Analysis of consumption trends for books reveals a marked difference between the South and the North, with Southern Europe characterised by relatively weak reading habits. The same considerations apply to newspaper reading and, to a much lesser extent, magazine reading. Books represent 27.5 % of leisure spending in Italy in 1991, compared with 18.7 % in 1981, but only 46 % of the population can be described as "readers", among whom 70 % read less than five books a year. In Spain 63 % of the population does not read for

leisure. However, with improved education and changing cultural habits the importance of reading in Southern Europe is increasing with the most committed readership among the young.

However, whilst changing cultural habits suggest continued growth in Southern Europe, slow population growth, the impact of the economic cycle and technological factors will be key variables influencing demand in Northern Europe. The ageing of the Northern Europe population will boost demand to the extent that the newly retired will have increased leisure time to devote to reading, but the decline in the younger age groups will impact negatively on demand. Stagnancy in new school entries intensifies this trend, as a reduction in the number of children has not been offset by a wider provision of education. The situation appears most favourable in the UK and France, where a slight rise in population is forecast. Meanwhile, the average birth rate in Europe has stabilised at around 11 per 1 000 population; the corresponding figure for the rest of the world is 26.

For a long time, children have been considered prime consumers: seen as the readers of tomorrow, they have spearheaded the youth sector as a major arena for socio-cultural activity. Educational success is a key factor for professional development and one of the main sources of parental concern. Encyclopaedias and dictionaries, as part of the educational publishing sector, also represent a rapidly expanding market. With the future health of the publishing sector, and by extension much of the printing sector, sector linked to overall levels of education, there is considerable potential for demand expansion in non-EU markets as levels of education and literacy improve world-wide. The impact of improvements in primary and secondary education in southern EU Member States on demand for publications is already indicative of this potential. Furthermore, third level education, which is increasing most rapidly in the less developed EU Member States is the most "intensive" in terms of publication requirements.

While reading ranks behind television and radio, nearly 50 % of Britons read one book per month. Despite such a high consumption rate, the level of buying is very low: of the 56 % of regular readers, only 60 % actually purchase their books. This situation is due to the importance of public libraries which are seven times more numerous in the UK than, for example, in France.

The impact of new technologies on demand for the output of the publishing and printing industry is multi-faceted. New technologies have opened up new markets both in terms of manuals and educational materials and in the way in which information is transmitted. As the benefits of advances of information technology become increasingly diffused across a wider population the market for "electronic" as opposed to "printed" information will expand. CD-based publishing is already relatively well established in educational and business subsectors and presents an increasing threat to the printing industry.

A CD-ROM (Compact Disc - Read Only Memory) is capable of storing up to 550 million characters - the equivalent of around 25 000 printed pages - and has become a vital storage medium for activities such as archiving, data banks, encyclopaedias and directories. Meanwhile, the CD-I (Compact Disk Interactive) has a storage capacity capable of storing and reproducing sound and images as well as text. The CD-I also permits interactive audio-visual applications via a simple remote control device. CD-I not only expands the possibilities for information transmittal for publishers, other applications of this technology also represent a competitive threat to the traditional leisure and business demand bases for printed materials.

Technological progress has also increased the capabilities of mainstream businesses (and to less extent individuals) to carry out printing jobs in their own offices (homes) which might otherwise have been contracted to specialist printing firms. These developments have however contributed to expanding the overall level of demand. Some of the "in house" printing being undertaken would not have occurred had the firms not acquired printing capabilities, whilst they often require extra inputs such as stationery, labels, compliment slips to facilitate their additional printing activities. The impact of technology on the quality and price of printed output has also stimulated demand. Far from leading to the "paperless" office, technology has to date led to increased consumption of printing materials. It has also led to a growth market in specialist magazines, manuals, etc. However, as discussed above, increasing diffusion of digital information and telecommunications technologies, and particularly the increasing use which businesses are finding for electronic communication methods, will place an upper bound on expansion of demand.

## Supply and competition

The European printing and publishing sector remains more a collection of national industries than an integrated European industry. This is evident from the small proportion of industry turnover accounted for by exports. Similarly, however, as is evident from rapid export growth, the industry is steadily becoming more internationalised.

The absence of an "international" industry is particularly evident in the printing sector where many contracts are small and often awarded informally to local suppliers whose track record is known. The need for frequent contact between purchaser and supplier also favours local producers as does the time-critical nature of much of the work. Technological advances, particularly in DTP (desk-top publishing) are also making it increasingly easy to enter the publications market with little capital outlay. Reflecting this, many printing and publishing companies in the EU are small firms employing less than 10 workers and few employ more than 500. Intergraf data indicates that in the printing sector in 1993, less than 1 % of the firms employed more than 500 workers, whilst 85 % of companies had less than 20 staff.

The multiplicity of languages in use across the EU provides a further barrier to Europeanisation of the industry. However, international publishing is growing particularly in English which as well as being an important first language is also one of the most important second languages in the world. This presents a market advantage to publishers in the UK (and the USA), reflected in its dominant position in the publishing industry, whilst the importance of Spanish, French and German (particularly in Eastern Europe) provides opportunities for operators in those countries. In contrast, whilst Italy has a well-developed publishing industry it is more or less confined to its national market.

In the European book market, stagnant sales in recent years have held down growth in the number of titles published and contributed to what some see as a crisis of over-production, resulting in a fall in the size of average print runs and contributing to price rises through increased unit costs of production. A recent study jointly undertaken by Intergraf and consultants PIRA (UK) indicates that in major European countries the average book run length decreased from 12 000 in 1985 to 9 000 in 1991, whilst the number of titles rose and overall production volume fell. Increasingly shorter print runs is a universal trend amongst other print media, as well as books. The share of new titles published is another indicator of book market vitality. Around two-thirds of titles published annually in the UK, the Netherlands and Spain are new titles compared with about a half in France and Italy and a third in Germany. Commercially, new titles are a high-risk area for publishers, whereas reprints reduce uncertainty and hold down fixed costs on a larger number of units over a longer period. The strategy of differentiation practised by the major publishing groups can be seen, to some extent, as "competition by attrition", with each publishing house attempting to secure maximum shelf space in retail bookseller outlets and, literally, crowding out its competitors.

Book publishing has been affected by developments in audio-visual media, but the press has been affected even more. While overall advertising expenditure, the principal source of finance for the press, has risen sharply over the last ten years, advertising spending in the newspapers has dropped continuously. In particular, press market share has been lost to TV advertising. Liberalisation of the broadcasting sector is an ongoing threat as governments loosen restrictions on advertising on TV and the importance of satellite broadcasting grows. On the positive side, for the publishing industry, as the number of available TV stations grow and audiences become increasingly fragmented, TV may become progressively less cost-effective as an advertising medium. Despite forecasts that dailies, weeklies and periodicals would disappear as a

**Figure 4: Printing and publishing**  
International comparison of production in current prices

Source: DEBA

result of the rise of audio-visual media, the principal newspapers have maintained profit levels. However, the role of newspapers is changing and whilst they continue to carry news increasingly their emphasis is on comment and analysis.

The growth of TV advertising also affects the printing industry directly. Intergraf estimate that almost two-thirds of turnover in the graphic industry depends either directly or indirectly on advertising with the result that the industry's development is susceptible to media advertising shares. Rising TV advertising share is not necessarily as gloomy a prospect for printers as it is for the press. While TV is used for awareness campaigns, printed mediums remain the key to dissemination of much of the background factual information needed to sell goods and services. Furthermore, market research and increasing ranges of electronic databases enable progressively finer market segmentation for targeted advertising using printed materials. Similarly, changes in the nature of press advertising have contributed to increased newspaper bulk with "advertising" features and inserts increasingly being used. Soft-sell publications, often provided for free (e.g. in-flight airline magazines), are also proliferating - Boots, the UK retailer and manufacturer, for example, is due to start publishing a quarterly women's magazine in 1995 which will "aim to apply Boots' brand values to a publication rather than a product".

The market for the press in Southern European countries remains relatively underdeveloped. Huge disparities are shown by the following figures on the ratio between daily newspaper circulation and population: Germany and the UK are the top ranking in the EU with 321 and 243 copies respectively sold daily per 1 000 inhabitants in 1992 against 122 in France, 88 in Spain and only 40 in Portugal. In addition, the press is highly competitive. In European countries on average, ten daily titles together account for more than 50 % of national circulation. This situation is most pronounced in the UK, where that percentage is reached by the combined circulation of only four titles.

As the 1990s progress the printing and publishing industry will be progressively challenged by technological developments. Given the enormous text and image data storage capacity and know-how of CD technologies, these will play a major role in shaping future markets for publishing and printing. The idea of paperless reference libraries or offices remains utopian, but the mere fact that this is the case and that movement in that direction has proved insignificant in the last decade is not a cause for the printing and publishing industries to be lulled into a false sense of security. Where CD-ROM copies of publications exist many businesses/institutions opt for them as a supplement to printed versions, but such instances are falling. This also appears to be the case among private consumers if the experience of Encyclopaedia Britannica is a guide. Available in printed, CD-ROM and on-line versions, sales of printed versions continue to rise with most people who buy a CD-ROM version also purchasing the printed set. The continued popularity of printed material even in "business" which can access the same information in electronic form reflects the level of familiarity which most people have with "hard" copy materials as opposed to their "soft" counterparts. It is likely to take considerable time before such attitudes are eroded and to this extent the view of the "paperless" office remains a concept which is beyond the medium-term horizon.

### Production process

The printing and publishing sector is characterised by strong value added and a high dependence on skilled personnel. In Denmark, where manpower is particularly expensive, printing labour costs represented about 38 % of total costs in 1993. This corresponds with 17 % of total costs in Portugal, a country with relatively low labour costs. Labour costs as a proportion of the total have, however, fallen across EU Member States. The fall is most evident in south European countries such as

Portugal where modernisation of the industry's technological base and the achievement of scale economies transformed the printing and publishing sector during the 1980s. The price of paper, the key input to the industry, was quite depressed until the second half of 1994 when it increased sharply following rises in pulp prices. Nevertheless, paper production has accelerated and could eventually stem price increases.

The main stages in the manufacture of a book are: editing the work following acceptance of the author's manuscripts; a technical stage where typesetting and pagination allow a calculation of the costs of production and the raw materials needed; return of the composed text to the publisher in proof form; initial correction; layout and illustration with preparation of a "dummy" copy for the printer; checking printer's final proofs; printing a determined number of copies; distribution of the requisite number of copies to points of sale; and acceptance of returns or unsold copies at the publisher's expense. A special feature of publishing is the cost burden of "returns", unsold copies. This burden is all the more difficult to bear in a period of recession. Publications which are not sold are burned and destroyed/recycled. In the book market part, of the problem is that available sales space tends to remain constant, whereas the number of titles on the market continues to grow. Inevitably, this disparity leads to a reduction in the time a book is on display, and its overall life-span. Volume and speed of returns have affected some book publishers disproportionately, with several experiencing rates of return over 60 %.

In the course of the last few years, computer-assisted publication (CAP) and desk-top publishing (DTP) have generated professional interests. As CAP is suitable to limited print runs it has proved particularly cost-advantageous to smaller publishers. Computerisation of design and manufacture has allowed considerable gains in time and cost, but CAP will add to salary costs in the short term, since the process requires new skills from the workforce. The Intergraf/PIRA report suggests that lack of suitably skilled personnel is likely to become a serious problem for the printing and publishing sector. On the one hand training may not keep pace with the industry's needs, whilst on the other the sector's image as "old and diminishing" will deter many "high calibre graduate personnel".

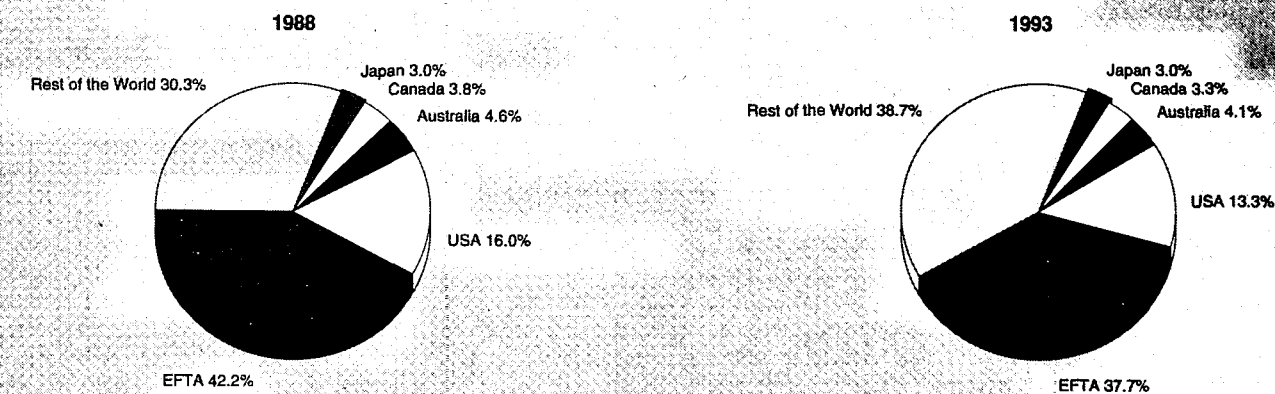

The growth of computer power is the major factor shaping publishing and printing technology in the 1990s. According to the Intergraf/PIRA study, in 10 years time computers are

**Figure 5: Printing and publishing**  
International comparison of production in constant prices

Source: DEBA

**Figure 6: Printing and publishing  
Destination of EU exports**

Source: Eurostat

expected to be 40 times more powerful at an equivalent or reduced cost compared with today. Software programmes are also being developed rapidly to utilise the associated increases in computer speeds and memory sizes. The digitisation of all means of communication is generating vast quantities of digital information which the printer needs to be able to process as an alternative to "camera ready copy". In these circumstances, pre-press systems have seen more rapid development than any other production machinery used by printers and publishers. At the pre-press stage, falling costs of equipment and simpler systems of monochrome and colour origination have been assisted by many new processes including Photo-CD, digital photography and colour calibration, high fidelity colour, stochastic screening etc.

At the printing stage, photo composition has replaced hot metal as the main technology. Press control systems, new and improved printing systems and electronic printing systems are developing rapidly, including automatic/computer make-ready, waterless litho, laser printing and plate-making, short run colour copiers and printers. The growth of computers' capacities are assisting these trends. Micro-publishing (desktop publishing) has also brought about considerable changes in the sector by facilitating PC-driven integrated text and image processing. These technological innovations imply improved qualifications for staff and increases in productivity. Labour productivity rose by 35 % in the ten years to 1993 whilst unit labour costs increased by just 13 %. In time, machines will be available which unskilled operators can use in offices to produce short runs of high quality colour print with clear implications for subcontracted out printing. At the same time this technology is opening up opportunities for small printers such as "network or in-plant" printers to large companies or groups of companies, and desktop publishing kiosk ordering systems in precinct locations where the customer does the job and pays by credit card.

Competing with printed media, digital electronic media (where information is held in digital form) are developing rapidly, including electronic books, prototype electronic newspapers, but above all new forms of published product such as CD-ROM and CD-I. For example, a 9-volume dictionary weighing 50 kg can now be captured on 6 cm disc weighing a few grams and the entirety of its information accessed in a matter of seconds. The main barriers to development are lack of software standardisation, a limited installed hardware base for CD-ROM drives and lack of good portable devices for reading digital media of all types, but in all these cases development is taking place and there are predictions that 40 % of all publishing revenues will come from digital media. The message is that

printers and publishers need to be closely involved in these developments.

Both the printing and the publishing industries require an increasing level of capitalisation, the best-known example is dictionaries and encyclopaedias, where long production and commercialisation lead times presuppose financial resources to absorb heavy cost burdens both during the period of investment and to cover the costs of promotion and publicity to launch the title on the market. These subsectors, however, are increasingly suitable for having parts of their production process sourced in lower labour cost countries.

## INDUSTRY STRUCTURE

### Companies

Europe's printing and publishing industry is highly fragmented. Most of the sector's constituent companies are small in size and serve local or regional markets. This is particularly true in the printing industry. There are, however, a number of major players whose activities involve both publishing and printing, as well as a wider range of economic activities involving paper-based and other media. The main groups such as Bertelsmann (D), Hachette (F), Pearson (UK) and the Anglo-Dutch group Reed Elsevier range even further afield. Pearson, for example, is heavily involved in the tourist sector. Other important companies include Groupe de la Cite (F), Mondadori (I), Watmoughs (UK), Wolters-Kluwer (NL) and VNU (NL). Axel Springer (D) top PIRA International's listing of Europe's top newspaper groups. Non-EU multi-media groups such as Time-Warner (USA), Paramount (USA) and News Corporation (AUS), with a presence in all the main mass media markets (books, cinema, television, press), are all extensively involved in EU markets.

The trend towards concentration by acquisition and merger is not equally marked in all countries, but it is growing everywhere. It has been most evident in the UK, where the aim is more to secure economies of scale in the domestic market than to expand internationally. However, there are important exceptions, for example, EMAP's (UK) 100 million ECU deal with Edition Mondiales (F).

### Strategies

The two main aspects of strategy are concentration and globalisation. Publishing groups are developing both vertical (publishing and distribution) and editorial (diversification) strategies in these new areas as well as in traditionally profitable areas, the net result being to favour economies of scale.

Scale is not the only motivation, however. Other reasons for media company expansion are the exploitation of trade-marks or other kinds of intellectual property, the desire to become multi-media firms utilising a range of technologies, particularly those which may create new markets, and a desire for geographical diversification as protection against cyclical domestic markets.

Mixed books/press houses are becoming more numerous, as a result of a growing synergy between the two activities: newspapers and magazines remain the most reliable media for book promotion. However, small publishing houses have a capacity for creativity and flexibility which allows them to stay in the market. In addition, the nature of the market, both in terms of technologies which facilitate small scale production and geographically defined niche markets, will continue to enable small firms to provide the bulk of the industry's firms, particularly in printing. While the impact of the Single European Market has accelerated the trend towards larger groups, change is not particularly rapid. Where there are casualties they tend to be medium-sized, rather than small companies. Recognising the growing importance of international links within the overall European market, Intergral have established a service to facilitate cross-border co-operation between small and medium-sized printing firms.

Globalisation strategies are generally pursued by way of subsidiaries or by acquisitions. In practise, publishing groups - acknowledging their limited knowledge of international markets and the cultural differences implicit in language and business practices - are more likely to expand by acquisition rather than by industrial or commercial means. Bertelsmann and Hachette are the most international of the major global groups but are being joined by groups such as Pearson and Reed Elsevier, which are diversifying away from their current Anglo-Saxon orientation. However, there is still a considerable emphasis on expansion by the latter companies in North America, particularly in electronic publishing where Reed Elsevier is making large acquisitions in the USA.

Major EU publishing and printing firms are now looking beyond their own national boundaries for less expensive methods of production. Thus, in sectors where time is not one of the critical factors, where economies of scale are important and transport costs form a relatively low proportion of output value, European companies have been sourcing production, or parts of production, elsewhere. This has favoured the subcontracting of work such as mail order catalogues, although advances in digital technologies which allow rapid and high quality transfer of images may open up additional niches in

the medium term. UK companies have favoured locations such as Singapore and Hong Kong. German companies have been looking towards Eastern Europe and firms in all Northern European countries have transferred capacity to Mediterranean Member States such as Portugal and Spain. Alongside rapid production growth, consumption in these two Member States also grew rapidly during the latter half of the 1980s and into the 1990s, thereby increasing their attractiveness for investment by Northern European firms. While the pattern established in Portugal and Spain may be followed in East and Central Europe, plants in these countries are well behind EU technological standards.

The Single European Market is obliging publishers to consolidate their positions in Europe: what is at stake is not so much Europe itself, but the principal European languages which predominate on world markets: English, Spanish, and, to less extent, French. With the growing importance of Eastern Europe, the importance of German is also growing. Expansion both in Europe and throughout the world is nevertheless limited by the national character of information.

### Impact of the Single Market

Most regulations in the Internal Market programme are of some relevance to the printing and publishing industries. However, because of the importance of local markets to many printing and publishing companies and because of the existence of language barriers their impact has been fairly muted. Reflecting this, horizontal policies relating to consumer protection, competition policy, SMEs, the social dimension, environment and training and education are considered by the industry associations to be of the greatest relevance to their members. Apart from horizontal policies, most other measures considered important to the publishing and printing industries are either under discussion or remain in the pipeline. These include liberalisation of telecommunications services, liberalisation of broadcasting, the harmonisation of VAT rates on newspapers and other publications and the issue of uniform postal rates for publications material across the EU. A key influence of the Single Market programme on the European printing and publishing industries has been the cumulative effect of ongoing integration of the EU market. Among the major players, this has reinforced the trend towards globalisation, while among smaller companies European issues have become more important and contacts between firms in different EU markets have increased.

**Figure 7: Printing and publishing  
Origin of EU imports**

Source: Eurostat

The production processes of the printing and publishing industries are relatively non-polluting. Nevertheless, firms in the industry are responding positively to environmental pressures to make their operations more environmentally friendly. This includes the introduction of new technologies aimed at reducing the amount of solvents used (both in inks and cleaning fluids), limiting VOC (volatile organic compounds) emissions from web-offset printing, more environmentally sensitive handling of liquid waste, encouraging the recycling of other waste and greater use of recycled paper. A key improvement in production technology has been the shift towards dryer and cleaner technologies and use of more environmentally-friendly inks (e.g. vegetable-based). The EU Commission is currently considering studies on emission controls/solvent recovery in the printing process and on water pollution and disposal of toxic wastes in the printing industry.

Recycling is only one of the pillars of the EU strategy towards conserving natural resources, with reduction in use being regarded as equally important. Legislation, such as the Directive on Packaging and Packaging Waste, is based on the philosophy that packaging, and hence printing output, should be reduced, as well as encouraging recycling. Total yearly paper and board consumption in the developed countries in 1993 was around 220 kg per person. Demand in the developed countries for paper and board is projected by the FAO (Food and Agricultural Organisation) to increase from 194 million tonnes in 1991 to 310 million tonnes in 2010. In 1993, Western Europe used a total of 30 million tonnes (including 26.8 million tonnes in the EU) of graphics papers, of which newspapers consumed 8.2 million tonnes. Of the remaining 21.8 million tonnes, the approximate breakdown is: books 1.5 million tonnes, magazines 5 million tonnes and advertising, free sheets, directories and catalogues 15 million tonnes.

The use of recycled paper is increasing. The publishing industry is itself involved in the debate about collection and recycling. Research is being carried out, not merely on how to increase paper recycling, but to analyse the overall environmental economics of the paper chain. New areas of interest include the valorisation of the energy content of paper fibres that have undergone different life cycles and have lost their useful mechanical properties.

Figure 8: Printing and publishing Trade Intensities

Source: DEBA

There are no regulations at EU level which pertain specifically to the printing and publishing industry although this is not the case at national level. As a cultural product, books ought to remain affordable to consumers. For this reason, most European countries apply various forms of resale price maintenance. Portugal being a notable exception. For example, in the UK, the Net Book Agreement governs the fixing of book prices and it is for the publisher to decide whether its books should be sold at a free or an imposed price. In Germany, publishers themselves operate the rules on price fixing and bookshops are bound by collective contract with 1 700 affiliated publishers to respect the fixed cover price. A similar arrangement operates in Italy. In France and Spain, legal provisions exist to enforce the obligation to sell at the published cover price. Such measures are important to the continued existence and development of the distribution networks needed to keep books available to the public and, by extension, for the survival of literary creativity in all its diversity.

Books, newspapers and magazines also benefit from zero (Italy, Portugal and the UK) or low rates of VAT in a number of EU Member States. Another key benefit in some Member States is preferential postage rates. Harmonisation of VAT rates across the EU was postponed from January 1992 until at least 1997 and the present differences in taxation policy with some zero-rate strongholds may come to an end if the EU were to decide to harmonise the rates applicable to publications. The industry is currently lobbying to safeguard the possibility of having zero VAT on printed products.

Competition in the printing sector is sufficiently strong not to attract the interests of EU competition authorities. However, there is growing concern both within some Member States and at the EU level about concentration of media ownership. In Ireland, for example, the government recently intervened to curtail Independent Newspapers increasing its dominance of the Irish Sunday newspaper market. At the EU level, rules are likely to emerge defining permitted levels of media concentration and proposing criteria for approving major mergers and take-overs. Finally, the development of EU regulations on media concentration as well as EU research programmes may influence the way the European media houses adapt to technological change and become competitive multimedia operators.

OUTLOOK

The publishing sector is best described as a mature sector with growth on a moderate upward trend. Because of its peculiar mix of historical and cultural factors, some publishing sub-markets are relatively immune from economic swings. The cultural habits of consumers are the key to future development in the sector. Its evolution depends on socio-economic factors such as demographic trends, education, industrialisation, political trends (as in Spain, Greece and Portugal) and, not least, tradition.

For over a decade it has been forecast that the demise of publishing and printing sectors was nigh as information technologies gathered speed. Into the 1990s the convergence of computer, telephone and television technologies has further fuelled this prognosis. Printed media are, and for the foreseeable future are likely to remain, the major players in the communications market. They currently represent around 60 %, by value, of the total consumption of communications media in Europe. The relative cost of distributing publishing products via a growing range of rapidly developing electronic media is becoming increasingly important, as are also the cost-related issues of waste reduction and environmental management. For publishers, the message is that the medium for communicating will change and there is a need to reformulate expansion strategies based on print to take account of screen-

Source: DEBA

based media. A report for DG XIII of the European Commission predicts that the electronic publishing market in Europe will be worth 12 billion ECU by the year 2000.

However, whilst information technology races ahead, corporate and individual consumers take time to adjust, not just to the new leisure and information possibilities offered, but to acquire a familiarity which allows them to forsake the printed products which have dominated their normal needs in this regard. To date, information technology advancements have complemented rather than substituted for the written word. In fact, those countries which have emerged as the prime consumers of images are also those which remain most attached to the written word. The application of new technologies in publishing - either as production aids or as new media per se - is still at an embryonic stage.

New products derived from books or developed from synergy between different media - sound, images, text and data - can be expected to multiply and stimulate global markets. As businesses and other consumers become more familiar with emerging information technology applications, the rate of substitution of electronic means of communication for paper-based media will increase. The emergence of this new information-driven economic paradigm, however, remains sufficiently unclear to preclude firm predictions on its net impact on printing and publishing. For example, there is little doubt that alongside the growing importance of digital technologies the demand for "information" itself will also expand rapidly. The synergies between traditional publishing activities and the demands of the users of new information technologies will also encourage the major firms in the industry to diversify into relevant information technologies such as "electronic publishing".

In terms of printed product sectors, prospects vary. The electronic media are likely to impact on corporate sector printing the most, hitting business forms in particular. A second area where they are vulnerable is books, particularly reference books, educational text books, coffee table books as a source of information and technical documentation. Newspapers will tend to acquire the characteristics of periodicals and both will develop fax and other interfaces with electronic communications. Promotional printed products will be impacted in a limited way by their delivery by fax and by electronic shopping, with catalogues probably the least affected, and advertising in newspapers and periodicals the most. In all of these cases, of course, the message is that publishers need to deliver their products across a wide and changing spectrum of media, and printers need to collaborate closely with them. The most promising subsectors of the publishing industry are those connected with knowledge itself - teaching, professional training, business information and specialised interests. Product markets which will gain include dictionaries, encyclopaedias, textbooks, practical guides and books, research reports and special interest publications. As the importance of post-compulsory education and training, both for adults and post-secondary students, increases across Europe, and service industries, particularly knowledge-based ones, continue to expand, so will the demand for information in all its guises.

In the medium-term the ongoing economic recovery in Europe, and indeed throughout the world economy, will contribute to relatively rapid growth in consumption and production. Reflecting the increasing internationalisation of the sector, exports are expected to outpace production growth. However, with the accession of three new Member States in 1995, the importance of intra-EU trade will grow substantially at the expense of extra-EU exports. Abstracting from the statistical implications of the accession of these new members, the EU's trade surplus in the publishing and printing sector will expand.

# Printing

## NACE 473

Comprising more than 60 000 firms and employing some 1 116 000 people, the graphic industry in the 15 countries of the Community handles a turnover of over 75 billion ECU. The industry consists mainly of small enterprises, as 85 % of them employ fewer than 20 persons. The graphic industry is a modern, high-technology industry which, by keeping up with the latest manufacturing processes and investing heavily in new machinery over the last few years, has placed itself at the forefront of technical progress. Image processing in modern printing is now carried out by computer or computer assisted equipment, requiring highly-skilled workers.

### INDUSTRY PROFILE

#### Description of the sector

Printing firms produce a wide variety of products ranging from visiting cards printed in one colour to bulky, four-colour direct mail catalogues. The smaller firms work mainly with local clients for whom they produce personal or commercial printed matter whereas bigger firms often deal with a more widespread clientele and supply for example printed advertising material, books or continuous stationery. Besides their printing activity some large enterprises run a publishing house specialising in newspapers and magazines.

In some countries of the Community, some larger firms involved in gravure printing produce catalogues, magazines and advertising material for the international market. The majority of printing companies operate however on a local or regional market as a consequence of their size and their products.

#### Recent trends

Production and employment figures in the printing industry have been decreasing since the beginning of the nineties as a consequence of the world-wide recession. The printing industry was affected by the decline of the economic activity to the same degree as other industry sectors on which it depends for its orders. In most West-European countries the worst seems to be over and growing trends can be perceived.

There are however persisting uncertainties, linked to increased competition and the sensitivity of customers to pricing policies. The narrow margins are worsened by the difficulty for printing companies to transfer the higher cost of raw materials, particularly of steadily increasing paper prices, on to the price of finished products.

#### Foreign trade

No detailed figures can be given on foreign trade for graphic products nor on the trade structure because foreign trade statistics do not distinguish between the trade of printing firms and that of publishing houses.

The production of graphic products in EU-Member States is mainly determined by the internal demand. The export rate, that is the percentage of the industry's turnover achieved by exports, is in general below 10 %. This relatively low rate is due to several characteristics of the industry, such as the need for frequent contacts with the client, the great need for communication during the work, linguistic barriers or the relatively high costs of transport. Exports concern mainly large runs or special contracts, such as catalogues or other printed advertising material, books or magazines. Exports are in general made by a small number of large firms working in gravure or web-offset.

Most of the external trade with non-EU countries is done with other Western European countries. The amount of printed work done by EU-printers for outside clients has increased considerably in recent years. Trade with Eastern countries remains low but is expected to develop in the near future. Exports to non-EU countries are about twice as important as imports.

### MARKET FORCES

#### Demand

In the graphic industry there is a direct link between demand and production, because this sector supplies mainly to order or to long-term contracts in the case of publishing and packaging. Printing firms are rarely able to manufacture for stock as other industrial sectors can.

Demand for printed products is influenced by a number of demographic and economic factors such as population growth, composition of households, training and education as well as economic growth. The graphic industry, just like the publishing

Source: Intergraf

sector, is above all a supplier of products which disseminate information and knowledge and cater for leisure activities. Its role stems from its cultural, intellectual and educational vocation within the context of the exchange of ideas and information in democratic societies. Despite the low growth of population, the number of households and managerial jobs continues to grow as does the proportion of income available for education and information. All this continues to stimulate the demand for newspapers, magazines, periodicals and books. Consequently, the number of books printed has never been so high. New technologies have opened up new and ever growing markets, such as for computer manuals and educational material.

Advertising expenditure by trade and industry is one of the most important factors influencing demand and production in the graphic industry. Almost two thirds of the industry's turnover depend directly or indirectly on advertising. Any political decision affecting advertising, in general or in particular also affects the graphic industry and consequently can jeopardise employment.

The printing of catalogues, advertising brochures, pamphlets and company reports, as well as advertising inserts in newspapers and magazines, are steadily increasing.

Another determining factor for the graphic industry are orders for printed products either for private or commercial use. This market includes for instance visiting cards, tickets, note-paper and all kinds of forms. The majority of small printing firms produce such printed products for local circle of private or business customers, such as authorities, small trades, industrial or commercial companies. These printed products in single sheets remain an important and stable market segment.

Forms produced as continuous stationery - with a side perforation intended to adapt to the printing units of computerised

systems are generally produced by larger printing houses, which operate on a trans-regional market area. Production for this market declined however over the last years and trends are expected still to worsen considerably. The market for this kind of forms is adversely affected by the growing use of laser printers, desktop publishing systems, and of electronic data interchange (EDI). To ensure the maintenance of a reliable market, forms producing companies have to offer customers flexible and multi-functional products by mixing, coupling and combining documents using the new IT, IC and digital printing technologies. Developing niche services likely to bind customers to the printer is the key for success.

Labels, printed packaging products, wall calendars, illustrations and postcards form another sector of the graphic industry. These products are often printed by specialised firms.

The upward trend in overall demand has been stimulated by the development of both new and existing products. At the same time, printers are trying to cater for special requests. Quality standards reached by printed products considerably rose. Multicoloured pictorial information is increasingly required for advertisements, magazines and company reports, and newspapers are now also making a considerable use of colour printing.

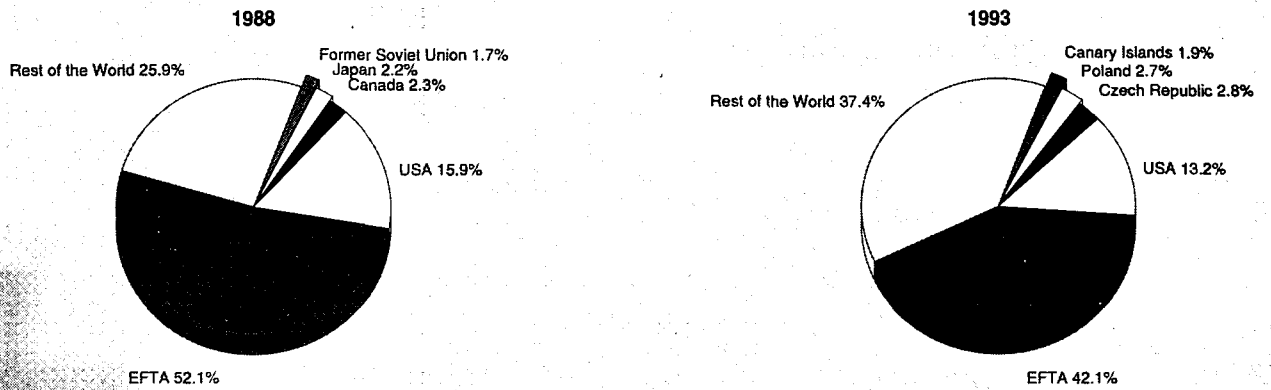

Information needs are satisfied by an increasing variety of electronic means and communication devices. Nevertheless, the permanence and high degree of information stored in the printed product have enabled it to retain its position as a simple, easily accessible and efficient means of communication. In future specific information will also be conveyed via electronic media, either by means of diskettes or CD-ROM, or via data transmission networks (ISDN), as it is the case for on-line data banks and E-mail (electronic mail). In some countries, Italy for instance, tariffs applied by the State, in

a situation of monopoly, are very low and cause a fast shift of economic operators towards electronic mail.

Multimedia is also to be mentioned among the new communication media. It presents information involving text, images (static or in motion) and sound (speech or music). Multimedia is consequently the meeting point of many skills in the various communication services, and printers will increasingly have to find their way in new partnership circles.

These new forms of distribution and presentation of information have a direct impact on some products of the printing industry. For instance, some kinds of books (encyclopaedia, directories, scientific or legal reference books) are also available on CD-ROM. It is also the case for some magazines or catalogues. On-line data banks increasingly make available similar information to the one provided by printed products. Although a few printed products are expected to be replaced by these new media, in most cases the new media will be complementary to the printed products. Opportunities for new markets can consequently be expected for printing companies.

