the industry, and has triggered a shift to higher value added products. SMEs have responded through strategies of specialisation and customisation. Cost reductions through rationalisation and increasing automation have had the effect of raising the required skill levels of the workforce, which has resulted in a lack of qualified labour. This highlights the need for appropriate training programs directed to the wood processing industry. Intra-EU trade is still hindered by remaining internal barriers, specifically technical ones related to the harmonisation of product standards.

## ENVIRONMENT

Wood is a recyclable raw material. The processing of wood requires a minimum of energy and, depending on the subsector,

**Figure 7: Wood processing

results in minimal to no pollution of the air, water or soil. However, there have been discussions on the use of tropical wood, the recycling and disposal of packaging waste and the tax related to CO<sub>2</sub> emissions. This is certainly not unique to this sector, and has to be seen in a much broader context.

### The protection of tropical forests

The deforestation of the tropics is an alarming situation that gives rise to general concern. The most important reason for this deforestation is the circle of poverty, population pressure, over-indebtedness and economic underdevelopment that produces an increasing demand for land for farming, industrial purposes and infrastructure.

Unqualified and destructive timber exploitation only accounts for a minor portion of the deforestation (approximately 6 %). Nevertheless, it is environmentally irresponsible. The tropical forests must be protected, but adequate account has to be taken of their ecological, economic and social functions. This requires land planning that designates protected forests, forests for commercial use and areas for agricultural, industrial and infrastructure purposes.

Environmentally sound and sustainable forest management schemes can make important contributions to a large extent to the preservation of forests. The European wood processing industry fully supports the introduction of such schemes. Gen-

eralised bans and boycotts do not contribute to the preservation of tropical forests. On the contrary, they are likely to accelerate the deforestation of tropical areas due to the increase in poverty that is likely to arise as a result. The ITTO guidelines for sustainable forestry, which have been adopted by all producer and consumer countries, constitute the first internationally recognised criteria for sustainable forest management. It is essential to achieve the implementation of these guidelines before the target year 2000 that has been agreed upon within the ITTO.

These measures should be implemented in collaboration with competent environmental organisations. An important incentive for the realisation of sustainable forestry is the introduction of an attestation of origin. An attestation scheme can be established on a country by country basis or on a case to case one. The interests of the wood producing countries of the Third World have to be appropriately considered when coordinating international measures for the protection of tropical forests. Even in the problem zone of the tropical forests, ecology and economy are no irreconcilable contrasts.

In the same context, certain ecological political parties also contest the use of wood from temperate forests. Although the European wood processing industry is in favour of a generalised labelling scheme in which temperate forests have to be submitted to the same criteria of sustainability, there is no fear for deforestation in this area.

On the contrary, studies and EU figures show that there has been an enormous increase in potential wood resources in the EU and in the EFTA countries. Data indicate that there is a potential for increasing annual yields by 170 million m<sup>3</sup>. This potential is likely to increase even more when 16 million hectares of agricultural land within the EU will be put to other uses, mostly by way of reforestation. It should be clear that these enormous wood reserves are bringing prices down very rapidly. This should be taken into consideration by the wood processing industry as well as national and international authorities. EFTA, the EU and its Member States should strengthen the market for wood products through promotional activities.

### Recycling and disposal

In recent years, national authorities, as well as those on the European level, have begun to focus on packaging and packaging waste. This resulted in the adoption in December 1994 of a EU Directive concerning packaging and packaging waste.

Among packaging materials, wood takes a specific place. Wood is a recyclable raw material. Wood requires little energy for processing compared to other raw materials, and therefore helps to reduce the use of valuable energy resources. Wood waste cannot be considered to be waste in its proper sense, since it can be used to manufacture other materials such as

**Figure 8: Wood processing**  
**Trade intensities**

Source: DEBA

**Table 6: Wood processing  
Breakdown by size of enterprise, 1990 (1)**

(%)	Number of enterprises (units)	Share of number of enterprises	Share of employment	Share of turnover
Less than 20 employees	230 462	94.4	48.3	36.3
20-99 employees	12 225	5.0	27.5	31.6
100 or more employees	1 537	0.6	24.2	32.1

(1) Based on data for NACE 4600; estimates.  
Source: Eurostat "Enterprises in Europe"

particle board, fibre board and laminated wood. If this use of wood waste is not possible, it can also be used as a fuel. Many wood processing companies burn bark and wood waste from their operations for heating purposes. Modern furnaces have reached very high standards and, from an environmental point of view, have to be regarded as being highly efficient.

Based on the arguments above, wood is a highly suitable packaging material. It can be recycled to produce other materials, or can be used for energy production. Treated or coated wood packaging can be burned in suitable furnace installations together with household wastes. The wood processing industry supports the re-use of wooden packaging materials for energy production as one of the solutions in recycling, and suggests positive discrimination of the use of wood in packaging.

#### CO<sub>2</sub> reduction policy

After considerable effort, the wood processing industries have managed to achieve some quite good results in the reduction of energy use. This sector of the industry is well aware of the necessity to reduce the emissions of CO<sub>2</sub> to protect the atmosphere. Therefore, it will aim at further CO<sub>2</sub> reductions and will support political policies consistent with that purpose if they can be realised in an economic way and be combined with the necessary political measures. One should also bear in mind that around 30 % of CO<sub>2</sub> emissions are caused by households, mainly from heating. It is therefore necessary to reduce energy use for the heating of houses. Wooden constructions could very well contribute to this. Expanding the use of wood wastes for heating would bring down the use of other non-renewable energy sources that are less "CO<sub>2</sub> friendly".

#### Outlook for the near future

The entry of Austria, Finland and Sweden into the Union will most likely lead to increasing emphasis on environmental issues, taking into consideration the high environmental awareness in these countries. At the same time, however, these three countries are highly dependent on their forest resources, and will therefore have a positive attitude towards wood and wood processing products.

### REGULATIONS

The wood processing industries strongly support the Single European market and regulations such as the Construction Products Directive, which aim at harmonisation on the European level. Despite the fact that the Single Market should have been realised by the 1st of January 1993, the wood processing industries still are confronted with a number of barriers to trade.

The following items are of specific concern for the wood processing industries:

#### German "Gefahrstoffverordnung"

In 1986, the German government issued a "decree on dangerous substances", introducing, among other things, a requirement that wood based materials and furniture made thereof should not result in test chamber concentration values of more than 0.1 parts per million (ppm) of formaldehyde. This gave rise to detailed opinions and observations from various Member States. Between 1986 and 1991 the subject remained under discussion.

On 12 February 1991, the German government released its "Prüfverfahren für Holzwerkstoffe" (test methods for wood-based panels) and stated that these could be considered as the implementing orders of the formaldehyde section in the "Gefahrstoffverordnung". Again, six Member States and the EFTA Secretariat as well as the Commission itself introduced detailed opinions and observations. In spite of this, a final decision on the implementing orders was taken when, at the end of October 1991, the German government published the test methods for wood-based panels in the "Bundesgesundheitsblatt".

Compared to the initial proposals of the German authorities, some beneficial changes were introduced. The main request of industry, that the results of the "derived test methods" (such as perforator and gas analysis values) should be considered as equivalent to the tests in "large chambers" was not met, however. Industry, therefore, remains opposed to this publication and believes it requires much more clarification.

#### Regulations related to wood dust

In some countries, there are very strict regulations on the exposure to wood dust in workplaces, due to its presumed health risks. For the time being, wood dust does not appear on the EU-list of carcinogenic substances in work places, because no direct relationship between exposure to pure wood dust and certain types of cancers of the higher respiratory system have been proven. Research continues, however. The industry launched a research programme to be performed at the Cancer Research Centre in Heidelberg. The programme, which will be co-financed by the EU, will take approximately 3 years and should be finalised by the end of 1995. It is expected to provide vital scientific evidence in the wood dust discussion.

#### Packaging and packaging waste directive

In December 1994, the Council of the European Union finally reached an agreement on a Directive concerning packaging and packaging waste that will come into force in 1996. Indeed, work on the Directive only began after the German authorities had introduced a national regulation and France intended to do so as well. It aims at harmonising national measures concerning the management of packaging and packaging waste and sets five-year targets for achieving specified recycling rates for different materials. The Directive authorises energy

Source: DEBA

recovery which is deemed to be the best solution for certain wood wastes.

### Volatile organic compounds

The Commission of the European Union is in the process of modifying its proposal for a Directive concerning the limitation of the emissions of organic solvents from certain activities and industrial installations. The aim of this Directive is to reduce the emissions of VOCs from certain industrial installations and processes. It is part of a strategy for an overall reduction of the emission of VOCs in the EU.

The proposal covers two activities of the wood processing sector, namely coating of wooden surfaces and wood impregnation. The most recent version of the proposal contains some important modifications based on the results of a cost evaluation study performed by Karlsruhe University. This study, and other data provided by the wood processing industry, clearly showed that the thresholds for the application of strict emission limits were set too low. For the coating of wooden surfaces, the threshold for small installations has been raised to a consumption of 15 tonnes per year. For the impregnation of wooden surfaces, it has been raised to 45 tonnes per year.

Although these modifications can be considered an important improvement, the VOC Directive could still have important implications on many SMEs in subsectors of the wood processing industries, such as the manufacturers of furniture, parquet and joinery. Discussions on this subject will continue.

### Biocidal products Directive

The wood preservation industry regrets that work on the preparation of the biocidal products Directive has been blocked at the European parliament for the moment. This Directive should enable the creation of a single market for biocidal products, including wood preservatives. Meanwhile, discussions have started on the possible revision of the EU Directive on Pentachlorophenol (PCP), where certain Member States now press for a generalised ban. This is a further example of the effect of a national regulation on the European decision-making process, as the European PCP Directive was drafted only after Germany had introduced national measures.

### Generalised tariff preferences

At the end of 1994, the EU adopted a revision of the GSP. Within this scheme, developing countries receive preferential tariff duties for certain industrial products. Whereas in the former system, fixed duty-free amounts or quotas were given to certain countries, all industrial products are now grouped into four categories: very sensitive, sensitive, semi-sensitive

and non-sensitive. Most products from NACE 46 have been classified as non-sensitive, which means that all tariff duties are abolished. Certain products, however, continue to be classified as semi-sensitive (e.g. wood-based panels, joinery and brushware), which means that duties will only be reduced to 70 % of the rate agreed upon in the context of the General Agreement on Tariffs and Trade.

### Co-operation with Central and Eastern Europe

Developments in Central and Eastern Europe will have important consequences for the wood processing industries in the EU, as these countries have large wood reserves and a qualified low cost workforce. Furthermore, companies are not as restricted by environmental legislation as companies in the European Union.

The wood processing industry does not believe that these problems can be solved by confrontation. Therefore, it is looking for co-operation with these countries, supporting them to develop their own market for wood products.

### OUTLOOK

Average nominal annual growth in the period 1995-97 is estimated at 5.8 % for apparent consumption and 5.7 % for production. This growth should be supported by general economic recovery in the EU. It is possible, however, that recovery in the wood processing industry may initially be somewhat slower than the manufacturing industry average. The two main user industries, building and furniture, are typically lagging sectors.

Extra-EU exports are expected to increase by an average nominal rate of 5.6 %. Exports of wooden boards to the emerging markets in the Far East will probably play a major part in this development. The wooden building components industry is likely to benefit from certain structural changes in the construction industry, such as the trend towards more subcontracting and the increasing use of prefabricated elements. Increasing consumer preference for wood as a building material is an additional advantage. Demand for containers and pallets will be stimulated by the recovery of international trade.

The decline in employment that began in 1990 will level out in 1995. In 1996 and 1997, employment is expected to grow again by 0.4 % per year. The stricter requirements with respect to health and environment will increase costs in the industry. Furthermore, the industry is facing increasing competition, especially from countries in Central and Eastern Europe.

With the entry of Austria, Finland and Sweden into the EU in 1995, the relative importance of the wood processing industry for the EU economy should increase considerably.

Written by: Cel-Bois

The industry is represented at the EU level by: European Confederation of Woodworking Industries (Cel-Bois). Address: rue Royale 109-111, B-1000 Brussels; tel: (32 2) 217 6365; fax: (32 2) 217 5904.

# Sawing and first processing of wood

## NACE 461

Although half the EU consumption of sawn, planed and dried timber is met by imports, the restructuring of the industry that took place in the 1980s has had a favourable impact on EU production and has already led to a decrease in extra-EU imports in the early 1990s and an improvement of the trade balance. Structural changes have taken the form of vertical integration and/or the merging of small production units. Average annual growth rates in the period 1995-97 are estimated at 3.8 % for consumption and 5.1 % for production.

### INDUSTRY PROFILE

#### Description of the sector

The first stage in the processing of wood falls under NACE code 461. The companies in the subsector are engaged in the following activities:

- saw milling;
- planing of wood;
- drying and seasoning of wood.

The subsector is an important supplier to the other subsectors of the wood processing industry, as well as to the furniture and the construction industries. Production in 1994 is estimated at 5.6 billion ECU. Value added in 1993 amounted to 1.7 billion ECU, compared to 2.7 billion ECU for semi-finished wood products (NACE 462) and 4.7 billion ECU for the wooden building components subsector (NACE 463). Sawing and the first processing of wood represents 14 % of the value added by the European wood processing industry. In 1993, the most important producers in the EU were Germany (representing around 34 % of added value), Spain (21 %), France (16 %) and the UK (15 %).

#### Recent trends

In recent years, sawing and first processing of wood has also been affected by the economic recession. In the period 1989-93, apparent consumption decreased at an average rate of 2.6 % per year, in real terms. Apparently, EU production (-1.5 % average real annual growth) was less affected by the decline in consumption than extra-EU imports (-3.7 %) were. After rising from 1986 to 1990, apparent consumption in current prices decreased in 1991 and 1992, as well as in 1993 (-3.4 %). Production in current prices also rose sharply until 1990 (3.6 % per year on average). In ensuing years, production growth was in the negative. The beginning of the 1990s saw stagnating economic activity. However, production is expected to do better in 1994, with an estimated increase of 3.9 %. In 1993, the real growth rate was negative for both consumption (-4.1 %) and production (-3.5 %).

Employment decreased by 10 % to 64 000 people in 1993, reaching its lowest level in ten years. Employment in the sector represents 16 % of total employment in the wood industry. The decrease in employment between 1990 and 1994 is more pronounced in the sawing and first processing of wood sector (-19.4 %) than in the total manufacturing industry (-13.3 %). According to the estimates for 1994, however, employment will remain relatively stable (-1.4 %) compared to the total manufacturing industry (-4 %).

In 1994, production in constant prices is expected to be 22.6 % higher than in 1984, slightly above the manufacturing industry average (+22.4 %). The sawing and first processing of wood

Figure 1: Sawing and first processing of wood  
Value added in comparison with related industries, 1993

Source: DEBA

sector performed significantly better than total manufacturing industry in the late 1980s, but was hit harder by economic recession during the early 1990s. This shows that the subsector is more cyclical than the manufacturing industry average.

#### International comparison

In 1993, EU production (5.4 billion ECU in current prices) in the sawing and first processing of wood sector amounted to 29 % of US production and 39 % of Japanese production. Canada and the Scandinavian countries are also important players on the world market. With the entry of Sweden, Finland and Austria in 1995, the relative importance of the EU will increase significantly.

Over the last years, production in the three trading blocks has developed more or less in parallel. Nevertheless, the average annual real growth rate of EU production (2 %) over the period 1984-93 was higher than that of US and Japanese production (both 1.5 %). In recent years, growth differentials have been larger. Whilst production decreased in the EU in

1993 (-3.5 % in constant prices), it also decreased in the USA (-2.9 %). After consecutive decreases in 1991 (-5 %) and 1992 (-2.5 %), Japanese production began to recover in 1993 (+4.4 %). However, production in these three trading blocks is still below their 1990 levels.