**Supply and competition**

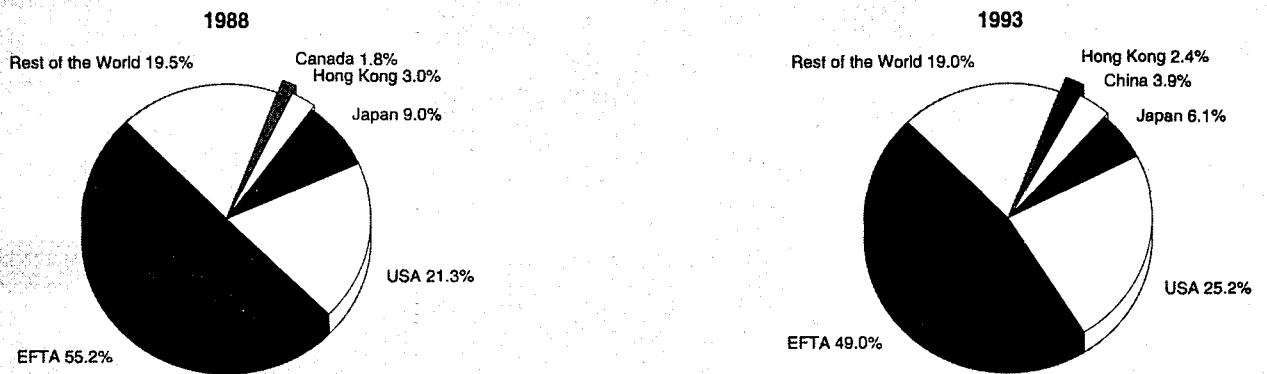

Publishers remain one of the printer's main clients, and account globally for about 40 to 50 % of production.

The printing of newspapers is almost exclusively carried out for publishing firms. Furthermore, in this area, publishing houses and printing houses often form a legal entity and belong to one owner. The printing of newspapers accounts for just under one-fifth of the total printing production.

Publishing houses are also important clients of magazine printers. In countries such as Germany, consumer magazines are often produced by printing houses which are owned by publishing houses. In other countries, United Kingdom and France for instance, such a situation is rare: printing and publishing represent two distinct and different activities. These publishing houses are increasingly operating on international markets. Other types of publications, such as specialised periodicals - religious, scientific or trade magazines - are printed for independent publishers or for publishing houses linked to printing houses. The production of periodicals accounts for just under one-fifth of the total print production.

Book printing follows a similar pattern. Orders for book printing, paperbacks or hardbacks, do not come exclusively from book publishers - independent or linked to printing houses. Industry, public authorities and other organisations are also regular customers. Book printing accounts for about one-tenth of the total printing production.

The market for printed advertising material consists of a wide range of goods, such as direct mail catalogues, prospectuses, advertising inserts, posters or leaflets. The structure of this market is as diversified as its products as a large proportion of the clients are made up of direct mail companies, commerce and industry. Political parties and other organisations are also big consumers of printed advertising material. This sector has grown considerably over the last few years, stimulated mainly by the development of new forms of advertising, such as direct mail. The production of printed advertising material accounts for a quarter of the total printing production.

Printed matter for individuals and professionals is often taken on by the small printing firms. These cater for the municipalities, various organisations, industry, commerce and local individuals to whom they supply visiting cards, business forms, headed paper, invoices and also possibly transport tickets. These small firms often print in single sheets. Larger, or more specialised firms deal with continuous printing and produce different types of continuous forms, completed on computer by the clients themselves. Some highly specialised firms are involved in the production of another category of printed products, i.e. security printing. The production of such printed matters accounts for about one-fifth of the total printing production.

Printing production also includes various products such as calendars, fine-art prints, postcards and greetings cards, cartographic products etc. Alongside these products the sector also produces rubber or polymer stamps, reprographic products such as photocopies, overhead foils and microfilms.

Services such as the design of printed matter and the production of layouts and dummies are also offered to the client. In the future, firms which will offer new services through desk-top-publishing processes will complete the existing structure of the graphic industry.

#### Production process

Current developments in the industry indicate a close link between the printing sector and progress in communication and information technologies.

Innovations in equipment and graphic machinery have put the printing industry in the forefront of technological progress. Equipment has therefore a major impact on the type, the quantity and the flexibility of the work carried out, as well as on the professional skills and the organisation of the work in general. Many aspects of the print production process are now commonly automated, measured and controlled by computers. In the last few years, there has been a substantial

increase in investment in new printing machinery in several Community countries.

There have been particularly fast changes in the pre-press sector. Even small printing and reproduction firms now use totally electronic pre-press systems.

New digital colour printing machines are gradually being introduced in workshops. This new type of machinery is mainly intended for 4-colour short runs up to DIN A3 size. Such colour presses are likely to affect the printing-on-demand market segment for existing products such as advertising material, and also to enable the emergence of markets for new products and new services.

Digitalisation is also increasingly applied to traditional presses and finishing equipment. Microprocessors allow for the operation of presses, as well as for measurement and control functions. Technology and know-how developed by machinery manufacturers are exploited world-wide. The printing industry in almost all West-European countries operates consequently under rather similar technological conditions.

The use of electronics in information and communication now plays a significant role on the whole printing process. A particularly significant effect is that the transmission of information from client to printer is now in most cases carried out through electronic media. The transmission of information within a printing house - for example, in newspaper printing, from the editing department to the printing floor or in the case of magazine printing, from one printing department to another - has become quite common.

On the other hand, publishing firms have tried to evaluate the impact of this new technology in communication on printed products and are looking into ways of becoming more involved in these areas. Publishers and printer/publishers have often invested in such areas as data-processing units, data banks, videotext and even local radio stations, whereas the printers tend to remain faithful to purely technical operations.

## INDUSTRY STRUCTURE

### Companies

The graphic industry in the Community, is made up of small and medium-sized companies. A typical printing firm employs fewer than 20 employees, as some 85 % of all the firms belong to this category. The remaining 15 % are essentially firms employing between 20 and 500 workers. Only a very small number of printing firms employ over 500 workers; in Germany this category stands for 0.3 % of all the firms and this percentage is even lower in a number of other countries.

### Labour and training

Printing has traditionally been a high wage industry, reflecting the above-average levels of skill required from its labour force. Printers have also often been among the first to benefit from improved working conditions - shorter hours, longer holidays and other advantages. In half the Community countries the working week is 37.5 hours or less. In most other countries it is below 40 hours. Only Portugal still has a basic week of 43 hours. German printers already enjoy 6 weeks annual holiday and in five other countries they have at least 5 weeks.

At the same time, wage costs have a considerable impact on total production costs and have even increased in the last few years. Furthermore, important investment costs need to be made to ensure that the necessary qualified personnel is available. Despite all this and the swift technological developments in recent years, which have enabled the emergence of new markets, employment has remained relatively stable in the graphic industry.

Training goals have been adapted everywhere over recent years to attract trainees with the necessary qualities to the industry, to give them broad-based knowledge of new technologies. Printing technology, which has undergone great changes in the last quarter of a century, is still evolving to become faster, more automated and better controlled with the help of electronics. The industry's labour force has to be receptive to continuous training to adapt to changing techniques with a view to greater flexibility, in which print workers are not limited to a single speciality.

## ENVIRONMENT

The European Graphic Industry is an industrial branch which has only a marginal impact on the environment. Nevertheless, the industry is devoting increased resources to meeting the stricter environmental requirements. For example, it has invested large amounts of money to limit emissions caused by web-offset printing, to improve the quality of water and to encourage the recycling of waste.

In some EU-countries the graphic industries federations collaborate closely with government departments to agree on the best measures for environmental protection. At international level, the international association for the graphic industry, Intergraf, is co-operating with the EU-Commission to define appropriate directives in this area. To maintain fair competition, the Single Market requires the harmonisation of legislation in all EU-Member States, particularly in the field of the environment. The graphic industry considers it has a responsible role to play in safeguarding the environment and therefore our living space.

## OUTLOOK

Further developments are expected in the future as a result of the structural changes in communication media. Innovations in information technologies call for deep modifications in organisational structures.

This new phase of development in the printing industry reminds us in some aspects of the deep changes occurred in other periods of economic-industrial history. The transition period is once again marked by recessive effects leading to reductions in employment and drastic re-organisations.

Technological progress leads towards a new configuration of the communication industry as a whole, and to new types of relationship with the printing industry. The new communication techniques reduce the distance between the printer and his customer, facilitate and intensify data transfer.

Frontiers are expected to fall down: between suppliers and users, between specialised markets and mass production. A new industry is emerging: the "digital printing" industry.

However, printed products will continue to be more than ever a communication means oriented to the future. The graphic market is innovative; graphic products perfectly meet individual needs and respect the environment.

## Rubber products

NACE 481, 482

After the economic recession and the resulting production losses, demand for rubber products is showing some signs of recovery, leading to increasing sales of car tyres. The European manufacturers will increasingly come under threat from non-EU suppliers of cheaper brands. This will put further downward pressure on prices and profit margins. In order to stay competitive, the industry must continue its current strategy of cost reductions and development of new product and processing technologies. For 1994 a small increase in EU consumption was estimated. In the period leading to 1998 modest growth rates are forecast as the economic recovery is expected to persist.

### INDUSTRY PROFILE

#### Description of the sector

The rubber industry comprises two main subsectors, the tyre and inner tube industry and the manufacture of industrial rubber products (also including some rubber consumer products).

The tyre and inner tube industry manufactures tyres and tubes for passengers cars, trucks and buses, agricultural vehicles, earth moving and mining machinery, bicycles and motorbikes, and other applications.

Industrial rubber products include pipes, hoses, sealings, belts, profiles, foam, soles, adhesives, etc. which are manufactured for such end-markets as vehicles, machinery, electrical engineering, construction, the chemical industry, the food and drink industry, the medical sector and sporting goods.

The rubber industry is related to the plastics processing industry (NACE 483). Both process polymeric material based on hydrocarbons. The larger enterprises in the sector of rubber products are often also active in the plastics processing industry. The processing machinery for both sectors is similar, with the exception that the rubber industry also uses mixing equipment because the raw material is mixed by the product manufacturers.

Compared with the processing of plastics and other related industries the manufacture of rubber products is a modest-sized industry. In 1993 the processing of plastics and the manufacture of basic industrial chemicals created a value added of 29 and 34 billion ECU respectively, compared to 12 billion ECU in the manufacture of rubber products.

Germany is by far the leading manufacturer of rubber products within the EU, accounting for about 30 % of total EU production. France is the next largest producer constituting 24 % of production, and the United Kingdom ranks third with a share of 14 %.

The production of tyres accounts for about 60 % and industrial rubber products for 40 % of the total rubber products output in the EU. As relatively more information is available about the European tyre market more attention is paid to that segment in this monograph.

#### Recent trends

In the 1980s the market for rubber products was affected by intensifying competition, technological progress and environmental concerns. EU production in current prices increased at an annual rate of 4.5 % between 1983 and 1992. In constant

Figure 1: Rubber products  
Value added in comparison with related industries, 1993

Source: DEBA

prices however, total production only increased by 1.2 % per annum in the same period. Demand expanded at a slightly higher rate than production, resulting in imports growing faster than exports. Due to the low output growth and rationalisation in the industry, employment declined from 1989 onwards.

In 1993 the economic downturn resulted in further drops in production, consumption and employment. The recession was especially felt in Germany where production declined by 12 %, resulting in a drop in employment of 10 000 people. Production decreases were also substantial in Italy (-11 %) and the United Kingdom (-5 %). In 1994, however, the market for rubber products improved. For the EU as a whole a production increase in current prices of nearly 6 % is expected.

#### International comparison

Measured in production value the EU has become the leading producer of rubber products in the world, followed by Japan

 Source: DEBA

and the USA. In 1984 this position was occupied by the USA. Although the Japanese production of rubber products has recorded relatively high growth rates during the 1980s, Japan still ranks third after the EU and the USA.

The USA is by far the largest consumer of rubber for tyre manufacturing, with a consumption estimated at 1 771 thousand tonnes in 1994. Japan follows with a consumption of 913 thousand tonnes. Within the EU, France is the major consumer with an estimated 335 thousand tonnes, followed by Germany (281 thousand tonnes), the United Kingdom (166 thousand tonnes) and Italy (137 thousand tonnes). Also in consumption of rubber for non-tyre products the USA has by far the largest requirements, at an estimated 1 337 thousand tonnes for 1994. Synthetic rubber mainly finds its destination in tyre manufacturing. Therefore production is concentrated in the countries mentioned above. The production of natural rubber, on the other hand, is dominated by Far Eastern countries, such as Thailand, Indonesia, Malaysia, India and China.

In the EU the car production and the accompanying sales of original equipment tyres (OE) has recovered in the course of 1994. For instance, in the first 6 months of 1994 German car production was 6 % higher than in the same period of 1993. Sales of replacement tyres and the manufacture of non-tyre rubber products also showed signs of recovery in the course of 1994.

**Foreign trade**

The EU is a net exporter of rubber products. In 1993 extra-EU exports reached nearly 4 billion ECU, whilst imports totalled over 3.1 billion ECU. Germany is the largest exporting country with extra-EU exports of over 1.3 billion ECU, representing one third of total extra-EU exports. German intra-EU exports, equalling 1.6 billion ECU, are even higher. The same picture applies to German imports. Extra-EU imports amount to just over 1 billion ECU, whilst intra-EU imports reached nearly 1.7 billion ECU in 1994.

The EFTA countries are the most important export markets of EU rubber products, accounting for roughly one third of total extra-EU exports, followed by the USA, Japan and the OPEC-countries. Furthermore, the growing importance of East European countries is worth noting. Within the EFTA, Austria, Sweden and Switzerland are the major foreign markets for EU rubber products.

With respect to EU imports, Japan is the major supplier of rubber products accounting for nearly 20 % of total extra-EU imports. The share of the EFTA-countries decreased significantly from 1987 to 1992 and became eventually lower than Japan's. In 1993 the EFTA countries Austria, Sweden and Switzerland together constituted about 18 % of EU imports, followed by the USA with 14 %. Malaysia has become a major supplier of natural rubber. During the 1987-93 period this country has more than doubled its share on the European market, and in 1993 accounted for 8 % of total extra-EU imports.

## MARKET FORCES

### Demand

Over the period 1984-92 demand for rubber products increased at an average rate of 4.9 % per annum. In 1993 the industry

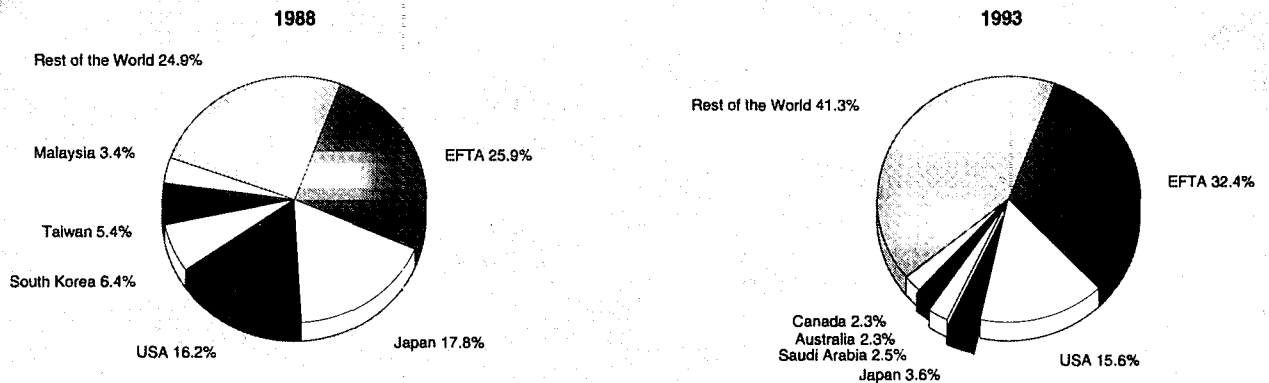

demonstrated its cyclical character, as sales were hit by the recession in major client industries. The fall in car production was the single most important factor behind the 7.4 % drop in rubber products sales in 1993. As a result, consumption in real prices only recorded a meagre annual growth rate of 0.98 % over the period 1984-1993.

The problems on the car market have forced the car manufacturers, the major client industry for rubber products, to rationalise production and lower costs. Moreover, cars are more and more tailored to the requirements of the end-user. This entails the production of many different types of tyres, which also last longer. Due to technological progress in materials the production of radial tyres with warranties of 80 000 miles has become possible, whereas 40 000 miles was customary only a few years ago.

Industrial products account for 40 % of the volume of total EU production of rubber products, while tyres account for 60 %. Sales values, however, are about the same for both sectors owing to the higher specific value of industrial products.

The European market for tyres can be subdivided into tyres for original equipment (OE-tyres) and tyres for replacement. In 1993 almost 33 % of tyre sales were OE-tyres and 67 % consisted of replacement tyres. The European tyre market

**Figure 7: Rubber products  
Origin of EU imports**

Source: Eurostat

can be further subdivided into car tyres, truck tyres, farm tyres and motorcycle tyres. Car tyres account for nearly 92 % of total tyre demand. Truck tyres constitute 5 %, followed by motorcycle tyres (2 %) and farm tyres (nearly 1 %). The remainder is made up of bicycle tyres, tyres for earth movers and tractor graders, industrial tyres and deep-loading trailer tyres.

An important segment of car tyres is formed by the market for winter tyres. These tyres represent 10 to 12 % of replacement tyre market shipments of new car tyres (between 13 and 15 million units). This segment is characterised by accelerating development and competition. Technological developments include the use of new compounds for winter tyres.

On the market for passenger car and light truck tyres a proliferation of brands and micro-segmentation has taken place in the recent past. In the economic recession demand for and supply of lower-priced products has increased. These products are either private brands from a host of sources, affiliate brands of major companies, or new brands coming from the Far East or from East Europe. House and private brand tyres account for only 10 % of market demand, but their share is rising.

### Supply and competition

The supply of low-priced tyres has expanded in a period when industry-wide utilisation of capacity was below 80 %, prices were under pressure, and OE production was a money loser. The resurgence of private brands and emergence of affiliate brands can be traced to the early 1990s when the major tyre makers instituted price increases across Europe of 10 to 12 % on their main product lines, thus creating a market opportunity for lower-priced products. These market opportunities have been picked up by new brands coming in from the Far East and Eastern Europe, but also by private brands from a host of sources, or affiliate brands from major companies. Goodyear (USA) and Pirelli (I), in particular, have been very aggressive in courting private brand business. The introduction of many new products into lower end price-conscious segments raises fears that prices across the range of products will be dragged down, and the difference between standard and premium products will become blurred.

The increasing share of imports in total EU consumption reflects the growing supply of non-European tyres. Over a 9 year period import penetration increased from 7.2 % in 1984

to 12.4 % in 1993. In contrast, the export to production ratio remained at a rather stable level, ranging between 12.9 % to 15.6 %.

### Production process

The pressure on prices and profits in the market for tyres induces constant efforts to reduce production costs, especially labour costs, by automation. As a result, employment in the industry has decreased by nearly 70 000 people since 1984, of which 48 800 since 1990.

Although the decrease of the number of employees has led to a higher labour productivity, unit labour costs could not be controlled by the industry. Labour costs have increased at a larger pace than total unit costs.

Automating production processes also yields other advantages, such as a better repeatability, shorter down-times during size-changes and more flexibility. Implementation of these technical developments will reduce labour costs. Currently, these costs represent 25 to 40 % of a tyre firm's turnover, depending on the data used.

The rubber industry processes natural and synthetic rubber. Natural rubber is especially used in truck and bus tyres because of its low heat build-up. For technical rubber products a much higher fraction of synthetic rubber is used, depending on the specifications of the product. An important raw material for the rubber industry is carbon black, besides textile and metal components.

## INDUSTRY STRUCTURE

### Companies

The world tyre market is dominated by large multinational companies. Among the world's top ten tyre makers three European companies are represented: Michelin (F), Pirelli (I) and Continental (D). Only Continental recorded a net profit in 1993, whilst the other two companies incurred losses.

Although foreign suppliers are gaining market share, European manufacturers still dominate the EU market. Michelin is the largest European tyre manufacturer with a leading market share of 31.7 % of total sales. Continental and Pirelli hold market shares of 13.8 % and 9.2 % respectively.

The largest tyre manufacturers usually produce industrial rubber products as well. However, specialised small and medium-sized enterprises only producing technical products or products for end-consumers dominate in this market segment.

### Strategies

At least three responses to the challenges resulting from intensifying competition can be identified. Firstly, higher investment in cost-reducing processes; secondly, increased efforts in research and development; and thirdly, mergers and acquisitions and/or alliances.

Investment activity in Europe is oriented towards cost-reduction and productivity-increases, not to new capacity, whereas in the Far East new plants dominate investment. In Europe capacity has been reduced in the recent past in answer to stagnating, or even declining demand and to reduced expectations. Michelin, Continental and Pirelli have all closed capacity in Europe since 1993. The low capacity utilisation has resulted in a proliferation of private brands. In order to utilise their remaining capacity and to face the price competition with cheaper foreign brands, the European tyre manufacturers are producing more and more private brands or associated/house brands.

As the car market became increasingly international, tyre manufacturers were forced to follow and adopt a worldwide strategy. The concept of dominant position at both national and EU level has disappeared. The recent past saw a reshaping

of the structure of the world tyre industry, in which the size of the large groups increased. Bridgestone (J) took over Firestone (USA), Michelin took over Uniroyal Goodrich (USA), Pirelli (I) acquired Armstrong (USA) and Metzeler (D), Continental took over Semperit (A), General Tyre (USA), and Uniroyal-Englebert (USA). Fulda (D) was acquired by Goodyear (USA) and Dunlop (UK) by Sumitomo (J). Besides acquisitions firms also engage in strategic alliances.

The European manufacturers are seeking and gaining presence in Asia through strategic alliances, but also by investing in new plants or by relocating European plants to this continent. Michelin for instance actively pursues manufacturing deals in India and China. In 1993 the French company invested more than 400 million ECU for expansion in Asia. Also Continental is expanding strongly in Asia with capital investments equalling more than 300 million ECU. Pirelli is already heavily active in China and is pursuing off-take agreements, technology licensing and joint ventures throughout the Far East. In 1993 the Italians invested nearly 100 million ECU in this region.

### Impact of the Single Market

The overall impact of the Internal Market programme is positive as the industry, like other industries, has been able to benefit from the horizontal measures which were adopted. Besides these there were few measures of direct relevance

to the rubber products industry. Among the remaining barriers or market distortions, the cost of inputs and especially of labour is perceived to be a real problem by the industry. An important remaining internal barrier concerns EU legislation with respect to waste management and the free movement of waste products, which is not sufficient to enforce proper action by the Member States and which leaves too much room for different interpretation. Removing this barrier should have the highest priority. Another priority is also related to waste management and concerns the imports of cheap non-retreatable rubber products, which creates problems from an environmental point of view.

### ENVIRONMENT

The main environmental issue for the rubber industry is the recycling, incineration or disposal of scrap tyres and rubber products. Retreading used tyres is a widespread recycling method which has many positive aspects from an ecological point of view. Also, the longer duration of tyres in comparison with the past contributes to limiting the amount of disposal. In contrast, the growth in the number of cars has a negative influence on the environment. Despite these developments, every tyre has to be incinerated or disposed at dumps at the end of its lifetime. There have been attempts to make chemical recycling by pyrolysis in order to get hydrocarbons, but so far this technology has turned out to be too expensive and to generate itself air pollution.

The EU is world leader in research and development of ecological technologies. In the long run this could lead to export opportunities either in the form of machinery and plants, or in the form of licences for ecological incineration technology. The United Kingdom has recently inaugurated a power plant fuelled by used tyres.

Other environmental developments which might affect tyre sales are the attempts by the EU and by most Member States to reduce car traffic by raising excise duties on fuel and/or planning the introduction of other taxes such as the carbon tax which might not only influence mobility, but also the production of tyres. Such a tax, however, will only be implemented in the long run and the direction and magnitude of the impact is not quite clear.

### OUTLOOK

In 1993, the economic downturn has caused a difficult period for most European manufacturers of rubber products, leading to disinvestments and job losses in Europe. The recession has shifted demand towards low-price tyres. Especially the new Asian brands constitute a real threat to the market positions

of European manufacturers in the coming years. The latter are responding by producing house and private brands. Already in 1994, a small increase in EU consumption was estimated. For the coming years a recovery in demand and production is expected, although growth figures will be modest and not sufficient to prevent a further decrease of employment in the industry.

Written by: Netherlands Economic Institute

The industry is represented at the EU level by: Liaison Office of the Rubber Industry of the EC (BLIC). Address: Avenue de Arts 2, Bte 12, B-1040 Brussels; tel (32 2) 218 4940; fax: (32 2) 218 6162.

# Plastics processing

## NACE 483

After a difficult 1993, with production and consumption of plastic products declining more than 3 %, plastic sales bounced back in 1994 with growth of about 5 %. Competition in the sector has become more intense, resulting in low profit margins. Rationalisation of production capacity resulted in a decline of employment of 5 % during the past two years. Environmental legislation and shifts in consumer preferences contribute to the substitution of materials, the development of new product designs and the introduction of plastic recycling schemes. Nevertheless, with expected overall growth rates of 3-4 % for the coming years, prospects for plastic processors are favourable.

### INDUSTRY PROFILE

#### Description of the sector

Consumption of plastics material in the EU plastics processing industry was approximately 30 million tonnes in 1994. The main plastics materials processed for the different plastic markets are: polyvinylchloride (PVC) 5.0 million tonnes, high density polyethylene (HDPE) 3.0 million tonnes, low density polyethylene (LDPE) 4.6 million tonnes, polypropylene (PP) 4.8 million tonnes, polystyrene (PS) 1.7 million tonnes, polyurethanes (PUR) 1.4 million tonnes and fibre reinforced plastics/composites (FRP/C 0.9 million tonnes).

In 1994 the industry employed around 752 000 persons in about 20 000 companies. Sales in the plastics converting industry are estimated to have reached about 97 billion ECU in 1994. The sector's main business is to convert plastic resins and compounds into products. The sector operates a range of different technologies, such as injection moulding, compression and blow moulding extrusion, and hand lay-up of fibre reinforced plastics and coating. It also carries out ancillary operations, such as decoration by silk printing, hot stamping and a variety of subassembly operations.

Plastics converters may produce finished articles which are used by other industries like food packaging and building articles, or distributed to consumers. They may also be custom processors who produce components on a subcontract basis for other manufacturers, or in-house operations integrated into the manufacturing process. Major markets for plastics are packaging, building materials, electrical goods and electronics, automotive components, furniture, and agriculture.

#### Recent trends

A production increase of 5.3 % was forecast for 1994 which will lead to a total processed volume of about 28.6 million tonnes in Europe. Both consumption and production increased during the 1984-1993 period, by 5.7 % and 5.4 % per annum, respectively. Trends in plastic processing differ between Member States though. During 1993, demand was down by 3 % in Germany (accounting for nearly one-quarter of total EU demand) and 1.4 % in France, but during 1994 growth resumed by 3-4 %. Spain, Italy and Benelux experienced growth below 1 % during 1993, but reportedly 1994 showed higher growth rates. The temporary dip in demand during 1993 was mainly caused by a fall in demand for cars (e.g. down by 0.5 million cars in France; 0.3 million in Spain; and Fiat selling 21 % fewer cars) and the worst crisis in the building industry for many years, affecting downstream sectors such as the manufacture of PVC-pipes. In contrast, demand for thermoplastics in the UK experienced growth of 3.6 % in 1993 after three years of poor performance.

Figure 1: Plastics processing  
Value added in comparison with related Industries, 1993

Source: DEBA

General trends indicate that PVC, conventional LDPE, polystyrene and ABS (acrylonitrile-butadiene-styrene) were among the materials that had a particularly difficult 1993, while propylene, high density and linear polyethylene and PET (polyethylene terephthalate) showed the strongest growth.

From 1984 to 1990 employment in the sector increased on average by 4.6 % per year, reaching a peak of 798 400 in 1991. Since 1991, however, employment has fallen by 4.8 % to 760 400 in 1993 and is expected to drop to 752 000 in 1994. Nevertheless, the decline of employment in plastics processing has been less pronounced than for manufacturing in general. Furthermore, there has been a trend towards greater rationalisation with larger processing groups getting ever bigger.

#### International comparison

In 1984, the USA was the largest producer of plastic materials. However, in 1993 Japan was on top of the list with the EU as a close second. During the past decade, average annual growth rates were 3.7 % for the USA, 6.1 % for Japan and

5.4 % for the EU. Nevertheless, during 1993 production decreased in the EU by 1.6 % and 1 % in Japan, while a surge in the American economy resulted in growth of 2.8 % in plastics processing.

The chemical and plastics converting industries are the only technology-intensive sectors in which Europe is ahead of Japan and the United States, although a lot of Japanese firms operate in Europe or have set up joint ventures with European manufacturers. Asian economies are becoming more integrated and less dependent on the US and Europe. Japan, Korea, Taiwan, China and Singapore are the main plastics processing countries with production of more than 25 million tonnes; i.e. one-quarter of world production. China's output of plastics products has been growing at an annual rate of more than 20 % during the 1990s.

**Foreign trade**

Extra-EU imports grew at a spectacular annual rate of 9.5 % during 1984-93. In 1993, extra-EU imports increased by 5.9 %. Extra-EU exports, with average annual growth of 4.8 % since 1984, increased by 10.2 % during 1993 compensating for the cyclical downturn in the EU. As a result, the trade balance increased by 24 % in 1993. Extra-EU imports in 1993 accounted for 8.1 % of plastics consumption in the EU, while exports accounted for 10.7 % of production.

The combined share of imports from the EU's two main trading partners, the USA and EFTA, decreased from 63.7 % to 57.4 % from 1988 to 1993. Imports from Japan, Taiwan and Hong Kong are giving way to rising stars such as China, Thailand and Indonesia. While Japan's and Taiwan's combined share in EU imports declined from 17 % to 13 % from 1988 to 1993, China's share nearly quadrupled from 2.8 % to 10.2 %. In general, imports diversified with respect to country of origin.

The share of extra-EU exports to the EU's main trading partners, EFTA and the USA, decreased from 58.6 % in 1988 to 49.7 % in 1993. Exports to Sweden, Finland and Canada decreased in absolute terms. Meanwhile, exports to countries, such as Poland, the Czech Republic, Hungary, Russia, Turkey and South Africa increased tremendously. Trade between EU Member States increased, reflecting an increase of both intra-EU imports and exports in EU production from 19 % to 22 %.

**MARKET FORCES**

**Demand**

Annual growth rates of thermoplastics consumption in the EU steadily decreased from 16 % in 1989 to -3.8 % in 1993. However, 1994 is expected to be a turning point with growth of approximately 4-5 %. Products made by plastic processors range from such mass produced items as small injection mouldings and continuously produced low density polyethylene packaging film to such specialised products as composites used in space shuttle components. In short, virtually every product manufacturer uses, or can use, plastic components.

There is an extensive and diversified demand for plastics goods. Consumer goods and technical applications are characterised by continuous developments. Demand for plastics can be subdivided in to six important markets: packaging (food, beverages, etc.); building (window frames, insulation, etc.); electrical/electronics (office automation, telecommuni-

Source: DEBA

cations, etc.); automotive; other transports (railways, shipping, aircraft, etc.); and other markets (agriculture, leisure, toys, household, garden, furniture etc.). The first five sectors deliver to other industries, while the last one delivers directly to consumers via distribution outlets, such as department stores.

Many industries use components made of numerous types of polymers. About 5 000 types of polymers, alloys and combinations enhance the design and manufacturing of various applications from compact discs to medical instruments. The energy crisis increased the need for low-weight materials. For example, in the automotive industry plastics have been replacing several parts previously made out of metal.

#### Packaging

Accounting for one-third of demand, production of packaging material is the largest subsector of the plastics processing industry. In the packaging sector, plastics have been replacing glass for bottles (mineral water, soft drink, milk) and jars (yoghurts). The food industry constitutes the major end-user followed by the distribution and beverage industries. Despite environmental concerns, the European market for plastics packaging is forecast to rise from 10.5 billion ECU in 1992

to over 13.67 billion ECU by the end of 1995. Nevertheless, the drive to reduce packing weight and volume is leading to long term changes in demand for materials. In spite of economic downturns in the EU and the burst of legislation which could impose severe pressure, pharmaceuticals, toiletries and cosmetics are large users of packaging. Cleaning powders are starting to move away from cartons to blow-moulding plastics, while cleaning fluids are changing from blow-moulding containers to bag-in-box packaging. The motor oil business is still moving away from metal cans to plastics containers. The greatest growth rate is expected for PET, particularly in the carbonated drinks market (from 512.8 million ECU in 1992 to 940.2 million ECU by 1995).

#### Plastic films

Film should remain the most common polymer grade used in packaging (although losing to blow-moulding and injection moulding) until 1995. Plastic films are mostly based on polyethylenes, but also on polypropylene, PVC, PET or co-extruded resins (polyamides, ethylene-vinyl acetate etc.). Major end uses of plastic films are printed films for automatic packaging, shrink and stretch film for overpacking films for agriculture and horticulture (greenhouses, mulching), films for construction, shoppers, carrier bags, refuse bags, heavy duty sacs, and films for a wide range of technical applications, such as magnetic tapes, credit cards, hot foil stamping, cables, motor insulation, furniture films and office films.

#### Building

On average, the building sector represents 20 % of plastic demand in the EU. Plastic window frames have a good market share in Central Europe, whereas in Southern and Northern Europe other materials prevail. Other applications of plastics in building are: insulation materials, floor and wall coverings, pipes and roof applications. In Germany, demand for pipes and windows has been buoyant in recent years because of reconstruction demand in the new eastern states.

#### Electrical appliances

Consumption of plastics in the West European household electrical appliances sector accounted for 7 % in 1993. Major polymers processed in household electrical appliances are polystyrene, polypropylene and ABS. The main household electrical appliances are: refrigerators and freezers, washing machines/dishwashers, ovens, food processors, coffee makers and vacuum cleaners.

**Figure 6: Plastics processing**  
**Destination of EU exports**

Source: Eurostat

### Automotive sector

This sector accounts for 7 % of EU plastic consumption. The West European average for plastics in vehicles is 11 % of total weight. In 1993, 1.35 million tonnes of plastics were used in car applications; 0.37 million tonnes of PP, 0.32 million tonnes of PUR and 0.16 million tonnes of PVC. PP consumption in cars is predicted to increase by almost 40 % by the year 2002. At the same time, PUR consumption is set to grow by about 10 %, while PVC consumption should remain stable.

### Agriculture

Agriculture accounts for 3 % of total plastics consumption in Europe. Plastic films for covering greenhouses have enjoyed spectacular growth over the last twenty years. From their original use as a simple tunnel, they have evolved into sophisticated multi-span structures which offer the same advantages of traditional glass-covered structures.

Consumption of plastics materials for 1993 in the EU was about 28 million tonnes. Although the global market for thermoplastic polymers increased, demand varied by individual polymers and markets. The following breakdown by material illustrates growth rates for total consumption in Western Europe.

### PVC (Polyvinylchloride)

PVC has maintained a 3 % annual world-wide growth, although in Europe demand for PVC grew by 1-1.5 % in 1993 after remaining static in 1992. PVC is increasingly being substituted by polyethylene in cable applications, by PE in stretch film, by PP and PS in sheet thermoforming applications, and by PET in drinking bottles. On the other hand, more home owners are installing PVC window profiles, replacing traditional wooden frames. The use of PVC in packaging applications, particularly films, tended to decline partly because of substitution by PP and PET films.

### PP (Polypropylene)

PP has been the fastest growing of all the thermoplastics, because of its increasing substitution of other materials; notably ABS, polystyrene and PVC. However, rising demand has been swamped by overcapacity in recent years, due to high investments in the PP subsector. For example, in France investments by Polychim, Exxon, Hoechst, Solvay and Shell have resulted in an increase of production capacity of 37.5 % since 1987.