**Foreign trade**

The negative trade balance is reflected in a very low ratio of extra-EU exports over extra-EU imports, averaging 5 % in the last decade. However, extra-EU exports increased by almost 10 % in 1993, whilst imports decreased by almost 3 %. The import penetration rate declined by approximately 6 percentage points in the period 1984-93, reaching 52 % in 1993. Although import penetration remains very high, European producers have been successful in gradually substituting for extra-EU imports over the last decade.

During the economic recession of the early 1990s, EU production was less affected by the decline in consumption than extra-EU imports were, leading to an improvement in the

trade balance. In 1993, the real growth rate was negative for extra-EU imports (-4.1 %). Extra-EU exports, on the other hand, grew by 9.7 % in 1993. In 1993, extra-EU imports mainly came from the EFTA countries (50 %), the USA (11.1 %), Malaysia (8.3 %), Canada (7.1 %) and Russia (5.3 %). Extra-EU exports mainly went to the EFTA countries (58 %) and Japan (6.5 %).

**MARKET FORCES**

**Demand**

Only 5.3 % of production is exported to non-EU countries, and an estimated 8 % of EU production is directed to the final consumer. The larger part of EU production goes to industry, more specifically to the pallets, carpentry and furniture industry. This situation is not expected to change in the near future. New products are emerging based on new techniques, such as gluing, in order to increase added value.

**Figure 4: Sawing and first processing of wood**

**Figure 5: Sawing and first processing of wood**  
**International comparison of production in constant prices**

Source: DEBA

**Figure 6: Sawing and first processing of wood  
Destination of EU exports**

Source: Eurostat

Automation is increasing in the large sawmills, more specifically in the softwood sector.

### Supply and competition

The EU sawmilling market has been overwhelmed by massive imports, mainly from Sweden and Finland. The devaluation of the currencies of these countries in 1992-93 led to a huge increase of exports to the EU and brought about significant tension on the European market. However, the situation has stabilised since then. The pallets industry is facing problems as inexpensive products are entering the EU market, mainly from Poland, but also from other Central and Eastern European countries.

Labour productivity has risen continuously over the past decade. In 1993, it increased by 7.3%. After a significant increase in the years 1989-91, unit labour costs in 1992 and 1993 fell below their 1990 level, due to the rapid growth in labour productivity. After having declined continuously since 1989, the gross operating rate in the sawing and first processing of wood sector showed significant improvement in 1993, and almost reached its peak level of 1988.

## INDUSTRY STRUCTURE

### Companies

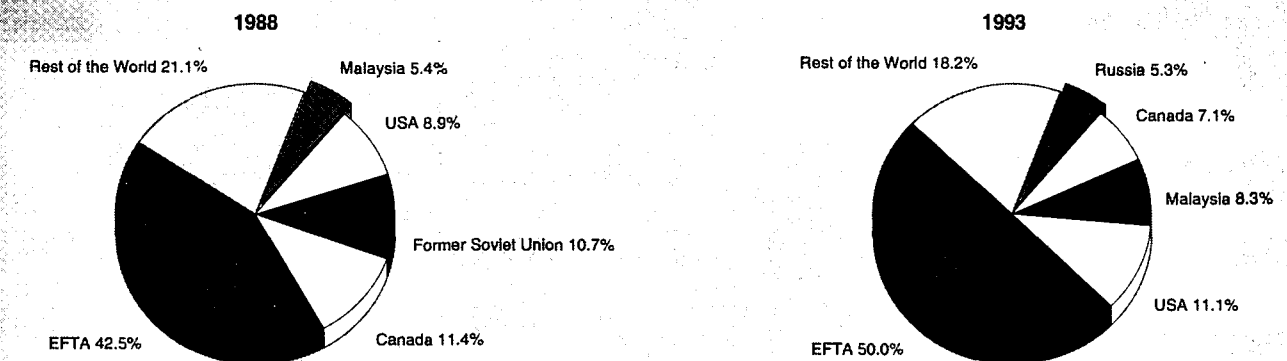

Around 1 350 enterprises employing more than 20 persons operate in the sector. In total, some 62 800 persons were employed by these enterprises in 1994. Since small and medium-sized enterprises predominate, total employment is likely to be considerably higher than official figures reveal.

The EU countries with the highest degree of relative specialisation in the sawing and first processing of wood are Portugal and Spain. Portugal has a production specialisation ratio of 4.92, which is more than twice as high that of Spain (2.14).

### Strategies

The investments that took place during the course of the 1980s contributed to the reorganisation of the industry, a necessity due to the stiff competition from non-EU producers. There were three main types of structural changes: the closure of non-profitable enterprises, the merging of small production units and an increased tendency towards vertical integration. Investments focus on plant modernisation and existing projects and are principally taking place inside the EU. There is a tendency for large companies to reduce or dispose of investments mainly because of liquidity problems. Furthermore,

**Figure 7: Sawing and first processing of wood  
Origin of EU imports**

Source: Eurostat

**Figure 8: Sawing and first processing of wood  
Trade Intensities**

Source: DEBA

there have been numerous mergers and acquisitions in the sector. Moreover, there is a growing need for highly qualified personnel.

The main strategy among the companies in the sector is to produce goods with higher added value. They therefore tend to subcontract for second stage processing, instead of remaining mere suppliers of raw material. By producing goods that are customised for further processing, EU companies can improve their competitiveness vis-à-vis extra-EU competitors.

Due to their geographical proximity, companies engaged in the first processing of wood may also respond in a more flexible way to the needs of companies involved in the second processing of wood (e.g. just-in-time delivery).

## OUTLOOK

Consumption, which decreased by 3.4 % in 1993, is expected to increase in the coming years. For the period 1995-97 an average growth rate of 3.8 % is expected. Production which is expected to grow by 3.9 % in 1994 (in current prices), is expected to increase further in the period 1995-97, at an average rate of 5.1 % per year. This means that EU production will continue to replace extra-EU imports. In short, the prospects in the short and medium terms are positive. After a continuous decline since 1990, employment is expected to grow slightly in 1996 and 1997.

Written by: Cel-Bois

The industry is represented at the EU level by: European Confederation of Woodworking Industries (Cel-Bois). Address: rue Royale 109-111, B-1000 Brussels; tel: (32 2) 217 6365; fax: (32 2) 217 5904.

# Semi-finished wood products

NACE 462

The manufacture of semi-finished wood products is the second largest wood processing subsector, representing 23 % of total sector production. Approximately 750 firms (each with 20 or more employees, with a total employment of 63 200 people, are involved in the production of semi-finished wood products. The main products are different kinds of wooden board material, such as particleboard, fibreboard and plywood. The real growth rates for 1993 were 1.7 % for production and -0.6 % for consumption, the difference in growth caused by a significant increase in extra-EU exports (+26.7 %). Since the second half of 1993, new extra-EU export opportunities have emerged in several Asian countries. The nominal average annual growth rates for the period 1995 to 1997 are estimated at 4.8 % for consumption and 4.9 % for production.

## INDUSTRY PROFILE

### Description of the sector

The subsector mainly produces wooden board material, such as particleboard, fibreboard and plywood. These in turn are used as intermediate products in the furniture or construction industries, or sold as end products. Apart from raw boards, there are also surface-improved panels (boards covered with veneer, laminates or resin impregnated paper). NACE 462 also includes companies that are engaged in the impregnation of wood with chemical preservatives.

Production of semi-finished wood products represents 23 % of the total production of the wood processing industry. Of the total volume of consumption of raw wooden board material, particleboard represents 73 %, fibreboard 11 % and plywood 16 %. Particleboard accounts for approximately 80 % of the total production volume of wood-based panels in the EU.

The value added in the subsector in 1993 amounted to nearly 2.7 billion ECU, compared to 1.7 billion ECU for sawing and first processing of wood (NACE 461) and 4.7 billion ECU for the production of wooden building components (NACE 463). 44 % of the value added was generated by Germany, the biggest producer in the EU, followed by France and Italy, accounting for 14 % and 12 % of value added, respectively.

### Recent trends

In the period 1984-93, apparent consumption of semi-finished wood products grew at an average real annual rate of 3 %. Decreasing consumption in 1986 and 1993, were the only exceptions to the trend. In the same period, production in constant prices increased by 33.7 %, performing well above the total manufacturing industry (+15.1 % on average), the poor 1993 figures of which further widened the gap. Average annual real growth rates in production were 3.3 % for semi-finished wood products and 1.9 % for the total EU manufacturing industry.

In 1993, production of semi-finished wood products increased by 1.7 % in constant prices, a slower pace than in the previous years. In the same year, production in current prices fell by 2.6 %, reflecting the downward pressure on prices due to weak demand from the industrial customers. Estimates for 1994, however, indicated a boost in the production of semi-finished wood products in current (+8.7 %) as well as in constant prices (+7.3 %). For the period 1995-97, production is estimated to reach an average annual growth rate of 4.9 %.

Figure 1: Semi-finished wood products  
Value added in comparison with related Industries, 1993

Source: DEBA

The real growth rates for 1993 were 1.7 % for production and -0.6 % for consumption, the difference in growth caused by a significant increase in extra-EU exports (+26.7 %). Since the second half of 1993, new extra-EU export opportunities have emerged in several Asian countries. Consumption suffered severely from the recession in 1993. That year, apparent consumption in current prices of semi-finished wood products amounted to 9.6 billion ECU, which was 3.2 % below the 1992 level. Between 1995 and 1997, apparent consumption is expected to increase at an average annual rate of 4.8 %.

The semi-finished wood products subsector employed around 63 200 people in 1994, which constituted 16 % of the total employment in the wood processing industry. Meanwhile, its share of total sector production amounted to 23 %. Hence, the subsector is relatively capital-intensive. Employment in the semi-finished wood products industry decreased by an estimated 11 % between 1990 and 1994. However, this negative trend in the employment level is slightly less marked than for the whole EU manufacturing industry (-13.3 %).

Moreover, the employment level is expected to stabilise in the period 1995-97.

**International comparison**

In 1993, EU production of semi-finished wood products equalled 65 % of US production and 72 % of Japanese production. However, in the period 1989-93, production in the EU of semi-finished wood products grew by an average real annual rate of 2.6 %, against 1.7 % in Japan and -0.5 % in the USA. EU production has grown continuously since 1986, whereas USA production has been more cyclical. The European wooden board industry is relatively young and is specialised in products such as particleboard and Medium-Density Fibreboard (MDF), the markets for which have displayed significant growth potential during the period. US industry is still largely engaged in the production of plywood. The plywood market is a more mature market, subject to cyclical fluctuations and also to substantial competition from low wage

countries in South America and Asia (e.g. Brazil and Indonesia).

**Foreign trade**

Following consistent growth since 1984, at an average annual rate of 4.6 %, extra-EU exports rose steeply by 26.7 %, in 1993. This is explained mainly by new export opportunities in the emerging Asian markets. Extra-EU exports, mainly consisting of particleboard and MDF, are expected to grow further during the period 1995-97, at an average annual rate of 8.6 %. The trade balance, after deteriorating almost continuously since 1985, improved in 1993 thanks to the significant rise in extra-EU exports. Nevertheless, the trade balance remained in the negative due to massive extra-EU imports of plywood.

The extra-EU exports over extra-EU imports ratio remained stable during the period 1984-92, averaging around 23 %. In 1993, it reached 29 %, also due to rising extra-EU exports. The import penetration rate has remained stable over the last

Destination of EU exports**

Source: Eurostat

years, averaging around 22 %. For the semi-finished wood products sector, the EFTA countries and the rest of the world are the major export markets, and each represented 40 % of EU exports in 1993. Indeed, EU producers have increased their share of the rest of the world markets (mainly the Far East) significantly over the past years, whilst the relative importance of exports to the EFTA countries has been reduced. In 1993, the most important Asian export markets were Japan (5.4 %) and South Korea (3.8 %). Meanwhile, 38 % of extra-EU imports originated in the EFTA countries. The USA (17.6 %), Indonesia (14.3 %) and Brazil (5.7 %) are important suppliers of plywood. In fact, extra-EU imports mainly comprise plywood and hardboard, whilst particleboard and MDF make up the bulk of extra-EU exports.

have joined other special products, such as very thin as well as very thick boards.

One trend in buyers' preferences is to replace solid wood, tropical wood, plastics and other wood based panels with MDF, especially for furniture manufacturing. MDF is a good substitute material for more expensive types of solid wood. Thin MDF is a strong competitor and substitution product for thin plywood and hardboard. As thin plywood and hardboard are mainly imported from outside the EU, intra-EU competition is not affected by this development. Apart from traditional applications for MDF (i.e. furniture manufacturing, the production of profiles and skirtings), MDF is becoming increasingly attractive for interior design, exhibition stands, window frames and door skins, etc. For plywood, one of the major developments in the world market is the reinforcement of export limitations for wood due to national and international environmental pressures (such as the reduction of trade in logs in Malaysia, the limiting of logging in the USA, etc.). Oriented Strand Board (OSB) is a relatively new type of wooden board material, at least in Europe. It is mainly used in the construction industry, due to its mechanical properties, and mainly serves as a substitution product for plywood.

**MARKET FORCES**

**Demand**

The development of new applications for particleboard will continue to gather momentum and, hence, influence demand. The range of special boards is expanding continuously. Special products, such as moisture-resistant boards, fire-resistant panels, bendable, lacquered, printed and melamine-faced boards

## Supply and competition

Wooden board production is practically fully automated and the investment threshold is very high, especially for continuous production lines. Important modernisation and concentration has taken place in recent years and the industry has reached an advanced level of technology and very high efficiency. This enables the industry to meet high quality standards also in the near future.

The risk of overcapacity in the European particleboard sector was reduced in 1993 and 1994, years in which few new production lines were installed. During the recession of the early 1990s, rationalisation, rather than investments in new production capacity, has taken place. In some cases this has led to the closure of older or less efficient production units. In view of the rationalisation and the increase in demand that can be expected from economic recovery, prospects for the EU particleboard sector appear more favourable than they did in the first years of the 1990s, at least in terms of production volume.

Whereas the risk of overcapacity weakened in 1993-94, EU particleboard industry was simultaneously confronted with another threat. In 1994, especially, prices of basic chemicals (e.g. methanol) began to rise due to speculation. This led to spectacular rises in glue prices, by 30 % or more at a time. Methanol is an important input material for the glues used in the production of particleboard and MDF. These glues rep-

resent around 20 % of the total production cost of particleboards. Whilst commodity traders are already anticipating economic recovery, the industrial buyers of wooden boards (mainly furniture and construction industries) are typically lagging sectors. This makes it very difficult for the particleboard sector to adjust its prices in response to the higher raw material costs. Caught between an upward price pressure from suppliers of input materials and a downward one from the said customers, which are still suffering from weak end product demand in the EU, profit margins in the particleboard industry have been reduced to nearly zero.

The popularity of MDF, especially in the furniture industry, is still increasing. The rapid expansion of MDF production in Europe is therefore likely to continue for the rest of the millennium. However, its growth rate may vary with the business cycle.

The impact of foreign competition may be distorted due to less environmentally friendly log harvesting or production methods, lower labour costs, greater availability of raw materials, trade practices and trade policies (such as dumping by countries in Central and Eastern Europe and the GSP countries). Technological advantages are not considered to be a factor affecting competition on the EU and extra-EU markets. It is therefore necessary for extra-EU competitors to respect the prevailing rules of international trade and competition. Large imports into the Community at very low prices from Eastern European countries and countries benefiting from the Generalised System of Preferences, constitute a real threat to the industry. The completion of the single European market will be very difficult for the industry if imports from Eastern European countries are not controlled in a fair manner, especially against the backdrop of the Europe agreements signed with these countries which will lead to the complete abolition of customs duties on imports.

The deficit in the EU trade balance for semi-finished wood products is the consequence of large, inexpensive wood reserves outside the EU (North America, Scandinavia and Eastern Europe) and the massive imports of plywood from North America and Southeast Asia and imports of hardboard from South America and Eastern Europe. In the plywood sector, the most important competitive advantage of the EU manufacturers over the large single-product manufacturers in the USA and Indonesia is that European industry is specialised in the manufacture of small series of special, custom-made goods from very different types of wood. The entry of Finland and Austria into the EU will have a significant impact on the EU trade balance figures for semi-finished wood products.

As for particleboards and MDF, competition is mainly intra-EU. In plywood and hardboard, there is significant competition from outside the EU.

In the hardboard sector, the number of companies switching from the so-called wet process to the dry process is expected to increase further due to strict regulations regarding envi-

**Figure 8: Semi-finished wood products**  
**Trade intensities**

Source: DEBA

ronmental protection. This development is accelerated by the pressure of imports from Central and Eastern Europe. Despite these problems, a new hardboard production plant is planned in the United Kingdom. If this project succeeds, it will be the first new hardboard production unit in the EU in many years.

OSB is mainly produced in the UK and France and the product has been well received in these and several other European countries. In the 1990s it should become a major product for the European panel industry. In the near future, OSB production is expected to grow substantially. Several new production units are being planned, e.g. in Ireland.

Labour productivity in the semi-finished wood products sector has increased significantly since 1990. In 1993 only, it increased by 8.9 %. Higher productivity led to a decrease in unit labour costs by 3.5 % in 1993, reducing them to their 1990 level. Following a continuous decrease since 1990, the sector achieved a substantial improvement of its gross operating rate in 1993, from 9.3 % to 11.3 %.

## INDUSTRY STRUCTURE

### Companies

According to estimates, some 750 firms (with 20 or more employees) are involved in the manufacture of semi-finished wood products. The particleboard industry counts around 120 companies, employing 20 000 people. Total employment in the industry is around 63 200, which equals an average number of 85 employees per firm. This figure is relatively high compared to other subsectors of the wood processing industry.

The EU countries that were the most specialised in the production of semi-finished wood products in 1993, are Greece (with a production specialisation ratio of 3.30) and Belgium (2.22). Belgium is the world's most prominent exporter of particleboard, with an export volume of approximately 1.8 million m<sup>3</sup>, representing 20 % of world trade. Germany, although the biggest EU producer, only just exceeds the European average (1.00) with a specialisation ratio of 1.10.

### Strategies

The chipboard industry is a capital-intensive sector. Production is practically fully automated, requiring massive research and development efforts, and the investment threshold is high, especially for the continuous production lines. These circumstances imply that an average chipboard firm exceeds the typical SME dimension of the wood processing sector, and that the added value of this activity is lower than in other parts of the wood processing industry, where a high percentage of labour costs raises the value added. In recent years, the sector has undergone major restructuring and an apparent concentration has taken place. Large competitors have begun to expand their market shares by investing in larger plants and by investing across Europe.

In the fibreboard sector, investments are focused on the development of new products, the modernisation of existing products, the increase of capacity and the shift to environmentally friendly production methods (such as converting from the wet process in the hardboard industry to the dry process in the MDF industry). In order to reduce overcapacity, diversification of products is taking place, e.g. aiming at the development of structural boards. With regard to company structures, there are several new joint investments by board manufacturers in MDF, but there are no major changes in hardboard yet.

Until recently, the plywood sector was quite labour-intensive. However, technological development and computer applications in production control and the operation of machinery have lowered production costs to a great extent. They have at the same time enabled a substantial reduction in wood

**Table 6: Semi-finished wood products

Source: DEBA

waste. The sector is still highly suited for product diversification (with greater utilisation of European wood species), especially when production methods allow for the manufacture of small series of special, custom-made products. Investments by European companies, are characterised by modernisation and finding new product developments.

## REGULATIONS

The common external tariff on imports from outside the EU is the same for particleboard, fibreboard and plywood. Having been maintained at 10 % for some time, it is now being gradually reduced as a result of the Uruguay Round of the GATT. On January 1st, 1995, a progressive reduction of the tariff started in order to lower the bound level of duty to 7 % by January 1st, 1999. The first step of reduction brought the common external tariff to 9.4 % on January 1st, 1995.

The Europe agreements signed between the EU and Hungary, Poland, the former USSR and Romania changed the regulations formerly applicable to these countries. Customs duties on imports to the EU of particleboard, plywood and fibreboard from Bulgaria, Estonia, Latvia, Lithuania, Poland, Hungary, Romania, the Czech Republic and Slovak were abolished on the 1st of January 1995. As far as the republics of the former Soviet Union are concerned, since their inclusion in the 1993 GSP a fixed duty-free quota of 4.2 million ECU applies to imports of fibreboard into the EU from Russia and Ukraine. With regard to plywood, there is a fixed duty-free quota of 90 300 m<sup>3</sup> for plywood from Russia, Ukraine and Belarus. Annual quotas on imports of particleboard and plywood originating in the Republics of Croatia, Slovenia, Bosnia-Herzegovina and Macedonia have been fixed for 1995. The annual ceiling for particleboard is 45 779 tonnes, whilst for plywood the annual ceiling is set at 177 681 m<sup>3</sup>. As soon as these levels have been reached, a customs tariff of 9.4 % may be reintroduced by a Commission Regulation.

## OUTLOOK

Consumption, as well as production, of semi-finished wood products is expected to grow in the coming years. The average growth rate for the period 1995 to 1997 is estimated at 4.8 % for consumption and 4.9 % for production. Extra-EU exports are expected to maintain their growth trend from 1994 to 1997, notably because of new opportunities in emerging markets such as the Near and Far East.

In the particleboard industry, it seemed that the countries of northern Europe would see a recovery in 1994 after many

years of recession. Countries in Central Europe suffered badly from the downturn of the German economy. Their recovery will also depend on their ability to build up a domestic market. The industry in the countries of Southern Europe is heading for a period of restructuring which has already started in some countries. All these developments will take some time to materialise. However, the structural reforms initiated in the Eastern European countries and in the Baltic States have begun to produce some results leading to expectations of forthcoming growth. However, the economic situation in the CIS countries is highly unstable and the prospects are quite uncertain.

In the fibreboard sector, the MDF industry represents a European production capacity of more than 4 million m<sup>3</sup>. Compared to particleboard (30.7 million m<sup>3</sup>) and sawn timber (68 million m<sup>3</sup>), the share of MDF in the market of wood and wood products is still quite moderate. European MDF industry will, furthermore, increasingly open up export markets outside the EU and EFTA for its products, more specifically for special MDF boards. Nevertheless, the setting up of new production capacity in the Far East will expose the European exporters to increased competition from local producers.

The semi-finished wood products sector is facing a number of risks, including the additional costs associated with increasingly strict requirements with respect to health and environment, in the light of competition from extra-EU imports. However, political reforms in Central and Eastern Europe offer a potential for exports and possibly joint ventures.

Written by: Cel-Bois

The industry is represented at the EU level by: European Confederation of Woodworking Industries (Cel-Bois). Address: rue Royale 109-111, B-1000 Brussels; tel: (32 2) 217 6365; fax: (32 2) 217 5904.

# Wooden building components

## NACE 463

The manufacture of wooden building components accounts for 37 % of the production value of the EU wood processing industry and thus constitutes its main subsector. The subsector is largely dependent on developments in the construction industry. It is highly involved in renovation work, which makes the sector less dependent on cyclical new building construction.

### INDUSTRY PROFILE

#### Description of the sector

This subsector produces a wide variety of wooden building components (doors, window frames, shutters, partitioning and other walls, staircases, constructions of glued laminated wood, prefabricated buildings of wood etc.). It is distinguishable from the carpentry subsector of the construction industry through its industrial scale and methods of production.

In 1993, production in current prices reached a value of 13.1 billion ECU, which represented 37 % of the total production of the wood processing industry (excluding wooden furniture). Hence, the manufacture of wooden building components is the most important subsector of the industry. Apparent consumption amounted to 14 billion ECU, thereby producing a slight trade balance deficit.

Subsector employment was approximately 146 600 people in 1993, representing 37.4 % of the total employment in the woodworking industries. In the same year, the wooden building components industry generated a value added of 4.7 billion ECU. Representing nearly 40 % of value added, Germany is the biggest producer.

#### Recent trends

In the period 1984-93, apparent consumption of wooden building components increased steadily, at an average real growth rate of 3.4 %. Unfortunately, EU production was not able to keep pace with the rapidly growing demand, despite a decrease in extra-EU exports. This resulted in a steep rise in extra-EU imports, especially between 1989 and 1993 (+20.6 % average real annual growth), and a trade deficit that increased from 1987 to 1993, to reach 885 million ECU. Nevertheless, production in constant prices grew by an estimated 30 % between 1984 and 1994, which was 8 percentage points above the EU manufacturing industry average growth. This rapid growth mainly took place between 1986 and 1990, years in which economic growth and construction activity recovered after a period of recession, and in 1994 (growth estimated at 6.1 %).

Between 1984 and 1989, the average real annual growth rate of production was 3.5 %, similar to that of the EU manufacturing industry. For the period 1989-94, however, the wooden building components industry outperformed EU manufacturing industry (average real annual growth rates of 1.9 % and 0.6 %, respectively).

Employment declined in the first half of the 1980s. Thanks to increasing demand, employment started to grow again in 1987 to reach a peak of 161 100 employed in 1990. However, employment fell sharply, to an estimated 146 600 in 1994, following the general trend of the entire wood processing sector.

The wooden building components industry also suffered from the economic recession of the early 1990s. In 1993, production

Figure 1: Wooden building components Value added in comparison with related industries, 1993

Source: DEBA

in constant prices decreased by 0.5 %. For 1994, production was projected to grow to 14.2 billion ECU (+6.1 %).

#### International comparison

Previously, the wooden building components industry was significantly larger in the USA than in the EU. In 1984, the production value of the EU industry represented only 60 % of that of its US counterpart. This is explained by the popularity of wood as a building material in the USA. However, the difference in production volume was reduced to 16.5 % by 1993. This was due not only to cyclical factors, but also to the fact that wood is becoming increasingly popular as a building material in the EU as well.

US production is subject to cyclical fluctuations to a higher degree than the EU and Japan are where production is growing more steadily. Japan has the smallest, but fastest growing, wooden building components industry of the three trading blocks. It amounted to nearly 64 % of EU production in 1993.

and managed an average real annual growth rate of 9.7 % between 1984 and 1993.

**Foreign trade**

Between 1984 and 1993, extra-EU exports declined at an average real annual rate of 6.2 %. This means that EU producers have been focusing mainly on their home markets. On the other hand, extra-EU imports grew at an average rate of almost 14 % over the same period. In 1989-1993, extra-EU imports even grew at an average real rate that exceeded 20 %. The trade balance deteriorated continuously during the period and became negative in 1987.

Extra-EU trade in wooden building components remains limited. Extra-EU exports amounted to only 2.7 % of production in 1993, whilst extra-EU imports equalled 9.1 % of consumption. In the long run, the consistently increasing trade deficit is a cause for concern. Between 1984 and 1993, the exports/production ratio dropped from 5.7 % to 2.9 %. Over

the same period, the imports/consumption ratio went from 3.7 % to 9.1 %.

Most companies in the wooden building components sector work closely together with the local building industry. Extra-EU trade remains limited to a few highly standardised products that can be transported at relatively low costs (e.g. plane doors).

Nevertheless, intra-EU trade is increasing rapidly. This is undoubtedly due to European integration, that has started a process of harmonisation of technical standards and a broadening of the "local" market horizon. Extra-EU exports are still mainly oriented towards the EFTA countries (52.6 % in 1993), because of the geographical proximity and the partial similarity in building practices. However, the EFTA countries' share of extra-EU imports has decreased (46.6 % in 1993). Imports of inexpensive standardised products are increasingly being imported from low labour cost countries in Eastern Europe and South East Asia.

## MARKET FORCES

### Demand

Demand in the sector is heavily dependent on developments in the building industry. Renovation work is expanding faster than total building activity. This particularly enhances the demand for wooden building components, which are well suited, and sometimes even specifically designed, for renovation work. It has also made this subsector less dependent on cyclical new building construction. Renovation already represents around one third of total construction activity in the EU. Wooden parquet flooring for private housing has benefited from changing consumer preferences in recent years.

In private housing construction, the Single Market will not have a significant impact on the demand for building components, since well-defined regional markets will continue to exist within Europe. This is largely due to the specific climatic conditions and local building practices and styles.

The demand for wooden building components is more and more influenced by the ability of wood to provide thermal and acoustic insulation, rather than the more traditional properties associated with wood, particularly in the non-residential building sector.

### Supply and competition

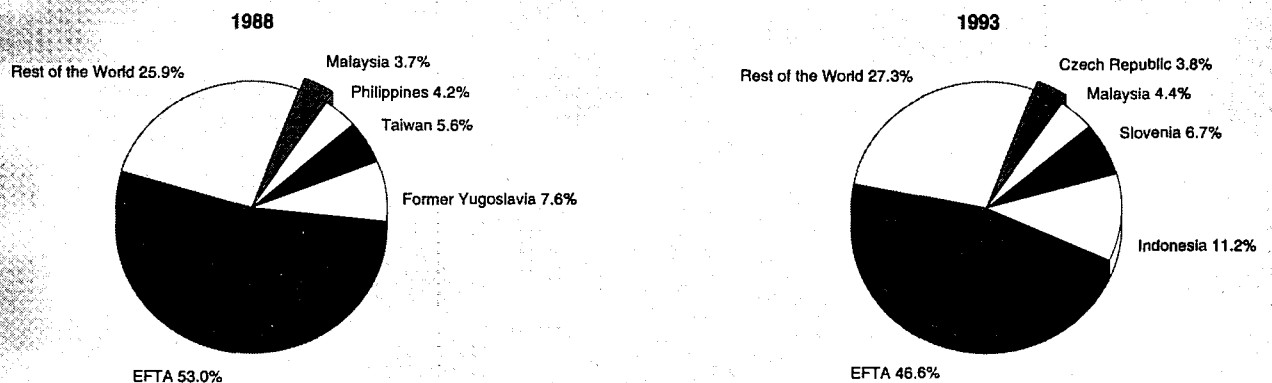

International competition remains rather limited due to differences in climatic conditions and building practices. Transport cost is also a limiting factor for international trade, since most products are heavy and voluminous. Nevertheless, foreign competition still makes its presence felt, mainly due to lower labour costs in non-EU countries. Factors such as exchange rate developments, improved availability of raw materials or technological advantages also play an important part.

Wood treatment enables the use of wood in applications where previously, its use had been excluded. This makes it possible for wood to take market shares from alternative building materials in non-traditional markets. Treated wood is now used in relatively new applications, e.g. in agriculture and horticulture, for enclosures, playgrounds, and in hydraulic engineering.

Products such as fire-resistant wooden doors may appear inconceivable. However, the high degree of dimensional stability of wood provides it with a competitive advantage over metal or synthetic materials, since the latter deform more rapidly at high temperatures.

Producers of wooden window frames experience competition from substitution products made from other materials, such

**Figure 7: Wooden building components  
Origin of EU imports**

Source: Eurostat

as aluminium and PVC (polyvinyl chloride). However, wooden frames still have the largest market share in the EU with 40 %, well ahead of aluminium and PVC. Debate on the environmental impact of use of the latter materials may seriously affect their market share.