### LDPE (Low Density Polyethylene)

The European polyethylene market is mired in recession and overcapacity, although performance is different for various grades. The increase in demand for low density and linear polyethylenes in 1993 was slightly more than 1 %. This can partly be explained by the fact that the markets for LDPE are more mature than other polymer markets and suffer from competition from other polymers, such as HDPE in bottle and film applications. Recycling is also a key issue and increasing use of recycled material will continue to limit growth for virgin polymers.

### LLDPE (Linear Low-density PE)

Consumption of LLDPE rose by 10 % as low prices caused converters to switch from low-density PE (LDPE). In addition to its lower price, an advantage of LLDPE is the down-gauging possibilities that it offers, allowing less material to be used to produce the same square metrage of film.

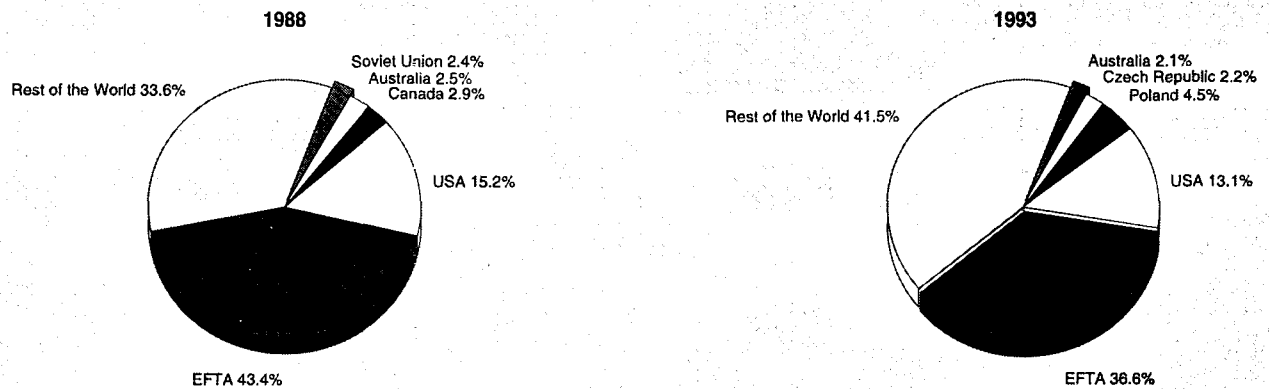

### HDPE (High Density Polyethylene)

Growth of demand is expected to continue at 3-4 % as HDPE competes well with other polymers and traditional materials. Growth in demand has been strongest in extrusion applications; especially for pipes and cables. More than 35 % of HDPE consumption in the EU is for injection moulding. The market for smaller bottles has been growing more slowly than other sectors because of the development of refill packs and concentrated household chemicals, which require smaller containers. With film, HDPE has found favour over LDPE and PVC in certain packaging uses, and injection moulding, especially for wheeled refuse bins. Virgin products will be increasingly vulnerable to substitution by recycled material.

### PS (Polystyrene)

With regard to PS, operating rates are high and supply is relatively tight all over Europe, due to good demand from packaging and electronics, in addition to new applications, such as 3.5-inch floppy disks. The use of OPS sheet in transparent packaging applications has increased, but growth has not achieved the speedy success its supporters expected. However, demand of PS is declining because of competition from producers in Southeast Asia (for teletronic products) and because of the substitution of PS by PP in some domestic and packaging applications. The future holds little prospect for growth.

### Other plastics

Market performance of engineering polymers was variable in 1993. PET performed well, with growth of 9 % in Italy. Italy is the leading consumer of PET resins accounting for nearly 23 % of European demand. Consumption in 1993 was put at 1 993 tonnes, of which approximately 85 % went into bottle production. The UK has the second largest market for PET, being one of the first European countries to adopt wide scale use of PET bottles for soft drinks.

The key end markets for polyurethane are furniture, transport and construction which together account for two-thirds of polyurethane consumption. The main constituents of fibre reinforced plastics/composites (FRP/C) are reinforcing fibres dispersed or imbedded in a continuous matrix (polymer). Glass fibres represent over 98 % of the total tonnage of reinforcing fibres used and the remaining 2 % is shared between carbon and aramid fibres. The main resins converted are: Unsaturated Polyester Resins (UP), Epoxy Resins (EP), Phenolic Resins (PF) and Melamine Resins. The most important markets are electrical engineering (wiring devices, electronics), domestic appliances (pot and pan handles, tableware), automotive industry (brake parts and other car parts), sanitaryware (toilet seats, bathroom equipment), closures (caps for pharmaceutical and cosmetic use) and other markets (sliding elements, sealings).

### Supply and competition

Existing capacity of polymer production, mostly in the hands of the main petrochemical groups, is in general in accordance with the demand of raw materials by processors.

The plastic processing industry is mainly composed of small and medium-sized companies. For the procurement of raw material, the medium-sized plastics processor has to deal with strong polymer producing companies, while it has to sell plastic products through large scale industries, like car makers, manufacturers of electrical and electronic equipment and department store chains.

The highly advanced technology in European processing companies enables them to export nearly 11 % of their total production, in spite of high transportation costs for plastics products. However, the general downturn that hit all major European markets in 1993 resulted in a number of small and medium-sized injection moulders going out of business with the automotive moulding firms having a particularly hard time.

Polymer producers need higher prices if they are to achieve decent margins. For European plastics markets, some products still experience price erosions due to overcapacity and the pursuit of market share over margins. In addition, competition is increasing because of the emergence of a world-wide market for polymers.

### Production process

The plastics processing industry utilises a variety of production methods and plastic materials. For every production method, a skilled labour force and important investments in numerically controlled machines are necessary. Professional training is very important for plastics processors in the EU. Different technologies are operated such as injection moulding, compression, extrusion, blow moulding extrusion, calendaring, thermoforming, film extrusion blowing, blow moulding, hand lay-up of fibre reinforced plastics and coating. Decoration by printing, hot stamping and other subassembly operations are also carried out.

During its early years in the 1950s the only technologies known for FRP/C were manual hand lay-up and spray lay-up. The first mechanisation appeared only in the 1960s, while pultrusion and winding were only introduced in the 1970s. The breakdown of EU production of thermoset GRP by manufacturing technique shows that manual techniques still account for about 35 % of production, followed by automated techniques like SMC and BMC. Semi-finished products in SMC (Sheet Moulding Compound)/BMC (Bulk Moulding Compound) and finished parts (118 000 tonnes) are at the centre of new technological developments, mainly linked to requirements of the automotive industry and transport sector, in general.

## INDUSTRY STRUCTURE

### Companies

Statistics from national plastics federations in the EU show that the number of plastics converting companies in Europe adds up to 20 000 (mostly small and medium sized companies), while only a dozen plastic processing companies employ more than a thousand persons. Plastics processors in Germany are generally larger than in other European countries. The average sized processor in Germany uses some 1 780 tonnes of polymer/annum compared with 1 280 tonnes in France, 1 110 in the UK and only 780 tonnes in Italy. Italy has a very fragmented

processing industry, accounting for at least 4 000 injection moulding companies.

In 1993 the industry employed around 760 400 persons in the EU. It is expected that rationalisation will result in a further decline of 9 000 people during 1994. Although the sector consists mainly of small and medium-sized companies, the plastics processing industry in Europe includes large companies such as: Wavin (NL); Dynamit Nobel (D); Plastic Omnium (F); Alphacan (F); Gebr. Otto (D); Rehau (D); CMB Packaging (F); BPI (UK); Scholler (D); Autobar (UK); Allibert (D); Klockner Werke (D); Peguform-Werke (D); Freudenberg (D); subsidiaries of Hoechst (D) and Solvay (B); Fardem (NL) and Nyborg (DK).

### Strategies

The general downturn in economic activity has resulted in rationalisation programs in the major firms. The impact of new manufacturing techniques and increasing use of Japanese work practices mean that only the leanest and fittest companies are likely to survive. The best growth opportunities may come from new markets in Eastern Europe and new applications in leisure and health care. Plastics lead to many new applications in consumer products, as well as in high tech applications. For example, the injection moulding industry has the ability to respond quickly and adapt to modifications in demand and technological developments.

Concentration is expected in different fields, such as subcontracting for the automotive sector and consumer electronics. The biggest companies in the field are establishing links within the EU and Eastern Europe and are looking for partners. For example, many of Spain's leading processors, particularly in injection moulding, are falling prey to foreign investors as the trend towards international markets grows. Several leading fuel tank producers, such as Plastic Omnium, Dyno and Solvay, have established production facilities in Spain to serve the local automotive industry on a just-in-time basis. Similarly, Sommer Allibert and Plastic Omnium are establishing US plants to supply BMW's new factory at Spartanburg in South Carolina.

### Impact of the Single Market

The impact of the creation of the Single Market has been positive, mostly because of the increased market potential for EU firms and because of the acquisition of a European

identity for producers and products. Nevertheless, some internal barriers, mainly in the area of environmental legislation, remain. The industry favours common environmental policies for the EU, as unilateral legislation by individual Member States results in internal barriers which hamper the creation of a Single Market. Two other types of measures from the Internal Market programme which are particularly relevant to this sector relate to improving access to finance for SMEs and the stimulus to privatisation within the EU.

## ENVIRONMENT

A difficult environmental situation for the plastics industry relates to the recycling discussion. Recycling quotas imposed by national and European authorities in the packaging sector, pending EU and national legislation for automotive waste, teletronic waste, building waste, and others are restricting growth, particularly in the PVC and packaging sectors. However, the plastics industry is taking up this challenge. The plastics converters industry is very conscious that plastics have become increasingly popular because of the immense social benefits they have brought and that they now constitute a prominent and durable component in the waste stream.

In France, a system for recycling packaging came into existence during 1993. The implementing organisation, Eco-Emballage, set up a subsidiary company, Valorplast, to be responsible for the disposal and recycling of plastic packaging. The aim is to recover 75 % of packaging by weight through either recycling or incineration by 1997. Like the Green Dot system in Germany, the scheme is funded by charging a levy on packaging. The French system has been discussed openly between government and industry. The result seems to be more realistic than in Germany, as incineration with energy recovery has been accepted by all parties from the very beginning. The European directive on household waste has been inspired by the French approach. Italy introduced an 'ecological contribution' tax of 10 % on polyethylene destined for film production and a similar tax on raw materials used for non-reusable liquid containers, which will be used to fund recycling schemes. The aim was to recycle 60 % of liquid containers in 1994.

The amount of plastics being recycled in Europe is growing at more than 20 % per year. The volume of post-consumer plastics recycled in the EU is forecast to grow from 1.5 million tonnes in 1993 to 2.4 million tonnes in 1996. In 1996 generated plastic waste is expected to amount to 14 million tonnes, while the proportion of recycled plastic will be 17 %.

Designing is a new trend for recycling. Products will be increasingly designed using compatible materials with the aim to remove or reduce the need for dismantling products into individual component parts at the end of their life, thus improving the economics of the recycling process. Relevant features include: minimising the number of fasteners used; using re-openable moulded-in snap-fit connectors; providing easily accessible fasteners; and confining contaminants to discrete areas of the product.

In Germany, there have been attempts by certain local authorities to ban the use of PVC in building applications. Although the industry has managed to lobby against such bans, they have been unable to stop the rapid decline in its use in packaging.

The industry wants to see common environmental policies for the EU. Unilateral legislation by individual Member States can lead to undesirable distortions in the market causing trade barriers which will delay the creation of a truly single European market. Such legislation must give due consideration to the entire life span of plastic materials and products. Recognition must be accorded to the environmental benefits they can impart from their initial conception (by saving energy) through their service life to their ultimate manifestation as waste, ensuring that their full potential for re-use is exploited.

Source: DEBA

There is no single solution to the problems of plastics. To different extents, waste management and recycling, incineration and landfill all have their part to play according to particular local circumstances. Possible waste management options include: resource efficiency and waste avoidance; material recycling/feedstock recycling; energy recovery/recycling; incineration; and landfill.

Plastics converters stand resolutely against limiting the use of any plastics material, as this would constitute an unacceptable barrier to trade. To encourage the development of plastics recycling, plastics converters wish to encourage the adoption of an EU-wide product marking system to facilitate easy identification and encourage the appropriate standards in those applications in which recycled products fulfil 'suitability for purpose' criteria. If replacement of materials by plastics proves advantageous to the environment, an announcement of these advantages in advertising is considered acceptable.

## REGULATIONS

The European Commission is designing and has designed directives, decisions or regulations which effect the industry of plastics converters. Concerning food contact applications, the Commission is specifying positive lists for monomer, additives, colorants, etc. used in plastic products. The building sector is awaiting the pending directive for building products.

One of the major concerns in the plastic industry is the management of waste. The EU Commission developed legislation, based on the framework set by the Directive on waste (91/156/EEC), which covers different fields touching the industry. Directives on packaging and packaging waste and other waste streams (e.g. automotive, building, hospital, teletronic) should soon be finalised and are of major concern to the plastics converters industry. The likely impact of these Directives and the packaging ordinance is a shift in favour of certain materials at the expense of others. This can be seen in PVC packaging, which appears to be in a permanent downward spiral in various countries.

## OUTLOOK

It is expected that consumption of plastics in the EU will grow by an average of 3-4 % per year until the end of the decade. The best growth opportunities will come from new markets in Eastern Europe and new leisure and health care applications. Despite the improving market, polymer processors also face some difficult long term challenges. High wages, social environmental and energy costs could increasingly lead larger enterprises to move production capacity to lower cost locations in Asia or Eastern Europe; particularly with regard to lower value goods. The plastics industry is working at heightening public awareness of its many initiatives to contribute to a cleaner environment. Taking into consideration the efforts in developing recycled plastic products, the plastics processing industry looks to a bright future.

Written by: the Netherlands Economic Institute

# Furniture

NACE 316.6, 467

The furniture industry is one of the largest manufacturing industries in the EU. Germany, Italy, the UK and France are the main EU producers in this sector. The furniture industry is highly fragmented, and is dominated by small and medium-sized firms. Concentration is increasing because of stiffer competition by foreign suppliers and the higher level of concentration of the retail business.

Demand for furniture depends greatly on the general economic climate. After a slowdown caused by the recession in the early 1990s, the furniture industry was on its way to recovery in 1994, and the outlook is brighter for the short term.

## INDUSTRY PROFILE

### Description of the sector

Furniture is a typical consumer durable good. It may be manufactured with a wide range of materials such as wood, metal, plastics, rattan, etc.

Today, traditional materials such as unfinished wood and wooden products (i.e. wooden boards, parts of furniture, etc.) represent less than 30 % of the materials used. Metal accounts for 12 %, hardware for 9 %, plastics and foams for 9 % and textiles for 6 % (see Table 1). In NACE 1970, furniture production was classified according to the main materials used: NACE 316.6 for metal furniture and NACE 467 for wooden furniture and upholstery. Wooden furniture generally represents 75 % of the total EU production of furniture. Since 1993, the NACE Rev. 1 classifies all types of furniture under the code 36.1, without distinction of the materials used.

More than 90 000 enterprises (among which are many very small enterprises) employ 842 880 persons. If only enterprises employing more than 20 employees are considered (total production of 48 164 million ECU in 1993), then Germany is the largest furniture producing country in the EU (with 38.7 % of the production), followed by Italy (17.7 %), the United Kingdom (14 %), France (13.1 %) and Spain (7.4 %). Italy and France have a proportionally higher weight if all the enterprises of the sector are considered.

In terms of value added, Germany remains the largest producing country followed by Italy, the UK and France. The furniture industry is a diversified, price-good industry in which technology and labour skills are of great importance. The contribution of labour costs to the value added, however, has been decreasing for the past twenty years because of spreading automation (either low-cost automation or fully automated operations) for serial production.

But the part of labour costs in the value added remains high in comparison with other manufacturing industries and the productivity (i.e. value added per worker) is less important than in other major manufacturing sectors. Nevertheless, productivity in the furniture industry increased by about 25 % in the ten years up to 1993.

The Danish furniture industry has the highest productivity (value added per employee: 37 000 ECU). Apart from the Danes, only the German, Italian and Belgian furniture industries reach a productivity above 30 000 ECU of value added per employee.

Figure 1: Metal and wooden furniture Value added in comparison with related industries, 1993

Source: DEBA

The furniture industry is made up of very distinct sub-sectors. Furniture manufacturers are usually highly specialised in one or two types of furniture (e.g. upholstery manufacturers only produce upholstered furniture; kitchen furniture manufacturers only produce kitchen furniture, office furniture manufacturers produce only office furniture, etc.).

In all, the furniture industry may be subdivided into ten main categories: kitchen furniture, upholstered furniture, bedroom furniture, dining room furniture, office furniture, chairs, mattresses, garden furniture, shop furniture and other furniture (e.g. contract furniture, furniture for laboratories, rattan furniture and furniture parts).

Together, the production of upholstered furniture, kitchen furniture, dining room furniture, office furniture and bedroom

furniture represent just over 60 % of the total EU furniture production. The production of upholstered furniture has the largest share of EU furniture production: it amounted to 9 201 million ECU in 1993 (+4 % in value; -0.2 % in volume from 1992). In terms of volume, EU production amounted to 37 million armchair-equivalent units or between 7 500 000 and 10 000 000 full suites of upholstered furniture. In the EU, 70 % of the upholstery production value is in fabric and the remaining is in leather. The largest producers are Germany and Italy, with about 30 % of the total production each.

In 1993, the EU production of kitchen furniture amounted to 7 963 million ECU (13.2 % of all furniture production). This represented an increase of 7.2 % over 1992 figures (due to substantial growth of the German industry, which accounts for 40 % of the EU production). In volume terms (+3 % in 1993), 4 million complete fitted kitchens were manufactured in the EU. This industry is the most concentrated segment of the EU furniture sector, with 50 manufacturers producing 50 % of the total production and exporting 50 % of the total EU exports.

The total production of the EU office furniture manufacturers equalled 5 867 million ECU in 1993. This meant a decline of 13.9 % in value compared to 1992. This was the second

Source: U.E.A.

year of decline, caused by the weak demand for office furniture as a result of the recession, following twelve consecutive years of increase. The office furniture sector was the fastest growing segment of the furniture industry (average annual real growth rate of 7.5 %). Production rose from 2 149 million ECU in 1980 to 6 905 in 1991 (+221 %).

Office furniture production can be sub-divided into two product groups. The first includes any and all seating arrangements. The second comprises other types of office furniture including desks, tables, cupboards and cabinets. EU production of office seating fell by 11.4 % in 1993 (-1.7 % in 1992 and +4.3 % in 1991). Meanwhile, on a global level, the production of seating, which accounts for 25 % of the total office furniture production, nearly tripled (+289 %) from 1980 to 1993. In volume terms, this represents 8 million seats.

The production of other types of office furniture declined by 14.7 % in 1993 (-1.7 % in 1992 and +12.3 % in 1991). 30 % of the total office production consists of office automation systems, 15 % traditional workstations, 10 % executive workstations, 10 % filing and storage systems and 10 % fitted partitions. In volume terms, other types of furniture globally represent 4 million workstations. 90 % of the EU office furniture production is concentrated in five countries: Germany (42 %), Italy (17 %), France (13 %), the UK (11 %) and Spain (6 %).

In 1993, dining and bedroom furniture represented 11.9 % and 9.7 % of the total EU production of furniture. The production of bedroom furniture is dominated by the Italian and German manufacturers which together make up about 60 % of the total production. The EU bedroom furniture manufacturers produce 13 million wooden wardrobes annually, 6 million chests of drawers, 5 million wooden beds for adults, 3 million bedside tables, 600 000 wooden beds for children and 500 000 metallic beds.

#### Recent trends

After five years of decrease in the early 1980s, the production of furniture in the EU increased from 1986 to the beginning of 1991. The volume of production grew yearly by 4.3 % on average during this period (outperforming the total manufacturing industry by 1 %). Over 65 000 jobs were created during this period (+2.1 % per annum in the furniture industry compared with a stagnation in the total manufacturing industry).

The furniture industry suffered a lot from the recession. In real terms, production fell 3.2 % between 1992 and 1993, and 46 000 jobs were lost between 1991 and 1993. Since the beginning of 1994, furniture production has increased again in nearly all the EU countries but with different growth rates. Meanwhile, the level of employment has remained stable.

In the EU, furniture enterprises with more than 20 workers employed a total of 581 500 people in 1993. If all companies are considered, 842 880 persons worked in the furniture industry in 1993.

Broken down by sub-sector, the upholstered furniture industry employs about 130 000 persons in about 7 000 enterprises. Meanwhile, total employment in the kitchen furniture industry exceeds 70 000 persons. This demonstrates the high concentration in the kitchen furniture sub-sector, where a limited number of large firms controls an important part of the production.

Employment in the office furniture sector is estimated at 62 000 persons in 1993. The four largest countries of the EU produce 84 % of the office furniture production with only 74 % of the work force. This demonstrates the high productivity and automation reached in these countries in comparison with the others.

In general, salaries are lower for the furniture industry than for other major manufacturing industries. Increases in real wages have averaged 3.5 % during the period under consideration.

#### International comparison

As is typically the case with other US manufacturing sectors, the US furniture industry has followed business cycles more markedly than its European counterpart. At the end of the 1980s, US furniture production volume dropped significantly. Since 1992, production has grown by exceptional annual growth rates of about 10 % (an average +5 % in volume). Now that the US economy is growing, the production of furniture is forecast to increase at least until 1995. The production value of wooden furniture reached 25 459 million ECU in 1993 and the production of metal furniture equalled 10 256 million ECU. Imports to the US are increasing and have recently exceeded 4 billion ECU or 7 % of the apparent con-

Production and employment compared to EU total manufacturing industry**

1994 are DEBA estimates.  
Source: DEBA

sumption: imports from the Asian countries are rising faster than imports from the EU.

In Japan, the production value of furniture increased constantly from 1985 to 1991. Since 1992, the production value has been declining due to a sluggish demand and a slowdown in the service sector activities. In 1993, production value of Japanese furniture totalled 25 873 million ECU of which 27.8 % was office furniture. The Japanese furniture manufacturers dominate in their domestic market, and about 95 % of furniture sold in Japan is Japanese furniture. The EU manufacturers account for a mere 1 % of the market.

EFTA countries are all important furniture producing countries. Their production amounted to 4 475 million ECU in 1993 (-4.3 % compared with 1992). Austria represented 40 % of the production, Sweden 21 %, Switzerland 14.3 %, Finland 12.7 % and Norway 12 %.

### Foreign trade

Since the beginning of the 1980s, EU furniture manufacturers have exported between 23 % and 25 % of their total production. Among the EU countries, Italy was the largest furniture exporting country with about 4.5 billion ECU worth of furniture exports in 1993 (Germany's exports totalled 3 billion ECU and France's exports equalled 1.3 billion ECU). Meanwhile, the largest importing country was Germany (4.8 billion ECU) followed by France (2.2 billion ECU) and the Netherlands (1.5 billion ECU). Excepting Italy, Denmark, Spain and Portugal, all the EU countries have deficits in their trade balance in furniture.

Exports of upholstered furniture represented 18.3 % of the total EU furniture exports (of which about 50 % came from Italy). Exports of dining room furniture totalled 1 780 million ECU in 1993 (or 13.3 % of total exports). Exports of bedroom furniture reached the value of 1 276 million ECU or 9.5 % of the total exports.

The kitchen furniture manufacturers do not export much of their production which is mainly aimed at the domestic market (only 771 million ECU in 1993). Total exports of office furniture totalled 1 127 million ECU in 1993, showing a decline of 8.1 % from 1992. Meanwhile, imports of office furniture amounted to 790 million in 1993 (-15.1 %). All the large office furniture manufacturers operate more or less internationally within the EU markets and are attempting to strengthen their positions further.

In 1993, 36.4 % of total exports were extra-EU exports and 31.5 % of total imports were extra-EU imports. For the most part, extra-EU exports have increased since the second half of the 1980s, except in 1992 and in 1993 when they fell because of the recession in the EFTA countries and in the USA, markets to which the majority of the EU furniture exports are oriented.

In 1993, the main trading partners for the extra-EU exports of wooden furniture are the EFTA countries, the USA, Saudi Arabia, Russia and Japan. Important destinations for the extra-EU exports of metal furniture are the EFTA countries, the USA, Russia, Saudi Arabia and Hong Kong.

Extra-EU imports have risen by more than 10 % each year since 1987. The East European countries and the south-east Asian countries have become important suppliers to the EU.

**Figure 7: Metal and wooden furniture**  
International comparison of production in constant prices (1)

(1) NACE 4670.  
Source: DEBA

In 1993, extra-EU imports of wooden furniture came mainly from the EFTA countries (26.9 %). Poland (13.5 %) and Romania (7 %). The majority of extra-EU imports of metal furniture originate in the EFTA countries (35.3 %), with Taiwan (19.8 %), the USA (11.2 %) and the Czech Republic (7.2 %) following behind.

The export/import ratio has been deteriorating since 1989. In 1993, the surplus of the EU trade balance in furniture was below 1 billion ECU for the first time and it is only one-third of the surplus of 1985.

## MARKET FORCES

### Demand

Furniture is an investment item (for both enterprises and households) as well as a casual consumer article that is sensitive to fashion trends. The substitution goods or services are cars, consumer electronics, vacation/travel packages, insurance, etc. Furniture is a durable good characterised by a high unit price

and an enduring life-span (some furniture is passed on to the next generation). Consumers need a certain amount of capital to purchase furniture, and buying furniture can be easily postponed as has been the case during the recent recession. In the industrialised countries, households are well-equipped and the market for new furniture is saturated. Generally speaking, 70 % of furniture purchases are replacement purchases, bought only when tastes change, incomes increase, etc. Only 30 % of the furniture purchased is bought after births, during the setting up of a new household, or to replace broken or tattered furniture.

Demand for furniture is very cyclical and mainly depends on its elasticity towards the disposable income of a household, which varies from country to country. The average elasticity is 1.5 which means that if the income increases by 1, the demand for furniture rises by 1.5 and vice-versa. In addition, demand is affected by the general economic situation (consumer confidence in the economy, growth of the GNP and therefore of purchasing power, level of unemployment, etc., as well as the level of investments in housing). Since the end of 1991, a deterioration in the consumer confidence in the economy has led to a decline in the consumption of furniture. At the same time, lower investments in the industry and services sector have led to a reduction in the purchases of office furniture.

Furthermore, the evolution of interest rates sometimes results in increased costs to borrow for the purchase of furniture and housing. Likewise, the distribution of wealth has a part to play. Demand for furniture is higher in countries where wealth is more evenly distributed than in countries where wealth is more concentrated. Finally, demographic variables (e.g. marriage statistics, formation of households, birth rates and the age of the population), as well as the intensity of advertising and of marketing (often times based on demographics) are two other important factors.

### Supply and competition

The production of furniture and the distribution of furniture are two separate fields. Although some manufacturers either have their own distribution networks or sell their furniture directly to the consumers, in general manufacturers sell their production to retailers (specialised or not) who sell to the final consumers.

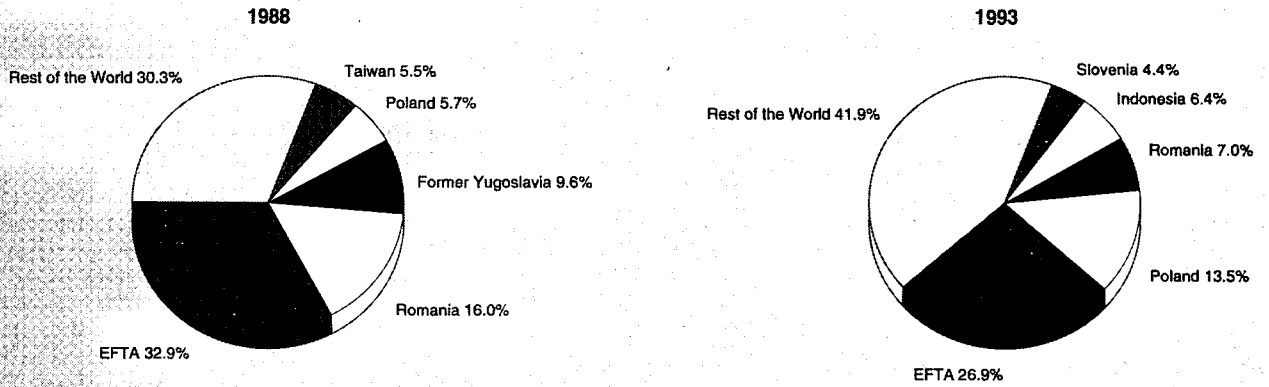

Furniture distribution is changing quickly, and is more concentrated (especially in Northern Europe) than the furniture manufacturing industry. In Germany ten buying groups and furniture chains control about 50 % of the furniture market;

**Figure 8: Wooden furniture**  
Destination of EU exports

Source: Eurostat

**Figure 9: Wooden furniture  
Origin of EU Imports**

Source: Eurostat

in France, the share is 40 % and in the UK 20 %. This leads to an increased bargaining power for the distribution sector. The concentration process has several forms. Apart from IKEA and a few German and French groups, the distribution is nationally concentrated. Distributors that make a part of their turnover outside their own country are scarce. Some retailers and buying groups are growing and forming alliances with their counterparts in different countries.

Most large retailers combine a good location with an attractive external store presentation, which they consider as an investment in advertising. There are over 100 000 furniture sales outlets in the EU. Among them, it is possible to distinguish different distribution networks.

First, there are the buying groups, which buy large volumes of furniture from different sources and sell them to their affiliated independent retailers. These are the most prominent in Germany (where the four largest buying groups represent 20 % of the sales), the Netherlands and France.

Next, one sees independent retailers (specialising in one or many types of furniture). Manufacturers' sales representatives and agents contact these retailers to sell them furniture. Ware-

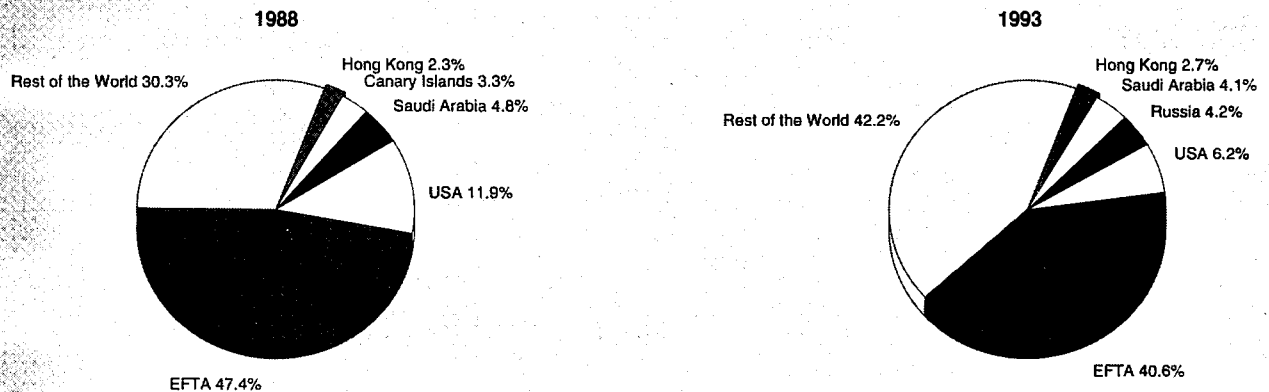

housing can be a problem (i.e. not enough space available), mainly when importing furniture.

Meanwhile, furniture chains are essentially oriented to the mass market. Generally, they operate with assembled ranges and also are leaders in ready-to-assemble (RTA) and flat-pack items. Their products are usually modern and appeal to young people. In addition, they have good customer facilities and discount prices. Examples are IKEA (from 1 to 3 % of the market in the seven EU countries where it is present), Conforama (about 10 % of the French market and also present in Spain) and MFI (10 % of the British market).

On the other hand, mail-order firms (between 2 to 4 % of all furniture distribution) mainly sell rental furniture, RTA and self-assembly ranges. Products are warehoused before dispatch to the consumer, who picks and orders the product directly from the catalogues.

For the most part, direct distribution is provided by small manufacturers who sell locally, while in department stores, furniture is a part of the total turnover. Distribution channels also vary according to the different sectors of the furniture industry. For the office furniture industry, one-third of the domestic markets is covered by the firms themselves (i.e.

those which are present in the country) and two-thirds through office equipment or general furnishing outlets. In export markets, nearly a half of all sales are made by subsidiaries of firms and the rest by agents or importers. All of the large companies have subsidiaries in the different EU countries.

For the upholstered furniture industry, independent furniture retailers account for 52 % of the sales, buying groups for 30 %, large department stores for 8 %, direct sales for 7 % and mail-order for 3 %. For the kitchen furniture segment, 50 % of sales are made through buying groups and independent retailers, 25 % through kitchen furniture specialists and 10 % through direct sales.

### Production process

Typically, innovation in the production process within the furniture industry is either necessitated by competitiveness and a need to reduce costs, or is market-led. In the first instance, automation, the use of Computer-Aided Design or Manufacturing and the introduction of new materials which are more resistant and/or cheaper than the existing ones are typical. Meanwhile, market-led innovation, which is guided by the market and consumers, touches more upon the design of furniture and the types of materials used (upholstery, recyclable materials, etc.). In addition, environmental concerns (e.g. safety and health) also may lead to changes in the production process (e.g. using coating without solvents).

## INDUSTRY STRUCTURE

### Companies

The number of enterprises in the furniture industry varies greatly, depending on whether the enterprises with less than 20 employees are considered or not. In 1993, there were 7 776 EU enterprises with more than 20 employees employing a total of 559 000 persons. However, there were also more than 80 000 enterprises with less than 20 employees. Real productivity is thus not easily seen: the high productivity of large-scale enterprises may be hidden by the low productivity of small and labour-intensive enterprises.

The distribution of the small, medium-sized and large enterprises depends on the country in question. For example, nearly all the enterprises in Germany employ more than 20 people, with the average number of employees in a firm being 78. In Italy, where there are 33 400 enterprises employing 220 000 persons, the average number of employees is six.

### Strategies

A concentration process is underway in the furniture industry. Furniture manufacturers are investing huge amounts of capital to expand their activities either by further developing the existing plants, creating new ones, or buying out other existing enterprises.

The average size of firms in the industry has increased recently. All enterprises are investing in automation and computerisation, in order to standardise their production, especially in the kitchen and office furniture segments. This requires huge

E	11 550	80 500
UK	6 000	114 000

Source: U.E.A.

amounts of capital which may be collected more easily by large firms than by smaller ones.

In Germany, for instance, the largest enterprises have invested in Poland and, to a lesser extent, in other East European countries, where labour costs are only one-tenth that of Germany's. In Italy, strong co-operation exists between small entrepreneurs in the area of design, marketing and production. Moreover, small enterprises often act as sub-contractors for larger firms (they produce components, semi-finished, finished or assembled furniture). This results in exceptional flexibility.

Almost all of the EU furniture firms are family-owned businesses. A few of them are quoted in the stock markets (mainly in the UK). The furniture firms usually have to borrow money or use part of their profits instead of raising capital on stock markets.

Some important furniture groups appeared in the late 1980s through internal and external expansion. The majority of the groups has one or more production units in several EU countries and sometimes even in the USA. These groups produce and sell either different types of furniture or only one type

of furniture. There are about 50 (groups of) enterprises with a turnover exceeding 100 million ECU.

#### Investments

Globally, the EU furniture manufacturers invest about 4 % of their turnover. In general, these investments are made in four main areas:

- New machinery: about half of all investments. Objectives are generally to automate production processes (Computer-Assisted Manufacturing) and to create synergy between different lines or sites of production. Important investments are made in this area by the medium-sized and large enterprises to maximise their mass production with very high quality/price ratios (i.e. economies of scale).
- Design and creation of new models are made either within the enterprise or by external designers and experts. These include changes in appearance (e.g. through the use of a combination of different types of materials), in ergonomics, in ecology (e.g. recyclable furniture), etc. The new models are presented to the retailers and consumers during furniture fairs or in the show rooms of the furniture manufacturers.
- Advertising and communication: this includes the development of a brand image, detailed catalogues for retailers and consumers, advertising through the media, participation in fairs, training of sales personnel, etc.
- Creation and/or management of distribution channels (see above).