Recently, traditional producers of wooden building components also experienced competition from other subsectors of the wood processing industry, such as sawmills, wooden board producers and even furniture manufacturers. The latter often produce building components, such as wooden flooring or doors, in order to increase the value added of their products (true for sawmills and wooden board manufacturers), or to be less dependent on cyclical demand (furniture manufacturers).

### Production process

The production process distinguishes the industrial manufacturer of wooden building components from the local carpenter. The machinery and production techniques used in a factory producing e.g. doors or window frames resemble those in the furniture industry rather than those of the individual carpenter. Computer aided design and computer aided manufacturing (CAD-CAM), state-of-the-art computerised numeric control (CNC) machinery and automated coating installations have already found their way into the wooden building components industry. The industry has thus become the supplier to individual construction firms or carpenters, which integrate the prefabricated components into the building at the local construction site.

## INDUSTRY STRUCTURE

### Companies

In order to cope with specific climatic conditions and local building practices and styles, small to medium-sized enterprises (SMEs) are ideal, with a size that fits established geographical limits and a technical specialisation. Indeed, it is the SMEs that make up the vast majority of the companies in the industry. There are more than 2 000 companies that employ 20 or more people in this sector, employing a total of 146 600 people. In view of the many SMEs in the sector, total employment is much higher. With a production specialisation ratio of 3.1, Denmark is the only EU country with a

specific specialisation in the production of wooden building components.

### Strategies

Recent investments have focused on plant modernisation and capacity increases, among other reasons, due to increased demand in Germany since the reunification. Investment is mainly undertaken by European producers themselves, and foreign investment is insignificant. Producers tend to specialise considerably and the sector is characterised by numerous acquisitions, particularly in Germany.

Most manufacturers of wooden building components are active on local or regional markets, because of the differences in climatic conditions and building practices. However, by conforming to the European construction products directive, many enterprises will be able to expand their potential markets to the EU level.

In brief, there are three generic strategies for companies in this sector. The first one is to specialise and to focus on the local market, by taking the specific preferences and requirements of local consumers and building companies into account. Aspects such as service and flexibility are very important parts of this strategy which is common among SMEs in the sector. The second strategy involves concentration and mass production of highly standardised building components. The market for these products is the entire EU. Economies of scale and price leadership are the keys to success. Large companies that employ this strategy have to reckon with competition from extra-EU imports. A third strategy is to focus on a product with specific technical properties. Unlike the first (specialisation) strategy, it allows firms, including SMEs to operate on the EU level. This strategy is likely to become more important as the harmonisation of standards for these products continues.

In the window frames sector, a growing number of manufacturers are combining the production of wooden as well as PVC frames. From the viewpoint of technology, this is perfectly feasible since the machinery for the production of wooden window frames may also be used for the processing of PVC. With this strategy of differentiation and complementarity, producers become less dependent on consumer preferences and the outcome of the debate on the environmental issues related to the use of these materials.

### Impact of the Single Market

Several measures in the Internal Market programme have had effects on the sector. Measures with regard to the free movement of persons, public procurement and consumer protection in the building industry indirectly affect the wooden building components sector as a supplier to the former industry. There has been no general trend towards mergers among the many SMEs in the sector as these are active on local markets, working closely with the local building industry. Nevertheless, increasing harmonisation has expanded the market and intra-EU trade is growing. In distribution, concentration has taken place as large DIY chains have set up units in other EU countries in response to harmonisation and a larger market.

## REGULATIONS

In March 1994, after five years of discussion within the Standing Committee on Construction, the interpretative documents relating to Council Directive 89/106 on the approximation of laws, regulations and administrative provisions of the Member States with regard to construction products, (known as the "Construction Products Directive", which defines the six essential requirements for a construction product) were finally published. This means that the Member States can now implement the Directive, and that construction products bearing the CE-mark of conformity can enter the market. The industry has prepared itself for the implementation of the Directive,

Source: DEBA

which it believes is necessary for the creation of a single internal market, by lending massive financial and technical support to the European standardisation process.

Recent events involving the Construction Products Directive, however, may weaken its impact on harmonisation. The European Commission has expressed the opinion that the harmonised standards should not impose limitations or prescriptions on products (such as minimum or maximum values), but should only contain definitions and test methods.

Meanwhile, the preparation of European standards concerning product specifications is progressing steadily. Five Technical Committees of CEN, the European Committee for Standardisation, are preparing standards for wooden construction products. Presently, no European technical approvals for wood processing products have been applied for in the context of EOTA, the European Organisation for Technical Approvals.

## OUTLOOK

Apparent consumption of wooden building components is expected to grow by an average annual rate of 6.8 % in 1995-97, thanks to the expected increase in construction activity. The average annual growth rate for production for the period 1995-97 is estimated at 5.4 %. Extra-EU imports are therefore projected to increase further. Extra-EU exports, on the other hand, will continue to decrease by approximately 6 % per year.

Apart from fluctuations that are purely cyclical, there are also three important structural changes taking place that may have a determining influence on the future of the wooden building components industry. First of all, there is the trend towards increasing renovation and maintenance, which highly benefits the use of wooden building components. Renovation and maintenance already represent around one third of total construction activity in the EU. This share will undoubtedly grow. Secondly, it is uncertain what effect the European integration of the construction market through increasing standardisation of building products will have on EU production of wooden building components (at least for some products). European standardisation not only stimulates intra-EU trade, but also facilitates extra-EU imports. Thirdly, there is a general trend in the building industry towards increasing subcontracting and growing use of prefabricated building components. This is visible as a decrease in the share of value added in building industry turnover. Such developments are also assisted by European integration and the standardisation of building products. They lower the labour intensity of the construction process and increase productivity (higher turnover per capita). They also increase the geographical mobility of (large) construction firms. This causes a shift in the value added chain from the building industry to the supplying sectors, such as the wooden building components industry, thereby creating considerable opportunities for the producers of wooden building components.

Written by: Ceil-Bois

The industry is represented at the EU level by: European Confederation of Woodworking Industries (Ceil-Bois). Address: rue Royale 109-111, B-1000 Brussels; tel: (32 2) 217 6365; fax: (32 2) 217 5904.

# Other wood products

## NACE 464, 465, 466

With the exception of 1993, production and consumption in this industry have improved consistently since 1982, despite increasing competition from low labour cost countries in Eastern Europe and the Far East. The industry is characterised by a large number of SMEs with relatively stable employment. Significant investments have taken place in recent years to increase automation in production as much as possible, in order to compete more successfully with imports. Still, the trade balance has continued to deteriorate.

### INDUSTRY PROFILE

#### Description of the sector

Other wood products comprises several smaller and highly heterogeneous subsectors of the wood processing industry. The most important is wooden containers (NACE 464), which includes e.g. boxes, crates, pallets, barrels, and cable drums. NACE 465 brings together miscellaneous wood products. The most important products are wooden frames for paintings, photographs, mirrors and similar objects. NACE 466 includes the production of articles of cork, basketware, wickerwork and other articles of plaiting materials (except case and wicker furniture) and the manufacture of brushes and brooms.

In 1994, the production value of these subsectors totalled an estimated 9 673 million ECU, which represented 25 % of the total production of the wood processing industries (except wooden furniture). Employment amounted to 119 500, which equalled 30.5 %. Hence, the sector is very labour intensive. In 1993, wooden containers and pallets accounted for 3.1 billion ECU (34.1 %) of the total production of other wood products. Extra-EU exports of wooden containers remained limited. Production of brushes and brooms amounted to 1.2 billion ECU (13.4 %).

The value added in the sector in 1993 was 3.4 billion ECU, roughly 27 % more than the value added of the semi-finished wood products and almost twice as high as the value added of sawing and first processing of wood.

Germany is by far the most important producer of other wood products within the EU, not only in absolute terms. The per capita production is also much higher in Germany than in other EU countries of similar size, such as France, Italy or the UK.

#### Recent trends

Apparent consumption grew continuously during the period 1984-91, at an average real annual growth rate of 3.4 %. Although growth was limited until 1986, from 1987 to 1991 it grew significantly, but then fell again in 1992-93 (-3.1 %).

EU producers were slow to respond to the upswing in consumption, however, and there was a strong rise in extra-EU imports in 1987-89. EU production reacted by strong growth in 1988-91. Over the period 1984-93, the average real annual growth rate of production was 2.7 %.

Employment declined steadily between 1984 and 1988, from 131 900 to 122 800, but rose again from 1989 onwards, reaching a peak of 133 900 employed in 1991. Since then, however, employment has fallen back sharply. For 1994, employment was estimated at 119 500. Nevertheless, in terms of employment, the other wood products sector continues to perform above the total EU manufacturing industry, mainly thanks to the expansion in 1989-91. Production of other wood

Figure 1: Other wood products  
Value added in comparison with related industries, 1993

Source: DEBA

products grew by an annual rate of 2.7 % in the period 1984-93, compared to 1.9 % for total manufacturing industry.

Because of the slowdown in economic growth and international trade in 1992-93, poor demand for other wood products lowered production to 9 042 million ECU in 1993. Production was projected to grow by an estimated 7 % in 1994.

#### International comparison

In 1993, EU production of other wood products equalled 62 % of US production and 102 % of Japanese production. Over the period 1984-93, EU production of other wood products grew slightly slower (with an average real annual growth rate of 2.7 %) than US production (3.0 %) and Japanese production (3.1 %). This growth differential can be attributed to the decline in EU production in the recession years 1992-93. Over the period 1984-91, production in the EU grew faster than in the USA or Japan.

**Foreign trade**

Extra-EU exports and imports amounted to 918 million and 1 383 million ECU, respectively, in 1993, producing a trade deficit of around 465 million ECU. Extra-EU imports have grown rapidly since 1987, increasing their share of EU consumption (from 10.4 % in 1986 to 14.5 % in 1993). Import penetration remains relatively low, despite the fact that most of the subsectors of the other wood products sector are exposed to competition from extra-EU, low labour cost countries. The export/import ratio deteriorated from 1.04 in 1986 to 0.66 in 1993. Extra-EU exports grew by an average real annual rate of only 1.0 % between 1984 and 1993. The exports/production ratio remains fairly stable around 10 %.

External trade in wooden containers and pallets is of limited importance but has nevertheless increased since 1989. Extra-EU imports now represent around 2 % of the consumption of wooden containers and pallets. These imports mainly consist of inexpensive pallets produced in East European countries

such as Poland, Hungary and the former Czechoslovakia. The trade balance for wooden containers and pallets, which remained strong at the beginning of the period 1984-93, has gradually become weaker and showed only a very small surplus in 1993. Most of the trade takes place within the EU. Trade figures may be underestimated, however, as some international movements of wooden containers and pallets are not visible in these due to the fact that consignments of empty containers and pallets are included in customs statistics, whereas loaded containers and pallets are not. Although the EU brushes and brooms industry is experiencing stiff competition from China and Eastern Europe, the trade balance retains a slight surplus. Distinguishing between product lines, there is a surplus for industrial brushes, paint brushes and rollers and domestic brushes. However, for toilet brushes, fine hair brushes and (since 1982) for brooms there is a trade deficit. Articles of plaiting materials are mainly imported from countries in the Far East, such as South Korea, Taiwan and the Philippines.

**Figure 4: Other wood products**

Source: DEBA

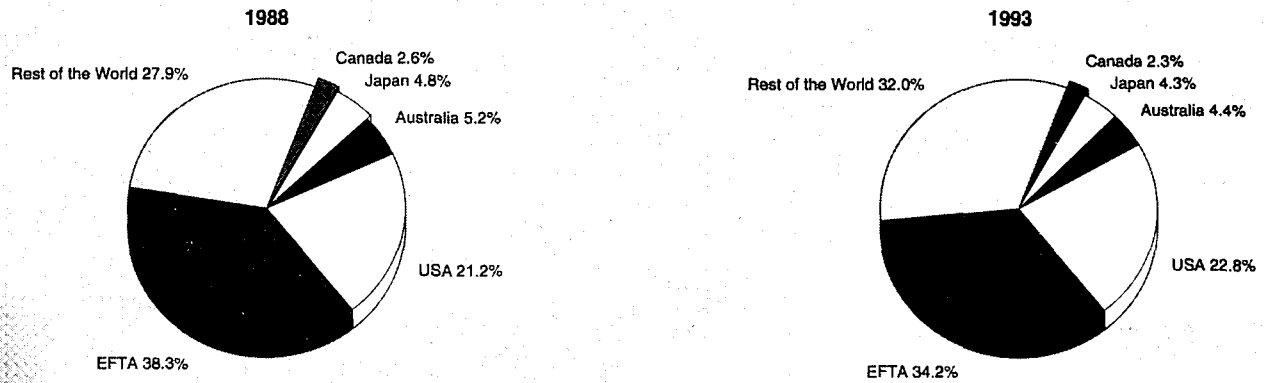

**Figure 5: Other wood products**  
**International comparison of production in constant prices**

Source: DEBA

**Figure 6: Other wood products  
Destination of EU exports**

Source: Eurostat

The most important extra-EU export markets for other wood products are the EFTA countries (34.2 % in 1993) and the USA (22.8 %). Extra-EU imports originate mainly in China (20.2 %, mainly fine hair brushes), Poland (12 %, mainly pallets) and Indonesia (7.8 %, mainly articles of plaiting materials).

## MARKET FORCES

### Demand

Since the sector is highly heterogeneous, its products typically have different types of buyers, i.e. industry or final consumers. Wooden containers are mainly sold to various industries. Demand for these products has an indirect character: since a large part of industrially produced goods are transported either in wooden containers or on pallets, demand for these packaging materials largely follows the general macroeconomic situation.

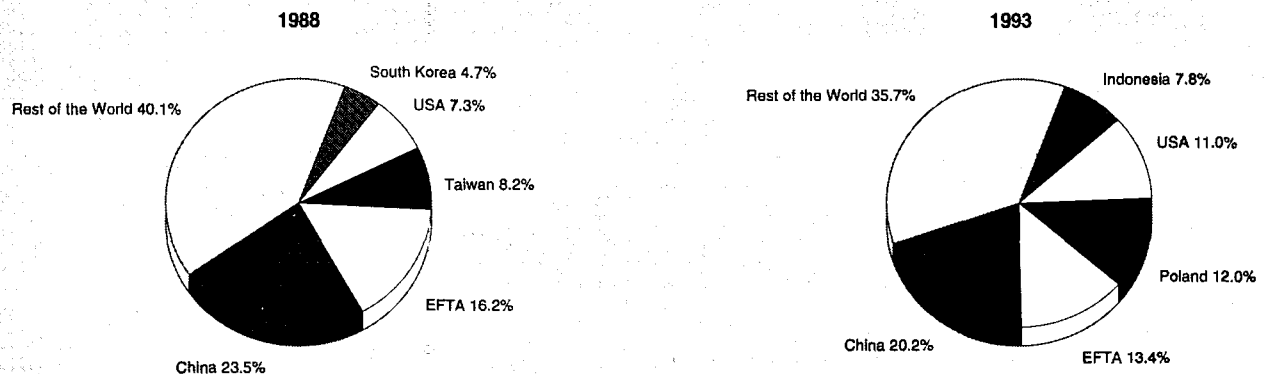

As intra-EU, as well as extra-EU, trade is increasing, there is a potential stimulus for sustained growth in the sector of transport-related packaging, such as wooden containers and pallets. During the early 1990s, however, demand for wooden containers was rather weak due to the slowdown in economic growth and international trade. Economic recovery had a sig-

nificant positive impact on production in 1994 (estimated growth was 7.0 % in current prices).

Wooden containers serve to facilitate the transportation or storage of various goods. This requires lightweight structures that are able to withstand rough handling. Standardised dimensions makes pallets highly suitable for repeated and different uses.

With the exception of industrial brushes, most brushes and brooms are sold to final consumers. Industrial brushes are sold by direct sales to industry customers. Personal hygiene products (toothbrushes and brushes for hair and make-up) are distributed by specialised retail chains, pharmacies and supermarkets. Paint brushes and rollers are mainly sold in DIY-stores. It is worth noting that large distributors may also import products directly from outside the EU. Wooden frames for photographs, paintings and mirrors are also mainly sold to consumers. These products are distributed by large outlets, such as department stores, as well as by small specialised businesses, e.g. photographers, art galleries and gift shops. Demand for bottle corks comes from producers of wine, champagne and beer. Cork is also used for insulation and, increasingly, for flooring.

### Supply and competition

Since 1990, demand for wooden containers has weakened due to the general slowdown in economic growth and international trade, putting pressure on the supply side to lower profit margins. The economic recovery that began in 1994 is expected to improve this situation. In the subsectors included, internal EU competition remains limited. Foreign competition from extra-EU countries, however, is fierce in all product lines. The major extra-EU competitors are the low labour cost countries in the Far East and Eastern Europe. It is clear that lower labour costs are the main competitive advantage of these extra-EU competitors. They are also less burdened by costs for social benefits or environmental protection.

Because of the relatively low degree of complexity of the production process, it is difficult for EU producers to realise technological advantages. Even at the highest possible level of automation it is often difficult to compete with lower labour costs and distorted trade practices, such as dumping. The EU brushes and brooms sector has already been involved in anti-dumping procedures with respect to Chinese brushes several times.

Since 1990, there has been a steep rise in the imports of pallets from Eastern Europe (especially Poland, Hungary and the former Czechoslovakia) at low prices, that barely cover transportation costs. These imports are a serious threat to the survival of the EU pallets producers. In this case it is clear that European standardisation of pallet dimensions has stimulated extra-EU imports.

Most of the extra-EU imports of brushes and brooms come from China and Eastern Europe. China has what may be characterised as a "quasi-monopoly" in paint brushes. Imports of brushes from China and Eastern Europe have disrupted EU production on more than one occasion, e.g. when products have been offered at dumping prices (which has often occurred). EU industry is hoping that trade agreements with these countries, as well as certain structural changes in their home markets, will improve the situation.

Availability of raw materials often plays an important part as well. China has nearly a monopoly in pig hairs, which are used for fine paint brushes. Articles of straw, cork and other plaiting materials are mainly imported from South East Asia. Eastern Europe has large reserves of wood, suitable for the production of pallets.

Because of the relatively labour intensive production process, productivity growth is rather slow. Between 1990 and 1993, unit labour costs increased faster than labour productivity. Understandably, this had a negative effect on profitability, reflected in gross operating rates going down from 10.5 % to 9.4 % between 1988 and 1993.

### Production process

Common raw materials used for the production of wooden containers and pallets are poplar and pine. The handles of brushes and brooms are mostly made of wood or plastic. Hairs for brushes can be made from synthetic fibres, animal hair (mainly pig hair) or plants (coconut fibre).

Although the production process is relatively non-complex, automation is possible. During the second half of the 1980s, the wooden containers sector made important investments in automation and rationalisation. Because of external competition, EU producers of brushes and brooms need to automate the production process to the greatest extent possible. Automation of production means acquiring high-performance machines that introduce the fibres, attach them to the frame and adjust the packaging material, all in one cycle. It enables toothbrushes, nail brushes, etc. to be produced in very large quantities. For these types of brushes, packaging and labelling are also performed by automated operations. The manufacture of paint brushes, particularly fine brushes, is less automated, although significant progress has been made.

Manual steps are still important part for certain operations (e.g. in the manufacture of paint brushes). In addition, automation has generated an increasing need for people with technical knowledge of machines and tools.

## INDUSTRY STRUCTURE

### Companies

Most companies in the other wood products sector are SMEs. The number of enterprises that employ more than 20 people is estimated at about 2 100, of which more than 800 are in the wooden containers sector. Among the subsectors, wooden

Source: DEBA

containers is the most capital-intensive. The average size of the manufacturer is also larger.

For most EU countries, production specialisation ratios are insignificant. The exception is Portugal, which has a production specialisation ratio of 5.86. Portugal is an important producer of cork and articles of cork.

### Strategies

The predominant strategy among the companies in the sector is to rationalise and automate the production process as much as possible in order to be able to meet the competition from non-EU countries with low labour costs. For the producers of wooden containers, specialisation in custom-made packaging products helps keep competition from low wage countries to a minimum as the latter mainly produce standardised products. Thanks to geographical proximity, EU producers are able to respond in a more flexible manner to the needs of their customers (e.g. special dimensions, just-in-time delivery). Producers of wooden containers, and pallets especially, are developing systems for recycling. This should provide them with a competitive advantage over producers of plastic and metal pallets.

### Impact of the Single Market

Among the effects of the Single Market of specific relevance to this sector, most concern the wooden containers and pallets sector (NACE 464). Among the measures to guarantee the free movement of goods, the elimination of internal border controls has been especially important in that it has stimulated intra-EU transport. The liberalisation of transport services has

been important for much the same reason and measures with regard to environmental protection are very important. The Directive on packaging and packaging waste will have positive effects for the industry as it allows incineration with energy recovery as an alternative to material recovery. Competition from outside the EU has increased significantly, as non-EU companies have found the increasingly uniform market of simple, standardised products, such as pallets, easier and more interesting to compete in. Since 1989-90 there has been a massive increase in imports of pallets from Eastern Europe, which has triggered EU producers to shift to higher value added products in response, such as customised packaging materials. Meanwhile, growing intra-EU trade has increased the demand for packaging materials which has helped to compensate the losses due to rising imports.

### REGULATIONS

In December 1994, the Council of the European Union finally reached an agreement on a Directive concerning packaging and packaging waste that will come into force in 1996. Indeed, work on the Directive only began after the German authorities had introduced a national regulation and France intended to do so as well. It aims at harmonising national measures concerning the management of packaging and packaging waste and sets five-year targets for achieving specified recycling rates for different materials. The Directive authorises energy recovery which is deemed to be the best solution for certain wood wastes.

### OUTLOOK

After a slowdown in 1992-93, production and consumption will grow again at a steady pace. It is expected that consumption will grow slightly faster (at an average annual growth rate of 7.6 % in 1995-97) than production (7.2 %). This means that the extra-EU imports share of consumption will continue to rise.

Therefore, increasing imports from low labour cost countries in the Far East and Eastern Europe constitute the main risk for the sector. European standardisation has certain advantages, but also poses the risk of facilitating increasing extra-EU imports (e.g. pallets). Opportunities for EU producers will come from specialisation in custom-made packaging and from developing systems for recycling (energy recovery, production of particle board, repeated use, etc.).

**Pulp, paper and board  
NACE 471**

Production volume in the pulp, paper and board sector reached 49.5 million tonnes in 1993. However, over-capacity and falling prices resulted in a 6.9 % decline in output value; paper production increased while pulp output fell. On a more optimistic note the EU's trade deficit fell for the fourth year running with strong exports; in particular, graphic paper grades. There was a sharp improvement in labour productivity for the third successive year, reflecting ongoing restructuring. Restructuring has also resulted in an improved environmental record, particularly increased recycling. In 1994, demand continued to recover and both prices and profits increased. Merger and acquisition activity also stepped up as restructuring continued. Prospects are good for the foreseeable future in the EU and export markets. Threats to growth include: currency instability; uncertainties about the timing of recovery in eastern Europe and the former Soviet Union; the ongoing costs of environmental measures; and uncertainty about the course of the business cycle beyond 1996.

**INDUSTRY PROFILE**

**Description of the sector**

The sector has three main product categories: pulp, paper and board. In Europe, paper and board is made mainly from waste paper and wood pulp, with a small proportion of fillers. The latter vary depending on the paper grade. "Market" pulp is wood pulp for papermaking sold in competition by producers on the open market. It excludes "integrated" pulp, used by the producing mill or by other mills owned or controlled by the same group in the same country. Market pulp does, however, include pulp shipped to affiliated firms in other countries. Paper and board includes products such as printing and writing paper, sanitary and household paper, wrapping and packaging paper and board, and various specialist grades.

There are three main final uses for the sector's products: communications for printing, writing and drawing; packaging for transport, storage and presentation of goods; and various specialist applications, including hygienic and disposable paper (toilet, towels, nappies etc.), fiduciary paper (money, cheques), and technical uses (filter, photographic, insulation, wallpaper). In the EU-12, market pulp production is concentrated in Portugal, Spain, France and Germany, in that order. The extension of the EU in 1995 adds Sweden and Finland, both of whom have larger outputs than any other Member State.

Newsprint production is concentrated in Germany, France, the United Kingdom and the Netherlands. With EU accession, Sweden and Finland will head the list with Austria entering lower down. Printing and writing grades are produced mainly in Germany, France, Italy and the UK. Germany and France dominate the packaging grades market with Italy, Spain and the UK being strong contenders. Germany, France, the UK and Italy lead in household and sanitary papers output, with Italy being a net exporter. Sweden and Finland are also net exporters of these grades.

**Recent trends**

Industry output decreased by 1.1 % in 1993 to 49.5 million tonnes. However, a continuing fall in prices due to over-capacity resulted in a 6.9 % fall in the current value of pro-

**Figure 1: Pulp, paper and board  
Value added in comparison with related industries, 1993**

Source: DEBA

duction. Pulp output fell by 7.4 %, with both chemical and mechanical pulp contributing to the decline. Paper and board output, in contrast, increased by 0.5 %, with graphic paper output up by 2.1 %, and household and sanitary papers up by 1.6 %; however, output of other grades decreased by 1.1 %.

Relative to other industry sectors pulp, paper and board is modest in size. Value added in 1993 was 28 % of that of plastics processing but over three times that of toys and sports goods. Value added of the closely associated paper and board converting sector was 83 % higher. Germany is the main EU producer, followed by France, the United Kingdom and Italy. However, the enlargement of the EU will alter these rankings significantly and the relative importance of the sector. Based on 1993 tonnage, the inclusion of Sweden, Finland and Austria, would have increased the output of this EU sector by around 85 %.

Source: CEPI

Recycling is important and increasing. Waste paper utilisation represented 56 % of total fibre furnished in 1993. Waste paper consumption increased by 619 000 tonnes while apparent pulp consumption fell by 1 817 000 tonnes. Waste paper recovery represented 41 % of total apparent domestic paper consumption in 1993 compared with 39 % in 1992.

The real value of production has shown little growth in recent years, averaging 0.6 % in 1989-93 compared to 3.9 % in 1984-1989 and 2.4 % per annum over the entire period. Preliminary data indicates a recovery in 1994 with production growth of 6.6 %. Output growth over the 1984-94 period, however, was more rapid than for the EU manufacturing industry as a whole. Nevertheless reflecting ongoing restructuring, the shake-out of jobs in the sector was more extreme than in most other industrial sectors. Employment has fallen by 19.7 % over 1984-1994, with accelerated job rationalisation during 1990-1994.

#### International comparison

In 1993, total EU pulp production (market plus integrated) was around 8.8 million tonnes and paper and board production was 41.0 million tonnes. In global terms, the combined figure of 49.8 million tonnes ranks behind that of the world leader, the USA, with 137.9 million tonnes. Canada and Japan follow with 40.4 and 38.4 million tonnes, respectively. The EU was the world's sixth largest pulp producer, but the second largest

paper producer after the USA. The addition of the three new EU Member States, at their 1993 levels of production, would have pushed up total EU production to 92.5 million tonnes, of which 34.0 million tonnes was pulp and 59.5 million tonnes paper, moving it in both cases to second ranking in the world after the USA.

In terms of rates of growth at constant prices, Japan's industry grew rapidly during 1984-1989, but suffered a severe cyclical setback in 1991, and was only just recovering in late 1994.

#### Foreign trade

The EU-12 has a substantial trade deficit in the pulp, paper and board sector. This deficit has, however, improved in recent years. Having climbed steadily in the late 1980s, the deficit fell from 14 billion ECU in 1989 to 10 billion ECU in 1993. Extra-EU exports increased by 8 % to 2.88 billion ECU in 1993, while imports decreased by 11 % to 12.9 billion ECU. The export/import ratio, which had fallen in the second half of the 1980s, increased in the early 1990s reaching a record .22 by 1993. Similarly, the extra-EU export/production ratio also reached a record 10.7 % in 1993, while import penetration fell.

Traditionally, EFTA countries have been the EU's main trading partners. In 1993 they received 25 % of EU export tonnage and provided 71 % of EU imports. The USA is the EU's second largest trading partner, receiving 14 % of export ton-

**Table 3: Pulp, paper and board

nage and providing 9 % of imports. Canada provided a further 9 % of EU imports.

**MARKET FORCES**

**Demand**

The market for pulp, paper and board products varies from intermediate industries to the final consumer. Pulp is largely an intermediate product, often sold within integrated companies but also to other firms. Customers for paper and board products vary from manufacturing industries (e.g. packaging) to retailers (e.g. toilet tissue). The diversity of markets also affects the susceptibility of the sector to the business cycle and other demand factors. For example, demand for packaging (which is also increasingly affected by environmental considerations) is relatively sensitive to economic developments, while demand for hygiene and sanitary products such as babies nappies is relatively immune.

Oversupply in 1993 and early 1994 supported the bargaining power of the main groups of customers, the paper and board converters, the printing and publishing sector and final consumers. The sector was under pressure from two directions: reduced revenues due to a continuing fall in prices in conjunction with a 1 % overall fall in domestic consumption of paper and board, and additional costs due to increasingly stringent voluntary and official environmental standards. In the second half of 1994, demand was growing and prices were rising, but environmental pressures remained severe.

**Newsprint**

Newsprint is an uncoated graphic paper which can be lightly calendered and is largely made from waste paper and mechanical pulp. It is used in letterpress, flexographic, and offset printing. Consumption is directly related to printed advertising revenue. Low advertising expenditures in 1992 lowered demand for newsprint. However, in 1993, although prices remained depressed, there was a 3.5 % increase in consumption

**Figure 4: Pulp, paper and board**

Origin of EU imports**

Source: Eurostat

tonnage. As in the previous two years, additional domestic capacity in 1993 caused another significant reduction in net imports. Consequently, production grew by 10 % and was 25 % higher than 1989 levels.

#### Uncoated graphic paper

These grades include directory, heavily filled and super-calendered papers used in rotogravure and offset printing and in books and stationery of all kinds. Production of these grades declined by 0.5 % in 1993, but this was confined to the mechanical grades (i.e. in part containing mechanical pulp which has been produced by grinding, milling or related processes). Output of wood free grades (i.e. made from at least 90 % chemical pulp) continued growing. Production of the mechanical grades in 1993 was 13 % lower than in 1989, but 14 % higher for the wood free grades. Though production fell in 1993, apparent consumption for these grades as a whole increased by 2.3 % due to an increase in net imports following Nordic currency devaluation.

#### Coated graphic paper

Coated mechanical grades are used to print catalogues, magazines and advertising material, while coated chemical grades are used for high quality "glossy" printed products. Both con-

sumption and output of these grades increased by just over 2 % in 1993. Growth in domestic capacity kept growth of net imports in check. For 1993, production of these grades was 14 % higher than in 1989.