Investments are higher in the office furniture industry than in the rest of the furniture industry. However, all the sectors seriously reduced their investments between 1992 and 1993.

#### Impact of the Single Market

The creation of the Single Market has not had any impact on this industry so far. For example, no increase in the already substantial intra-EU trade has been observed. Furthermore, some measures with relevance to the industry, such as the technical harmonisation and the mutual recognition of rules, and public procurement, are not yet fully implemented. Remaining internal barriers still exist with respect to public procurement markets and safety regulations. Inconsistent applications of both competition and advertising guidelines also constitute internal barriers. Differences in technical standards are not explicitly regarded as trade barriers. According

Source: DEBA

to this industry the next priorities should be policies to facilitate the working environment for SMEs, which dominate this sector.

## REGIONAL DISTRIBUTION

Furniture enterprises are relatively concentrated in the different EU countries. In Germany, the enterprises are concentrated in three Länder: North Rhine-Westphalia, Bavaria and Baden-Württemberg. In Italy, about two-thirds of the enterprises and employment are situated in the northern part of the country. In France, the greatest concentration of firms and employment is in the regions of Brittany, Ile-de-France, Normandy and Rhône-Alpes. In Belgium, nearly all the firms are in the western part of Flanders.

## ENVIRONMENT

The furniture industry is very attentive to the protection of the environment, and the eco-label regulation is an important piece of legislation for the furniture industry. Also, as it is an important user of packaging, the industry already has invested in recyclable packaging to respect the packaging and packaging waste directive.

At the time of this writing, the furniture industry is closely following the development of the integrated pollution prevention and control draft directive, which would ask manufacturers to explain how their firms work and what they are doing to protect the environment in order to obtain permits for their activities.

## REGULATIONS

There are no restrictions between the EU and the EFTA countries: manufacturers can export furniture freely in these countries. As far as access to the Single European Market is concerned, there are different possibilities.

The EU has recently signed Association Agreements with six East European countries in order to prepare them for their eventual accession. The import duties on furniture will gradually decrease until 1997 when they will reach a zero rate. Imports into the EU are duty-free under certain ceilings but imports are taxed if they exceed these ceilings.

In the framework of the GATT, a double zero rate option has been adopted. From 1995 to 2000, import duty rates will decrease by 15 % per year (to eventually reach zero) in the

signing countries. Under the Generalised System of Preferences (GSP): there is a zero rate under certain ceilings, and Member States must ask for the application of the import duty when ceilings are exceeded.

The EU countries often have their own labelling requirements and quality and performance standards, which they try to harmonise with the standards of the Comité Européen de Normalisation (CEN). The CEN/Technical Committee 207 specifically concerns furniture. It has appointed groups for the specific sectors of the furniture market to decide on EU standards. In all, five working groups (WG's) have been set up to discuss and draw up specific standards and testing methods: WG1 for domestic furniture, WG2 for kitchen and bathroom furniture, WG4 for outdoor furniture, WG5 for contract and educational furniture and WG6 for methods of fire safety. In addition, one sub-committee (SC), i.e. SC3 for office furniture, has been devised, and there is also a joint "SC3-WG5" for reception area furniture.

Three standards on furniture have been finalised (i.e. adopted and published): EN 747, Parts 1 and 2 on bunk beds; EN 1021, Parts 1 and 2 on the assessment of flammability of upholstered furniture and prEN 1178, Parts 1 and 2 for high chairs. Two standards have been formally adopted but not yet printed: prEN 597, Parts 1 and 2 for the assessment of the flammability of mattresses and upholstered bed frames and prEN 1129, Parts 1 and 2 for foldaway beds.

In addition to these, many other regulatory measures are being discussed. For example, the EU is awaiting legislation on design protection which could be very important for the furniture industry. The proposed regulation outlines the creation of a registered and unregistered design for the EU. Under this method of registration, furniture manufacturers would have the possibility of registering their model or design with the EU Office of Designs and Models for either the twenty-five years (split up into five-year segments) offered by the registered design option, or for five-year protection under the unregistered design alternative. On the other hand, a proposal of directive would harmonize the different national legislations on the protection of design.

EUFAC is a voluntary industry labelling system made to identify upholstered furniture that is cigarette resistant, i.e. that which has a combination of materials (e.g. fillings, covers and/or interliners) that make it so. This is an alternative to

**Figure 12: Metal and wooden furniture  
Trade intensities**

Source: DEBA

a draft directive on the fire resistance of upholstered furniture. The European Commission supports this voluntary initiative and therefore has decided not to present a directive on this matter.

Another draft directive requires that the new furniture factories using organic solvents (mainly in coatings) or the existing ones exceeding specified threshold limits of VOC emissions shall be registered and authorised by the national authorities. Hence, firms will be required to limit their VOC emissions.

The directives concerning the minimum safety and health at the workplace are generally applicable to the furniture industry. One of these directly concerns the office furniture industry: the Directive on Working with Visual Display Units, which outlines specific requirements for the equipment in the office (desks, chairs, computers, etc.), the environment and the interface of computers and people at the workplace.

---

## OUTLOOK

---

Optimistic macro-economic forecasts (rise in the GDP, increase in the private consumption, stagnation and even a decrease in unemployment and interest rates) should result in positive trends for the furniture industry for at least the next three years. The increase in production in 1995 should result from the strong demand for exports from EU countries with a competitive exchange rate or to those countries where the economy has completely recovered. The consumption of furniture in the Member States themselves should be moderate and even slightly negative in Germany (re: new taxes). In 1996 and 1997, the recovery should be more pronounced (real growth rates exceeding 4 %) both because of increasing intra- and extra-EU exports and domestic consumption. Rising imports from East European and Asian countries will remain a threat for the less competitive EU furniture manufacturers who should be helped a bit by the cooperation of and/or sub-contracting with other EU or non-EU manufacturers. The concentration process in the industry should continue and the large groups should reinforce their positions.

The outlook for the office furniture segment in 1994 also was slightly more favourable. Overall, the decline seems to have come to an end, even though a decrease of 8.5 % was registered in the German office furniture production in that year. Many vacant office buildings remain available which should stimulate the demand for office furniture from 1995 on once they are let. A number of long-term developments in the sub-sector will continue, e.g. investment in office automation and growth in the service sector which also will increase the demand for office furniture in the long run. The attention focused on the office workstation can only increase.

# Jewellery

## NACE 491

The current economic recovery following the two years of recession in 1992 and 1993 will positively affect market demand for jewellery. As the economy recovers and disposable income increases again, demand will shift somewhat towards the higher end of the market. A growing demand for more valuable jewellery with a superior level of service and quality is also caused by the expanding segment of the population made up of middle-aged people. A contrasting trend - the decline of the amount of young people - will negatively influence the lower end market in the medium term. Overall, the outlook for 1995 is optimistic in view of the economic upswing. After 1995 prospects remain promising, as general economic growth is expected to persist.

### INDUSTRY PROFILE

#### Description of the sector

The jewellery sector is divided into six subcategories:

- precious metal or precious plated ware;
- goldsmiths' and silversmiths' wares;
- costume (or "fancy") jewellery;
- diamond cutting;
- precious and semi-precious stones; and
- coins and medals.

An article made of base metal that is simply coated with precious metal and then set with imitation stones would be regarded as costume jewellery. However, if the plating is of high quality, the metal may be set with natural stones, making it difficult for some to recognise the difference between costume and precious jewellery. The industry also includes objects made of precious metals (particularly silver) that are not worn on the person. It is estimated that the share of precious jewellery is somewhat less than 80%; costume jewellery accounts for more than 20% of total market demand for jewellery.

It should be noted that Eurostat data on production and employment show the relative volume of the industry in each country and the trends in production and employment. However, the absolute figures underestimate the importance of the industry, as units with less than 20 employees are not counted in the official statistics. Small firms can account for more than 40% of the jewellery production in a country.

#### Recent trends

On a global scale, the demand for gold for the specific purpose of jewellery fabrication rose markedly in the 1980s, from 54% of total gold production in 1980 to 70% in 1990. In the early 1990s this share fluctuated, and was at 71% in 1993. Demand increased from 2 128 in 1990 to 2 693 tonnes in 1992. In 1993 demand dropped by 7%, equalling 2 501 tonnes of gold. In the course of 1994 some recovery of gold demand occurred, with a small increase recorded in the third quarter (1.4% against the same period in 1993). This upswing, however, is mainly caused by rising investments in gold, rather than by a rising need for gold in order to manufacture jewellery.

In 1993 the economic downturn caused a drop of 4.5% in the EU fabrication of carat gold jewellery, mainly due to a slowdown in Italy, where gold fabrication dropped by 4%, down to 441 tonnes.

The EU market for costume jewellery expanded during the 1980s. In 1993 the total retail sales of costume jewellery was

Figure 1: Jewellery  
Value added in comparison with related industries, 1993

Source: DEBA

estimated at 1.6 billion ECU for the EU. Total retail value of diamond jewellery amounted to nearly 630 million ECU. In 1993 the sales were under pressure throughout Europe leading to drops in jewellery sales of 6% in Italy, 4% in the United Kingdom and 2% in Germany. In France sales increased by 1%.

Due to the economic recession, employment in the jewellery industry has been decreasing since it peaked in 1990, after which it has fallen by an average of 3.5% per annum. Labour costs, however, do not demonstrate a similar downward trend. Until 1992 these costs increased before decreases were recorded in 1993 and 1994.

#### International comparison

The European production of gold jewellery is mainly concentrated in Italy. Globally, however, jewellery manufacture is concentrated in the Far East and Middle East, which constitute nearly 58% of production worldwide.

1994 are DEBA estimates.  
Source: DEBA

When one looks at the demand for diamond jewellery, some noticeable geographical differences can be observed. Retail sales in Japan and the USA are estimated at around 10 billion ECU. However, retail sales per capita are higher in Japan, which has fewer inhabitants. With 1993 retail sales of close to 2 billion ECU, or 35 ECU per capita, Italy has a retail value per capita comparable to that of the USA, and is by far the largest market within the European Union. In contrast, retail sales per capita do not exceed 20 ECU in the Netherlands, Germany and other Western European countries.

**Foreign trade**

The US dollar exchange rate has a large influence on trade and demand in the global jewellery market. In 1993, devalued local currencies vis-à-vis the US dollar in large European markets for jewellery had a negative impact on sales volumes. In contrast, in 1994 the weakness of the US dollar vis-à-vis European currencies resulted in drops in local currency prices

of gold. The impact of these lower prices, however, may not have been passed on to the consumer yet.

Another characteristic of the jewellery industry is that trade is quite intense, resulting from the fact that the enhancement of raw materials and production of end products often involve cross-border trade. Over the 1987-1992 period, import growth rates kept up with export growth, resulting in a fairly stable trade surplus between 4 and 4.5 billion ECU. The EU remains a net exporter of jewellery.

In current prices, extra-EU exports to the USA, India, Israel and EFTA countries increased over the 1988-1993 period. Since these growth rates kept up with the overall export growth, the relative shares of these countries in EU exports did not change dramatically: they remain the most important export markets for end products. Furthermore, exports to the Far East are increasing. The bulk of these exports are semi-finished products, which are exported back to the EU upon completion.

International comparison of production in current prices

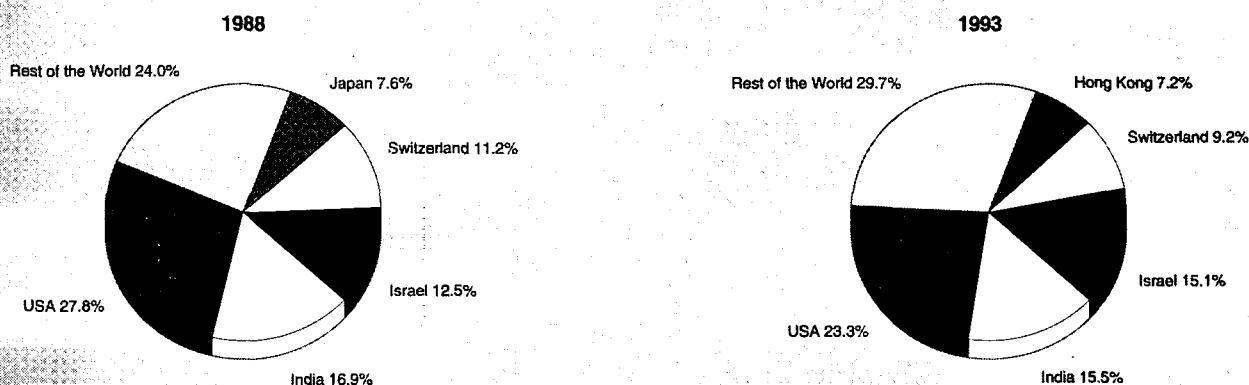

Source: DEBA

**Figure 5: Jewellery**  
International comparison of production in constant prices

Source: DEBA

**Figure 6: Jewellery  
Destination of EU exports**

Source: Eurostat

As a consequence, the Far Eastern countries are registered as importers and exporters of jewellery, but they are not the major foreign suppliers of jewellery on the EU market. The EFTA countries and Switzerland are ahead of India, which is followed closely by the USA.

## MARKET FORCES

### Demand

More than half of the demand for jewellery is constituted of plain gold items, followed by gold with gems (around 25-30 %). Silver and platinum lag far behind, with 7 % and 1 % respectively. Costume jewellery accounts for around 10 % of jewellery sales by metal type.

Regional patterns of demand also can be seen in terms of product line. For example, in the UK earrings, neckwear and rings all account for around 25-30 % of total demand for gold jewellery, followed by wristwear (11 %) and other items (8 %).

The purchase of jewellery is highly seasonal, with one-third of diamond jewellery being bought in December. The rising demand for precious jewellery is a direct result of higher standards of living and personal disposable incomes. It should be noted, however, that national differences can be quite large, depending on the amount of disposable income people are prepared to pay for luxury items. For instance, the World Gold Council has estimated that in Italy, 38 % of all adults buy gold jewellery, compared to 33 % in the UK, 15 % in France and 14 % in Japan.

Most jewellery purchasers are women. However, the percentage of men buying jewellery is rising, not only for gifts, but

also for the increasing portion of men wearing jewellery. Male or female, it is the younger generation that purchases the most jewellery overall, although the older generation purchases the higher end products.

Thus, an ageing population is one of the factors likely to stimulate demand for more costly jewellery in the EU. The demand for unusual pieces and natural materials is the other. Among the discernible trends for more ornate and luxurious fashion items, some interesting developments can be distinguished. There is increased consumer interest in Far Eastern, Indian and African styles; folklore, heraldic and Art Deco themes; floral and animal motifs; and the use of raw materials. The last two trends emerge out of a general concern for ecology and nature.

The results of a recent survey concerning trends in demand for jewellery not containing diamonds were published in a report of the British National Association of Goldsmiths. Not surprisingly, responses from 26 000 adults showed that the effects of the recession limited consumer expenditure over the 1990-1993 period. Also, while the ownership of jewellery is heavily biased towards women, the proportion of men who have their own jewellery has increased marginally. In terms of age, the highest level of penetration is found among the 25-34 year olds. Purchase for self is higher than gift purchase and is biased towards the young. Furthermore, men are more likely to buy jewellery without diamonds for someone else, as are younger people and those who are working.

Customers are increasingly looking to buy one-of-a-kind, high-quality jewellery pieces, rather than discounted, run-of-the-mill items. This fact has been recognised by more and more retailers, who have had to adjust their buying and marketing strategies accordingly.

## Supply and competition

There is little or no brand marketing in the precious jewellery sector, which makes analysing competition at an industry level irrelevant. It is more significant to determine competition at the retail level. Manufacturing for costume jewellery as well as precious jewellery is highly fragmented, with many small companies made up of highly-skilled artisans. At the retail level there is also fragmentation. Precious jewellery is sold mainly through specialty jewellers, whereas costume jewellery is sold at a variety of outlets: department stores, clothing shops, etc.

In the 1980s, some retail chains became important jewellery vendors, including Ratners (parent company of Ratners and H. Samuel) in the United Kingdom, and Magic Moment and Gold Market in Italy. A major shake-up of the retail jewellers involving consolidation and rationalisation is expected throughout the EU. The Ratners Group, for instance, has changed its name to Signet Group, while at the same time undergoing a major reorganisation. In 1992 the Group announced the closure of 330 stores, and in July 1993 a further 54 stores were closed.

Independent jewellers have been hit hard by rising overhead costs, and are expected to give up more of their market share to the multiple specialists and catalogue showrooms. The latter made gains during the downturn in consumer spending and are expected to increase their share in total jewellery sales because of their discounting policy.

Competition in the costume jewellery industry comes mainly from East Asian countries, especially Hong Kong, South Korea, Taiwan and Thailand. Usually these countries operate at the lower end of the market, but product quality is improving. Competition from East Asia takes place mainly through price.

## Production process

Following trends in demand, manufacturers of fashion jewellery are urged to produce up-to-date designs. In theory, new collections are introduced two to four times per year, but in practice new series appear much more frequently. This makes short distribution lines necessary, giving local EU producers an advantage over overseas manufacturers. Much costume jewellery is shipped by air because of the need for quick delivery. In view of the rapid turnover of new collections, high mark-ups (of up to triple keystone) are necessary to compensate for the risk of goods becoming un-sellable. The manufacture of jewellery includes a broad variety of products: brooches, earrings, necklaces, bracelets, rings, hair ornaments, hat ornaments, shoe ornaments, cuff-links, tie-clips, etc.

## INDUSTRY STRUCTURE

### Companies

Most of the enterprises in the precious jewellery industry are artistic in nature, with much time-consuming detailed work involved in the fabrication of each piece. Therefore, it is sometimes difficult for the industry to keep up with the fast pace of demand, as was the case in the 1980s. Compared to costume

**Figure 7: Jewellery**  
**Origin of EU imports**

Source: Eurostat

**Figure 8: Jewellery**  
Pre-tax profits to turnover ratio (1)

(1) Estimated as a percentage of non-labour income in value-added.  
Source: NEI

jewellery, however, the precious jewellery industry has the advantage of not being influenced by fashion trends, and therefore designs last much longer.

Jewellery manufacture, for both precious and costume jewellery, is highly fragmented. For example, Italy's industry has 6 500 businesses, employing 40 000 people (estimated). Generally, the largest companies are private, family-owned and operated businesses.

The primary European precious jewellery firms include: Lyon Alemand Louyet (F), Engelhard (F), Trattamento Ceneri Auroargentari (I), Uno a Erre Italia (I), Rosy Blue (B), Lens Diamond (B), Franz Golz (D) and Guthmann & Wittenauer (D). Among the costume jewellery companies with the highest sales are Bijoux GL (France), Moranduzzo Dario (Italy), Modern Creation München Reisegepack (Germany), and Rudolf Zenner (Germany).

### Strategies

The use of brand marketing is rare in the jewellery industry, with the few existing brands being active in the costume jewellery sector, mainly originating from enterprises with well-known brand names in other industries such as cosmetics or clothing (e.g. Kenzo, Moschino, Fiorucci) which branch out into jewellery. Distribution, therefore, plays an important role in competition and strategy.

Precious jewellery is mainly sold through speciality jewellers, but there is a growing number of multiple and non-specialist outlets. The share of multiple jewellers is increasing, as is the share of catalogue showrooms. The latter operate a discount policy which has enabled them to gain share during the economic recession. Department store and mail order retailers account for minor market shares.

Within the EU, independent jewellers have been losing share since the 1980s, due to the affects of falling demand and rising overhead costs. However, independents still account for a substantial part of all jewellery sales, even higher than in other retail sectors. This is mainly due to the fact that these traditionally family-run jewellers are often located at the middle to upper end of the market and are distinguished from the large collectives by their level of service. They are able to retain their position as jewellery goods are still viewed as luxury items, which means that price does not play a dominant role in consumer buying decisions. In order to reduce

costs, most independent jewellers organise themselves into buying groups in order to gain preferential buying terms.

Most of the enterprises of the industry are too small to activate rigid strategies other than simply following the market. As competition with foreign industries increases, however, more emphasis could be placed on quality.

### Impact of the Single Market

Although mainly indirect, the impact of the Single Market on the jewellery industry has been positive. This industry has indeed benefited from the improvement in the overall economic environment in the Member States, which has been stimulated by the Single Market as it facilitates trade. The jewellery industry is an extremely international industry. To a certain extent the completion of the Single Market has been beneficial to the sector as it has facilitated intra-EU trade. However, EU exports to third countries are also important. Due to the international character of the industry, factors such as the development of the world economy and trends in prices of precious metals and diamonds are also extremely relevant. Within the EU, an important internal barrier still exists. The removal of this barrier, the harmonisation of the marking of precious metals, is considered to be highest priority.

### REGIONAL DISTRIBUTION

The industry has a great need for specialists and therefore remains concentrated in places where the infrastructure has been built over many years. Some locations lend themselves to higher-quality jewellery, some to mass production, and some to the production of larger silver articles.

The main manufacturing centres in Italy are Arezzo, Vicenza and Piedmont. In Germany about 75 % of the trade is based in Pforzheim, with Idar-Oberstein being an important centre of the gemstone industry. Other centres are Schwabisch Gmund, Hanau and Kaufbeuren. In France, Paris and Lyon account for a major part of the industry, as does St. Amand. In the United Kingdom the main centres are London, Hatton Garden, Birmingham and Sheffield (the centre for cutlery and a large portion of the silverware industry). In Belgium, Antwerp is the centre of the jewellery industry. Belgium ranks among the major diamond cutting centres in the world, along with India, Israel and the United States.

## REGULATIONS

---

An important matter for the EU jewellery industry is the progress towards proposed EU Directive (93/C 318/06 amended by 94/C 209/04) for the harmonisation and free movement of precious metal articles. The Directive addresses harmonisation of standards which would replace existing national provisions and would require Member States to comply with "fineness" conformity attestation procedures beginning 1 January 1997.

---

## OUTLOOK

---

The nature of jewellery is changing and the future is likely to see a bigger emphasis on service and quality, as an ageing population and improved standards of living contribute to a growing demand for higher end products. Thus, an intensifying competition in the lower-price market segments is anticipated. However, as the costume jewellery segment remains very sensitive to developments in the world economy, demand is expected to increase in the medium term.

Furthermore, industry demand depends on the price of gold, especially in periods of economic recession, when the gold price might have a particularly negative impact on jewellery demand. In times of economic upswings, this link is much looser. The price of gold showed a relative stability in the course of 1994. Thanks to the economic recovery, demand for gold jewellery is expected to outweigh gold price increases in the medium term.

Competition is expected to intensify further as a result of the Single European Market and production in East Asia. Another threat to domestic EU manufacturers is the assembly of imported pieces into final products by importers. At the same time, subcontracting to manufacturers in the Far East is also growing. These developments put pressure on prices.

After the downturn in 1992 and 1993, the current signs of recovery in the Western European markets will stimulate the production and consumption of jewellery. In 1994 an overall growth of 1.5 % took place. In the medium term an annual average growth of 2 % until 1998 is forecast.

Written by: Netherlands Economic Institute

The industry is represented at the EU level by: International Confederation of Jewellery, Silverware, Diamonds, Pearls and Stones (CIBJO). Address: 78A Luke Street, London, EC2A 4PY United Kingdom; tel: (44 171) 613 4243; fax: (44 171) 613 4450.

# Musical instruments

## NACE 492

The European musical instruments industry specialises in the manufacture of high-quality, high-end, traditional instruments. The industrial performance varies strongly per market segment. Due to the fact that the Eurostat statistics only include data of companies with 20 or more employees, the figures in this monograph are strongly influenced by the performance of the piano segment. After a period of declining sales, total sales have increased slightly in 1994. In the medium term, the slow growth rates are expected to persist, but it is not likely that EU production will be able to reach a higher level than its peak in 1988.

### INDUSTRY PROFILE

#### Description of the sector

Musical instruments include both traditional instruments, whether early or modern, and electronic instruments. The market for musical instruments is highly diversified and can be categorised into the following groups:

- pianos (upright and grand pianos);
- pedal organs and electric organs;
- woodwind/reed instruments (saxophones, oboes, flutes and clarinets);
- brass wind instruments (trumpets, trombones);
- stringed instruments (violins, cellos, violas and double-basses);
- fretted instruments (acoustic guitars, mandolins and banjos);
- percussion instruments (drums, cymbals);
- electric pianos, electric keyboards, portable keyboards;
- synthesisers;
- other instruments (accordions, rhythm machines, harmonicas, harpsichords, pipe organs); and
- accessories and parts (bows, strings, bridges, reeds and components for electronic music).

Within the EU, the production of musical instruments is mainly concentrated in Germany and Italy with respective shares of 47 % and 27 % of total production. Together with France and the United Kingdom, these countries account for more than 94 % of total EU production. Whilst Germany mainly produces traditional instruments, Italian production is primarily in electronic instruments.

#### Recent trends

Over the period 1984-93, the EU production of musical instruments recorded a decline per annum in real terms of 3.3 %. The statistics, however, do not include the production of companies with 20 employees or less. Consequently, these figures mainly reflect the poor performing producers of pianos with more than 20 employees, and do not give a complete picture of the development in all market segments.

According to the available figures - which mainly concern the piano market - it is clear that the musical instruments industry has been performing at relatively low levels. Whilst the total manufacturing industry has been able to maintain or even to increase its production (in constant prices) during the 1980s, the production of musical instruments has demonstrated a structural decline since 1984.

Figure 1: Musical instruments  
Value added in comparison with other industries, 1993

Source: DEBA

Due to the decreasing production, the number of people working in the musical instruments industry has been declining rapidly. Despite a slow down of job losses in 1989, employment has declined structurally by an average of 4.7 % per annum. Again, it should be taken into account that many countries only report employment for firms with 20 employees or more. In Germany alone, 30 % of the workforce is employed by firms with less than 20 employees. When one considers that labour force reduction is more difficult in small companies than in large ones, the decline in employment in recent years is likely to be less significant.

In contrast with production, consumption has demonstrated higher growth rates in current prices, offering non-EU suppliers the opportunity to increase sales within the EU over the period. Between 1984 and 1990, demand grew by an average 5 % per annum. From 1991 on, the economic recession caused a drop in demand, such that EU consumption declined by more than 13 % in only two years. Some recovery of demand was expected for 1994.

**International comparison**

The production of musical instruments is mainly concentrated in the Far East and more specifically in Japan. The Japanese production exceeded 3 100 million ECU in 1993, far ahead of US production (795 million ECU) and EU production (667 million ECU). In the nine years between 1984 and 1993, Japan increased its production in ECU by 17 %. The production of musical instruments is also increasing in other countries of the Far East, namely China and South Korea (which, by the way, accounts for 11 % of extra-EU imports of musical instruments; see below).

**Foreign trade**

The EU is a net importer of musical instruments. During the 1980s, demand shifted towards electronic and digital instruments, which are primarily manufactured in the Far East. This growing demand for foreign instruments has resulted in the increase of imports into the EU at a rate faster than that of extra-EU exports, thereby causing the trade deficit to grow.

In 1989 this deficit reached its highest value equalling nearly 400 million ECU. From 1990 on imports slowed down, whilst exports recorded slight increases. Consequently, the trade deficit dropped by nearly 20 % over the 1989-1993 period.

The USA and Japan are major importers of European musical instruments. Both countries together accounted for 46 % of extra-EU exports in 1993. Other major destinations are Switzerland, Austria and South Korea.

Japan is by far the largest supplier of musical instruments for the EU market, constituting nearly 47 % of total extra-EU imports and far ahead of the USA (14.5 %), South Korea (11 %), Taiwan (8.8 %) and China (6 %).

**MARKET FORCES**

**Demand**

Demand for EU-manufactured musical instruments has been negatively affected by the economic recession of the early

**Figure 4: Musical Instruments**

Source: Eurostat

1990s. Total piano sales worldwide fell from a peak of 1.1 million in the mid-1980s to about 600 000 in the early 1990s. Despite an expected slight recovery of demand, the consumption of musical instruments in the EU remains low compared to the United States.

The development of electronic musical instruments has led to a wider range of products, thus enlarging the total market. These electronic instruments have an advantage over traditional instruments in that they offer new ways of making music which are easier for and more accessible to non-professional musicians. During the 1980s, demand for electronic instruments grew faster than demand for traditional instruments. From 1990 on, however, demand for electronic instruments began to decline.

Demographic developments have opposing effects on the musical instruments market. Decreasing birth rates will lower total demand for musical instruments in the longer term, while in the shorter term the growth of demand for easy electronic instruments (e.g. portable keyboards) will decline. The increasing number of 30 to 40 year olds, however, means more purchasing power and more interest in acoustic instruments in the future.

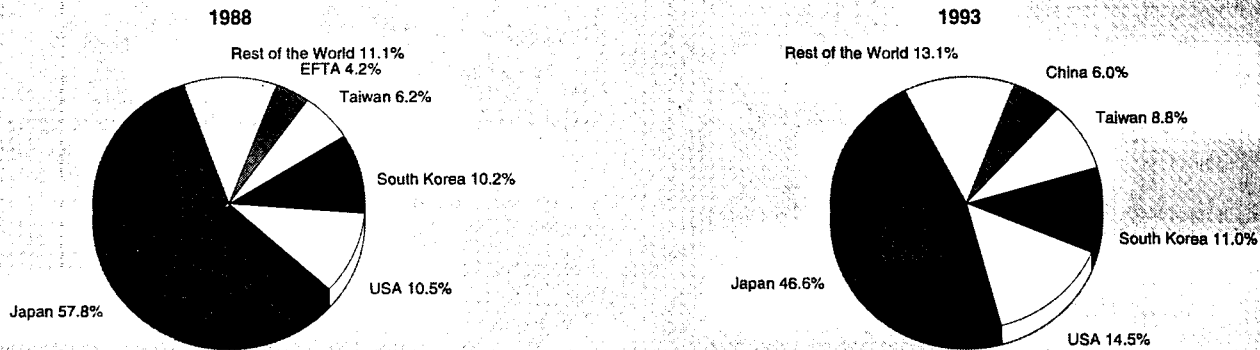

According to market reports from Germany and the UK, there is a trend to use more traditional, acoustic instruments. The renewed interest in jazz in some countries also leads to more demand for traditional instruments like stringed and fretted instruments and wind instruments.

### Supply and competition

Despite a large domestic market and an increasing level of productivity, the EU musical instruments industry lost ground during the 1980s in the competition with instrument makers abroad. Above all, increasing labour costs had a negative impact on EU competitiveness. Moreover, the depreciation of the yen during the second half of the 1980s made Japanese products relatively cheaper in the EU. As mentioned above, the EU production of musical instruments is mainly concentrated on traditional instruments. Japan, in contrast, has benefited from the growing demand for electronic and digital instruments during this period (e.g. keyboards). Since 1990, however, the demand for electronic instruments has started to decline.

In terms of the quality of acoustic instruments, European manufacturers are far ahead of their main competitors. As these manufacturers are highly specialised, trends in demand determine the market performance of the different segments. Recently, for in-

stance, saxophones, other wind instruments and percussion instruments all have been selling quite well.

Competition in the market is intense. EU demand in real terms has shown only a modest growth, while supply and competition from Asia, Eastern Europe and the USA has increased. Moreover, due to the differing composition of EU demand and supply, competition between European suppliers is also high.

Only until 1988 was the industry able to record higher growth rates of labour productivity than unit labour growth rates. From 1989 to 1993, unit labour costs increased by nearly 17 %, whilst the labour productivity grew by 12 % over the same period.

European firms concentrate on high-end products. The high-quality production implies smaller production runs or even custom-made, one-of-a-kind instruments. The EU musical instruments industry, with its specific national features, also plays an important role in transferring European music culture through the instruments it manufactures: all kinds of instruments in Germany, with emphasis on pianos, wind instruments, violins, accordions and harmonicas; a variety of other instruments, including electronic ones in Italy; some woodwind instruments in France; guitars in Spain; and finally, brass wind instruments and some piano manufacture in the United Kingdom.

## INDUSTRY STRUCTURE

### Companies

The EU musical instruments industry is fragmented, with many small and medium-sized firms which are highly specialised. In contrast with the United States and Japan, the EU lacks multinational firms. The small production scale has led to restructuring and mergers in all EU countries.

There are only a few large companies in the EU musical instruments industry. They include: Hohner, Steinway and Sons, Schreiber & Söhne, VMI/IMM-Gruppe and Schimmel in Germany; Bontempi, GEM and Roland Europe in Italy; Selmer and Buffet-Crampon in France; and Boosey & Hawkes in the UK. Steinway Hamburg in Germany is a subsidiary of the American multinational company.

The world's leading company, Yamaha, faces stiff competition from its Asian rivals, and has been losing market share in recent years, a situation which has pressed down on operating margins. Yamaha has tried to strengthen its presence in the EU by acquiring stock in Kemble (UK) and Schimmel (D) and by setting up large subsidiaries throughout Europe. In 1993, however, European sales of Yamaha were negatively affected by the appreciation of the yen against the ECU. Other Asian producers are also trying to enter the European market.

The shift in demand and the development of new markets has led a number of companies to enter the musical instruments industry. An increasing use of computers (in synthesisers and Public Address (PA) systems) has facilitated the entry of a few computer manufacturers into the market.

The development of new electronic instruments has hit the lower quality market the hardest, as EU companies still have an outstanding reputation for the higher quality products. Steinway pianos and Selmer saxophones are still regarded as absolutely the best, as well as Buffet-Crampon clarinets and Hohner accordions and harmonicas.

### Strategies

Owing to large investments in the Italian industry during the early 1980s, productivity improved considerably, causing a serious drop in employment, while the production value in constant prices increased. On the other hand, productivity figures for Germany and the UK have slightly deteriorated since 1987. Nonetheless, overall the EU countries have shown a more or less steady rise in productivity.

Several structural factors influence the industry's operations. First, the EU's most important competitors (Japan, Korea, Taiwan and other Far Eastern countries) have lower labour costs. However, within the EU the value added per employee increased in real terms from about 23 886 ECU in 1984 to 27 256 ECU in 1993, as a result of its increasing production and decreasing workforce. Second, with the small size of the European firms and a tendency toward national specialisation,

**Table 6: Musical instruments

(1) Ratio of production in the sector compared to manufacturing industry for each country, divided by the same ratio for the EU. Estimates.  
Source: DEBA

manufacturers of musical instruments tend to be individualistic and highly independent. As a result, investments in production and marketing are low for the sector as a whole, except for one or two larger companies which have achieved reasonable profitability levels. Finally, because of poor financial resources and of the predominantly manual production process, production automation has developed only slowly. The EU industry, however, still has a few dynamic firms with good technical and human resources, which are beginning to be utilised to their maximum potential. The concentration of products in the top of the market range exemplifies this.

#### Impact of the Single Market

The overall impact of the creation of the Single Market is positive. However, competition from Far Eastern countries (especially from rather large companies from these countries) has increased and threatens the position of many European SME's. All the Internal Market measures which were aimed at improving the working environment for SMEs, such as financial market liberalisation and support to training, are thus extremely important to this sector. At present, the companies in this sector feel that not enough has been done yet for SMEs, to the point that non-EU suppliers may have benefited more from the Single European Market than the EU-firms. For the future, the priority should be measures to improve the working environment for SMEs.

#### REGIONAL DISTRIBUTION

Some local regions have gained world-wide reputations. These include Bayern, Hessen, Sachsen (Vogtland) and Baden-Württemberg in Germany; Castelfidardo in Italy; Paris and Mirecourt in the Vosges in France; and London in the United Kingdom.

#### OUTLOOK

After a dramatic drop of production in 1993 (according to Eurostat figures for pianos and other instruments with keys) a slight recovery was expected for 1994 due to the economic upturn within the EU. In spite of its advantages, the EU musical instruments industry is likely to face a number of difficulties in the next few years. This is owing to the nature of its professional structure and its lack of flexibility in responding to the latest consumer trends, in addition to the fact that its consumption has reached a stage of saturation.

However, some growth of EU production is expected in the coming years due to changing demand patterns resulting from a gradual return to acoustic music (favouring the EU production) and the economic recovery (favouring sales of the higher quality, more expensive European instruments). This growth, however, is expected to be lower than the overall growth of demand.

# Toys

## NACE 494.1

During the early 1990s, the toys market grew significantly. The major factor underlying the overall increase was the explosive growth in the video games category. Imports of video games and toys at low prices from Japan, the US, the Far East and most recently the Eastern European countries have increased competition. Meanwhile, the production of traditional toys has not shifted out of the EU. Its high quality and innovative character give the EU toys industry a competitive advantage. However, the structure of the industry is changing in the EU, leaving at one end of the market small, specialised enterprises and at the other end large, international firms (through mergers and acquisitions).

### INDUSTRY PROFILE

#### Description of the sector

The toys industry is a relatively small sector in the EU; total EU toy production amounted to 3 883 million ECU in 1993. Almost one-third of the total EU production originates from Germany. The shares of total EU production (including Austria, Finland and Sweden) of France, Italy, Spain and Denmark amount to 20 %, 18 %, 17 % and 10 % respectively.

The toys market consists of a very diverse range of products, with wide differences between target markets and unit prices. Recently, electronic products (the largest category in terms of production) have made substantial gains in share because of the growth in video and computer games.

The toys market can be divided into ten subsectors: electronic toys (e.g. video and computer games, radio-controlled vehicles), dolls and figures (e.g. dolls and accessories, action figures, plush toys), indoor toys (e.g. games and jigsaw puzzles), pre-school toys (e.g. toys for infants aged 2 to 36 months), outdoor toys (e.g. riding vehicles, play sets), creative toys (e.g. arts and crafts, scientific/educational, musical), construction toys (e.g. construction sets, model kits), model wheeled toys (e.g. non-riding vehicles, car and train sets), adult imitation toys (e.g. play houses, kitchen sets) and other toys (e.g. activity toys).

Nearly 2 500 manufacturers, most of them small or medium-sized enterprises, provide direct jobs for 80 000 employees, in addition to the particularly high rate of indirect jobs, especially during the last quarter of the year (i.e. during the Christmas season).

#### Recent trends

There has been a buoyant trend for the toys market throughout the mid-1990s. Besides the expansion of the video games market (although a strong decline was recorded in 1994), business innovation is the main factor behind this growth. Electronic games continue to be the key sector, entirely because of video and computer games. The dynamic expansion of dedicated console systems and software continued in 1993 and then gradually slowed down and declined substantially in 1994.

The growth in video and computer games is likely to further lower the age at which children are "lost" from the toys market to areas such as clothes, recorded music and consumer electronics. As growth in the video game sector slows down, the more traditional areas like indoor games, play sets, model wheeled and adult imitation toys are likely to receive a small boost. Nevertheless, the video games are to be considered more as a complement buying than an alternative buying. However, if the interest in electronic entertainment products

Figure 1: Toys  
Production in comparison with other industries, 1993

Source: TME, DEBA

persists, it could eventually cause substantial changes in the structure of the market. Alternatively, the development of more sophisticated and more expensive products may push the focus of the video game market onto young adults rather than children. Sectors which are expected to benefit from the growing child population are those targeted at very young children, such as pre-school and plush toys.

Other more general trends include the continued importance of character licensing, which is used in marketing many child-targeted products such as clothing, books, magazines and food. This should prove a more powerful medium with the effective timing of film, television and video promotion of the relevant toys.

Since March 15, 1994, the import of some Chinese toys into the EU has been restricted. Although, final import figures were not available at the time of publication, this is expected to result in a 20 % decrease of EU toy imports from China.

### International comparison

China accounts for 40 % of the world toy production, and the toys industry is the fastest growing export sector of China. Since the early 1980s production lines have undergone a rotation within the Far East, shifting from Hong Kong to China, where labour costs are lower. Although labour costs in countries like Vietnam and Indonesia are nowadays lower than those in China, most toy manufacturers feel that China is still the most economical manufacturer of toys when quality is taken into account. At the time of this writing, there are some production moves from China to other south-east Asian countries as a result of the EU import quota system adopted in March 1994 (see above).

Geographically, the EU toys industry is highly concentrated. More than 90 % of total EU production (including Austria, Finland and Sweden) stems from the following six countries: Germany (26.2 %), France (22.9 %), Italy (17.4 %), Denmark (9.9 %), Spain (9.2 %) and the United Kingdom (7.4 %).

**Figure 3: Toys**  
**National toy markets at retail prices by country, 1993**

Source: TME

### Foreign trade

Many EU countries are net importers of toys (with the exception of Spain and Denmark). The former EFTA countries and the USA were the main destinations of EU exports (almost 49 % of all exports go to these countries), while EU imports mainly originate in China (43.4 %) and Japan (22.7 %).

The EU trade deficit in 1993 amounted to about 3 446 million ECU. The most important EU exporting countries of all toys and video games are Germany (19 %), Italy (16 %) and Denmark (15 %). The situation is slightly different if figures for video games are excluded. Then, the top three exporting countries are Germany (38 %), Italy (14 %) and Spain (13.5 %) (Source: FEJ). The share of exports of video games in total exports was about 5 % in 1993. The exports of video games originate mainly from the United Kingdom (33 % of total EU video games exports), Germany (21 %) and France (20 %).

More than 60 % of total EU imports is destined for three countries: Germany (24 % of total EU toy imports), the United Kingdom (21 %) and France (19 %). Again, if one looks at EU import figures of toys without the video games segment, these three countries still predominate, albeit to a slightly different degree: Germany accounts for 26 %, the UK for 25.5 % and France for 15 %. Almost 20 % of total imports consist of video games. The main destinations for the imports of video games in the EU are the United Kingdom (36 %), France (24 %) and Germany (15 %).

### MARKET FORCES

#### Demand

The toys industry is relatively insensitive to business or trade cycles. In other words, the influence of a recession on this sector is rather small. Despite the decreasing number of children, the size of the toy market has been increasing. This is a result of the higher average age at which parents have their first child, i.e. they have a larger disposable income, thus the number of toys received per child per year and the amount spent on these toys have increased. Furthermore, although the total number of children in the EU has been decreasing since 1985, an expected increase in children aged 0-5 years will moderate this decline. Therefore, the demand for mainly pre-school and plush toys will increase.

The two main factors which influence demand are product development and strong marketing campaigns. Increasingly, fashion and promotional best-sellers play an important role in demand. Demand, however, can switch from one best-seller to another in a short period of time. The toy industry is, above all, an industry which responds to a highly cyclical demand pattern, i.e. seasonality is an important characteristic of the demand for toys. In fact, some 65-70 % of the total volume of toys is sold to consumers in the last three months of the year (around Christmas).

**Figure 4: Toys**  
Production in constant prices compared to EU manufacturing

Source: TME, DEBA

### Supply and competition

Foreign competitors come mainly from the US and the Far East. More and more, the Far East has become a sourcing location for European manufacturers, thus enabling them to better compete on a worldwide basis. However, since March 15, 1994 supply from China is restricted.

The concentration of toy manufacturers is increasing through mergers and acquisitions. The number of toy retailers also decreased significantly between 1984 and 1994, resulting in a concentration on the supply side into the hands of fewer, more professional, internationally operating companies.

Unlike in the United Kingdom, where toy specialists are the leading retail channel followed by mail order/catalogue, in France approximately 48 % of toys is sold in supermarkets and department stores. In the United Kingdom, department stores are responsible for only 5 % of total sales. In Germany on the other hand, most of the sales originate from traditional full-range specialist retailers (34 %), followed by department stores (21 %) and supermarkets (22 %). The distribution of the different channels in Spain is: superstores 35 %, retailers

and specialists 28 %, wholesalers 23 %, department stores 12 % and others 2 %. The French distribution mark-up is lower than the average EU distribution mark-up, implying that the average EU share of department and super stores in its total toy sales is smaller than in France. At the opposite end of the spectrum are the Scandinavian countries, where one finds the highest concentration of specialist retailers, and consequently the highest mark-ups in Europe.

It is worth noting that over the last few years, the presence of the American toy retail chain Toys R' Us in Europe has increased the competition among specialist retailers, supermarkets and department stores. This is a reflection of the fact that it offers a comprehensive assortment of toys all year long.

### Production process

The lower labour costs in the Far East have attracted EU manufacturers. However, some successful companies still manufacture in Europe as well, e.g. LEGO (DK), Playmobil (D), Hasbro (US), Meccano (F), Waddington (UK), Ravensburger (D), Jumbo (NL), Majorette (F), Famosa (E) and Mattel (US). For some of these, the European share in production is sometimes up to 100 %. Although the labour costs in Denmark and Switzerland are especially high, the LEGO group continues to produce in these countries because of the high level of automation and the need for high precision manufacturing.

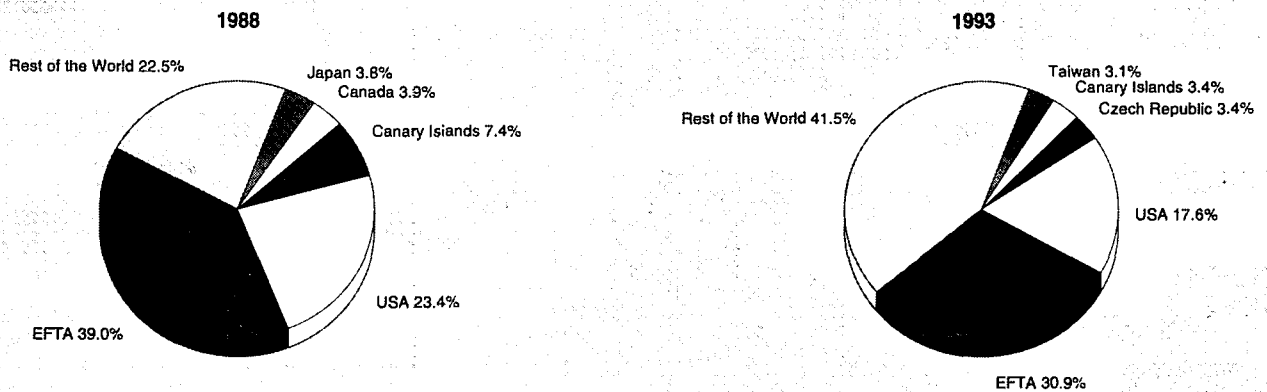

The concession of licensing is, in addition to the development of manufacturing in Europe or the Far East, a key element to the success of EU companies. International companies, armed with appropriate distribution networks, benefit from the licensing system. However, the majority of EU companies lack a proper international distribution system.

## INDUSTRY STRUCTURE

### Companies

The EU toys industry consists of a wide spectrum of companies of different sizes: from small, privately-owned, domestic manufacturers to large, international toy companies. Multinationals can be found in Japan and the US. In the EU the average firm size is relatively small; 80 % of the toy manufacturers in the EU employ fewer than 20 salaried workers. With the exception of LEGO (DK), Playmobil (D) and Idéal Loisirs (F), multinational firms comparable to American and Japanese groups are absent in the EU.

The most important manufacturers in the EU toys market are:

- LEGO (DK): construction sets, e.g. Duplo, LEGO System, LEGO Technics;
- Ravensburger (D): indoor games;
- Playmobil (D): plastic figures and accessories;
- Hasbro (US): indoor games (MB, Waddington, Parker), fashion dolls (Sindy) and pre-school toys (Playskool);
- Mattel (US): fashion dolls (Barbie), pre-school toys (Fisher Price), indoor games (Spear), die-cast vehicles (Corgi);
- Idéal Loisirs (F): dolls, figures and accessories, pre-school toys and die-cast vehicles (Majorette, Solido);
- Superjouet Group (F): plastic toys (Berchet-Favre, Charton, Clairbois);

Other important enterprises in the EU toys market are Meccano (F), Hornby (UK), Clementoni (I), Burago (I), Jumbo (NL), Märklin (D), Jeux Nathan (F), Brio (S), Smoby (F), Famosa (E), Chicco (I), Steiff (D) and Schmidt (D)

The EU toy and games industry consists of a wide spectrum of companies of different sizes: from small privately owned domestic manufacturers to large international toy companies. With the exception of LEGO, multinational firms comparable to American groups like Hasbro and Mattel are absent in the EU.

### Strategies

The internationalisation of the industry has led to mergers and acquisitions. The French firm Idéal Loisirs is now one of the biggest international companies in the EU, due to its alliance with the Hong Kong-based Playmates company and its acquisition of the French firm Majorette. Apart from this

**Figure 7: Toys**  
**Trade intensities**

Source: TME, Eurostat

concentration of resources into fewer and larger international companies, a process of polarisation is appearing: at one end large companies increase their market shares by becoming multi-product firms, at the other smaller niche manufacturers acquire strong positions by focusing on a particular segment of the market.

European toy manufacturers specialise in traditional toys. The EU video games market is dominated by the Japanese companies Nintendo and Sega. The two leading toy manufacturers in the US and the world, Mattel Inc. and Hasbro Inc., are multi-product firms, which have condensed several smaller enterprises into one. Playskool, Milton Bradley, Kenner Parker, MB Games, Waddington and Tonka form divisions of Hasbro. Mattel acquired Fisher Price and Spear in 1994. The third toy manufacturer in the US and the world, Tyco Toys Inc., includes Matchbox, View Master and Playtime.

In January 1995, four French toy manufacturers (Berchet, Charton, Clairbois and Favre) merged to form the French Superjouet Group. The group was mainly formed for export purposes and since has become a leader on the French market.

Western know-how and financing have been used to support East European toy manufacturers. Nowadays, the quality of the toys manufactured in Central and Eastern Europe is on par with western standards, and enhance the competition on the EU market.

## Impact of the Single Market

The impact of globalisation on this international industry has been larger than the impact of the Single Market, though the latter has been positive overall. Nevertheless, some internal barriers remain, for example with respect to television advertising and safety requirements for infant care products. A harmonisation of these aspects would be welcomed by the industry. The different interpretation and implementation of certain EU regulations and directives in the various Member States is also a major problem in this sector.

## ENVIRONMENT

The toys industry has proved to be pro-active in the face of the increasing environmental consciousness among consumers. Wooden toys have benefited from the increased public ecological awareness. The "Green Movement" has led national governments, followed by the EU, to prepare rules designed to ensure the reduction of packaging waste. The toys industry has taken an active part in these debates and favours a single EU system aimed at reducing packaging waste.

## REGULATIONS

The EU Toy Safety Directive (adopted on May 3, 1988) contains essential physical, mechanical, chemical, electrical and flammability requirements, which, if fulfilled by toy manufacturers, allow them to affix on their products (or packaging) the CE mark. This sign is an indication to surveillance officers that the product conforms to relevant EU safety regulations and can therefore circulate freely within the Internal Market. The Toy Safety Directive lays out a set of harmonised standards (elaborated by CEN and CENELEC), which are constantly being revised and extended.

Advertising regulations (misleading information) and regulations relating to intellectual property (trademark and design protection) also affect the toys industry. Toy manufacturers in Europe also face unfair competition, which takes the form of: dumping practices on the prices of low-range toys; piracy and imitation of design, trade-marks and models; and manufacturing of products which do not comply with European safety standards.

The Council regulation (EC) 339/93 provides conformity controls on products imported from third countries and on EU rules concerning general product security (which apply especially to toys).

The European toy industry is increasingly affected by trade measures (i.e. GATT rules and specific EU regulations). As a result of the GATT negotiations, customs tariffs on toys will be lowered over the next five years. On the other hand, two regulations with major consequences for the EU toys industry were adopted on March 7, 1994: Council Regulation

**Table 6: Toys**

(EC) 519/94 on common rules for imports from certain third countries and repealing Regulations (EEC) 1765/82, 1766/82 and 3420/83; and Council Regulation (EC) 520/94 establishing a Community procedure for administering quantitative quotas of imports of products covered by regulation 519/94 and originating from 20 countries of Eastern Europe and the Far East (including the People's Republic of China, Vietnam and North Korea). Of particular relevance are the quotas on three categories of toys imported from China organised and set by these two regulations.

---

## OUTLOOK

---

In the short term, EU production will increase slightly as a result of the rising demand for traditional toys. Two trends in the pattern of demand can be observed. First, the demand for video games, which exploded in the early 1990s and peaked in 1992, is expected to decline slightly in the near future. Second, the child population aged 0-5 years is predicted to increase during the 1993-2000 period. In the medium term, the disposable income will increase as the economy recovers further. Apparent EU consumption is therefore expected to increase as well.

The EU imports originating from China will diminish as a consequence of the recently adopted EU regulation mentioned above. Total EU imports, however, are not expected to decrease, as China's production will shift to other countries in the region which offer cheap labour. The EU toy and game production plants will not be shifted out of the EU, as quality and innovation will continue to be important competitive advantages of the EU products. Therefore, in the medium and long term, total EU toy exports and production are expected to increase.

# Sporting goods

## NACE 494.2, part of 451, 453

The EU market for sporting goods comprises numerous smaller market segments. Sporting equipment, sports footwear and sports clothing are the three main sub-markets which themselves are highly fragmented. Total demand is increasingly related to overall trends in consumer preference. EU production has been shifted to the lower labour cost countries in the Far East. As a consequence, EU imports from Asian countries have increased, leading to a further growth of the EU trade deficit.

### INDUSTRY PROFILE

#### Description of the sector

The sporting goods industry can be divided into sporting equipment (NACE 494.2), sports footwear (part of NACE 451) and sports clothing (part of NACE 453).

The key problem of analysing the sporting goods market is determining how to differentiate a sport from a general leisure activity, as it is often nearly impossible to distinguish between sports use and leisure usage. Moreover, the diversity of the sporting goods market hinders the survey of every market for sporting goods. Given these complications, most of the tables and figures in this chapter refer to NACE 494, toys and sporting goods.

For sport shops, footwear is the most important source of income (40-50 % of total sales) followed by equipment (25-30 %) and then clothing (20-25 %). The share of the sports clothing market in the market of sporting goods, however, is around 50 %, followed by the footwear market (32 %) and the equipment market (18 %).

Like the sports market as a whole, the sports equipment sector is diverse and fragmented. In the United Kingdom, for example, golf is the largest sector of the sports equipment market (in sales), followed by fitness and fishing.

Six EU countries account for over 95 % of the value added of the toy and sporting goods sector: Germany (33.5 %), France (25 %), the United Kingdom (13 %) and to a lesser extent Denmark (11.7 %), Spain (8.5 %) and Italy (4.7 %). Germany, France, the United Kingdom and Italy are main exporters of sporting goods.

The largest markets in the EU for sporting goods are Germany, France and the United Kingdom. Belgium, the Netherlands and Denmark are characterised by high purchasing power. However, South European countries offer prospects for increasing consumer expenditures on sporting goods.

The EU countries with the largest share in total EU value added are also the major employers. Within the EU the total of the countries' value added/employment ratios amount to about 3 500 ECU/employee. This ratio is relatively low if compared to the corresponding Japanese and US figures: 6 500 and 5 100 ECU per employee respectively. A further decline in the industry's employment is expected as most manufacturers will continue to move their production plants to low-wage countries.

#### Recent trends

Three factors have stimulated and will further stimulate sports activities: the rising income per capita; the increase in leisure time and the increased interest in sports because of health reasons.

Figure 1: Toys and sports goods  
Value added in comparison with related industries, 1993

Source: DEBA

The sporting goods market is characterised by fashion-led demand. Consumption increasingly depends on consumer preference, e.g. popular sports and popular styles. Therefore, sporting goods manufacturers must be flexible to adapt quickly to these changing fads; thus, competition between the large manufacturers increases.

By way of example, in France, sports like walking, cycling and jogging are increasingly popular. Expenses on golf and basketball goods are increasing as well. The sports equipment market has suffered from the growth of sports such as swimming and aerobics which involve minimal equipment purchases by individuals. Currently there is a rapidly developing market in fitness equipment.

#### International comparison

The production capacity in the USA has expanded during the 1987-1990 period. Since 1990 production shifted from the US to countries with lower labour costs (Asia). From 1990 on the EU production in constant prices dropped, while the

Source: DEBA

Japanese and US production in constant prices continued to increase until 1992. The Japanese growth rate amounted to approximately 8-9 % per year during the 1984-1993 period.

While the EU production of toys and sporting goods (in current prices) increased by around 38 % during the 1984-1993 period, the Japanese production almost doubled. This significant difference in Japanese production, however, is partly a consequence of the change in the value of the yen.

**Foreign trade**

The EU countries are all net importers of sporting goods. The shift of production to lower labour cost countries, has led to the growth of imports from East and Southeast Asia and a decline in imports from the USA. In 1993, the six most important countries from which EU imports of sporting goods originate were Taiwan, Austria, USA, South Korea and Japan.

Taiwan is a net exporter. The Taiwanese production of sporting goods declined in 1993 as a result of the global recession.

Taiwanese imports of bicycles, bowling and golf equipment, however, are increasing. These imports originate mainly in the USA, Japan and Germany.

The most important EU export destinations for sporting goods were the EFTA countries, the USA, Japan and, to a much smaller extent, Canada and Bulgaria. Destinations for the EU sports footwear industry were Japan and the USA as well as Switzerland, Austria and Russia. There is a rapid growth in demand from Eastern Europe, which has proven to be a booming market for the running shoe suppliers.

**MARKET FORCES**

**Demand**

The public sector is responsible for most of the demand for sports equipment. A case in point is France, where the public sector's share of total demand for sports equipment was 50 %. The share of the public sector in overall EU demand for sport-

**Figure 4: Toys and sports goods**  
International comparison of production in current prices

Source: DEBA

**Figure 5: Toys and sports goods**  
International comparison of production in constant prices

Source: DEBA

**Figure 6: Sporting goods  
Destination of EU exports**

Source: Eurostat

ing goods, however, is much smaller than 50 %. And, while household demand for sports equipment is fairly constant, the demand of the public sector is decreasing.

Outdoor sports like walking and cycling, year-round recreational activities, higher quality products and more individualistic sports are all becoming more attractive. Demographic changes with a growing proportion of the population over 25 years old also have contributed to the changing pattern in demand.

In the late 1980s and early 1990s the sports equipment market lost out to the rise in individual sports like jogging and aerobics, which required little or no equipment. Against this trend, however, has come the rise in popularity of golf and the boom in health and fitness. Even the aerobics market is being opened to equipment, with the growth of step and slide aerobics.

Europe still has great potential for the sports footwear industry. In the US, sales of sports shoes per capita are much higher, although the "sneaker boom" is over. 80 % of sports shoes are purchased for casual wear and 20 % for performance. This will continue as sports shoe suppliers move into the outdoor style of casual footwear typified by the US Timberland brand.

### Supply and competition

The sports footwear industry has become a very specialised industry. The presence of niches and specific requirements for each of the different sports together involve market segmentation. The market segmentation means that Adidas, Nike and Reebok each have their own area of specialisation; soccer cleats, running shoes and women's' aerobics shoes, respectively. These three suppliers dominate the European sports shoe market, but there are local brands competing for the business as well.

Unlike the sports footwear and sports clothing markets, the sports equipment sector always has been less influenced by fashion and branding, with technical factors being of more importance. Over the next five years the sports equipment market could see relatively good growth. As in other sectors of the sports market, however, the price competition will intensify as a consequence of the internationalisation of the retail industry across Europe. This internationalisation is putting increasing pressure on consumer goods firms (and thus on sporting goods manufacturers) to align their prices.

There is a particularly strong competition coming from manufacturers in the Far East. The size of their production capacity and new production technologies allow them to deliver large

**Figure 7: Sports footwear  
Destination of EU exports**

Source: Eurostat

**Figure 8: Sporting goods  
Origin of EU imports**

Source: Eurostat

orders of relatively good quality at low prices because of the low labour cost in this region.

### Production process

Most of the companies in the sporting goods industry have moved their factories to the low-wage countries in the Far East and Eastern Europe. The manufacturing is usually carried out by independent companies while design, quality, control, distribution and marketing functions are controlled and carried out by the respective brand companies. For example, Adidas no longer owns the factories that produce its shoes. Rather, the only Adidas production line within the EU - in Scheinfeld (Germany) - concentrates on development work.

## INDUSTRY STRUCTURE

### Companies

The market share of the European branded sports footwear market is held as follows: Nike (20 %), Reebok (17 %) and Adidas (16 %). Adidas dominates Germany, Europe's biggest market. Nike, however, is probably the overall European market leader. Puma is a contender for fourth place. Smaller shoe suppliers in Europe include High Tech, which is sold mainly in the UK, and Kelme and Diadora, sold primarily in Italy.

The Japanese are also making inroads into the European market, with the Mizuno and Asics brands.

The UK has around 400-500 sporting goods manufacturers. The number of factories and the level of employment in the UK have been declining. The largest number of suppliers are found in markets where consumers tend to replace products on a regular basis, such as soccer balls, rackets, cricket balls and darts. Major suppliers in the United Kingdom are the following: BRT (leader in the UK racket markets, with the brands Dunlop, Slazenger, Carlton, Maxfli); Mitre Sports International (multi-product organisation); Pro Kennex (the world's largest manufacturer of rackets) and E.J. Riley (the leader in the snooker and billiard table market).

Other important manufacturers in the EU sporting goods market are: Rossignol (F), Salomon (F), Fisher (D), Lacoste (F), Bogner (D), Kettler (D) and Donnay (B).

### Strategies

The sporting goods industry benefits directly from the promotion of specific products and indirectly from the promotion of sports in general. In order to attract the younger generation, sporting goods manufacturers moved away from print media and are concentrating their advertising in television.

Source: Eurostat

Although the sporting goods industry consists of a large number of small and medium-sized enterprises, there is a growing concentration of large companies within the EU. To protect themselves from this phenomenon, smaller firms are finding ways to cooperate more and more. A well-developed distribution network is a crucial factor in such a highly competitive sector. Reebok's newly adopted distribution approach entailed the selling of its products (footwear, clothing and accessories) together in theme collections. This merchandising strategy resulted in improved sales resulting from more impulse purchases.

Important strategies in the Taiwanese sporting goods sector are innovation and creativity. The following examples illustrate these strategies: the application of electronics in fitness equipment and the usage of certain high-tech materials in tennis or golf equipment. In order to enhance the technological level and quality of the products while simultaneously keeping the costs as low as possible, sporting goods manufacturers cooperate with specialised firms in other industries (e.g. machinery).

#### Impact of the Single Market

The creation of the Single Market has positively influenced the sector of sport goods as the removal of the internal barriers and the harmonisation of regulations have stimulated intra-EU trade and paved the way for a more perfect competition. Furthermore, the creation of the Single Market has given incentives for companies to think more internationally and to operate in more than one Member State. Important remaining internal barriers are differences in indirect tax rates (VAT) and the still cumbersome bureaucracy. Next priorities should be (in order of importance): an easing of the access to finance by

SME's, a better harmonisation of environmental regulations, and improvements in the availability of statistics. Finally, the EU should continue to work on the removal of external barriers (following-up the outcomes of the Uruguay-round).

#### REGIONAL DISTRIBUTION

Figures about the number of sporting goods manufacturers in the EU can only be indicative. This is not only because the sporting goods industry is very heterogeneous, but also because it depends on subtle differences in interpretation to determine whether or not a company is considered to be a part of it. The largest number of firms are found in the sports clothing sector, the smallest number in the highly concentrated sports footwear sector.

The geographical pattern within the EU is very different. In countries like Italy and Spain production is concentrated in certain regions, while the companies in Germany and France are spread throughout the country.

#### REGULATIONS

Of importance for sporting goods manufacturers are the harmonisation of standards, intellectual property rights and competition policy.

Imports of sporting goods from a number of developing countries are admitted duty-free or granted preferential access under the Generalised System of Preferences (GSP). A revised four year scheme begins in 1995 which will replace the quotas and ceilings of the previous system by a modulation of tariffs

and preferences for the various country/product group combinations.

Product liability laws increase the responsibility of producers and importers in the EU markets. These laws concern aspects like design and construction standards, production or assembly defects, false advertising and misleading or inadequate user instructions.

---

## OUTLOOK

---

In the short term, the most important influence on the sporting goods market will be the performance of the economy, which shows a slow and patchy recovery from the recession since 1993. In the medium and long term this economic recovery will result in an increasing demand for sporting goods in the EU.

EU production will not grow at the same rate as EU consumption because an increasing part of production will be done by outsourcing production to countries with cheaper labour. Moreover, the fierce competition from foreign suppliers will not allow for a significant increase in production and exports.

The sports market will face another major challenge. Its core market of 15-34 year olds will decrease by around 11 % by the end of the 1990s. The demographic changes point towards a growth in sports like walking and golf. The equipment sector could benefit from a rise in spending on golf, although a decline in demand of health and fitness equipment would offset this positive trend.

The industry is represented at the EU level by: Federation of the European Sporting Goods Industry (FESI). Address: 5 Avenue de Janvier, B-1200 Brussels; tel: (32 2) 762 8648; fax: (32 2) 762 7506.

## Overview

### NACE 50

Construction is one of the biggest sectors of European industry with gross output accounting for 10-12 % of GDP in the EU; value added is about half that. Construction also represents about 60 % of gross fixed capital formation. The sector is a major employer with around 9 million employed by contractors. It also generates direct employment for 3 to 4 million in construction products. This is around 10 % of civilian employment. It probably generates as much again in indirect employment.

Construction is mainly a local activity, with few large firms and little export activity. However, EU firms are successful in world markets. Intra-EU cross-border activity is increasing on large projects and there is extensive migrant labour.

Future markets are highly uncertain because they depend on economic growth rates and levels of public expenditure. EU infrastructure needs are expected to boost demand. Privatisation is generally reducing the share of public sector financing, which is approximately half of total demand.

Technology and the use of materials is rapidly changing. Research and development, training and quality management are key factors for future developments in the sector.

tirely separate, however, as some major construction groups have invested in quarrying and the production of basic construction products. More recently, a growing part has been played by specialists who manufacture and install major components and sub-assemblies (e.g. structural steelwork, curtain walling, heating and ventilation systems).

Mention should also be made of the contribution of independent practices of construction professionals responsible for design, measurement, etc., including architects and construction economists (described in Chapter 24). The contribution of these construction professionals, in terms of economic significance, is relatively small, accounting for only 6-10 % of total construction output. However, the quality of work of European architects and consulting engineers is a major factor raising the competitiveness of the European construction industry.

Classification of construction activities differs between countries. Most construction activity is recorded under NACE 50. However, some construction, involving a substantial input of metal components or process plant (e.g. steelworks, petrochemical plants, power stations, hydroelectric plants, pipelines) or carried out by enterprises also engaged in the manufacture of construction materials, may be included in the output of other industries.

Manufacturers of construction products are mainly classified under NACE 24 (Non-metallic mineral products), NACE 31 (Metal products), NACE 462 (Semi-finished wood products) and NACE 47 (Pulp, paper, printing and publishing). Construction professionals are mainly classified under NACE 837 (Professional services). Construction is traditionally divided by statistics and regulations into NACE 501 (Building) and NACE 502 (Civil engineering). Some countries further subdivide building into structural works and finishing works. Other commonly used sub-divisions for building and civil

### INDUSTRY PROFILE

#### Description of the sector

At the simplest level, the construction sector has two main constituents: constructors of works and suppliers and manufacturers of construction materials. These groups are not en-

engineering include: housing and non-residential building; work for public and private sector clients; and, new construction and repair, maintenance and improvement. However, these distinctions are not clear-cut and do not necessarily correspond to distinct types of firms.

Many large enterprises are active in several of these activities and may have specialised subsidiaries for each market segment. The great majority of construction enterprises, however, are small and medium-sized firms, including a large number of micro-businesses. As shown in Table 7, about 97 % of the firms have less than 20 employees.

#### Distinct technologies

Modern buildings and structures make use of a multitude of specialised technologies. In recent years, there has been rapid technological progress in the industry with respect to better construction methods and the manufacture of construction products. However, the need to repair, maintain and alter the existing built environment means that the industry needs to retain a competence in older technologies as well. Consequently, the construction industry's technologies range from traditional, labour intensive, site-based crafts to sophisticated, industrialised technologies in, for example, control systems in intelligent buildings.

Many construction firms specialise in one technology or in a small group of related technologies. Because clients frequently require heavily one-off designs, many projects bring specialised firms together to form a unique project team. Therefore, in addition to individual specialised technologies, the industry uses general contractors, with or without independent design consultants, to create an overall design and management framework for individual projects.

Specific technology trends are affecting the construction industry: for example, computer-aided design (CAD) systems are gradually integrating traditionally fragmented processes. Prefabrication is moving work away from construction sites into factories; at present, this is mainly 'light prefabrication' of sub-components, such as building frame members and modules like toilet pods. However, discredited large scale building systems may again become viable using CAD and flexible manufacturing technology. Electronic control and communi-

cation systems are providing a basis for intelligent buildings and infrastructures that are linking the industry's products with its processes in ways that were previously impossible. The industry is also developing answers to the challenges of new environmental criteria and providing solutions for repair of environmental damage and constructions that respect the environment.

#### Types of clients

The sector is also fragmented because of the requirements of different types of clients.

- Most clients are small firms or individuals who have a problem that can be solved by simple construction work; e.g. repairs, maintenance or alterations. This creates an industry with many small firms serving local markets.
- Firms or public bodies, another type of client, need more substantial construction work. They are not expert in construction matters and require professional advice that they can trust. They also want to be involved in determining the design, price and schedule. This type of client tends to use medium or large construction firms working with independent architects or consulting engineers.
- A third type of client needs construction work but is experienced in employing an appropriate mix of consultants and contractors. These clients tend to determine contract conditions to suit their own way of working and buy specific services to suit the needs of the project. This category includes many clients in the public sector and utilities who are required, by the Public Procurement Directives, to organise competition among suppliers.

Market developments also show a tendency towards more integrated services, combining design and construction and, sometimes, maintenance, operating, etc. in varying degrees.

#### Recent trends

Construction activity in the EU fell by 1.6 % between 1992 and 1993 compared to an increase of 1.9 % between 1991 and 1992. In 1993, activity in Germany grew with investment in the new Länder, but was static or fell in all other EU countries. This was also the case in the EFTA countries. In 1994, however, total EU output was expected to increase by

**Table 2: Construction**

Source: FIEC (12/94)

a little over 2 %. Continued growth in Germany and recovery in most other Member States will offset continued reduction in construction output; particularly in Italy. FIEC expects that in 1995 the recovery will spread with a return to growth in activity in all countries except France and Italy (Table 1).

In 1993, total building output fell by 1.1 % and civil engineering fell by 3.6 % (see Table 1 and 2). There was growth in housebuilding and repair and maintenance of housing stock, but reductions in public and private non-residential building. For 1994 and 1995, FIEC expects stronger growth in the entire housing sector, recovery in public non-residential building, and a slight recovery in civil engineering. Private non-residential building is not expected to recover until 1995, when there should be growth in all sectors.

### International comparison

The EU, USA and Japan are presently the largest construction markets in the world. However, future construction growth may become more rapid in China and, somewhat later, in the former Soviet Union and Central Europe. Construction output in Japan is about the same value as the EU, but prices are generally believed to be higher, indicating a lower physical volume of output. Deliberate government policies have increased Japanese gross construction output from 15 % (1985) to 19 % (1993) of GDP, and average output per head to 4 500 ECU, twice as high as the EU average.