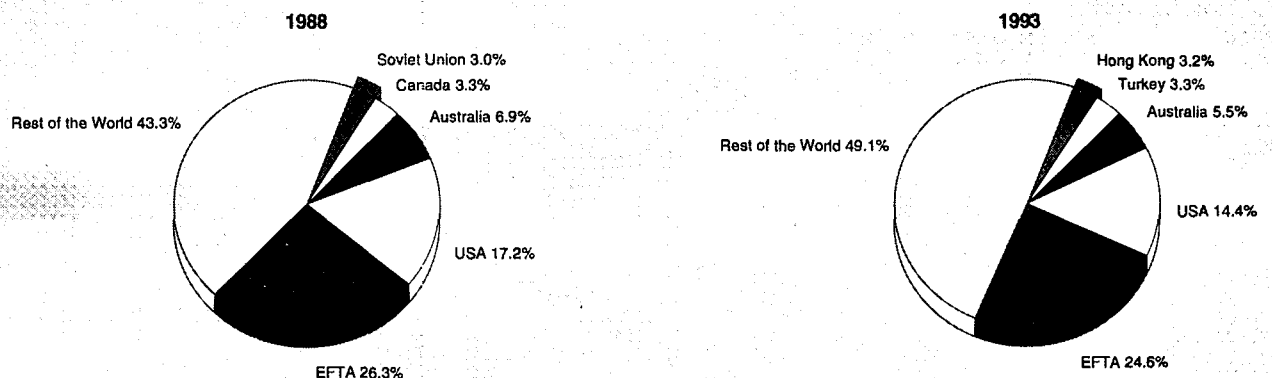

#### Hygienic and sanitary products

The main final products of these grades are hygienic paper and napkins and industrial wipes. In 1993, growth in tonnage of these grades slowed for the third year running to 4.0 % in production and 1.4 % in consumption due to a small fall in net imports. Nevertheless, output was still 19 % higher than in 1989.

#### Non-graphic grades

These include kraftliner and corrugated case materials, packaging paper, folding boxboard and greyboard. Kraftliner, used for the outer and inner lining of corrugated board, is produced mainly in France, Spain and Portugal with large imports from the Nordic countries and the USA. Apparent consumption of these grades in 1993 fell by 4.3 % while production decreased by only 1.1 %, cushioned by a fall in net imports. Production increased by 11.2 % for these grades between 1989 and 1993, but overall growth masks developments in different niches; output of specialist paper grades nearly doubled, case materials

**Figure 6: Pulp, paper and board  
Destination of EU exports**

Source: Eurostat

**Figure 8: Pulp, paper and board Trade intensities**

Source: DEBA

increased by 17.5 % and folding boxboard by 8.2 %, while output of wrappings and other boards fell by 19.3 % and 44.2 %, respectively.

## Supply and competition

### Paper and board

In 1993 over-capacity in the magazine paper grades and depressed prices in all grades were the industry's biggest problems. Capacity utilisation rates in the magazine grades were in the region of 85 % to 88 %. CEPI reports, for example, that the German paper industry was operating at a net loss in 1993. This squeeze on margins created considerable pressure to improve labour productivity. Between 1990 and 1993 labour productivity in the sector as a whole (including pulp) increased by nearly 18.8 % and unit costs fell by 11.3 %.

In 1994 demand improved and relatively little new capacity came on stream. CEPI estimates 1994 utilisation rates in the EU/EFTA regions of 88 % and 94 %, respectively, for SC (super calendered) magazine paper and coated mechanical reels, rising to 94 % for the former by 1995. The 1994 newsprint operating capacity rate is estimated at 95 %. Following an increase in pulp prices, paper prices in all grades increased sharply in the second half of 1994 and into 1995. While pulp prices in early 1995 were still marginally below their 1989 peak, the speed of the increase in price rises was dramatic, more than doubling since 1993. Production accelerated in response, increasing by 8.2 % in the first nine months of 1994. However, there is a risk of excessive stockpiling; although this could eventually stem paper and board price increases. Further pulp price increases will considerably penalise the non-integrated buyers of market pulp.

Over-capacity problems in 1992 and 1993 stemmed from a downturn in the North American and European business cycles when considerable capacity, both from large new machines and from upgraded machines, was coming on stream. This capacity had been planned and its foundations laid in the growth years of the late 1980s. In 1994 the situation has reversed. Only modest growth in capacity was planned but a continued rise in demand is likely in the short to medium term. Germany, the key EU market, plans no growth in overall capacity in magazine grades up to 1998. Finland, Sweden and Austria, however, are planning substantial increases, while other EU Member States plan only modest growth. In the case of newsprint, the United Kingdom and Germany plan

major expansions of their waste-based newsprint capacity and the Nordic countries and Austria plan smaller, but still significant, reductions in newsprint capacity.

Nordic companies benefited from profit recovery in 1993, via improved exports, following currency devaluation. EU-12 companies, however, did not begin to feel benefits from restructuring policies until the first half of 1994. But, more significant gains are expected in the second half when prices and revenues improve.

### Pulp

The European market is a net importer of pulp and, as such, is closely linked to the North American market, where the average mill is much larger. In 1993, EU/EFTA combined net imports of pulp were 4.6 million tonnes, contributing 12.6 % to apparent consumption. Of the region's gross imports of 6.1 million tonnes, two-thirds came from North America and most of the rest from growing sources in South America and East Europe. The weakness of the USD assisted North American exports.

As an internationally traded, standardised commodity produced in large scale production units (latest investments sometimes reaching 500 000 tonnes annual capacity), the inventory, investment and price cycles for market pulp are more pronounced than that for paper. Between mid-1989 and the end of 1993, the price of Canadian BSK pulp, the industry's prime grade, halved, with similar movements for its Nordic equivalents. However, the situation has virtually reversed with prices nearing 1989 levels in early 1995. This unstable situation is particularly damaging for non-integrated pulp buyers, of which there are many in Europe's relatively fragmented industry.

Recent price instability may, however, be about to end. Harvesting of lumber will rise in response to current price trends, which fell in recent years as a result of uneconomic prices. Furthermore, the FAO's 1994 capacity survey reported plans for only a 1.1 % per year increase in world pulp capacity from 1993 to 1998, with only 0.4 % per year in North America, and nil growth in the EU compared with 1.9 % for its Nordic suppliers. If this moderation persists, prices could possibly stabilise at profitable levels. This is essential if Europe is to improve the scale, efficiency and environmental cleanliness of its mills and reduce its dependence on outside sources. Since the FAO survey, however, new capacity plans have been upgraded. But again, as is the case for capacity plans in the newsprint, graphic and packaging grades, an increasingly coordinated pan-European industry strategy is emerging.

### International competition

International competitiveness of the EU paper industry is relatively good. It scores well on labour productivity vis-à-vis its competitors. EU companies have invested less in super-capacity and more in strategically flexible production techniques. This gives many EU companies an edge in dealing with the rapidly changing market conditions for various paper grades. The current rapid response of output to improving market conditions is an example of this. However, the concept of an industry delineated by the current geographical boundaries of the EU has been overtaken by events. Nearly two-thirds of the industry's capacity is owned by non-EU firms, primarily Swedish and Finnish companies. The accession of the new Member States in 1995 will remove yet another legal obstacle to pan-European strategies. EFTA's accession to the EEA in 1993 broadly meant that these groups had to conform to EU monopoly and merger rules, company law, and environmental, R&D and social policies. Full EU membership will extend this conformity to other areas such as agriculture, forestry, fisheries, energy, and transport; all of which are vital to the future of the pulp and paper sector.

Development of Europe wide economies of scale by the larger European paper groups is evident in ongoing restructuring.

A central objective is to specialise in core product grades for sale across national frontiers, rather than owning groups of small, nationally oriented production facilities with a high degree of product diversification. Merger, acquisition and divestment activities have been aimed at economies of scale to match those of world competitors. Some are concentrating on graphic grades, some on packaging grades, some on household and sanitary grades and yet others on niche markets for high value-added products. Some are acquiring and expanding trade networks for pan-European marketing of specialist grades and converted products. Yet others, particularly in the packaging and newsprint segments, are managing increasing proportions of their own waste paper supplies.

The USA paper industry began pulling out of recession in 1993, earlier than the Europeans. According to USA Bureau of the Census data, the net pre-tax profit margin of the industry fell to 1.5 % in 1992 from 11.4 % in 1988. In 1993, it had crept back to 3.4 % and in the first half of 1994 to 3.9 % on sales up by 4.7 %. Pulp & Paper Week's survey of 33 major companies reported a 22 % increase in turnover in the third quarter of 1994 over 1993 and more than doubling of post tax-earnings. The already cheap USD depreciated further contributing to a surge in USA exports.

CPPA (Canadian Paper and Pulp Association) data shows that the heavily indebted Canadian forestry industry recorded losses in 1991, 1992 and 1993. However, these were progressively improving due to improvements in the 'lumber and panels' sub-sector, which by 1993 made net earnings of 1.3 billion ECU, not quite offsetting the 1.4 billion ECU losses of the pulp and paper segment and other minor items. In the first half of 1994 there was a dramatic return to overall profits as the industry benefited from buoyant export markets in the

USA and overseas; particularly Europe, with the benefit of a cheap currency.

Japan is an inward-focused paper and board market because of its shortage of raw materials. It exports little and has high recycling levels. Its main influence on world markets is via imports of wood chips, pulp and waste paper. These have been depressed by deep recession and only by mid-1994 were there signs of a slow improvement. Japan's paper industry has a number of world class companies but profits have been low in recent years. Two major mergers in 1993 resulted in companies with a 10 % share (each) of Japanese paper and board output. This may signify the commencement of a major restructuring process.

The ASEAN and Chinese paper markets are the fastest growing in the world, with consumption outstripping rapid growth in production capacity. With the low value of the USD and European currency turmoil, North America has benefited most from growing Asian imports of pulp, waste paper, and paper and board. Lack of currency stability is a major problem for European exporters. Additional competition in the region also arises from Indonesia, which is actively developing a graphics paper capacity based on developing local pulpwood supplies. In Asian markets, the graphics and niche paper grades, in which Europe excels, offer the most promising export opportunities.

### Production process

Pulp, paper and board manufacturing has been traditionally linked to the forestry and wood processing sectors. With increasing use of waste paper, fillers and other materials, however, vertical integration above the pulping stage has been abandoned. Many of the major players are focusing on horizontal integration and drawing on a range of raw materials to produce a range of higher quality, specialised products within their chosen segment of the European and world markets, as well as forward integration into the converting sector.

Innovation, modernisation and increasing scale economies are an integral part of the development of new pan-European groups. Major investment is ongoing in two areas: environmental technologies aimed at reducing, and/or improving the environmental friendliness of emissions and effluents; and recycling technology, particularly in stock preparation. Considerable restructuring to obtain economies of scale has also occurred among the sector's machinery suppliers. Investment, labour and training costs associated with increasing demand for higher technical skills are high, resulting in many large companies increasing their financial gearing.

## INDUSTRY STRUCTURE

### Companies

Although concentration is increasing, by world standards the European pulp, paper and board industry is still relatively fragmented. Even when the new Member States are included, concentration remains low. Pulp & Paper International's list of the world's top 150 companies, based on 1993 financial data, included 41 North American companies with an average

turnover for their pulp, paper and converting operations of 1.58 billion ECU, 64 European companies averaging turnover of 0.71 billion ECU and 31 Asian companies averaging 0.91 billion ECU. It also included four Australasian, two South African and eight Latin American companies. Of the 64 European companies listed by PPI, 39 are based in the EU-12 and 18 in the new Member States, averaging company turnover of 0.67 billion ECU and 0.97 billion ECU, respectively.

In 1993, the largest ten EU pulp and paper companies, measured by value of sales, were: KNP BT (NL); Arjo Wiggins Appleton (UK); PWA (D, acquired by Sweden's SCA at the beginning of 1995); Jefferson Smurfit Group (IRL); Jamont (B); Haindl (D); David S Smith (UK); Cellulose du Pin (F, acquired by Jefferson Smurfit in late 1994); Cartiere Burgo (I); and, Torraspapel (E). However, the picture is very different when companies in the new Member States are included: Stora (S); United Paper Mills (SF); Svenska Cellulosa (S); MoDo (S); and, Enso-Gutzeit (SF) join the current first five (including SCA-PWA) on the EU list. In addition, two Swedish, two Finnish and three Austrian companies join the rest of the above list. Most of these companies produce between one and six million tonnes of paper and board and are integrated forward into converting (some also into paper distribution). The largest have operations in two to 13 countries world-wide.

Only two European companies, KNP BT and Stora, were among the world's top ten paper and board companies in 1993. However, the 1994 purchase of Cellulose du Pin, Saint-Gobain's paper and packaging operations, by Jefferson Smurfit and of PWA by SCA in early 1995 now bring these into this league. Of the remaining world top ten in 1993 six were USA companies and two were Japanese. Typical of European companies are the fifty or so which produce between 100 000

and one million tonnes per year. However, the Finnish company Enso-Gutzeit would be included in the top ten (and JS and KNP BT excluded) if company size were measured by production capacity rather than value of sales.

Between 1983 and 1989 the number of paper and pulp mills in the EU increased, but between 1989 and 1993 there was a fall in numbers as the industry became more concentrated and average output and productivity of mills increased. Spain, Portugal and Italy, with their more fragmented industries, experienced the largest numerical falls. The United Kingdom, Belgium and Denmark also saw small falls in numbers. In contrast, the number of paper mills in Germany increased following unification, while France also saw a small increase in both the number of pulp and paper mills.

During 1984-1993, the effect of industrial concentration increased significantly the production specialisation index of the sector in France, the Netherlands and the United Kingdom and reduced that in Germany. More recently, European paper manufacturers have been involved in internal restructuring, with the recession in the early 1990s providing the catalyst. The emphasis was on disposing of peripheral operations and concentrating on "core" activities.

Acquisition activity in Europe has varied with the availability of finance and swings in the business cycle. Many companies are highly geared and finance has been difficult to obtain. Over the last three years, however, and particularly in 1994, acquisitions picked up. Important deals have included:

- the creation of KNP BT (NL) in 1993 followed in 1994 by the creation of KNP Leycam (A) a major coated paper producer;

- the acquisition by Jefferson Smurfit (IRL) of Saint-Gobain interests and later of a 27.5 % stake in Nettingsdorfer (A); and
- SCA's purchase of a 60 % controlling stake in PWA (D) at the beginning of 1995 to create Europe's largest paper company.

More modest acquisitions include: AssiDöman (S) of NcB (S) and later of MoDo Packaging (S); Sappi (South Africa) of Hannover Papier (D); and, Enso-Gutzeit (SF) of Tampella's (SF) pulp and papermaking operations and later of 35 % of Veitsiluoto Oy (SF). Modest investment in Europe continues to be made by North American companies, while Sappi and Amcor (Australia) have also appeared on the European scene in their general world-wide expansion.

According to PPI data, average capacity of the 1 039 EU paper mills in 1993 was 46 000 t/y, compared with 205 000 t/y for the 112 Nordic mills and 155 000 t/y for the 659 North American mills. Many of the European mills are non-integrated and, clearly, further restructuring could involve shutdowns of uneconomic units. However, further restructuring would not necessarily entail scale expansion of remaining mills. In many market niches the industry needs small, flexible production units which are close to their markets. In addition, the financial risk associated with large production units producing a limited range of products is often daunting.

### Impact of the Single Market

The Single European Market (SEM) Programme has had a highly positive effect in this sector, dramatically accelerating the restructuring process, increasing sales, productivity and competition especially in price. The free movement of goods and the EU's competition policy have been important in this respect, leading to a substantial increase in intra-EU trade, as have the measures related to the free movement of capital and to the energy sector. The SEM has boosted merger and acquisition activity, resulting in increased concentration on the one hand and more specialisation in niche products on the other. Distortions based on different national environmental policies is seen as an issue to be addressed in the future. Other remaining barriers which need to be addressed relate to technical harmonisation issues and prevention of intermittent bouts of currency instability.