There are more than ten Japanese construction companies with a substantial presence in Europe. Six key groups in the EU are: Kajima, Obayashi, Shimizu, Taisei, Takenaka and Kumagai-Gumi. Japanese construction companies also compete with EU firms in: Africa, the Middle East and mainly South East Asia, where they have a strong presence. In Japan, they operate through a pyramid of subcontractors, specialists, suppliers and designers. It is an industry which is dependent on an interlocking system of patronage and non-contractual relationships.

Specialised construction contractors, who have been pioneers in the field of industrial manufactured products for construction, might compete with these general construction companies but, even here, the construction industry is characterised by complex inter-relationships between these actors.

The US market is the third in size, slightly smaller than those of Japan and of the EU. The Japanese and the US markets have the benefit of a common language, currency, economic policy, culture and education system. The US market also benefits from a significant number of highly competitive manufacturers of materials and components based on common stand-

ards. It is also true, however, that regulations and market conditions differ in the 50 states, creating distinct local construction industries. US firms are particularly renowned for their construction management expertise. For European contractors, the main competitors are those overseas contractors with special engineering experience that are present in the EU, as well as, in the Middle East and South East Africa.

### Employment

Table 4 shows the total number of persons employed in construction. In 1993, employment was a little over 9 million in the EU, which corresponds to 1989 levels. This is the result of reduced employment in general and the addition of East Germany in 1992. Employment has naturally followed construction activity levels, which have been cyclical, but with an underlying downward trend linked to rising productivity and increased off-site assembly of components.

While there is no single definition of "self-employment," FIEC estimates that there are approximately 2.1 million self-employed workers in construction in the EU (Table 6). This represents 23 % of total employment. The UK has the largest proportion of self-employed persons with around 600 000.

## MARKET FORCES

### Demand

The construction industry serves a highly cyclical market, suffering from the normal 4 to 5 year business cycle. But, its own demand variability is greater than that of most sectors because private sector demand is dependent on investment by other sectors and is highly sensitive to interest rates. In addition, there are long period fluctuations in demand which have an obvious effect on output levels. In Europe, a peak of activity was reached in 1974, after which, the oil crisis caused a slump in European construction for a period of 10 years (and a corresponding boom in OPEC countries). Recovery accelerated in 1987, coinciding with the signing of the Single European Act and the accession of Spain and Portugal. However, a downturn followed in 1991. This was partly a cyclical reaction to the inflationary pressures of the boom and to the stock of new empty properties in the EU. It also coincided with major structural changes in world trade, caused by the end of the cold war, the break-up of COMECON and the collapse of the centrally planned economies.

As always, the future for construction is uncertain. Within the EU, future growth will depend on, among other things, the success of policies to increase growth, employment and competitiveness. The speed of convergence towards monetary

integration and the constraints that this convergence may impose on public spending for construction will also effect growth.

The cyclical nature of construction demand has a tendency to depress the profitability of construction enterprises as they compete to win orders when demand shows signs of falling. There is also pressure on profitability from procurement practices of public and private sector customers, who award contracts solely on the basis of the lowest price. The industry is seeking to raise its profitability by promoting measures designed to stabilise demand and procurement systems, which give weight to quality criteria and total lifetime costs of the projects.

## INDUSTRY STRUCTURE

### Companies

The structure of the contractors' sector is similar, under certain aspects, in most countries. As a general rule, markets are local or regional, with few national firms, and even fewer operating on a European or international scale. There are a small number (usually 5 to 10) of large firms in each country, a relatively less significant band of medium-sized firms, and then a mass of small firms which are either specialists or work in extremely local markets. Although each country has a number of well-known names, there are no dominant firms. The largest have less than 5 % of their home market.

Some large firms are expanding by acquisition of medium-sized specialists or by taking interests in firms in other EU countries. Some medium-sized firms are disappearing, either as a result of acquisition by larger firms or by bankruptcy or break-up; in which case, they may spawn a larger number of small specialist firms set up by individuals. The number of small firms and self-employed increased in the late 1980s, but fluctuates with the cycle. There is also a high turnover of entrants and wind-ups. Within the EU industry, there is a growing trend of larger construction enterprises forming joint ventures and consortia, to bid for individual major contracts or a succession of similar projects. This trend is a response to the completion of the Single Market and, particularly, the opening of public markets in Europe.

#### Small firms

In the EU, construction is characterised by a large number of SMEs, with a large group of very small businesses. The number of firms and employees in construction indicates that 97 % of enterprise units have less than 20 employees, and 93 % have less than 10. The data also include some self-employed persons, but not all, depending upon whether they are considered to be one-person enterprises or casual employment. However, it is difficult to record the true number of self-employed persons. Many workers may in fact be temporarily employed and then move on or become self-employed. Thus, their employment pattern has the characteristic of self-employment. It is also probable that the number of self-employed

varies with the business cycle. Workers made redundant in a recession may change to self-employment or set up a small firm to carry out repair and maintenance, or short term contract work. Such enterprises may then be wound up when employment conditions are better.

Statistics on the number of SMEs among contractors disguise the fact that there are a number of distinct types of small firms:

- small contractors, active in building or civil engineering (or both) working in a local market or a specific market sector, e.g. housebuilding. They may work as a main contractor using a network of subcontractors and self-employed craftsmen. Many of these are family firms and have a limited life based on the life of their proprietors;
- specialist contractors, ranging from piling contractors to painters and decorators, mainly in the finishing trades, who may operate over a wide geographical market. These, if successful, will grow and may become quite large, or be taken over by larger groups; in which case, they may continue to trade as independent companies;
- self-employed craftsmen who may be registered as small firms and work with family members or casual help;
- opportunistic start-ups by individuals, or partnerships, who are made redundant or seek more independence than working for a larger firm, or craftsmen expanding their range of activities. In some countries, these firms have been strongly favoured by advantageous social security and other wage related costs for independent workers; and
- one-off companies, set up for financial or fiscal reasons by larger firms to develop a single project. There may be a very large number of these in existence which cease to have any life after the end of a project. These are not in any real sense SMEs, yet appear as such in statistics on the number of firms.

The fragmented nature of the industry is somewhat reduced by long-term networks of firms or quasi-firms. This is a well developed feature in Japan and becoming increasingly significant in the USA and Europe. Many firms work regularly with the same subcontractors, while some small firms collaborate to share common administration and sales services.

It is also increasingly common for major clients to develop groups of consultants and contractors that undertake all their work on a more or less regular basis. Franchising is also relevant in this context, especially in repairs and maintenance. The parent franchising firm ensures the competence of the small firms who buy into the franchise.

#### Large contractors

Europe has some very successful large contractors. As reported by "Le Moniteur des Travaux Publics", Table 8 shows Europe's top 20 in 1994. These are mainly based in the larger EU countries: France (8), the UK (4), and Germany (4). However, lists of top contractors in other publications show some dif-

Source: FIEC (12/94)

ferences. Nevertheless, despite contractors appearing in different positions on various lists, and some large contractors not appearing at all, the general picture is consistent. The EU has about 45 large contractors, or firms with an annual turnover in excess of 1000 million ECU (1992 prices). None of the large EU contractors has a turnover (which includes payment to subcontractors and suppliers, often 80 % of their turnover) which reaches 5 % of their national market.

Many of the EU's largest contractors are part of groups of companies that work in several industries of which construction is just one. In many cases, these groups engage in work in several construction subsectors; e.g. manufacturing materials and components, providing various services (such as transport, water, waste treatment) and owning property-related businesses.

The EU does not have any contractors as large as the largest US and Japanese contractors, such as Fluor Daniel (turnover 17 380 million ECU), Bechtel (14 900 million ECU) and Shimizu (25 535 million ECU). However, it should be noted that the very large US contractors are specialists in engineering construction and infrastructure work and operate as turnkey contractors. They mainly provide design, procurement, finance and project management services in-house, while subcontracting nearly all site and manufacturing work. In comparison, the largest Japanese and EU firms tend to be more directly involved in actual construction work on site.

It is felt in some quarters that Europe would benefit from having larger contractors, better equipped to compete with US and Japanese firms. They could also play a leading role in shaping the image of the industry, and take the lead in R&D. However, this would not change the overall structure of the sector which will always reflect the structure of demand.

Within the EU, it is increasingly common for several contractors to join in bids for major construction projects in close cooperation with financial institutions. For example, the construction and financing of the Channel Tunnel involved some 10 contractors and over 200 banks and other financial institutions. Many contractors believe that new opportunities are to be found through joint-ventures, strategic alliances, mergers, acquisitions and cooperation. These strategies generally spread risk, provide access to a range of technical knowledge and

experience not possessed by any one contractor, and may well provide access to a wide range of sources of finance.

Some contractors in EU countries such as Germany, Spain and France, have formal links with industrial banks. This can provide important advantages in access to finance and allow contractors to take a long-term view in developing their business.

In general, it can be observed that large contractors come from large countries. This leads to the conclusion that as soon as the single EU construction market becomes a reality, some of the leading European contractors will increase their size. This has already happened to a large extent in anticipation of the forthcoming Single European Market. Growth in size has mainly been achieved through cross-border mergers and acquisitions. In 1993, the French construction industry continued to hold the largest number of foreign interests (with 227 active holdings), followed by Germany (111) and the UK (68). The highest level of foreign participation in domestic companies is to be found in Germany (142) (Source: EIC: "Mergers and Acquisitions in the European Construction Industry", Nov. 1994).

### Impact of the Single Market

The overall effect of the creation of the Single European Market, rather than the actual legislative measures implementing it, continues to have a generally positive impact on the construction sector. This overall effect is evidenced through the gradual approximation of construction procedures and the regulatory framework in which the sector operates, as well as in regional economic development. Owing to the nature of construction, this impact has not yet extended to the entire sector. Construction is by nature a local or regional activity, in which a majority of firms do not usually move far from their local geographical base. Consequently, transnational activities do not usually result in exports of goods as such, but rather take the form of exports of capital or services through international mergers, acquisitions and joint ventures. European legislation in the areas of the opening up of public procurement markets, the free movement of goods and the free movement of persons has facilitated transnational activities. This is, however, only relevant to the fairly small number of enterprises that engage in such operations. The practical im-

plementation of the Single Market has only just started and therefore is still far from being accomplished. The sector considers as main priorities for the future the timely realisation of the Trans-European Networks, and a further simplification of the regulatory framework.

## REGIONAL DISTRIBUTION

The EU Structural Funds will continue to be a main determinant of future regional patterns of growth and construction demand. Without regional policy, however, it is likely that disparities would increase. As long as the Structural Funds increase, they should assist construction growth in Objective 1 regions. However, the outcome heavily depends on individual national infrastructure policies.

The total volume of financing from EU funds is significant. For 1994-99, 141 billion ECU have been allocated to the Structural Funds, of which 96 billion ECU will go to Objective 1, less advantaged, regions. However, not more than one-third will be for infrastructure projects. The Edinburgh growth initiative provides a further 8 billion ECU. The Cohesion Fund, agreed to by Member States as part of the Maastricht Treaty, adds a further facility. EIB loans within the EU, which are largely related to infrastructure, run at about 12 billion ECU/year. It can be assumed that around 100 billion ECU of EU funds will be available for infrastructure, or 20 billion ECU/year. If it is assumed that the average EU component is 50 % of total project funding, the EU funds will, in effect, influence about 40 billion ECU per year, or about 30 % of the 125 billion ECU/year of civil engineering expenditure.

The accession of Austria, Sweden and Finland to the EU in 1995, brings in countries which, under existing rules, will make a net contribution to EU funds and hence help increase regional development. These countries, however, have construction markets which have been in decline for several years. In addition, they have powerful contractors who are strong competitors for the existing EU industry.

The European Commission's White Paper on Competitiveness, Employment and Growth emphasised the importance of infrastructure, and reaffirms Community priorities for trans-European networks and support for infrastructure investment.

The allocation of funds to the Growth Initiative may be increased.

These trans-European networks should be extended to include the new democracies of Central and Eastern Europe, several of which may join the EU in the future. The new political and economic freedoms in these countries have exposed the need for infrastructure investment, including transport links with Western and Northern Europe. Other principal construction needs, which will require substantial financial assistance from outside, include housing and the treatment of pollution. These countries have a large capacity to carry out construction work, with ample experience in managing large projects, but their technology is not fully up to date by Western standards. Likewise, productivity of the labour force is relatively low, as are wages. In the short to medium term, they may provide an additional market for western enterprises competing on quality or technology, however, they will be powerful competitors in low-cost building and basic infrastructure.

Despite efforts to reduce disparities in regional development, the main construction markets will continue to be in the backbone of Europe (the banana-shaped region from SE England, through western and southern Germany, to northern Italy) and the growing sunbelt region from the northern Adriatic along the Mediterranean coast of France and Catalonia. There is some evidence of convergence of per capita incomes in EU regions, but recent evidence shows that overall disparities have not changed much.

The regional development and cohesion effects of the Maastricht process and the growth initiative should have a positive impact on construction demand. However, monetary integration, if followed according to the Maastricht programme, is likely to severely constrain demand. The convergence process, by which Member States must bring budgetary deficits, debt and inflation levels within strict limits, is restricting the ability of States to increase public spending on building and infrastructure programmes. It may also restrict the freedom of governments to carry out an economic recovery policy, since social security payments are higher in a recession and tend to squeeze infrastructure spending. The White Paper on "Growth, Competitiveness and Employment" sets out policies to try to remove these constraints, including the introduction of private capital in public-private partnerships.

## ENVIRONMENT

The construction sector faces enormous challenges and market opportunities from the emphasis on protecting and improving the environment. In response, the industry is providing solutions to environmental problems by developing new services and products, something which has provided positive contributions to the environment.

The internal environment of buildings is an emerging area of concern, which requires more research and development of standards relating to air quality, microbiology of buildings, allergenic and toxic effects of materials, and emissions from land and buildings.

Energy conservation remains a priority issue, as about half of Europe's energy consumption is related to buildings. Designers and contractors are responding to the need for more energy efficient buildings, including the use of passive thermal principles, which in some countries are requested by law. The existing stock of buildings has potential for refurbishment to conserve energy. There is also likely to be increased use of less energy-intensive materials. These changes will be accelerated if energy prices rise through a carbon tax or other macro-economic energy conservation measures.

Energy and eco-labelling of buildings and products is beginning to be promoted and will create a market mechanism favouring these changes. The analysis of the environmental impact of specific projects is also increasing through development of techniques and enforcement of impact assessment requirements.

In some parts of the EU, there is growing concern over the availability of natural resources for construction and the consequences of meeting future demand. This focuses attention on making more effective use of materials. Waste management and the recycling of construction materials are subjects of extensive research and development. This is leading to changes in site practices and design principles, in order to minimise the use of materials which are damaging or not recyclable, and to facilitate ultimate demolition and recycling.

The built environment is to a large extent synonymous with our cultural heritage. It is difficult to exaggerate the importance of this heritage, and conservation is a major task for the con-

struction industry. It is also worth emphasising the importance of local building practice in creating the diversity which is such an attractive feature of Europe's towns and villages. Small firms of designers and craftsmen continue to have a valuable role in maintaining this cultural dimension.

## REGULATIONS

In many respects, the construction sector is subject to different policies and legislative treatment from other sectors of the economy. At national levels these include: land use plans and planning controls (which affect land prices), building regulations and standards, planning permits, building inspection, registration of contractors and professions, regulated fee rates, and so on. Governments also directly control a large share of construction work and provide research, training and information services.

Some major EU regulations affecting the industry are:

- Public procurement directives. There are a full set of directives covering supply (93/36), works (93/37) and services (92/50) contracts awarded by public sector clients and the utilities, including the Works Directive (93/37) and the Utilities Directive (93/38), which set out procedures for procurement of construction work for projects over 5 million ECU. The directives require advertising of calls for tender, use of specified selection procedures, and the use of European Technical Standards. In addition, the "Remedies" Directives (92/13 and 89/665) establish a system of judicial review of procurement procedure.
- Construction products directive (89/836). Interpretative documents enabling the Construction Products Directive to be implemented were adopted at the end of 1993. CEN and CENELEC (the European Standards bodies) are drawing up new harmonised EU Standards for construction products and new procedures for technical approval of innovative products.
- Liability and guarantees. There have been changes in legislation on liability and insurance requirements in some countries over the past decade. In the last three years, experts from various segments of the construction sector have been discussing proposals for possible harmonisation of liability

law and arrangements for guarantees and insurance ("GAIPEC").

- Health and safety. A variety of health and safety measures affect the construction sector. The Temporary and Mobile Construction Sites Directive (92/57), which is currently being implemented, defines new responsibilities for designers and contractors and requires a safety plan to be produced for each construction site.
- Posted workers. The proposal of a directive currently under discussion requires all workers to be employed under the labour legislation and collective agreement terms of the host country. This would have an important impact on the construction sector, which, in some EU countries, uses a lot of foreign labour.
- Pre-qualification. The possibility of a system of proof for pre-qualification of construction firms has been studied by CEN. Currently, the Commission is elaborating mandates for CEN/CENELEC to develop standards in this area. These rules are intended to provide a basis for the mutual rec-

ognition of nationally acquired proof of qualification, in particular, pre-qualification procedures for public procurement. If adopted, it might also have an important impact on marketing by contractors and on selection procedures by private sector clients.

## OUTLOOK

Because construction demand is closely linked to total demand for investment, the industry's future depends upon the success of the EU and national governments in stimulating economic growth. European integration and socio-economic changes are generating increasing needs, but demand is constrained by public expenditure constraints and the financial capacity of the private sector and households.

There has been fear in some countries that there might be a long-term or a once-and-for-all drop in construction demand as population stabilises or declines, and as major infrastructure and housing needs are satisfied. However, the EU's construction sector strategy study ("SECTEUR"), carried out for the

European Commission in 1992/93 and published in 1994, argues against that view. Social and economic changes, as well as the upgrading of environmental standards, are generating increasing construction needs. The problem will be to satisfy these needs. The share of GDP for construction needs to increase. However, this will be difficult to achieve, because it implies increasing macro-economic savings rates, at the same time as public expenditure is constrained by tax and public deficit restrictions and more expenditure is needed to meet the needs of an ageing population and long-term structural unemployment.

Overall, there are enormous needs for infrastructure investment in Europe. In most areas, there is a problem of housing quality or housing stock. These must be growth areas for the industry. For commercial property, the needs are weaker. Needs in these sectors are dealt with in the chapters on Building and Civil Engineering.

### Demand scenarios

The "SECTEUR" study suggested three future scenarios:

- An optimistic, but attainable, high growth scenario shows construction output doubling by the year 2005, with employment rising rapidly at first and then more steadily, creating 5 million new jobs in construction and 15 million throughout the EU by the year 2000. This scenario promises continual improvements in housing, cities, and infrastructure enabling Europe's industry to restructure and become increasingly competitive.
- A more conservative scenario, with GDP growth and construction's share of GDP returning to historic levels of the 1980s, shows a return, after about 4 years' growth, to the output levels attained in the boom of 1990/1, and then steady growth in construction output, averaging 3 % per year. This scenario would create 2 million jobs in construction by the year 2000 and 6 million in total throughout the EU, reversing the decline in employment which took place over the 1980s.
- A pessimistic scenario, with low growth, a lower share of construction in GDP, and low innovation and productivity growth, shows construction output continuing to fall for several years, followed by slow growth, but never returning to the levels of 1992, let alone the boom levels of 1990/1. Here, 2 million construction workers and 6 million workers in total would become unemployed, despite continuing labour intensive technology. In this scenario, the living and working environment will deteriorate, European industry will become increasingly uncompetitive, and the standards of construction would be likely to decline.

Continuous rationalisation of industries is leading to plant closures, re-investment, and relocation which will be accelerated by EU integration. The EU is also becoming a more attractive target for inward investment by global firms; particularly Japanese. Changes in economic structure and consequent migration will stimulate new construction needs. In the future, more sophisticated EU regional policies and free market industrial policies should permit more rapid and efficient responses to such changes and help to convert construction needs into construction demand.

# Building

## NACE 501

The building sector is influenced by the overall economic situation in terms of current trends in economic activity and expectations of future trends. Government policies play a direct role in terms of economic policy, and credit and fiscal policies, as well as an indirect role in terms of regulations for the sector. Competition has increased markedly in both housing and non-residential building. A fall in prices and the level of demand has been followed, in some countries, by a reduction in capacity.

Certain key factors affecting the building sector have already been discussed in a previous chapter entitled 'Construction'.

### INDUSTRY PROFILE

#### Description of the sector

There are two principal divisions of total building construction: housebuilding and non-residential building. The latter includes factories, warehouses, shops and offices, mainly for private sector clients, and various public buildings including schools, hospitals and prisons.

#### Housebuilding

Total housing stock may be broadly divided into three categories: social housing, the construction of which benefits from the support of public authorities; private rental sector; and, owner-occupied housing. The relative importance of these sectors varies from country to country, depending on a variety of factors. For example, the owner-occupied sector is influenced by: income levels; the availability of house purchase loans with varying percentages (4.5 % - 22 %) of the purchase price; differing levels of transfer costs when buying and selling houses; and, different government policies with regard to home

ownership, including tax treatment (e.g. VAT between 0 % and 20.5 % on new housing construction), the best example of this being the UK, where during the 1980s the proportion of population owning its own house rose to 60 %.

For Europe as a whole, and for most Member States, statistics show a small excess in the number of dwellings over the number of households. Yet, in practical terms, there is a shortage of housing across Europe, which has become a pressing political problem. There are large numbers of households suffering poor housing conditions, who wish to be re-housed in new or refurbished dwellings and others whose housing expectations have been raised by increases in their incomes. In addition, changes in the structure of the economy and completion of the Single Market, are causing considerable shifts in population in Europe. Thus, there are growing regional imbalances between demand and supply of suitable housing.

Meanwhile, trends in the construction of new housing and in repair and maintenance of existing housing stock, varies between sectors. However, all are affected to a considerable degree by the overall state of the economy and by shifts in governments' economic and financial policies. In both the owner-occupied and private rental sectors, demand for new housing is influenced strongly by movements in interest rates. Demand for new social housing varies with expansion or contraction of levels of public spending.

Generally, demand for and construction of new housing reflects the overall trend in economic activity. Table 4 shows significant declines in new housing construction coinciding with the recent recession in most EU and EFTA countries. Although, for the EU as whole, growth in new housing output remained positive in 1991, 1992 and 1993 on account of massive investment in Germany's new Länder, and the relatively early recovery from recession in the UK.

Equally as important as new housing, in terms of value of construction output, is the repair, maintenance and improvement of existing housing stock. However, fluctuations here tend to be less pronounced than in new housebuilding, as

people may decide to improve their existing dwellings when they cannot afford to move to a new house.

Housing repair and maintenance offers many opportunities for small construction enterprises and individual craftsmen. There are also SMEs specialising in new housebuilding, but many large construction firms also have housebuilding divisions engaged in the construction of large estates and, in some cases, maintenance of existing estates.

#### Non-residential building

The non-residential building sector is also sensitive to the overall state of the economy. As a result, manufacturing enterprises and those engaged in distribution and other services vary their demand for construction in response to their assessment of prospects for demand for their own products. However, in the commercial sector (shops, offices) there may be speculative building on the part of developers or of construction companies themselves. If economic conditions deteriorate, this can exacerbate cyclical fluctuations in construction as demand for office or retail space weakens and newly constructed buildings are left unsold or unlet. If this happens, demand for non-residential buildings may be slow to recover when general economic conditions begin to improve. Large short-term fluctuations in new non-residential building are clearly evident in many countries (Table 2).

Public sector non-residential building also experiences large variations in output from year to year as governments change their spending plans in response to changing economic conditions (Table 3).

Of growing importance in non-residential building is investment in refurbishment of existing buildings; for example, improving energy efficiency or accommodating modern information technologies for communications.

#### OUTLOOK

The population of the EU has been growing slowly and is projected to increase by 2 % per year to 2000 and then begin to decline. The future level of migration, however, is unknown. It is expected that there will be increasing pressure for immigration from the third world (including ex-colonies

and North Africa), the former Soviet Union and Eastern Europe. Immigration policy may well be conditioned by the ability of the housing and social infrastructure to absorb immigrants. Conversely, the level of immigration will influence the pattern of demand for housing and infrastructure.

Average household size is likely to continue to fall, thus increasing demand for multi-dwelling buildings and complexes for singles and childless households. More significant, however, is the changing age structure. The number of older people will increase rapidly after the year 2000. This will create increasing demand for sheltered accommodation and for communities which are designed around an urban structure with minimal transport needs and a small nuclei of social infrastructure (shops, medical, recreation). In particular, in amenable locations, possibly far from the main urban and industrial centres.

This type of development is also being encouraged by those who are concerned that urban areas are being developed without sufficient regard to the need to protect the environment; e.g., construction on the edge-of-town industrial estates or, particularly, shopping centres. In some European countries land use policies have already been revised to discourage such development and to stimulate the regeneration of run-down inner city areas. Urban regeneration is also capable of creating many opportunities for the building industry.

# Civil engineering

## NACE 502

*Civil engineering principally involves public infrastructure in sectors including transport, communications, energy and public health. The level of activity depends primarily on demand from government bodies, so the sector is highly dependent on the budgetary policies of governments and public institutions. Pressures on public finances have resulted in lower investment and demand for civil engineering. In some projects, particularly roads, communications and energy, private sector finance is providing an alternative to government financing, or a source of additional investment.*

*Certain key factors affecting the civil engineering sector have already been discussed in an earlier chapter entitled 'Construction'.*

### INDUSTRY PROFILE

#### Description of the sector

Civil engineering provides the basic infrastructure for transport systems and the utilities. Its traditional market has, in the past, been mainly public sector, but this is changing because of the privatisation policies being pursued throughout the EU. Privatisation means that contractors will increasingly face a new style of procurement. Clients are placing increasing demands on contractors with respect to quality of construction, control of costs, completion date, and joint responsibility for design. Public sector clients also are joining in this movement which alters the balance of risk between client and contractor.

Although plans for trans-European networks (for all forms of transport) are being drawn with increasing precision, problems of public sector deficits and attempts to comply with the convergence criteria for economic and monetary union are severely limiting the availability of public finance for infrastructure investment. As a result, methods are being sought by which to mobilise private capital to help fund construction

of these networks. Generally, the financing of infrastructure projects has become more complex and contractors are increasingly expected to help find the financing for new construction. This increases the range of the risks faced by contractors, but can also provide significant additional demand for construction.

These developments have been taken further by some large contractors and represent a major change in their approach. They are taking the initiative in setting up new construction projects. Various combinations of owning, leasing from government, designing, constructing, operating, and transferring back to governments are being planned and put into practice throughout the EU. Proposals are being worked on by contractors for a wide variety of schemes and types of construction. A common feature, however, is the central importance of finance. Today, large contractors need a sophisticated understanding of finance or, at least, joint venture partners with this expertise.

Another significant change in the market for civil engineering includes a growth in demand for works to protect and improve the environment. Although some civil engineering contractors see environmental issues more as a threat to their work, e.g. because of the success of environmental pressure groups in some European countries in delaying major road building projects, others see environmental concerns as offering a major opportunity to expand their activities. Within the construction industry the civil engineering sector has a special responsibility to find solutions to environmental problems, particularly with regard to preventing pollution of land and groundwater. Civil engineers are also exploring ways of making more use of recycled materials, e.g. in road construction.

While there is increasing emphasis on major projects, where the work is organised and executed by larger civil engineering contractors acting individually or forming joint ventures or consortia, there is also an extensive range of smaller works and maintenance requirements providing employment for smaller contractors.

## OUTLOOK

- **Transport infrastructure:** There is an increasing need for investment in transport infrastructure to: cope with increasing trade and movement of people in the single market; reduce the cost of transport to European markets from the peripheral regions; promote development and cohesion in the less developed regions; and, reduce the increasing problems of congestion and air pollution in cities. All modes of transport have urgent needs. However, the emphasis in the near future will be on completion of European rail networks and the development of a high speed railway network. Nevertheless, the largest volume of expenditure has to be on upgrading and maintaining the road systems. There are still important missing road links, particularly across the Pyrenees and Alps, and links to Portugal, Ireland and Greece. Major new road corridors are also needed to link up Central and Eastern European centres. In addition, the whole of Eastern Europe has huge road building needs. There will also be increased air traffic, requiring development of the single European system of air traffic control and new airport developments. Furthermore, investment in ports and inland waterways is also being planned. The European Commission is taking an active role in the strategic planning of major EU transport infrastructure projects and in planning links with Eastern Europe. There will be EU financing from the Structural Funds, EIB and, for Eastern Europe, from aid funds such as PHARE and TACIS. Car ownership continues to grow rapidly in the richer EU states; except Denmark. Poorer states will, however, continue to catch up. Consequently, there is growing recognition of and concern over the impact on the environment of road transport. In particular, air pollution caused by growth in the use of cars which has prompted reconsideration of transport and land use planning policies. For the longer term, there will have to be massive investment in improved public transport and people movers requiring separate infrastructure. This may be supported by increased taxation on fuel and cars and increased application of road user charges which will help finance infrastructure and public transport systems.
- **Telecommunications:** It is expected that there will be a rapid increase in telecommunications investment in the next two decades to bring the peripheral regions up to the level of the centre and to cope with the demand for new value-added services, mobile communications and ever increasing electronic data interchange. Currently, most direct investment is in equipment, but it will also generate construction work in towers, cable networks, and in building upgrades.
- **Energy:** The emphasis of energy-related investment for the next two decades will be on energy conservation and reduction of pollution from existing energy sources. There has not been much investment in new power stations in Europe in the past, but investment should continue at a low, increasing level, particularly for replacement of older stations by cleaner energy efficient stations (including gas fired stations). The main energy investment will be in extending the networks of gas pipelines and power transmission networks and their interconnection. A major source of new construction industry demand will come from the rebuilding or decommissioning of nuclear power stations. In Western Europe many nuclear stations are now reaching the end of their useful life and will need replacement in the next decade. More importantly, there is an urgent threat to public safety caused by the nuclear stations in the newly emerging democracies of Eastern and Central Europe. This situation will require a major focus of western aid resources. In many respects, the technology for dismantling and disposing of the materials from these stations does not exist. The size of the civil engineering problem for nuclear waste recycling and radioactive waste repositories, likely to in-

volve deep underground construction, is enormous. In the long term, new alternative energy sources will become important. Wind, wave, tidal and solar power have not been viable up to now because they have very high capital costs (largely construction) and because R&D, which would bring down costs, has not been funded on as large a scale as, for example, nuclear power. However, these energy sources have low or zero fuel and manpower costs.

- **Water:** Total water use is likely to grow, but more slowly than in the past as irrigation and industrial uses are conserved. Nevertheless, average household consumption varies enormously between regions and is likely to continue to increase as living and housing standards rise. Recent problems of drought, flood, and past lack of investment in several member states will lead to increasing investment in water collection, transport and storage. Enforcement of EU water quality directives will require increasing construction for water treatment. Environmental legislation and municipal waste water directives will require continuing increases in waste and effluent treatment for at least the next 20 years.
- **Other environmental needs:** Waste disposal and contaminated land are developing rapidly as sources of future construction work.

# Industrial plant construction

The European industrial plant construction sector emerged relatively unscathed from the deep recession of the years 1991-93. In 1993, European plant manufacturers, with a world market share of over 50 %, are reported to have won orders to the value of around 70 billion ECU.

The industry's high export ratio makes it very sensitive to all forms of protectionist tendencies. The entry into force (in 1995) of the GATT agreement concluded in the spring of 1994 is therefore essential for this technically forward-looking branch of industry, with its 250 000 employees and the impulses which it imparts to employment in the supplying industries. In view of the already strong international competition, the industry hopes that there will be no further worsening of the accompanying political conditions. Basically, the European industrial plant construction sector is cautiously optimistic with regard to medium-term prospects.

## INDUSTRY PROFILE

### Description of the sector

The picture presented by the industrial plant construction industry has two salient features: the large scope of its activities and its international structure.

Depending on the form of the plant contract, what is offered is a combination of constituent parts which are often independent in the function which they perform, such as machinery, appliances, electrical drive units, controls, connecting elements (steel scaffolding/staging, piping, electrical connecting lines) and plant-related building construction and civil engineering. These constituent parts together, on the basis of technical production or operating processes, are used to extract and process basic materials, to perform further processing of primary products, to manufacture end products, to produce and convey goods and to generate and transform industrial energy. The manufacturing of industrial plant is based on extensive know-how concerning production and operating processes, planning and design, manufacture, procurement and supply of equipment, installation and commissioning and also project management.

In addition there are important services which are displaying a tendency for strong growth. Mention may be made, for instance, of financial engineering and the training of the customer's operating personnel. This increasingly involves, in addition to staff training, operation of the plant itself, although this is not the actual field of activity of these firms. Apart from that, plant operation by engineering companies would be quite contrary to their intention to return to the engineer's core functions.

From this point of view, important types of plant are, for instance, power stations, equipment for the chemical industry, plant for the electrical engineering, iron and steel and rolling-mill industries, facilities for environmental protection and plant for the construction and construction materials industry. The international nature of the sector emerges from the fact that the European plant construction industry exports its products to over 100 countries. Although industrial plant construction plays an important part as a standard for measuring a country's state of technical development, there is no uniform way of recording it statistically. The European industrial nations which operate in this field all define plant construction in different ways; in particular, it is difficult to draw the line between it and mechanical engineering. The same applies to the competitors in Japan and the United States. Nevertheless,

Figure 1: Industrial plant construction  
World market for plant-makers, 1994

Source: Europlant

a regular exchange of experience taking place within the framework of the European Plantmakers' Committee (Europlant) makes it possible to gain an overview of the worldwide development of the business.

### Recent trends

At the beginning of the 1980s plant manufacturers were still benefiting from an investment wave based primarily on the abundant supply of oil revenues of a few developing countries. The subsequent collapse to an all-time low was followed again in the mid-1980s by a uniform rise in the volume of orders of about 10 % per year.

The European industrial plant construction sector has emerged comparatively unscathed from the 1991-93 slump. The distribution of orders is not uniform, however, among the industries represented, 39 % of them being in fact accounted for by the building of power stations. Furthermore, the volume is achieved in the case of many projects by means of price concessions which are justifiable only from the point of view of employment in production locations and engineering design offices.

Figure 2: Industrial plant construction  
Breakdown of contracts by industrial sector

Source: Europlant

## International comparison

On the basis of various estimates, the annual volume of contracts awarded for major industrial plants should be in the region of 125 to 150 billion ECU. In view of the lack of statistics, assessment of world market shares in industrial plant construction is chiefly based on estimates. The reliable data which exist for mechanical engineering provide a firm point of reference for this. On the other hand, an industrial nation will be better able to win a world market position in general mechanical engineering rather than in plant construction. Therefore, the number of firms to be taken into account worldwide as suppliers of industrial plant is basically limited to three groups: those in the European Union, the United States and Japan. While newly industrialised countries such as South Korea, India and Mexico are already appearing as serious competitors in individual cases, they still fall short with regard to the range and consistency of what they have to offer. European plant manufacturers probably account for about half of the world market. The United States, based on its immense internal market, takes over a quarter and Japan's share is 17 %.

## MARKET FORCES

### Demand

The overall distribution of orders by sectors is influenced by the fact that the various European suppliers concentrate on different fields of activity. Generally speaking it can, however, be said that the largest proportion of orders, 39 %, is accounted for by power stations, while 15 % of the volume consists of plant in the fields of oil, gas and petrochemicals. On the other hand, the shares of manufacturing of iron and steel metallurgy, electrical engineering and environmental protection equipment have been declining markedly in 1994.

Foreign buyers are prepared to pay for advanced technology only if it is of immediate benefit to customers; there is a latent danger of over-engineering. The share of exports in the volume of orders is 45 %; one fifth of foreign orders come from the European Union. The Asia-Pacific area has developed into the most important market; its relative importance as a customer region has more than doubled over the last five years. Important customer countries have proved to be, during the last decade, those of the CIS, the People's Republic of China, the United States, Iran and India.