### REGIONAL DISTRIBUTION

Increased recycling is having profound effects on regional location within the industry. New plants and expansions of existing enterprises are increasingly located near waste paper supplies in major conurbations. However, this trend varies according to grade. It is particularly true for the new large scale, waste-based newsprint plants in Germany, France and

Benelux, while the traditional Nordic suppliers are importing increasing quantities of waste paper to satisfy end-user demand for increased recycled content. Packaging grades have always been intensively recycled so relocation is less apparent; although recycling demand is putting pressure on Nordic supplies of the virgin pulp-based grades. Hygienic papers are affected in a similar way to the packaging grades with Nordic and Italian exporters feeling the pinch. Recycling in the remaining graphic grades is less developed but is increasing and eventually similar trends towards relocation may emerge.

Regional relocation trends are being assisted by the progressive integration of the industry across national boundaries and are a further counter-development to large scale mills serving Europe as a whole.

### ENVIRONMENT

Although the industry was among the first to acknowledge the importance of monitoring the environmental side-effects of its production processes and has always recycled high proportions of its output, it has become the target of several hard hitting protest campaigns. These campaigns have focused on four main issues: the quantity of forest wood used in paper production; the high and growing consumption of paper; the proportion of paper which is recycled; and the use of chlorine and its compounds for bleaching pulp and paper to high levels of brightness.

In response to these pressures and growing consumer awareness, the industry has a strong case to present. First, unlike other resource-based industries, it is one of the few which regenerates its own raw materials, employing sustainable forests and actually increasing afforested areas in Europe. Second, in 1994 the EU and EFTA already recycled 42 % of their paper consumption, a proportion they have been stepping up annually. Third, EU countries are increasingly accepting incineration with energy recovery as an effective means of disposal of poorer quality wastes which are costly to recycle, including various contaminated and mixed waste paper grades. Finally, the industry has phased out elemental chlorine in favour of chlorine dioxide, producing "elemental chlorine-free" (ECF) products. However, "totally chlorine-free" (TCF) bleaching is now being phased in, albeit with controversy about the best method to use. A major Swedish supplier is predicting that by 1996 the market share of TCF for printing papers will reach 60-70 % in the Germanic-speaking countries (in 1993 it was 37 %) and their Nordic suppliers (in 1993 it was 37 %), but only 6-10 % in all other European countries.

### REGULATIONS

There is a growing amount of legislation at national and EU levels aimed at the sector, mainly prompted by environmental

**Table 9: Pulp, paper and board

Source: DEBA

considerations. It is largely aimed at cleaner production processes and at reducing the volume of packaging and paper consumption, while placing responsibility for recovering and recycling waste on industrial producers and on users of packaging. National legislation includes Germany's strict Packaging Ordinance, together with similar legislation in France, Belgium and the Netherlands. Other EU countries, notably the United Kingdom, are about to introduce similar measures. Variations in the timing of introduction and the relative strength of this legislation from country to country distorts trade flows. The initial effect of the German Ordinance, for example, was to flood the European market with waste paper, pushing prices down to negative levels for the lower grades in 1993; although demand recovery in 1994 has corrected this.

Harmonisation of this type of legislation at the EU level to reduce such distortions is supported by the paper industry. After several disputed drafts, the EU Packaging and Packaging Waste Directive was approved by the European Parliament and adopted by the Council of Ministers at the end of 1994, following rewording to allow for Belgium's concern that its postponed Eco-tax on packaging was endangered. The Directive sets a five-year target obliging members to recover between 50 % and 65 % of waste packaging, and between 25 % and 45 % must be recycled leaving room for other disposal methods such as composting and incineration. These ranges allow for national variations in the progress of waste legislation. Some countries, however, feel the measure is not stringent enough to achieve an acceptable level of harmonisation; while others feel it does not go far enough to reduce the distortions caused by the stringent legislation of their neighbours. International competition, however, is forcing industry in countries with less advanced environmental legislation to adopt the standards of stricter countries.

The paper industry also supports the objectives of the regulation for a Community Ecolabel Award Scheme (i.e. to promote products with a reduced environmental impact during their life cycle and to provide consumers with information on their environmental impact), but is profoundly concerned with the initial operation of the regulation in the case of toilet tissue and kitchen towels. It considers that the criteria recently established for labelling these products may mislead consumers and will exclude many environmentally sound products.

As an industry with a small number of major players, the EU competition authorities keep a watchful eye on proceedings. Major mergers are scrutinised and participants asked to divest subsidiary interests where deemed appropriate. Price fixing is also an issue. Cartonboard producers were fined for alleged price fixing. This is a constant issue in that prices are liable to rise across the industry at roughly the same time as each company faces similar supply conditions and takes principal raw material prices as given on world markets.

## OUTLOOK

The accession of Sweden and Finland, and to a lesser extent Austria, has substantially altered the profile of the EU paper industry. However, companies in these countries have been expanding into the EU in readiness for membership and from a strategic perspective company objectives and policies remain largely unaffected.

Domestic demand and prices for the industry's products are rapidly increasing and there are prospects for more stable employment and improved profits until at least 1996. Economic recovery in North America and the Pacific areas is also providing opportunities for the industry's exports. It is anticipated that net exports will increase rapidly to 1997, averaging around 10 % per annum from 1995 to 1997. Consumption is expected to increase at around 5 % per annum over 1995-97, slightly ahead of production.

Continued restructuring and an acceleration in industrial concentration seems likely. Investment caution, however, should continue to underpin the recovery and, now that prices are reaching viable levels, any further price increases will be more moderate.

The industry, however, faces four long term problems: currency instability, which is restricting its ability to compete in growing markets in developing countries, as well as in its own domestic markets; uncertainty about the timing and recovery potential of the former Soviet Union states and Eastern Europe and, to a lesser degree, Central Europe; the ongoing cost of environmental measures; and uncertainty about the future course of the business cycle beyond 1996.

Written by: Fitzpatrick Associates

The industry is represented at the EU level by: Confederation of European Paper Industries (CEPI). Address, Avenue Louise 306, B-1050 Brussels; tel: (32) 2) 627 4911; fax: (32) 2) 646 8137.

# Paper and board converting

## NACE 472

The paper and board converting sector is strongly influenced by the general health of the economy. It is highly dependent on domestic demand and the sector's external trade balance is small. Packaging products make up about 60 % of its total output, whilst hygienic products, stationery and office supplies constitute the rest. The sector is also highly influenced by supply and capacity conditions in the pulp, paper and board industry, its main source of input materials. In response to general economic trends, the growth in both production value and volume in the converting sector slowed down in 1992, fell in 1993 and began to recover in 1994. In response to the sector's increasing demand for the main input materials, paper and board prices rose rapidly in 1994. The industry is fragmented in terms of ownership and regional distribution of its operating units, although there has been a considerable acceleration of mergers and acquisitions, and forward integration into converting, by the major paper and board manufacturers. Prospects are for increasing production, profits and employment in the sector. The sector's main concerns are the costs of participation in the various national waste management initiatives, how to benefit from increasingly pan-European product marketing, to reduce costs, profitably tap the potential of Eastern European markets, and the uncertainty about the future course of the business cycle in 1997 and beyond.

### INDUSTRY PROFILE

#### Description of the sector

The paper and board converting sector covers all processing of paper and board for their final applications in packaging, communications and other special uses. The sector manufactures a wide variety of products including packaging (often in combination with plastics and metal foils), stationery and office supplies, hygienic products, wallpaper, labels and many more such products.

There is considerable overlap between this sector and paper and board manufacturing. Increasingly, the major European paper producers are integrating forward along the production and distribution chain and becoming active in both the paper production and converting markets.

#### Recent trends

The volume and production value in the sector increased steadily in the EU during the 1986-91 period but slowed down in 1992, fell in 1993 but recovered in 1994. Input prices fell sharply in response to falling demand in 1992 and 1993. A reversal of this was evident in 1994 and there was a sharp increase in paper and board prices, increases which are being passed on in converted products, particularly in the packaging segment.

The EU external trade balance of the sector, although mainly positive, has always been small compared to other large industries. In 1992 and 1993, there was a significant improvement in the trade balance, in contrast to reductions in previous years due to increasing imports. Between 1990 and 1993, extra-EU exports rose by between 5.4 % and 6.2 % per year, whilst imports fell by 0.5 % in 1992 and 0.6 % in 1993. Around 75 % of total EU trade flows are within the EU. With the accession of Austria, Finland and Sweden to the EU, this proportion will rise substantially in 1995.

Figure 1: Paper and board converting  
Value added in comparison with related industries, 1993

Source: DEBA

Paper and board converting is a major contributor to overall industrial activity. In 1993, its value added was 83 % higher than that of the pulp, paper and board industry, the main source of its input materials. The largest producer in the EU is Germany, with 4.7 billion ECU in value added in 1993, followed closely by the UK (3.3 billion ECU), France (3.0 billion ECU), and Italy (1.7 billion ECU). For the nine EU countries for which data are available for 1993, the converting sector's total added value was 1.7 times that of the supplying sector. For the four largest countries the corresponding figures were: the UK 2.6 times, France 2.2, Germany 1.7 and Italy 1.6. For the smaller countries the figures were: Denmark 5.4, Spain and the Netherlands 1.4, Greece 1.8 and Portugal 0.3.

From 1984 to 1993, production in the sector measured in constant (1990) prices, grew more rapidly than in EU manufacturing industry as a whole, by 3.5 % and 1.9 %, respectively, but showed a similar cyclical pattern. The upturn in 1994 was slightly delayed, however, at 2.8 % for the sector compared to 3.3 % for EU manufacturing industry. The cy-

Source: DEBA

clical pattern of employment was much more pronounced for the sector than for all EU industry.

Whilst employment in the sector in 1994 was lower than at any time in the previous ten years, this reflected sharp falls since 1991 rather than a gradual decline over the last decade. Employment rose continuously, by 36 000, over the 1986-91 period, but fell by 39 000 over the following three years. Rising labour costs throughout the late 1980s and into the early 1990s is likely to have contributed to the recent decline in employment.

Average growth rates in consumption and production during the 1984-93 period were 3.6 % and 3.5 %, respectively. Both grew much faster during the first five years of the period, by 4.3 % and 4.2 %, respectively, compared to 2.6 % and 2.7 % in the last four years.

Extra-EU exports grew at an average annual rate of 5.0 % in the nine years from 1984 to 1993, but at a higher rate in

the latter four years of this period (+5.9 %). Extra-EU imports grew at an annual average of 6.5 %, but in this case at a higher rate in the first half of the period (+7.1 %).

**International comparison**

Because of the wide range of activities and product groups which the sector includes, it is difficult to make simple comparisons between the EU's paper and board converting sector and those in the Nordic countries, North America and Asia. In current prices, however, the value of EU output in the paper and board converting sector in 1993 was 55 % of that of the USA and 30 % higher than that of Japan.

The prosperity of the sector in all three regions is closely related to the economy as a whole and in the 1984-93 period the real rate of output growth in the sector in the EU was 3.5 % per year, compared with 7.2 % in Japan and only 2.0 % in the USA.

**Figure 4: Paper and board converting  
International comparison of production in current prices**

Source: DEBA

**Figure 5: Paper and board converting  
International comparison of production in constant prices**

Source: DEBA

**Figure 6: Paper and board converting  
Destination of EU exports**

Source: Eurostat

The recession, however, hit Japan's growth rate far more severely than the other two regions. Recession also affected the EU a year later than in Japan and the USA: in the latter country output rose rapidly (+5.9 %) in 1993, whereas it fell slightly in the EU (-0.5 %) and rose modestly in Japan (+2.5 %).

### Foreign trade

Extra-EU trade in converted paper and board products is limited but has grown rapidly from a small base, particularly in the 1984-91 period. For many packaging materials, in particular corrugated cases, the volume/weight and value/weight ratios make transport over long distances uneconomic. For hygienic products, labels, stationery and office supplies, the higher value/weight ratio makes long distance trade more profitable and larger volumes of these are products exported, e.g. to markets in Asia and South America.

In general, however, production in the sector is located as close as possible to the market in order to minimise costs. In 1993, the exports to production ratio, and imports to consumption ratio, were 7.8 % and 6.3 %, respectively. Whilst the former fluctuated around 7 % in the 1984-92 period, the latter increased slowly from just below 5 % in 1984 to over

6 % in 1992. In 1993, the exports to production ratio rose faster than imports to consumption.

The main trading partners are the EFTA countries, which reflects the importance of geographical proximity. They accounted for 38 % of EU exports and 67 % of imports in 1993. The USA was the destination of only 7 % of EU exports and the origin of 14 % of imports. A significant 55 % of exports went outside EFTA and the USA, particularly to developing countries. Paper and board companies are also increasingly looking to Eastern Europe as a potential market.

Exports to Poland, Hungary and the countries which constituted the former Soviet Union are growing. In particular, the Kaliningrad free trade zone provides an important trade link facility for EU-based paper and board converters expanding their markets eastwards.

### MARKET FORCES

#### Demand

Packaging products, including corrugated and solid fibre board, folding and rigid board boxes and containers, paper packaging and carrier bags and other wrappings for consumer products, accounted for about 60 % of the value of the in-

**Figure 7: Paper and board converting  
Origin of EU imports**

Source: Eurostat

dustry's output in 1993. The downturn in overall demand for these products in 1992 and 1993 coincided with a sharp increase in packaging waste management throughout Europe, augmented by legislation in many countries. At the same time, the resolute growth of container transport continued to take its toll on demand for secondary packaging, whilst competition from rigid and flexible plastics packaging continued to increase. Both prices and volumes fell for most packaging products. In general, demand for bags, sacks and packaging papers suffered more than that for board products. Within the latter, folding box board did less well than case materials.

Following the Packaging Ordinance, German production of paper and board packaging fell by around 8 % in value and 3 % in weight between 1991 and 1993, affecting all types of converted packaging products. In 1993, French production fell by around 1 % in value, but waste management legislation in France only began to be implemented in 1993. 1994, and particularly the second half of the year, saw a considerable recovery in demand and in prices of paper and board packaging, particularly in the northern Member States.

Household and hygienic paper goods is the second largest segment of production in the sector. Demand for high-quality products used in nursing, baby care and feminine hygiene has grown rapidly in the past two decades, as has that for lower value added products, such as toilet paper, kitchen towels and handkerchiefs. The market was already reaching saturation levels by 1992, particularly in northern Europe, so the recession struck a blow to overall demand which fell by 3.7 % in 1993. 1994 saw a modest improvement in demand although strong competition held down prices of disposable sanitary goods. However, per capita consumption of most of these products in the EU is on average lower than that in the USA and growth in demand is expected to be concentrated more to Southern Europe.

Stationery and office supplies is the third largest segment of production. It includes envelopes, labels, printing and copying paper and products for special applications such as facsimile and photographic papers, note books, binders and file covers. The developing information technology (I.T.) has shifted the emphasis in demand from education and mail-related stationery such as envelopes, note books, ruled papers and ledgers, towards I.T.-related stationery such as facsimile, computer, label and photocopying papers. The growth in overall demand for office supplies, is slowly but steadily increasing as I.T. spreads

to smaller businesses and to private consumers. Whilst 1993 saw a limited slowdown in sales of these products, sales growth and rising prices were resumed in 1994.

### Supply and competition

During the recession in 1992 and 1993, lower prices for input materials were more than offset by increased costs of labour, transport, energy and investment financing. These effects were combined with final prices that were brought down by the bargaining power of the sector's customers, including the food and consumer products processors and above all the increasingly integrated major retail chains. The spread of pan-European product marketing by these integrated distributors, together with signs of increasing co-operation between the major players, has stimulated lower prices, especially for medium-sized and smaller, non-integrated paper and board converters. Similarly, part of the benefits of the recovery in demand in 1994 were eroded by rising input material prices which were extremely difficult to pass on to the powerful customers.

One reaction to such price pressure is the integration of the industry's customers backwards into paper and board converting. The most common trend has been forward integration of paper and board manufacturers into converting and sometimes into distribution. These merged companies have been building their own pan-European chains with operations in the proximity of as many of Europe's major urban markets as possible. In the packaging converting segment, many of these developing groups are headquartered in the Nordic countries and have had a significant positive impact on the productivity of EU-based industry. The accession of Finland and Sweden to the EU will give a further boost to the development of these groups. The hygienic products segment is dominated by several North American groups including Scott Paper Corporation, Kimberly-Clark, and Proctor & Gamble, which have brought a vigorous consumer-oriented marketing approach to this segment. The recent merger of Sweden's SCA with PWA (D) is an important competitive move in the segment. In the office supplies sector, the two major companies are KNP BT (NL) and Arjo Wiggins Appleton (UK), both of which have distribution networks that are developing, as well as converting operations.

### Production process

In many areas, and particularly in the conversion of packaging materials, the sector is integrated backwards into paper and board production, but as a whole it still remains an industry of small and medium-sized firms with a variety of different production processes. However, the increasing concentration of groups of production units under the ownership of prominent paper and board manufacturing groups is boosting productivity in the sector generally. Concentration is providing firms with benefits which include access to large investment funds, interchange of technology and know-how, guaranteed input material supplies and joint product marketing.

## INDUSTRY STRUCTURE

### Companies

There are a number of large European paper and board companies which are integrated forward into conversion of various types. In 1993, the largest ten EU companies in the sector were KNP BT (NL), Arjo Wiggins Appleton (UK), PWA (D, acquired by Sweden's SCA at the beginning of 1995), the Jefferson Smurfit Group (IRL), Jamont (B), Haindl (D), David S. Smith (UK), Saint-Gobain Paper-Wood (F, acquired by Jefferson Smurfit in late 1994), Cartiere Burgo (I) and Torraspapel (E).

The inclusion of companies from the three new Member States of the EU will considerably strengthen this list both in terms of input materials supplies, converted products in all three main categories and export orientation beyond Europe. Stora

**Figure 8: Paper and board converting  
Trade intensities**

Source: DEBA

(S), United Paper Mills (SF, part of Repola), SCA, MoDo (S) and Enso-Gutzeit (SF) join the current first five on the EU list to make the leading ten (nine), whilst two Swedish, two Finnish and three Austrian companies join the rest of the above list in terms of size. Most of these companies produce between 1 and 6 million tonnes of paper and board, are integrated forwards into converting and some also into paper distribution, whilst the largest have operations in as many as 13 countries world-wide.

Only two of the European companies, KNP BT and Stora, were among the world's top ten paper and board companies in 1993, although the 1994 merger of Saint-Gobain and Jefferson Smurfit and of SCA with PWA now brings them into this league as well. Six of the other eight of the world top ten in 1993 were US companies and two were Japanese.

In the 1984-1993 period, the effect of industrial concentration has been to increase significantly the product specialisation index of the sector in France and to less extent in Germany compared with a sharp fall in the UK. Elsewhere, the tendency has been mainly for a stable or slightly lower degree of specialisation.

### Strategies

All of the major manufacturers in the sector have been involved in internal restructuring, particularly during the recent recession with the main emphasis being on the disposal of peripheral operations and concentration on selected core activities. North American companies continue to invest modestly in Europe, whilst Sappi (South Africa) and Amcor (Australia) have also entered Europe as part of a general world-wide expansion. Despite these developments, there is still a large number of small non-integrated converters throughout the EU.

Acquisition activity in Europe has varied with the availability of finance and swings in the business cycle. Many companies are highly geared and finance has been difficult to obtain. The recovery in 1994 and early 1995 spurred a boost in acquisitions. The largest recent mergers were the creation of KNP BT (NL) in 1993 followed in 1994 by the creation of KNP Leycam (A) a major coated paper producer in 1994, and the acquisition by Jefferson Smurfit (IRL) of the Saint-Gobain Paper-Wood interests and later of a 27.5 % stake in Nettingsdorfer (A).

More modest acquisitions include: AssiDomän (S) of NcB and MoDo Packaging (both S); Sappi of Hannover Papier (D); Enso-Gutzeit of Tampella's (SF) pulp and paper-making operations, and 35 % of Veitsiluoto Oy (SF); and David S. Smith of Kaysersberg (F) in 1991, and of Spicers (UK) in 1993.

### Impact of the Single Market

The effect of the Single European Market (SEM) process on the paper and board converting sector has been largely positive. The free movement of goods and services within the sector is helped by EU geography and short lines of communication by comparison with North America, the former Soviet Union and the Pacific region countries. The marked stimulation of intra-EU trade has also encouraged restructuring in the industry. This has resulted in increased M&A activity, particularly by large companies integrating forward into converting, although this has led to problems for smaller firms. While Single Market measures also have a major impact on the distribution channels of the larger companies in the sector, industry location, which is dependent on the sector's raw material sources, has not been as significantly affected. Major remaining internal barriers are currency instability, access to finance for small firms and a range of environmental and technical barriers which may hamper trade with countries outside the EU. The industry regards a level environmental playing field for products and countries within the EU and with countries outside it as the major priority to be addressed.

## REGIONAL DISTRIBUTION

Since the industry produces products with higher value/weight ratios than the commodity grades of pulp, paper and board and its production runs are short, the regional location of this industry has generally been more widely dispersed with production units located near markets rather than materials. Increasing acquisition activity by the suppliers of input materials is by no means always reflected in physical integration. The tendency for input materials suppliers to locate near their waste paper supplies also coincides with the market location requirements of the converting operations. This tendency towards widely dispersed regional distribution of production units is assisted rather than hindered by the increasing transnational ownership in the industry.

## ENVIRONMENT

This sector's environmental concerns are twofold: they reflect the concerns of the pulp, paper and board sector through the demands of its own customers to use environmentally friendly paper and board input materials; and, more directly, by the sector's own need to use environmentally acceptable production processes and to participate in Europe's developing national waste management initiatives.

The paper and board converting sector already manufactures products that meet modern environmental standards. With regard to its most important input material, waste paper accounted for 56.4 % of the total fibre use for the EU's paper and board production in 1993, whilst waste paper recovery represented 41.0 % of total new supplies of paper and board. The two rates have increased steadily over recent years. In the tissue and board packaging segments the percentage of recycled fibres used ranges between 60 % and 100 %.

In the office products and stationary segments, recycling rates are lower but are also increasing. For non-recycled fibres, "elemental chlorine-free" (ECF) bleached pulp has been phased in across Europe, and "totally chlorine-free" pulp is now being phased in, particularly in the northern Member States.

## REGULATIONS

There is a growing amount of legislation at national and EU level stemming from environmental awareness. This is largely aimed at holding down the volume of packaging and paper used, and places the responsibility for recovering and recycling waste upon the industrial producers and users of packaging. National legislation includes Germany's strict Packaging Ordinance, together with similar legislation in France, Belgium and the Netherlands. The UK is about to introduce similar measures and other Member States are at various stages in their waste management strategies. Variations in the timing of introduction and in the relative strength of this legislation from country to country tends to distort trade flows. The initial effect of the German Ordinance, for example, was to flood the European market with waste paper, pushing prices down to negative levels for the lower grades in 1993, although this was corrected by demand recovery in 1994.

Harmonisation of this type of legislation at the EU level in order to reduce such distortions is supported by the paper industry. After several disputed drafts, the EU Packaging and Packaging Waste Directive was approved by the European Parliament and adopted by the Council of Ministers at the end of 1994, following rewording to allow for Belgium's concern that its postponed Eco-tax on packaging was endangered. The Directive sets a five-year target obliging Member States to recover 50-65 % of waste packaging, and to recycle 25-45 %, leaving room for composting and incineration.

These ranges allow for national variations in the progress of waste legislation. Some countries, however, feel that these

**Table 5: Paper and board converting

Source: DEBA

measures are not stringent enough to achieve an acceptable level of harmonisation, whereas others feel that it does not go far enough in reducing the distortion effects caused by stringent legislation in their neighbouring countries. International competition, however, is forcing industry in countries with less advanced environmental legislation to adopt the standards of stricter countries.

## OUTLOOK

Demand is rising and prices are going up for the sector's products and there are prospects for a steady increase in the sector's profitability until 1997, and for a stabilisation in 1995 of the, until recently, falling employment levels. Indeed, steady output growth suggests the possibility of a slight increase in employment in 1996 and 1997.

The positive trade balance generated by the industry is small, representing only about 1.6 % of the value of the sector's total output, and is unlikely to change significantly. It could possibly deteriorate a little with growing domestic demand, although the impact of the accession of the three new Member States means that the consolidated statistics for the EU 15 will show a sharp increase in the external trade balance. There is likely to be a continued growth in investment by the sector in Central Europe, and to some extent in Eastern Europe and the former Soviet Union although the benefits of such investment may take some time to develop.

Restructuring and concentration in the industry seem likely to accelerate during the next two years and will concentrate ownership in the industry, supporting a continued improvement in the industry's productivity, but having less effect on the relatively fragmented regional distribution and small average size of its operating units.

The main concerns in the sector in the longer term are: the increasing costs of environmental measures and the labour costs and additional expenses. Particularly the participation in various national waste management initiatives across the EU causes an increase of costs and the paper and board converters have to find new ways to respond to the increasing cost and the pan-European nature of the sector's major customers. This will force the paper and board converters to look into new market possibilities in Eastern Europe, the Baltic Rim and Russia. Especially the Baltic Rim with its Russian exclave Kaliningrad has a central and unique geographical position on the crossroad between North, East and West trade routes. This area is a valuable gate to new international co-operation in Europe. These views will help to reduce uncertainty about the future course of costs and will give better access to the business cycle beyond 1996.

# Printing and publishing

## NACE 473, 474

Printing and publishing, with all its historical and cultural importance, is a mature sector of moderate and steady growth. The industry is currently undergoing a technological revolution which threatens the future of paper-based production, but the changes implicit in this process can only occur over a long timeframe. In the medium term the economic upturn and increasing demands for information in all its guises will underpin steady growth in output, particularly in the short term as Europe emerges from recession.

### INDUSTRY PROFILE

#### Description of the sector

The printing and publishing sector comprises all the stages necessary to transform a piece of creative work into a manufactured product available for distribution to the public. The finished products of the printing and publishing sector are diverse and include books, encyclopaedias, daily and periodical press, maps, and musical scores. The publishing sector overlaps into computer and other consultancy services which produce written reports and secretarial support services. Because of the diversity of the publishing sector and its close links with the printing industry, EU statistics cover both sub-sectors together.

#### Recent trends

In most EU countries, consumption and production in current prices nearly doubled between 1984 and 1993. Overall consumption growth slowed down in 1992 and was negative in 1993, reflecting the recession in the EU, but picked up again in 1994. The slowdown was particularly apparent in the UK, the largest printing and publishing producer in the EU. Growth in consumption in Southern European countries such as Italy, Spain and Portugal, on the other hand, held steady.

The EU trade balance with the rest of the world remains in surplus both in value and volume terms. Extra-EU exports have grown less rapidly than extra-EU imports, but from a much larger base. As a result, the extra-EU trade balance surplus has increased steadily over the last decade. In 1993, the value of EU exports in the printing and publishing sector was well over twice the value of imports.

Employment in the sector grew steadily from 1986 until the onset of recession in 1991 when employment peaked at 884 400. By 1994, it had fallen to an estimated 820 100. The USA remains the world leader in printing and publishing. In 1991, USA production was worth 36 % more than that of the EU and nearly twice that of Japan, which had the fastest growth during the 1982-91 period. However, the gap between USA and EU production is narrowing. Over the ten years between 1984 and 1993, production growth in constant prices in the EU was nearly 40 %, whilst the corresponding figure for the USA was 16 %.

#### Foreign trade

The EFTA countries (37.7 % share in 1993) have traditionally been the EU's main export markets in the printing and publishing sector, surpassing trade with the USA, whereas the latter is the most important source of EU imports (36.4 % in 1993). Intra-EU trade is growing compared to trade with the rest of the world. The accession of Austria, Finland and Sweden to the EU in 1995 will further increase the relative importance of intra-EU trade. Trade intensities are very low in the printing and publishing industry: the export/production ratio is about 4-5 %, and the import/consumption ratio is

Figure 1: Printing and publishing  
Value added in comparison with related industries, 1993

Source: DEBA

around 2 %. This reflects a number of factors. On the one hand, much of the output of the industry is based on locally or regionally articulated and specified demand preferences, whilst on the other hand major national markets are often dominated by large domestic business groups.

Although language considerations do predominate in matters of trade, new markets are developing as economic frontiers expand. Within the EU, wide use of the English language has allowed the UK to benefit the most from the Single European Market, closely followed by the Netherlands. The UK is becoming a crucial centre for European publishers, as well as an important entry point for North American printers and publishers wishing to establish themselves in the European market.

### MARKET FORCES

#### Demand

The potential market for the output of the printing and publishing sector in the EU is all persons above a very young age, reflecting the very low levels of illiteracy which prevail.

**Labour productivity, unit costs and gross operating rate (1)**

(1990 = 100)	1984	1985	1986	1987	1988	1989	1990	1991	1992	1993
Labour productivity index (2)	78.7	81.2	85.9	90.1	95.1	97.8	100.0	99.1	102.4	106.0
Unit labour costs index (3)	92.5	96.5	95.0	94.3	94.2	97.2	100.0	107.9	108.9	104.4
Total unit costs index (4)	82.9	86.8	86.6	89.3	92.6	97.0	100.0	105.6	107.0	104.7
Gross operating rate (%) (5)	11.8	12.1	13.5	13.2	14.2	14.0	13.6	13.2	13.5	14.1

(1) Some country data have been estimated.

(2) Based on index of production / index of employment.

(3) Based on index of labour costs / index of production.

(4) Based on index of total costs (excluding costs of goods bought for resale) / index of production.

(5) Based on (value added - labour costs) / turnover.

However, developments in the book, magazine and newspaper trade depend on a complex variety of factors. For private consumers these include economic and social aspects such as demographics, education, leisure trends, number of public libraries, buying power and financing possibilities ranging from sponsoring to advertising. Demand from the commercial sector is related both to the overall level of development of particular economies and current economic conditions. Print, in particular, is a sensitive indicator of economic activity and was an early harbinger of the recent onset of recession in the UK. While the publishing sector is the key market for printing output - newspapers alone account for 20 % of printing output - and is slightly less susceptible to the vagaries of economic cycles than other media, commercial printing for individuals, businesses, government and community organisations is also important. These markets are, on the other hand, strongly influenced by business cycles.

There is a positive correlation between the level of education attained, income levels, age and propensity to read. However, this varies across countries with the importance of these factors more evident in Southern European Member States where the market is less mature. For example, on average, 93 % of graduate Italians read regularly compared to a figure of 26 % for those less qualified. On the other hand, analysis in the Netherlands indicated that the aggregate explanatory power of sex, age, education, profession, income and wealth on book reading was low. Rather, it was concluded that there were people in all strata of society in the Netherlands who are intensive readers with others who hardly read at all. In general, it was found that females read more than males and people under thirty read more than their older counterparts. While growing female labour force participation has the beneficial impact of increasing household incomes, it will, however, create time pressures which reduces leisure time available for reading.