From the technical point of view, fewer industrial complexes are now required to be supplied on a turnkey basis. Customers are, on the contrary, more interested in modernisation and rationalisation measures, with a greater emphasis on energy-saving and protection of the environment. The latter cannot be statistically recorded when it relates to integrated environmental protection.

### Supply and competition

International competition is marked by aggressive pricing. This is forcing suppliers, especially those in the European Union with high costs at national level, to look around for more favourably-located customers for their procurement. While this trend has been confined to hardware during the last few years, European plant manufacturers, giving in to cost pressures, have also recently begun to offer engineering services from subsidiaries located in lower-cost countries. The resultant loss of employment for the European Union is considerable.

In addition to price competition, the appreciable deterioration of contract terms is another factor of weakness. The need to maintain order levels, motivated by reasons of employment policy, is prompting many competitors to give unreasonable promises with regard to guarantee periods, performance undertakings, penalties or additional services. A further cost aspect is the shifting of the operator risks to the plant

manufacturer. Furthermore, the patterns of activity of plant operators are often contrary to the optimum division of labour from the economic point of view.

## INDUSTRY STRUCTURE

### Companies

The stringent requests made in industrial plant construction have led to an appreciable thinning-out of suppliers during the last twenty years. Taking part on a sustained basis in lengthy and cost-intensive tendering procedures is now possible only for larger firms, which endeavour, by means of strategic alliances and under international cooperation arrangements, to lower their costs and reduce risks. This can have adverse consequences for mobility and creativity. A number of firms are therefore already adopting restructuring measures aimed at setting up independently operating companies under the umbrella of a coordinating holding company. On the other hand, the European industrial plant construction sector still has a high technical standard and only by maintaining such standards will it be allowed to continue to play a leading international role.

## ENVIRONMENT

Environmental protection aspects are playing an increasingly important role in plant business. Unfortunately, however, many customers have still not realised that the necessary investment in plant may considerably increase the price. Customers are prepared to pay this additional price only if there is obvious benefit to them, because they believe that additional expenditure on environmentally friendly plant does not make any direct contribution to productivity.

A further important problem is the different level of environmental protection in the countries of the European Union, which distorts costs. Suppliers from countries with a proclivity (albeit concealed) towards environmental dumping obtain unjustified competitive advantages in this field.

## REGULATIONS

The European plant construction is co-operating with the European Commission services in order to ensure that European regulations do not harm the activity of the sector.

The Commission is working on the harmonisation of export credit insurance schemes and the seconding of workers of EU-based companies for the provision of services in other EU countries. If these plans come to fruition, they will greatly increase costs. The draft EU construction legislation, too, unfortunately still does not make it clear enough that it is not intended to apply to industrial plant construction. The specific concerns of the industry ought to be taken into account when drafting new legislation, in order to avoid a worsening of the competitive situation.

As a matter of principle, the European plant construction industry is following all the Commission's moves on the trade front. An industry which operates worldwide is dependent on free world trade. From this point of view this branch of industry welcomes the conclusion of the GATT talks. These have created the basis for an unprecedented liberalisation process and a transparent world trade system.

## OUTLOOK

The course of the European plant construction industry's business in 1994-1995 will depend on how well investors in the major branches of industry have been able to cope with the latest recession. The currently favourable worldwide economic conditions ought to boost industrial plant construction too, albeit with a time-lag. Nevertheless, prevailing trends in the

European chemical industry, steel industry and automotive industry are forcing European competitors out into the international markets, where, as in the past, they have to contend with Japanese and American competition.

The hopes of market opportunities in Eastern Europe following the collapse of the traditional political systems have not been fulfilled. There is undoubtedly immense demand here, but it cannot be financed in the foreseeable future without great joint efforts. High expectations are at present directed towards the Asia-Pacific area, especially the People's Republic of China, which, after the political opening-up, offers opportunities particularly to manufacturers of large plant who are willing to commit themselves with cooperation structures and joint ventures. Further potential major markets for the future are South America, the countries of the Middle East and, in principle, all raw-material-producing countries.

The European industrial plant construction sector is viewing the medium and long term with cautious optimism. It will continue to rank among the European Union's forward-looking industries.

## Overview

### NACE 61-65, 67

*The EU distribution sector is undergoing considerable restructuring. Changes include concentration, reduction in the number of traditional wholesalers, transformations in the retail sector and a tendency towards diversification and internationalisation. Moreover, the future of the distributive trade sector will be influenced by the increasing integration of the internal market and the EEA, the accession of Austria, Finland and Sweden, and the opening-up of Eastern Europe. The sector represents about 14% of output and employment in the European Union. These figures have remained relatively constant over the last ten years, showing that the distribution sector has grown in line with economy.*

### INDUSTRY PROFILE

#### Description of the sector

The industry is divided into two subsectors: wholesale distribution and retail trade.

Wholesale distribution (NACE 61) is defined as "units exclusively or primarily engaged in the resale of goods in their own name to retailers or other wholesalers, to manufacturers and others for further processing, to professional users, including craftsmen, or to other major users".

Retail distribution (NACE 64 and 65) is defined as the distribution to final consumers of:

- food, drink and tobacco;
- dispensing chemicals;
- medical goods, cosmetics and cleaning materials;
- clothing;
- footwear and leather goods;
- furnishing fabrics and other household textiles;
- household equipment, fittings, appliances, hardware and ironmongery;
- motor vehicles and cycles;
- motor fuels and lubricating oils;
- books, newspapers, stationery and office supplies;
- photographic, optical, jewellery and other retail distribution.

These definitions describe the function and product areas characterising wholesalers and retailers. They do not cover the fact that many organisations perform both functions, or that the ownership of wholesalers and/or retailers may reside in operators from another subsector of the supply chain (such as manufacturers), or that manufacturers in some areas carry out their own wholesaling and retailing and are not thus covered by the statistics for the latter sector.

A further important point is that the definition of wholesalers ignores the increasingly wider role that many operators within the sector are playing. For example, the change in manufacturing to tightly-managed production techniques (such as Just-In-Time) means that the whole distribution chain is becoming more sophisticated, and that wholesalers are also taking on functions such as packaging, quality control and administration. None of these is included in the NACE definition, but

they nevertheless affect the contribution to the economy of the sector as well as the profile of the wholesaler.

### INDUSTRY STRUCTURE

There is great change occurring within and between the subsectors of the distribution industry. This change can be summarised as:

- concentration, expressed in terms of a reduced number of larger operators, and closer vertical and horizontal links between manufacturers, wholesalers and retailers, in particular through the creation of networks;
- a general reduction in the number of traditional wholesalers, bearing in mind the fact that the concept of wholesaling seems to have different meanings within different Member States;
- a series of transformations in the retail sector, with significant differences between Member States. Overall a slower increase than before in hypermarkets, a rise in franchising, an increase in cooperation, especially where there already exists a high degree of concentration or further concentration is expected, and a proliferation of forms of distance selling are prominent features;
- a tendency towards diversification of activities into other service areas and some specific moves towards internationalisation.

The concentration phenomenon - the reduction of the number of enterprises - is more evident among both large and small enterprises in northern Member States, including the three new ones, with not only a rationalisation - a reduction in costs - in the direct retail sector, but also the emergence of purchasing groups and voluntary chains to benefit from economies of scale.

There remains a higher number of independent enterprises in the southern Member States although a reduction in their number is almost certain. Also, modernisation strategies continue to bring enterprises together in the form of chains and larger logistical structures in order to make them more competitive.

Wholesaling is often thought of as an activity of the past, in that traditional operators now often find themselves squeezed out either through manufacturers' wish to control distribution themselves or through the large retailer's practice of upstream extension.

However, some forms of wholesaling are on the increase, such as wholesaler-owned voluntary chains and specialist operators who focus on specific end-users (such as schools and hospitals). An increasing number of wholesalers are supplying not only goods and services but in the areas of technical wholesaling and high-value consumer goods, such as home furnishings, are offering complete packages (translated from "Problemlösungen"). In combination with a further expansion of out-sourcing by producers, such complete packages could provide one of the most important long-term opportunities for the survival of wholesaling. "Traditional" wholesaling does survive in raw materials and bulk products because of the logistics involved.

Geographic variance remains of great importance in the structure of the distribution industry. The structure of retailing continues to evolve, with marked differences between the north and the south of the Union. In the north, concentration and larger outlets are the new trends. In the south, smaller shops remain very prominent, although purchasing groups are be-

coming increasingly important as independent enterprises re-group in order to survive.

An interesting trend is emerging within the retail sector, whereby,

- networks of multi-function distribution centres (reseaux de centrales distributeurs) are the typical operators in food retailing. In northern Member States, such as Germany, Finland, Sweden and France independent organised commerce is particularly important;
- purchasing groups feature in non-food retailing; and,
- franchises are moving into services (travel, financial services etc.) as well as goods.

Diversification of activities is occurring, whereby producers (typically non-food) set up retail operations, or where retailers offer services such as travel, financial services, restaurants, etc. In several Member States, such as France, the United Kingdom and Germany, discounters continue to grow in importance.

Internationalisation tends to occur towards neighbouring Member States at first because of cultural similarities. Non-food retailers are the operators most prone to internationalisation. The Euro-consumer does not yet exist, even if consumption patterns are moving closer together.

## Impact of the Single Market

Recently, the EU distribution sector has undergone considerable restructuring. Thus, concentration, expressed in terms of the number of large operators and vertical links between manufacturers, wholesalers and retailers, has increased in the sector. Moreover, a tendency towards diversification of activities into other service areas and into new geographical markets has been observed.

In this context, European market integration has created a need for Europe-wide distribution networks. The Community's actions in the transport, competition, investment, structural funds and enterprise policy areas are helping this to come about. However, operators in the distributive sector face two conflicting pressures in trying to meet the challenge. Firstly, the concentration and integration in the distributive sector, encouraged by cost reductions following the completion of the Internal Market, have forced operators in the sector to seek cross-border opportunities. Secondly, there is still a requirement to respect local culture in the delivery of services. In the future, the top priorities of the sector are that the consumer protection and social legislations should take into account the specificities of companies in this sector.

## REGIONAL DISTRIBUTION

The most obvious influence of geography on the sector is in the different definitions of what a wholesaler is and in the role of the small retail outlet.

In Germany, for example, wholesaling tends to be thought of as the distribution and procurement activity of manufacturers. In France, the tendency of manufacturers to subcontract sales activities and of retailers to subcontract buying, results in wholesaling being seen as a large growth sector. The Dutch import-export agencies, which are major economic operators, contribute to that country having the feeling that the sector is dynamic, while in the United Kingdom, a more restrictive view is taken, namely that of the old-style "middle man" between manufacturer and retailer, now in decline.

Taking these differences of perception into account, the major feature of geographical variance in wholesaling is that the northern Member States exhibit much more evidence of a blurring of activities between manufacturer, wholesaler and retailer than do those in the south.

For retailing, countries in the two main groups - Mediterranean and Northern Europe - may have similar sales formats, but these may not be at the same stage: concentration in retailing is thus correlated with the level of economic development of the Member State, except for Italy, which retains its high number of small shops. Franchising, cooperation networks in general, discount shops and non-shop retailing are also notable for some geographic variance, explained in the monograph on retail distribution.

## ENVIRONMENT

Traditionally, the distributive trades have been seen as purely intermediate functions, only operating in response to supply impulses, and therefore not at all involved in the environmental debate. This view, however, is set to change. Distributors, especially purchasing centres in the retail sector, are increasingly playing a pivotal role in translating trends in consumer preferences into final demand and are thus able to boost the sales and the production of so-called "eco-goods". In some Member States, such as Germany, this is particularly the case.

Moreover, more and more distributors are taking on new functions, including packaging. This activity entails a series of environmental issues which has to be taken into account by the sector.

## OUTLOOK

The changes inherent to the sector itself (concentration, increased use of technology, segmentation, vertical and horizontal integration and diversification) must be seen together with extraneous developments such as the entering into force of the internal market on 1 January 1993, the potential opening-up of East European markets and changes in consumption patterns as a result of ageing population structures.

While the achievement of an integrated EU market will require a European distribution system (and the Community's actions in the transport, competition, investment, structural funds and enterprise policy areas are helping this to come about), operators in the distributive sector face two conflicting pressures in seeking to meet the challenge. The first is the increased competition from other Member States as the concentration and integration in the sector, encouraged further by cost reductions following the completion of the Internal Market, forces them to broaden their horizons and seek cross-border opportunities. The second feature is the continuing requirement to respect local culture in delivery of services, a feature which reduces the scope for rationalisation and internationalisation.

Accordingly, there is a growing awareness among small, independent enterprises that their position can only be defended by their working together in groups, whatever form such co-operation may take.

Another key element may thus be effective streamlining of operations through technology, enabling the operator to carry out more activities at an overall higher level of sophistication. Electronic Consumer Response (ECR), Electronic Data Interchange (EDI), Electronic Point-of-Sale (EPOS), and Direct Product Profitability (DPP) techniques are used widely as essential tools in upgrading activities. The use of multimedia will also play an increasingly important role.

The problem is, of course, for smaller players, who may find that the required investment in technology is too great for them to support. Again, through cooperation, they are able to benefit from the services offered by the group to which they belong and participate in such technologies.

The opportunities created for logistics planning and management by the abolition of internal frontiers should contribute to expansion in physical distribution activities. Taken together with the liberalisation in road transport, this area should see major change. This will in turn produce a situation where distribution strategies will influence consumption patterns and where marketing activities typically performed by manufacturers may be taken on by distributors and traders.

Lastly, as consumer spending on retail goods has not yet returned to pre-recession levels, the battle for market shares will be reinforced and therefore influence the present structure of the industry. Perspectives for growth of private consumption remain modest because real disposable income might come under pressure from falling employment, continued wage moderation, higher taxes and social security contributions which will constrain output growth of the distributive trades in consumer markets. On the other hand, export orientated wholesales (capital goods) are expected to rebound strongly. Cost structures are forecast to change in the coming years as retailers attempt to reduce costs mainly by improving the efficiency of their operations, perhaps, for example by cutting unit labour costs by removing levels of management. Food retailers are likely to take the lead in the process.

Written by: European Commission, DGXXIII

# Wholesale trade

## NACE 51

Wholesale trade represents 20 % of commercial firms, accounts for 32 % of persons engaged in trade and employs 3.3 % of the working population in the European Union. Its turnover represents 58 % of the trade sector. It accounts for a substantial proportion of the import and export trade of every Member State. It is a dynamic sector as regards employment. Its continuous expansion (apart from the food sector) depends on how it adapts and above all on how it develops in the functions which it performs and the services which it offers (logistics, trading functions, financial and technical services).

### INDUSTRY PROFILE

#### Description of the sector

Wholesale trade embraces all purchasing and temporary storage activities relating to goods which are to be resold generally in large quantities to professional users and retailers, to the exclusion of final consumers. The sector embraces firms and intermediaries operating in the fields of foodstuffs, non-food consumer goods and products which are to be processed (fuels, ores, chemical products etc.). Its intermediate position makes it dependent on the general trend of the branches of which it forms part: industries producing consumer goods and retail trade (in the case of wholesale trade in food or non-food goods); sectors of activity consuming or using intermediate products or equipment (in the case of other wholesale activities).

Wholesale trade occupies an important position in the economy of the European Union and in service activities. In 1991, it comprised: 637 605 firms, or 20 % of commercial firms, and 7.3 % of all firms. The sector's turnover amounted to 1 772 million ECU (not including Greece), or 58 % of trade. Its wage and salary earners numbered 5 069 883, or 32 % of the total workforce employed in trade and 3.3 % of the EU's working population. Economically, four countries (Germany, the United Kingdom, France and Italy) account for over 80 % of EU wholesale trade.

#### Recent trends

Between 1981 and 1990 the average annual growth rate of GDP was between 1.5 % and 3.0 % in the various EU Member States (excluding Ireland). During the same period the average annual growth rate of industrial output ranged from 1.1 % to 4.1 % (excluding Ireland). The 1990s have witnessed a gradual slowing of the EU economies. Some recovery is observable in 1994.

#### International comparison

The wholesale trade does not have the same relative weight in the three major world economic areas. Its weight is particularly great in Japan, where intermediary trade has always occupied a larger place than in Europe and the United States. This difference can also be seen in the weight of the wholesale food trade in the sector (1987-88).

#### Foreign trade

Wholesale trade has a pronounced international function. Although it is not possible to assess its statistical extent at EU level, it should be noted that wholesale trade is an important element in both imports and exports. In France, a survey carried out by the Direction du Commerce Intérieur shows that 12 % of the turnover of the wholesale trade sector comes from exports (involving 32 % of the firms in the sector).

### MARKET FORCES

#### Demand

Demand is affected by two main factors:

- the wholesale food trade is tending to decrease in all countries where large-scale distribution occupies a dominant position in wholesale trade. The supply function of wholesale trade is declining, more generally, in all countries characterised by increased concentration of retail trade;
- the customer base of the wholesale trade does not have the same structure in all the sectors concerned. While two-thirds of the sales of the wholesale food trade go to resellers (central purchasing bodies and retailers) and one-third to professional users (producers or collective bodies), the proportion is reversed for the wholesale non-food trade: one-third to resellers and two-thirds to professional users.

### Supply and competition

The position as regards competition varies considerably between the sectors of activity in which wholesale trading is involved. The degree of concentration of the wholesale trade varies greatly according to the degree of concentration of the customer base. While the wholesale trade serving craft undertakings and small businesses consists mainly of small independent businesses, that serving medium-sized or large businesses is much more concentrated. The first case involves short-range trading depending on the local density of the clientele. In the second case the type of distribution involved is more modern and the competitive challenges are more complex.

### Production process

Traditionally, the intermediate position of the wholesale trade has involved three types of functions:

- a complete logistical function comprising transport, storage, packaging of the products to be resold or processed,
- an intermediate financial function, financing storage and assuming responsibility for part of inter-firm credit,

- a function of dissemination of information between the producer, the reseller and the processor.

These traditional functions are now changing significantly. Several points should be noted in this connection:

- Wholesale trade in the food sector is becoming less important, but appears to be becoming increasingly international, with a growing proportion of its activity being focused on the distribution of imported products. The role of supplying the retail trade remains strong in the fresh produce sector (fruit, vegetables, fish, meat), where it is also accompanied by an internationalisation of export activity.
- Wholesale trade in non-food consumer goods has also seen a decline in its role of distribution to the retail trade, with the concentration of the latter and the growing role of procurement centres, which buy direct from producers. This applies particularly to maintenance and clothing products and footwear. On the other hand, this sector is still essential for the perfumery, pharmaceuticals and stationery business.

Many concentrations have taken place in this type of wholesale trade in recent years.

- Inter-industry wholesale trade is, on the other hand, growing steadily. Its role as intermediary between producers is strengthening with the adoption of new functions:
- Wholesale trade is tending to enlarge its role of marketing of finished or semi-finished goods intended for processing firms. Its selling techniques have developed considerably, and include mail-order selling from catalogues and telephone sales.
- Its logistic functions are diversifying, to include stock management or procurement for third parties, maintenance and after-sales services. In some fields the wholesaler is the guarantor of the service offered to the final user.
- Wholesale trade can also include participation in industrial activities. In the timber sector, wholesalers undertake drying, planing and pre-cutting operations.

- In some cases wholesale trade even includes still more specific services: installation, training of users, financing of retail facilities (as in the beverages sector), etc.

- The development of the wholesale trade in the branches of activity in which it is involved is accompanied by changes in structures, management methods and the use of information systems (development of links between the customers' and suppliers' systems).

The separation between the retail trade and the wholesale trade is furthermore tending to become less clear-cut in a number of cases:

- in the case of goods for mass consumption we are witnessing the formation of large groups engaging in both retail and wholesale trade. Similarly, in the inter-firm wholesale sector, some firms are subsidiaries of industrial groups;
- the wholesale trade is opening up to individual customers in some countries. In France, especially, wholesalers of

building materials and supplies for the home have opened up significantly to the do-it-yourself market.

The same is happening in the sectors where cash and carry firms, initially confined to professional customers and then gradually opened to individual customers (footwear, clothing, equipment for the home), have developed.

---

## INDUSTRY STRUCTURE

---

### Companies

The numbers employed in this sector are rising in most Member States of the European Union. The number of wage and salary earners rose by between 5 and 15 % in the main EU countries between 1988 and 1991.

The level of concentration of the wholesale trade in Europe is illustrated by the emergence of large groups and firms.

### Strategies

Mergers, acquisitions and alliances have become more and more numerous during the last five years in the pharmaceutical products distribution sector, in the wholesale food trade sector and in the building materials sector. Several developments should be noted in this connection:

- an internationalisation of big wholesale firms within the EU
- an even greater concentration in the case of suppliers to large firms (iron and steel products, for instance)
- increasingly frequent incorporation of retail trading (e.g. the Metro group or the Pinault group).

### Impact of the Single Market

Wholesale distribution represents a key factor for many industries, as it provides the integration of different added value functions that have to be performed to distribute products from manufacturer to users such as catalogue composition, sourcing, storage, assembly, re-packaging, distribution, support and financial services.

The common market has been globally positive so far for this sector. Measures reducing delays and transport costs are of obvious benefits to the sector. This has been the case with the abolition of controls at internal frontiers to achieve free movement of goods, and with the liberalisation of transport and telecommunications. Moreover, measures of technical harmonisation such as uniform standards in sizes, weight, qualifications, safety, hygiene and veterinary requirements will simplify and facilitate trade and allow economies of scale. Besides, the legislation on environment protection is relevant to the sector as the activities in this sector includes activities such as butchers, and also results in packaging wastes.

- The creation of the Single Market has created a need for European wide distribution networks. However, operators in the distributive sector face two conflicting pressures in trying to meet the challenge. Firstly, the concentration and integration in the distributive sector, encouraged further by cost reductions following the completion of the Internal Market, have forced the operators in the sector to seek cross-border opportunities. Secondly, there is still a requirement to respect local culture in the delivery of services. In addition, the regulation on consumer protection and social issues has not taken enough into account the ability of the EU companies to achieve ever increasing standards. A simplification or better explanation of the legislation would address this problem. Another top priority for the sector is the Community's external policy, due to the growing importance of this sector internationally.

---

## REGIONAL DISTRIBUTION

---

The wholesale trade is located geographically in the main centres of activity and consumption in the largest EU countries. With the growing role of large wholesale firms in imports and exports, an increasing number of establishments of these firms are being sited in the hinterlands of the main EU ports, chiefly in Northern Europe: Belgium, the Netherlands and Germany.

---

## ENVIRONMENT

---

The wholesale trade is subject to the same constraints as the sectors of activity from which it buys and those which compose its clientele. Many national professional organisations have technical agencies which draft quality recommendations or charts for use by their members. They distribute, in varying quantity, data and information designed to make the markets more transparent.

---

## REGULATIONS

---

The wholesale trade is subject not only to all national or EU regulations concerning trade but also to those concerning specific types of products (regulations on foodstuffs, pharmaceutical products etc.). With regard, more specifically, to Community rules, the wholesale trade has to comply with all provisions forbidding concerted practices: concertation between a number of undertakings and practices which have restrictive effects on competition and especially on prices.

The foreign trade activity of the wholesale trade might be affected by new EU legislation resulting from the implementation of the GATT's Uruguay Round.

---

## OUTLOOK

---

The wholesale trade will be affected by several trends during the period 1994-97:

- a diminished presence for the wholesale food trade, which will at the same time do more for its customers;
- a growth in turnover of the sector similar to the GDP forecasts;
- a further concentration of the sector, particularly in the area of supplies for industry.

# Retail trade

## NACE 52

Retail trade occupies an important place in the European economy. It comprises 80 % of commercial undertakings and 26 % of all businesses. The numbers employed represent 68 % of the commercial sector as a whole and 7 % of the working population. Two trends are changing the sector: increased concentration, highlighted by the size of the large distribution groups, and the growth of independent organised trade, accompanied by increased Europeanisation and even internationalisation. As a result of this development relationships between industry and commerce are undergoing major changes.

### INDUSTRY PROFILE

#### Description of the sector

Retail trading comprises all activities involving the purchase of goods for resale to the end consumer or user, generally in small quantities and without significant processing.

The retail trade is a vital element in the economy of the European Union and in the service sector. In 1991, it comprised 2 552 913 undertakings or 80 % of commercial undertakings and 26.1 % of all businesses. The sector's turnover was ECU 1.261 million or 42 % of commerce as a whole. Numbers employed amounted to 10 971 842 or 68 % of commercial employees and 7 % of the working population. The development of this sector depends more and more directly on retailable consumption. The development of purchasing power plays an important role in this, but other phenomena, too have become increasingly important. Since 1991 there has been a decline in consumption, the causes of which are not solely economic. Conversely, the relative revival of growth in 1994 has not been accompanied by a real revival in consumption. This trend of consumption is also partly attributable to socio-cultural factors.

#### Recent trends

The national markets which make up the single European market vary widely. In 1990, the standard of living (Source: Eurostat) was half as high in Greece, Ireland and Portugal, on the one hand, as in France, Germany, Italy and the United Kingdom, on the other. Consumption per head of population varies in the same proportion (around 5 000 ECU in Greece, Portugal and Ireland and 9 000 to 10 000 ECU in Germany, France, Italy and the United Kingdom). The share of retailable goods in total consumption varies even from country to country. Even within this retailable consumption, the proportion of expenditure under different headings (food, clothing, domestic equipment, etc.) varies significantly from country to country. In countries like Greece, Portugal and Ireland, with a low standard of living, food still accounts for 40 % of retailable consumption (which represents 65 % of total consumption) whereas in countries like Germany, France, Belgium and the Netherlands, it accounts for 16 to 19 % of retailable consumption (which represents slightly over 50 % of total consumption).

#### International comparison

Retail trade continues to be largely marked by its national features. The internationalisation of retailing groups is slower than that of the industrial groups which are their suppliers. Few examples are to be found of the establishment of retailers outside their country of origin before the 1970s. Today, ten groups achieve over 30 % of their turnover outside their country of origin (EU and other countries). All the other major groups have an international turnover of below 30 %, or even below 20 %. Two phenomena, on the other hand, are tending to involve the retail sector in international trade (in other words, cross-border trade):

- its increasingly diversified purchases, including outside the EU (often via specialised subsidiaries);
- the emergence of EU-wide shopping centres.

## MARKET FORCES

### Demand

Demand is affected by several phenomena. It is considered nowadays that the development of demand is governed by four factors:

- the level of household consumption;
- the movement of prices: between December 1993 and November 1994, this movement differed in the largest EU countries: +2.7 % in Germany, +1.6 % in France, +3.7 % in Italy, EU average +2.6 %;
- unemployment rate: 6.2 % in Germany, 11.3 % in France, 12 % in Italy, 9.1 % in the United Kingdom, EU average 6.1 %;
- the development of GDP.

### Supply and competition

The dominant feature is the growing concentration of distribution groups, together with the development of trading in large stores. The progress of this form of distribution is not the same everywhere. It is much more advanced in the countries of northern Europe and in France. It is also beginning to affect Italy, Spain, Portugal and Greece. Wherever large-scale retailing has increased, traditional small-scale retail trade has declined.

SMEs can only be competitive if they discover new niches or cooperate in buying groups, franchises or voluntary chains.

With regard to the structure of retail trade, the relative extent of its various forms within the European Union differs from country to country. Three phases can be distinguished in the

development of retailing, each characterised by a specific balance of power between the retail trade and its industrial suppliers

- a phase with traditional trade domination, and industrialists in a position of strength in dealings. This is the case at present particularly in Greece and Portugal.
- a phase with modern retailing emerging and gradually beginning to impose new rules of the game (especially in the food sector). This is the case at present in Italy and Spain.
- lastly, a phase of consolidation of large-scale retailing (including the non-food sector). The relationships between industry and retailing sometimes involve conflicts, but may also be characterised by the emergence of new forms of cooperation. This is now the situation in France, Germany and the United Kingdom.

### Production process

The most fundamental development in the field of retailing has been the growth of information systems comprising both the processing of management data and also all logistical operations upstream of selling.

This phenomenon is highlighted by the growth in the number of points of sale equipped with terminals with bar-code readers.

## INDUSTRY STRUCTURE

### Companies

In recent years, total numbers employed in this sector have been growing in most of the Member States of the European Union. They increased by between 2 and 25 % between 1988

and 1991 in the main EU countries. However, more recent estimates show that employment in the sector has started to decrease.

The level of concentration of trade is evident from the emergence of large retailing groups in the various Member States of the EU.

### Strategies

The strategies of the retailing groups are formulated in terms of several parameters:

- the reference market, which is defined geographically. It is thus possible to distinguish national strategies (aimed at one or more national markets) and international strategies (centred on the European market as a whole or on markets outside Europe)
- a level of diversification, while remaining within the basic profession, particularly through the creation of new spe-

cialised chain stores or going outside the basic profession (creation of joint ventures in other sectors of activity, with incorporation of upstream activities)

- lastly, a price policy ranging between two extremes: value enhancement through sharp differentiation of what is offered, especially in terms of associated services, or, at the opposite extreme, strategies of domination through prices, as exemplified by discount and hard-discount practices.

Also worthy of mention, side by side with the move towards concentration highlighted by the emergence of big groups, is the considerable growth in franchise trading (which is giving a stimulus to some sectors of traditional trade). At the beginning of 1993 the European Union had 2 216 franchisers with a total of 111 340 franchise-holders (or over 4 % of points of sale).

## Impact of the Single Market

Retailing is the activity in the distribution channel which makes goods and services available for purchase and consumption by consumers. It is the point of sale where manufacturers are able to display their products and where the final customers make a choice. Thus, campaigns have been focused on creating customer preferences. However, a number of common themes can be identified. Thus, at the operational level, the adoption of the marketing concept has been fundamental in order to enhance sales. Consequently, these developments have led to investments in ways to control costs and to manage the operation more efficiently.

Various aspects of the Single Market have influenced retail trade. Firstly, the mutual recognition of national product safety standards, along with the removal of border controls, has influenced positively the sourcing, transport and movement of product. This has been further facilitated by the liberalisation of transport and telecommunication. The European legislation on environment of protection has also been relevant to the sector, especially in the area of packaging waste. Thirdly, aspects of the social charter have influenced the employment structures, making them less flexible. Finally, fiscal harmonisation (particularly of VAT) will potentially affect the final transfer process to consumers. Nevertheless, the retail sector remains a mainly local business, not only because of geographically determined cultural differences, but also because of differences in organisation and selling techniques. The Internal Market programme has contributed to a growing internationalisation of the sector, and has led EU retailers to grow in size. Future priorities for this sector on the European policy front are the further harmonisation of EU legislation in the area of consumer protection and social issues, and standards harmonisation.

## REGIONAL DISTRIBUTION

The geographical pattern of retail trade is determined by the main areas in which consumption is centred. In the largest EU countries it is estimated that the consumer has to make a journey taking about 11 minutes to do his shopping. The growth in large-scale retailing at the expense of its traditional forms has not fundamentally changed this idea of proximity, which is a dominant feature of retail trade.

The structure of the commercial sector varies greatly from country to country. A distinction can be made between:

- high-density countries, where the number of traders per 10 000 population ranges between 110 and 175. This is the case in Portugal, Greece, Ireland and Spain;
- low-density countries, where the number of businesses per 10 000 inhabitants ranges from 60 to 95. This is the case in the rest of EU Member States.

Average turnover per business also varies considerably from country to country. In 1990 the figure was between 114 000 ECU and 116 000 ECU for retail trade in Greece and Portugal and over 800 000 ECU for Germany, Luxembourg and the United Kingdom.

## REGULATIONS

The retail trade is subject to all national and EU trade regulations. Several points should be mentioned in this connection:

- the largest EU countries have enacted regulations for commercial town-planning which are binding in varying degrees for the development of large-scale retailing and selling areas. These rules have played a considerable part in determining the pattern of large-scale retailing and its establishments (especially in Belgium, France, Germany and Italy);
- national legislations still differ as regards the rules governing price fixing, recommended prices, refusal to sell and loss leaders;
- with regard to Community rules, retail trade is subject to the provisions prohibiting concerted practices which restrict competition, prices and distribution agreements (franchising, exclusive and selective agreements);
- lastly, the Community has established a specific system for the protection of customers' health and safety, economic interests, rights to information and rights of representation.
- Product legislation also has an impact on the retail trade, given the increase of own-branded products.

## OUTLOOK

The retail trade will display several trends during the period 1995-97:

- continuation of the concentration process which began during the 1980s;
- the main retailing groups will become still more Europeanised (by strengthening their positions in the southern markets such as Portugal, Spain, Italy and Greece but also in markets outside Europe);
- the continuing development of hard discount;
- lastly, forecasts of the development of retail trade predict annual growth rates ranging from 3 to 5 %.

## Overview

NACE 665, 667, 771, 661

*The tourism industry in Europe is in a constant state of evolution. This is in direct response to the changing demands being placed on suppliers by tourism consumers who are becoming ever more sophisticated in their tourism expectations in terms of quality of service, diversity of tourism products, and improved provision of accommodation, 'winning and dining' facilities, entertainment and travel services. With more disposable income and leisure time to devote to leisure, increases in both short-break and long haul holidays segments of the tourism market are taking place.*

*So far, the European tourism industry, in the main, has responded to the current challenges put before it by developing appropriate tourism products to satisfy the new demands. Rapid changes in demand means that analysis of this constantly evolving market continues to be necessary. Tourism is an extremely "horizontal" industry which comprises a wide variety of services and industries. The performance of the industry to date on the world and home markets has continued to grow and to improve.*

*Analysis of market forces, trends and the regulations which impact on the development of tourism in Europe, all indicate a positive outlook for the future development of the industry. However, in order to improve the performance of the European industry, future strategies should incorporate greater diversification of tourist products, bearing in mind the "value-for-money" aspects.*

## INDUSTRY PROFILE

### Description of the sector

Tourism represents a complex economic and social phenomenon which affects millions of citizens in Europe as well as all over the world. The impact of tourism on these citizens is felt both as beneficiaries of tourism products and services and as providers of a variety of services which seek to meet the various needs of tourism. The pervasive impact of tourism throughout the world on local communities is matched by very few other industries. It entails a complex network of businesses engaged in the provision of accommodation, food and drink, transport facilities and services and entertainment for the tourist.

According to the World Tourism Organisation (WTO) definition adopted by the United Nations Statistical Commission in March 1993, a tourist is defined as a visitor staying at least one night and for no more than one consecutive year in a place other than that corresponding to his usual environment. However, when considering the nature of travellers engaged in the various forms of tourism, the term "visitor" represents the basic concept of tourism statistics: there are visitors making pleasure trips for purely tourist purposes or in order to visit friends and relatives as well; and then there are those who make business trips. Another important and growing segment of the market is that of the excursionist or same-day visitor who does not stay overnight away from his usual environment.

The tourism industry is thus better viewed as a market rather than as a sector given the wide range of related industries

and services involved right across the economy, the most important of which being the lodging subsection, catering, sports and entertainment, travel services and the transport and crafts industries.

The aim of this chapter is to focus on the following sub-sectors:

- Hotels (NACE 665);
- Other accommodation (NACE 667);
- Travel services (NACE 771);
- Restaurants (NACE 661);
- Recreation parks;

The diversity and fragmented nature of the tourism industry is a disadvantage when collecting and aggregating statistics particularly when making comparisons at the international level. The current work developed by the European Commission is co-operation with EU and EFTA Member States and international organisations such as OECD and WTO aims to harmonise methods and definitions used on tourism statistics in order to gather reliable and coherent figures at the international level.

### Recent trends

According to the World Tourism Organisation (WTO), of international tourist arrivals were estimated at over 200 million in 1994 in all EU Member States, (EU 12) representing 38 % of the world market share.

For the same year international tourism receipts, excluding transport expenditure, represented over 100 billion ECU which constitute 35 % of the world market share. In order of importance the principal international tourist destinations in the Community, are France, Spain and Italy which together receive 1/4 of all international arrivals in the world and 1/5 of receipts.

These figures exclude domestic tourism as well as same-day visitors. The volume of domestic tourism - overnight stays

in the country of residence - exceeds outbound tourism considerably. It is estimated that about 2/3 of all holidays generated by the EU population can be classified as "domestic"; 22 % is related to international tourism between the EU Members States and 13 % of all holidays are spent at destinations outside the Community. Domestic tourism is even more important in the Mediterranean countries (84-87 %) and in Portugal where the rate (90 %) is the highest of the Community.

The growing importance of same-day visits as part of tourism is confirmed in many industrialised countries. At the international level, it is estimated that day trips to neighbouring countries, constituted in Europe one out of every two trips.

The fact that tourism constitutes an important source of revenue for EU Member States is confirmed by Eurostat's estimate that tourism contributed 5.5 % of the Community's GNP. In Spain and France the relative importance of tourism activities in their economies, is approximately double that of the Community average. Greece, Portugal and Ireland are also above average.

### International comparison

According to WTO estimates the world tourism industry has maintained its rate of growth. The economic recovery has had a positive effect on trends in travel abroad. In 1994 intentional tourist arrival increased by 4 % in respect of the previous year, reaching 533 million world-wide. The increase in receipts has been important, being more than the double of the arrivals in terms of growth rate.

In 1994 all Europe registered 320 millions internationals arrivals (3.9 % more than in 1993). Europe, with a world market share of 60 % of all international arrivals, still represents the principal driving force of international tourism. However, between 1970 and 1994 Europe has lost 14 % of its world market share to new destinations located in third countries particularly in South East Asia and the Pacific area.

(2) Estimates

Source: Eurostat estimates

At world level in 1994 East Asia and the Pacific area have continued to experience significant progress, with an increase of 7.2 % in terms of arrivals and 12.4 % in terms of receipts.

The United States continued to lead the world in terms of tourism expenditure (36.6 billion ECU) and tourism receipts (48 billion ECU) in 1994. WTO's estimates indicate for 1994 an increase of the expenditures of 5 %.

American tourists coming to Europe in 1994 are estimated as 13 millions in terms of arrivals. The United Kingdom is still their principal destination (over 3 millions arrivals) followed by France, Germany, Italy, and Spain.

With 14 million Japanese travelling abroad, of whom 46 % visited other Asian countries. Japan is the third most important spender in the world on travel abroad. It has been estimated that Japanese tourists spend on average four times more than the European tourists and twice as much as American tourists travelling abroad. 1.7 million Japanese visited Europe in 1994 12 % more than in 1993, principally in the United Kingdom, France, Italy and Germany.

France continues to maintain its position as the world's leading tourist destination, receiving 60.6 million international tourists in 1994. After the United States, France maintains also second place as a top earner or international tourist receipt, followed by Italy, Spain and the United Kingdom.

### Foreign trade

According to WTO, international tourism receipts represent 1.74 % of the total GNP of the European Union in 1993. The contribution of tourism receipts to GNP is substantially higher in Portugal, Greece, Ireland and Spain. More than 50 % of tourism receipts finance the trade deficit of France and more than 40 % in Italy and Spain. In Austria, the top earner country in the world in terms of tourism receipts, tourism represent 2/3 of export and 7.39 % of GNP.

As a positive contribution to the balance of payments, tourism represents 27.7 % of the services exported by the Community to third countries.

Even though European long-haul travel almost doubled in the last decade, intra-Community flows still dominate the mar-

ket. The most important markets for tourism into the EU are the EFTA countries, United States and Japan. Europe is also important as a source market for most regions: in South Asia, in the Middle East and in Africa.

With 35.1 billion ECU, Germany is the main European spender at world level, second only to the United States. Other main European spenders, the top eight at world level include the United Kingdom, France, Italy and the Netherlands.

## MARKET FORCES

### Demand

The demand for holidays is influenced by a variety of factors which affect the decision whether to take a holiday, what type or length of holiday and where to take it. The most important of these factors include: income, available free time, age and family circumstances, comparative price level, environmental conditions.

Overall European demand, in terms of nights spent by tourists in accommodation establishments of the commercial circuit, is estimated for 1993 to be around one billion and seven hundred fifty thousand. Of this, 59 % is attributable to domestic tourism, the remainder to international tourism.

During 1993 the overall demand for tourism in EU and EFTA countries has suffered a reduction in terms of nights (-1.8 %). The decrease is slightly less for tourists who have chosen hotels (-1.6 %) as compared to those who have chosen supplementary accommodations (-2.0 %); similarly the difference is slightly less for international tourists (-1.6 %) as compared to domestic tourists (-1.9 %). This phenomenon is explained by the fact that domestic demand (in which vacation tourism has the greatest weight) is more sensitive to economic crises as compared to international demand.

The countries which have felt the greatest decline in demand are Belgium (-13.3 %), Portugal (-7.2 %) and Denmark (-5.47 %). The countries that have greatly increased their overall flows, besides Luxembourg (8.9 %) whose role in the tourism market is of a special nature, are the following: Sweden (8.9 %), Finland (6.7 %) and Spain (6.3 %). The Scandinavian

**Table 4: Tourism**

Source: WTO

countries have therefore registered high performances both on the foreign and domestic markets. This latter fact is probably due to a shift from flows that were once towards international destinations towards national destinations.

Domestic tourism also seems to show a close correlation with the devaluation of the currency, even though it is less obvious than in the case of foreign tourism, since it is also more sensitive to other phenomena. The revaluation of currency results in a decrease in domestic nights due to the propensity of tourists in one country to look for more economical offers abroad (particularly in those countries that have witnessed an inverse monetary variation), while the devaluation results in an increase in domestic demand as a response to decreased purchasing power abroad.

The less than brilliant trend of 1993 tourist activities is evidenced also by the utilisation levels of hotels and similar establishments. In almost all the countries in fact, a decrease in the use of beds in such establishments has been registered when considering either the gross or net usage (that is excluding the periods in which the hotels are closed). Only Portugal is an exception; its negative year in 1993 was preceded by another negative year of similar magnitude. It can be observed in fact that from 1990 to 1993 to gross usage rate has fallen from 37 % to 34 % although a slight recovery has taken place during the last year.

Income, linked with education and social status, in particular affect the level of holidays taken. Those with high disposable income tend to travel more frequently. In addition, business travel, which is becoming increasingly important, is usually much more frequent than leisure travel.

There are a number of new trends which are characterising tourism demand in Europe: the expansion of the short-breaks market and second holidays as well as growth in outbound travel from the southern Europe markets.

Changes in population age-structure also strongly influence the nature, incidence and timing of holidays during the last decade of the century. An emerging fast growing segment market is the "senior travel market" which constitutes the 20 % of the trips taken by the Europeans.

Mobility of holiday-makers in terms of varying destinations and seasonality and more active behaviour is increasing. Even though traditional tourist products associated with sun, sea and beach resorts still dominate the market, the interest when taking holidays in cultural activities, in a broad sense, is growing and may contribute to the better staggering of holidays.

Another important factor which may strongly influence tourist flows is the emphasis placed on value-for-money. As tourists continue to become more sophisticated they demonstrate willingness to receive higher standards of quality and services.

#### Supply and competition

The tourism industry comprises both a wide range of economic activities and a supply of products which come from a whole range of different types of enterprise. Their common characteristic is the variety of the existing enterprise structures as well as of the number of services available. For this reason in this domain there co-exist various forms of ownership from small individual proprietors to multinational corporations. Supply reflects demand, both in terms of structure, and in terms of trends. According to this hypothesis, concentration of the industry within a country will only occur in a sustainable manner, if the aspects of demand encourage and justify it economically in the long-term. The basic factors of demand are very asymmetric across the European market, as they vary significantly from country to country. Government regulation together with the number and size of enterprises determines the degree of competition which in the main tourist activities seems to be relatively high.

**Table 5: Tourism**

### Production process

According to Eurostat of over 1.3 million enterprises involved in hotel and restaurant activities in the Community, 96 % are made up of micro-enterprises (less than 9 employees). European leadership at world level in terms of accommodation capacity is confirmed. For Hotels and similar establishments, the trend in the Community is towards a reduction in the number of enterprises and a gradual increase in the accommodation capacity in absolute terms as well as in terms of average size in the Community which went up from 43 to 45 beds; the rate is however still low in relation to areas outside the Community. Nevertheless, in this case also, the situation varies from one individual Member State to another:

- lower than EU average in United Kingdom (25 beds per establishment). Germany (34) and Luxembourg (38);
- higher in Denmark (170 beds), Portugal (106), and Spain (101), where the boom in package tourism had led to investment in large hotels.

In spite of the difficulty of evaluating the impact of tourism on employment, it is certain that all sectors of the tourism industry are labour-intensive. Jobs in tourism activities in the Community number some 9 million. Tourism represents about 6 % of total jobs in the Community, taking into account only jobs directly linked with tourism products and services. Besides these direct jobs, it is also necessary to consider the indirect or spin-off jobs, created in sectors outside tourism in the strict sense. The structural flexibility and, in some cases, the weakness of this segment of the market may explain the degree of attraction which the sector has for women and young people, often constituting their first employment. Moreover in the services sector, which employs six people out of ten in the Community, tourism also has a high proportion of female employment which varies from 45 to 65 % from one Member State to another. The seasonality of employment, another particular feature of tourism, is moreover very variable in different branches: low in cafes and restaurants and in travel agencies, medium in hotels and high in holiday camps and open air facilities.

Important new technologies have been introduced into all segments of the tourism industry in recent years. However, the general impact has been on improved quality of service rather than in labour content reduction.

### INDUSTRY STRUCTURE

#### Companies and strategies

Estimates by the World Travel and Tourism Council indicate that investments in these areas of activity in the Member States reached 192 billion ECU in 1995 equivalent to 15.5 % of total investments.

In 1995 in terms of capital investment planned for tourism in relation to the total investments for all the industries, the largest investors in travel and tourism are expected to be

Ireland (32 %), Spain (24 %), Belgium and Finland, (21 %), and finally France (18 %).

The structure of the tourism industry is moving towards rationalisation:

- gradual withdrawal from the market of very small, marginal establishments;
- reinforcement of partnerships in various forms (integrated chains, franchising etc.).

In Europe, as has been the case in the United States, the main trends of market strategies are:

- concentration on niche markets on a world-wide scale;
- differentiation and segmentation

This approach is being applied in the hotel industry: on the one hand, the major European groups through mergers and acquisitions are trying to compete with US groups which are the leaders in the market world-wide; on the other hand, the early 1990s saw the emergence of associations of small hotel groups and consortia whose aim is to improve market awareness.

The performance of the tourism industry can be better achieved through:

- wider integration between the tourism sector and the other economic activities, especially through planned regional development;
- improved balance between price and quality of services provided;
- rapid response to changing tourist behaviour;
- the further application of new technologies in marketing and managing businesses;
- the improvement of the so called "internal marketing".

Human resources are a key factor to success in the process of change being experienced in the sector. The cross-frontier mobility of manpower is higher than in other sectors. The full implementation of the internal market encourages mobility and offers reinforced guarantees for employees and their families. The mutual recognition of diplomas also contributes to this mobility. Conscious of the importance of vocational training, the European Union will continue to support this field in order to improve the quality and performance of labour in the sector and stimulate exchange of experience at international level between the major "actors" involved.

### REGIONAL DISTRIBUTION

The tourism industry continues to be concentrated in certain regions, generally in seaside and mountain locations. Urban tourism, which takes in historical and cultural cities, is another relevant segment of the tourism market that still continuing

to expand. Among the European capital cities, London, Paris and Rome are the principal destinations.

## ENVIRONMENT

The success of tourism relies to a great extent on the quality of the environment where it takes place. While tourism activity is influenced by the environment, the environment is greatly influenced by tourism. While tourism activity is influenced by the environment, the environment is greatly influenced by tourism. Without proper planning and management the industry may damage the resources it depends on for its success. Over the last 20 years the European tourism industry has been characterised by sustained growth which has led to development pressures, both in established tourism resorts and in previously unexplored areas, particularly coastlines. This has led to resource-management problems, both in terms of physical tourism development and the management of facilities and visitors.

The growth in general consumer awareness of environmental problems has led to actions by both the public and private tourism sectors to combat the problems which can be caused by tourism. Development related issues can cause substantial impacts on physical and built environments and tourism in general may cause air, noise and water pollution, congestion, erosion and various social disturbances. The importance of particular locations and seasonal factors may also aggravate these problems while historically the diversity of tourism has made it a difficult industry to plan and regulate. The industry has diversity of tourism has made it a difficult industry to plan and regulate. The industry has responded to the call for better environmental practice in a number of ways, these include:

- the development of sustainable tourism strategies in the public sector and the setting up of environmental associations in the private sector;

- the development of various codes of conduct and self-regulation measures by the private sector;
- a range of joint partnerships at European, national and local level related to research on sustainable tourism and pilot projects which test its applicability;
- the development of new holiday products for certain environmentally conscious market segments.

Alongside these activities broader environment policy at European and national level continues to influence the development of tourism. The increasing (on occasions mandatory) use of Environmental Impact Assessment in tourism may signal a first step towards greater legislative intervention in the industry, particularly in the form of taxation related to energy use and of anti-pollution laws. Tighter planning regimes at a regional level are already in evidence in many parts of the EU. Often environment focused activity enables parts of the industry to come together to tackle a common and fundamental interest. The improved protection of the environment will remain one of the main challenges facing the industry during the next decade.

## REGULATIONS

Given the horizontal nature of the tourism industry, a wide range of local, national and EU regulations impact on the tourism industry, although few are prepared with the specific intention of regulating this particular sector.

Within the framework of the European Union, many measures have had either a direct or indirect impact on the tourism industry because of the sheer number of activities that the comprises. A full assessment of Community measures affecting tourism has been made by the Commission in its communication of April 1994.

The legislation relevant to tourism can be considered in four main groups;

**Table 8: Tourism**

Source: WTO

- measures associated with the completion and functioning of the Internal Market associated with the removal of physical, technical and financial barriers;
- measures aimed at protecting the environment and consumer interests;
- measures intending to bring about social and economic cohesion among all the Member States;
- measures included in the Community Action Plan to Assist Tourism.

Of most interest to tourism firms within the Union, are those Community measures affecting the removal of technical and legal barriers, employment, the promotion of fair competition, the development of a business environment which in particular is more conducive to encouraging small and medium sized enterprises (SMEs) to succeed by promoting transnational co-operation and the use of new technologies and the development of a comprehensive, environmentally-sensitive European transport network linking even the peripheral regions.

The multi-annual action programme, adopted by the Council in 1993, serves to reinforce the main lines of action of Community enterprise policy.

The abolition of tax frontiers and the introduction of minimum rates for VAT and excise duties across the Member States from January 1993 are expected to let market forces pull VAT rates closer together. In the interest of consumers and enterprises much effort continues to be put in towards achieving a greater level of harmonisation.

Directive 92/77/EEC on the approximation of VAT rates, modifying the 6th VAT Directive (77/388/EEC), set the minimum standard rate of VAT at not less than 15 %. However, on products or services of a social or cultural nature - a list of items which includes passenger transport, tourist accommodation provided by hotels and similar establishments, sports and entertainment - the Member States can introduce one or two rates of at least 5 %.

Another aspect of VAT which is under review is the simplification of the system in order to reduce the administrative burden placed on businesses. Within the framework of the preparatory work to establish a definitive regime on VAT, the Council has already identified key conditions to be considered.

The implementation of the White Paper on Employment, Growth and Competitiveness includes major initiatives to tackle the long term underlying presence of unemployment in the Community and to stimulate the speed of new job creation, growth and employment. The nature of tourism as an employment sector lends itself well to the issues addressed in this initiative and the potential of tourism in this context has been recognised within the framework of the social dimension. Proposed legislation concerning the regulation of working time and young workers which still under consideration has implications for the tourism industry.

With the use of the new structural funds for 1994-1999 and the new cohesion fund 1993-1999, tourism continues to be an important tool for regional development and the reduction of social and economic disparities between the regions. Within the previous Community Structural Frameworks (1989-1993), measures concerning tourism were focused on improving the supply and geographic spread of tourism, reducing the seasonality of the industry, full exploitation of the cultural and environmental heritage, developing rural tourism and developing tourism training for employees. The reforms of the objective areas 1-5, taking place with the implementation of the new structural funds are likely to continue to favour tourism development.

With the creation of the Cohesion fund, an extra billion ECU has been made available to assist Ireland, Spain, Portugal and Greece and those regions which are largely rural or suffering industrial decline and thus lagging far behind the richer regions of the Union. This assistance and investment is intended to enable them to achieve a comparable level of development in terms of communications networks while at the

same time ensuring the protection of the environment. Both items clearly benefit the tourism industry.

Since the Treaty on European Union, consumer policy has been given clear recognition of its role in establishing the internal market. The removal of barriers to freedom of movement offers fantastic opportunities for the development and exploitation of tourism in Europe. Tourism, by its very nature, enables tourists to move outside of their usual environment both in order to purchase and to take their holiday. This phenomenon can also make tourism consumers very vulnerable and in special need of information and also legal and financial protection. The provision of information about products and services, and the provision of insurance and compensation, in the event of a faulty product or service, may seem burdensome for the entrepreneur but, in the long term these measures are necessary for the full functioning of the internal market. Well informed consumers, safe in the knowledge that wherever they make purchases in the Union they will have access to justice are more likely to take advantage of the opportunities afforded by the internal market, which should in turn lead to increased enterprise activity and competition. In the third Consumer Policy programme adopted by the Commission in 1993, there is a certain amount of proposed legislation to safeguard the interests of the tourist but also to help to establish a level playing field on which firms can compete fairly with each other.

In the field of Computer Reservation Systems, the Council adopted a regulation (3089/93/EEC) on 29 October 1993, modifying the original of 24.07.89 (2299/89) on the implementation and operation of a code of conduct for air transport and air passengers using central reservation systems. The scope of the regulation has been extended to non-scheduled services and bundled products. Also the ranking criteria for the display of information on air transport services have been strengthened and clarified. The aim of the code is to ensure the non-discriminatory and transparent use of such systems and improved information for air passengers.

Of the proposed consumer measures under consideration during 1994, it should be noted that the Directive concerning Timeshare property contracts (94/47/EC) was adopted on 26.10.94 by European Parliament and the Council following modifications to the text by the Consultation Committee. Under this Directive, having signed a contract, consumers will have a 10 day period, in which they can withdraw from the contract should they not wish to go ahead with the purchase. During this period vendors are not allowed to take any advance payments as a means of guaranteeing the commitment to purchase.

The proposal for a Council Directive concerning the protection of consumers when negotiating contracts at a distance, despite undergoing a series of modifications, has still to be adopted in its current form, tourism services are exempted from the majority of the Directives provisions. Monitoring of the implementation of the package travel Directive still continues. At the present time only Ireland, Spain and Greece have not adopted national legislation. A major problem with regard to implementation has been the need to establish a system of guaranteeing the safety and protection of consumers interests. Tourists more than other consumers are vulnerable in gaining access to justice across frontiers. Following the adoption of the Green Paper on access to Justice, further action is being taken by means of a proposal for a Directive and a recommendation for the development of extra-judicial measures.

On 21.04.94, the Commission adopted a proposal for a Council Directive concerning comparative advertising amending the Council Directive (84/450/EEC), on misleading advertising.

While protection of the tourist as consumer is an essential consideration, a balance has to be struck whereby the industry can still function without being overburdened by excessive regulation.

Since January 1993, the first Community Action Plan to assist tourism has been in operation. The three year action programme, with a budget of 18 million ECU aims to ensure the co-ordination of its own action with actions being imple-

mented under other Community measures and policies. It will be achieved by focusing on three main lines of action:

- ensuring that tourism is taken more into account in Community and Member States' policies;
- co-operation between representatives of the sector and its various professional associations;
- support and development of specific actions.

The first objective seeks to achieve greater consistency in the initiatives taken within the Commission, with other bodies implementing policies or taking measures that might have an influence on tourism, with Member States, to complement their actions in certain fields of tourism, develop actions allowing the broadest possible convergence of their policies, or provide them with the overall information necessary about the activity, in order to direct their actions better, and encourage all forms of international exchanges on tourism.

The second objective will be implemented basically by means of consultation and co-ordination activities with tourism professionals in order to convey the importance of this industry in economic and social terms, ensure better representation of its interests, and develop information within the industry itself about the policies and measures by the Community with direct repercussions on its business.

The third objective is mainly concerned with actions to guide future policy: to provide better information regarding tourists and those working within the industry, for supporting demonstration projects and which could be transposed to various regions of the Community and for a general improvement in the quality of tourism services.

Promotion is the subject of a pilot projects, to enable distant markets to be explored and tested, and to increase the numbers of tourists from those markets, on the basis of an a single tourism image of Europe as a whole.

The scope of specific measures will be quite broad, covering a very varied number of fields (cultural, rural or social tourism, environmental tourism; vocational training). These actions are directly aimed at the public authorities, industry decision makers and at tourists themselves.

---

## OUTLOOK

---

The World Tourism Organisation forecasts a growth of 50 % in intentional tourist arrivals by the year 2000. An annual growth rate of 3.5 % is envisaged for the first decade of the 21st century: by the year 2010 there will be an estimated 937 million arrivals. The regions generating this flow of tourism are expected to include Central and South America, Asia and Africa. These host tourist regions which experience above average growth, including the Caribbean, East and South Asia and the Pacific area. Even if Europe will still be the main tourist destination, it may continue to lose market share, mainly to East Asia and the Pacific area.

# Restaurants

## NACE 661

The restaurant sector includes a diverse range of establishments from fast food take-away to haute cuisine. Throughout the 1980s, changing tastes, rising levels of disposable incomes, greater female labour force participation and increases in tourism expenditures contributed to a steady increase in restaurant revenues. The industry is very susceptible to economic conditions and turnover declined in some EU Member States in recent years. Entry and exit barriers are very low. As a result the industry is predominantly populated by small independent establishments, although rapid growth of fast-food chains, particularly franchise outlets, has provided a high degree of uniformity in that subsector. The use of new technology, mainly in food preparation, has increased, while attraction and retention of workers is a growing problem in many Member States. Despite the recent slowdown, the outlook for the industry is relatively buoyant and the factors which drove growth during the 1980s should continue to operate over the remainder of the 1990s.

### INDUSTRY PROFILE

#### Description of the sector

Among the most vibrant and visible commercial sectors of the EU, restaurants are present in virtually every local community. As a sector, restaurants are important to the European economy and to the economies of Member States and regions, but they play their most significant role in their contribution to the local economy of almost every village, town and city in the EU.

There is substantial variation within the restaurant sector, from fast food outlets to high class restaurants, providing very different markets with a variation of the same service, the provision of ready to eat food. Most restaurants are stand alone

operations, although some are an integral part of the services provided within other sectors, principally hotels but also including recreation parks, public houses, railways, ferries and night-clubs. There are also other service branches specialising in the provision of food including contract caterers, work canteens and messes, and hospitals/convalescent homes. However, while the type of operations are diverse, the sector is dominated by family restaurants.

There is a fine distinction at the margin between sub-segments of the restaurant industry. Unlike hotels, most grading of restaurants is unofficial, often relatively subjective and generally only applies to the top end of the market.

#### Recent trends

Official employment figures in the restaurant industry are available for only a limited number of EU Member States. Eurostat data indicates strong growth in employment across all Member States, except Portugal, for which data is collected.

While the number of restaurants and cafe-restaurants in the EU increased in the late 1980s and early 1990s across Member States, the trend in both Denmark and Luxembourg is downward.

The increase in enterprise numbers and employment is in line with growth in restaurant turnover along a well established upward trend over the last decade. There are variations across different Member States and growth has slowed over the last two years reflecting the impact of economic recession on business, tourism and other leisure demand. Within the overall trend increase, turnover in the fast food and take-away sector has grown most rapidly, although again there are substantial variations across countries with meals in bars and public houses showing the fastest growth in both the United Kingdom and Ireland.

Restaurant services are not internationally traded although an important market for their services are foreign visitors on holidays or business trips. Estimates for expenditure by tourists on food vary from 20 % to 25 % of their total expenditure.

## MARKET FORCES

### Demand

The demand for restaurant services is influenced by a variety of factors including disposable incomes, demographic factors, changing consumer tastes and the level of tourist activity. Restaurants also compete with other leisure activities including cinema, theatre, home video and sports for the discretionary spending of the consumer. The propensity to eat outside the home is most strongly, and positively, linked to increases in disposable income. As a result, the general trend in demand

for restaurant services has been upwards, although it has come under new pressure from the development of home-delivered foods and retail sales of high quality pre-prepared meals.

Private expenditure on eating out is generally a luxury and is vulnerable to dips in disposable income. Similarly, corporate entertainment, important at the upper end of the restaurant market, is closely linked to the level of economic activity. Growth in this area is inhibited by policies in several Member States which have imposed tax penalties on corporate entertainment.

Source: *Néo Restauration Magazine*

Overall, however, the proportion of total consumer spending on eating out has risen over the last decade. It is estimated that the EU average is over 5 %, although this hides substantial variations between Member States. In some cases these differences reflect the importance of the tourism sector. The proportion is above average in Spain and Portugal, while in others it reflects traditional attitudes to eating out.

If the EU catering industry is to follow the USA, where it is often cheaper to dine in a fast food or family restaurant than to buy equivalent ingredients and cook at home, then the tendency for locals to choose to eat out on the basis of cost and convenience will become more established. The trend, in the EU, towards eating out is in fact becoming more commonplace and relatively less expensive.

The growth of tourism is clearly a major source of business for the consumer catering industry in the EU. Even when staying in self-catering accommodations the tourist tends to eat out rather than cook for himself; when staying in hotels and similar establishments there may be little choice but to frequent restaurants and cafes. In common with many other companies who deal in the totems of popular culture, the large fast food firms view the relatively young and increasingly affluent populations of southern European Member States as providing the best prospects for continued growth in Europe in the 1990s. The ageing of the EU population will, however, dampen the growth of fast food outlets in the medium term. In addition, the "saturation point" for fast food restaurants is approaching in a number of northern Member States and is thought to have already been reached in the United Kingdom. Relatively rapid growth in demand for ethnic restaurants, particularly those with cuisines which are not well represented at present, is also expected across the EU.

The increasingly rapid spread of communications media, through satellite television for example, aided by the growth

of international tourism flows has accelerated the trend towards greater internationalisation of the restaurant market and aided the growth of US-type food outlets serving hamburgers and pizza. There are significant trends also towards healthy foods, e.g., pasta and the replacement of red meat and red wine by their white counterparts and by fish. In addition, the number of ethnic restaurants in many European cities is growing, reflecting internationalisation trends and the increased confidence and sense of experimentation among consumers. Conventional food service styles, products and concepts are being rendered obsolete by 1990s lifestyles. An exception to these trends is the resurgence of regional cuisine; especially in France, Spain and Germany.

Family restaurants relying usually on local business may also benefit from growth in tourism. Smaller restaurants in remote areas may gain from international tourism slumps, as EU nationals spend their holidays exploring their own countryside. Transport restaurants are also susceptible to fluctuations in tourism. A recent trend has been the development of fast food and theme restaurants in airports, rail and ferry terminals.

### Supply and competition

The key competitive factors in the restaurant industry are location, food quality, price and decor. Entry and exit barriers in the restaurant sector are negligible at most levels of the industry and small, often family-run, firms predominate. As a result, and because of the localised nature of competition, there is little danger of monopolistic practices emerging and strong competition is evident both within and across segments of the industry.

Take-away and fast food has been the main growth area in the European restaurant sector in recent years. USA chains provide the driving force behind this growth. Having expanded initially in the United Kingdom, they are spreading through mainland Europe, though facing increasing competition from

indigenous companies. Theme restaurants are also rapidly spreading. This spread is not simply driven by ethnic entrepreneurs but also by the larger restaurant chains who are increasingly using sophisticated market research techniques to examine concepts, test pilot operations and are utilising Epos (Electronic point of sales) information and geo-demographic databases to determine suitable locations. Like fast food outlets before them, a new set of US-based theme restaurants are now well established in the UK - Tex-Mex, Cajun, and 1950s nostalgia themes - and expanding elsewhere in northern Europe. A more recent development has been the growth of home-delivery food services in Europe. These outlets prepare pizza and oriental dishes in a central location for delivery within a neighbourhood. This service, coupled with the growth in home video and satellite television is encouraging more Europeans to eat prepared food at home rather than in a restaurant.

A critical issue facing the restaurant sector within the EU over the coming decade is labour availability and the ability of the sector to compete with other industries in offering a worthwhile career to staff. Because it is dominated by family owned enterprises, the concept of "employment" in much of the European restaurant sector is blurred. Very frequently husband and wife work together in a restaurant and may be helped by grandparents, children and other family members whose remuneration may be "in kind" rather than through cash payment. Throughout the EU, however, owners of family restaurants are discovering that their offspring are being attracted to other employment areas.

Staff turnover in restaurants is high and there is a lack of structured training in several countries. Where employment is regulated, pay and conditions in EU restaurants tend to be towards the minimum for each Member State. There are exceptions, but generally employment conditions in restaurants involve long and unsociable hours, relatively low levels of basic pay and a reliance by employees on gratuities and service charges. Pay and conditions tend to be best where agreements have been reached between employers and trade unions; but, these agreements tend to be confined to the larger and more structured employers. Many restaurants in the EU offer pay and conditions at the lower end of the scale applicable to unskilled workers at the national level and this is a contributing factor to high levels of staff turnover.

EU Social Legislation will improve the working conditions of thousands of restaurant workers in the Community. It will also raise the cost-base of employers in the sector. Organisations representing European restaurant owners have expressed concern about the impact of the legislation and the ability of Member States to guarantee fair competition through EU-wide enforcement of the legislation.

As demographic patterns develop and family sizes decrease, particularly in northern Member States, and turnover continues to grow, the restaurant sector will experience staff and skill shortages. This is already evident in the United Kingdom, Germany, Benelux, France and Denmark where restaurant chains are seeking to recruit part time workers, students and senior citizens as well as immigrants from outside the EU. The problem is not as serious in southern Member States. However, tourist authorities in these Member States have expressed concern that there will be migration of restaurant (and other hotel) workers from Greece, Spain, Portugal and south Italy to fill vacancies in north Europe. Such migration is likely to add to pressures to improve wages and other working conditions.

Competition in the restaurant sector is similar to that in other services which are dominated by small individually-owned enterprises. The cost of entry to the business is relatively low and this encourages entrepreneurs to enter a local market, particularly when the restaurant business is seen to be growing. The establishment of restaurants is, however, governed by

regulations in all Member States. These include the granting of planning permission, the certification of the premises by the local health authority and in some Member States the granting of a license to sell alcohol. Generally, different regulations governing restaurants are not a barrier to competition. Future mergers to create national or supranational chains are also unlikely to distort competition in the sector.

Competition within the sector is complex and differs across market segments and locations. Price elasticity tends to be lower at the top end of the market where competition is based on reputation, image and a perceived high quality of food and service. These competitive criteria also exist in the broad segment of family restaurants in which marketing and advertising are rarely undertaken. Location is a key factor but ambience, quality of food and personality of the proprietor are also important. Price assumes greater importance when the reputation of the restaurant is largely confined to the local community. Price as a key factor is also particularly evident in "in store" cafeterias and restaurants, in coffee shops and in the fast food sector. Overall the trend has been for prices to move in line with inflation but strong local competition has kept price increases below inflation in larger cities throughout the EU.

The relatively minor position of corporations and chains in the European restaurant sector and the USA base of some major players make it difficult to comment on profitability. Statements from HOTREC, the EU hotel and restaurant lobby organisation, and from national associations of restaurant owners indicate a relatively high level of business failures among EU restaurants over the past decade and that the lack of expansion by the vast majority of restaurants reflects lack of profitability. For a majority of European restaurant owners the business is a "way of life" which is sufficient to provide a modest standard of living for a family. In the case of some of the major players, such as retail stores, restaurants provide a service that attracts customers and make a contribution to the overall profitability of the enterprise. Within each Member State there are also large numbers of restaurant businesses which provide a good commercial return on investment.

### Contract catering

In addition to public catering, the contract catering sector is a fast growing segment in the restaurant business (15 % a year, according to FERCO). The number of meals served by the EU contract catering industry grew from 1.1 billion in 1980 to 2.1 billion in 1990. It is forecast that 3.3 billion meals will be served by the year 2000. The market segmentation in the contract catering business sees the predominance of business, industry and State institutions which together account for 66 % of the market. The remaining third is shared by healthcare (14 %) and education (19 %).

Contract catering, provides quality food at an economic price. In 1990, sales reached 1 982 million ECU in France, 1 884 million ECU in the United Kingdom and 1 708 million ECU in Italy. By contrast, sales in the German market did not exceed 445 million ECU.

The future of the contract catering industry looks optimistic: as it expands from offices and factories into schools, clinics and military establishments, the growth projection continues on its steep upward curve.

### Production process

The preparation and service of food has traditionally been a labour intensive exercise and this is still largely true. In most restaurants the raw materials tend to be supplied in a fresh state, prepared by hand, cooked by traditional methods and served to diners at their tables. Fast-food outlets differ from this categorisation in that the raw materials are often semi-prepared and take-away business is of considerable impor-

**Table 6: Restaurants, snack bars, cafés and other eating places

tance. It should be noted that some restaurants have reacted to the recession by moving into the "home deliveries" market.

Some machinery may be used in the chopping and mixing of raw materials and some foods may be stored under frozen or chilled conditions, but these are often the limits of technology in a European family restaurant. Pressures on the availability of skilled staff as well as high labour costs are, however, forcing the industry to look towards technology to help reduce unit costs. Automation and technology are playing an increasingly significant role in the preparation of restaurant meals.

While progress in introducing new technologies is relatively slow in the small independent restaurants, use of new technologies are very evident among restaurant chains and larger enterprises. Fast food restaurants and contract caterers have practised bulk preparation of food and its storage under frozen or chilled conditions for many years. Such methods are also used in hospital catering and in the provision of meals in industry and institutions. Frozen products, including meat, fish, potatoes and vegetables are used extensively in the fast food and "quick service" sectors and there has been widespread development of freezers and regeneration cookers. However, the refrigeration industry has been subject to criticism because of its use of CFC gases in refrigeration units. As a result, a new generation of "environmentally friendly" refrigerators and freezers which are "CFC free" are now on the market.

Worries about meal "quality" are a key consideration limiting the spread of bulk preparation methods throughout the restaurant industry. New technologies used in "cook chill" and "sous vide" systems have helped reduce the importance of this barrier. The principal advantage of the "cook chill" system is that food can be prepared in batches, according to strict specifications, and these "batches" are then used to compile meal menus. The ability to cook food in bulk and to "hold"

it for several days has enabled restaurants to reduce staff requirements; particularly at night or over week-ends. Clusters of restaurants, particularly in the non-hospitality sector, are increasingly investing in central production units (CPUs) from where prepared food is transported to the point of sale for finishing and service. "Sous vide" originated in France and is growing in popularity at all levels of the market. Under this system, dishes and delicate sauces are cooked and preserved in a plastic pouch, which is chilled, for regeneration prior to serving. The system has enabled caterers to expand their menu by having additional dishes under storage.

Electronic technology has offered greater control over traditional cooking media such as ovens and gas or electric ranges. The "combination oven" which can cook foods in several ways, is a product of this technology and enables designers to add "cooking cycle programmes" and electronic probes that measure temperature and moisture content of the food during the cooking cycle. Microwave ovens, which are now widely used at all levels of the market, are also enhanced by electronic controls. Energy costs in restaurants are relatively high and this has led to greater emphasis on energy efficient cookin

The advent of halogen elements in electric ranges and induction cookers provide the most promising developments.

The principal "stock in trade" of restaurants is food in a raw or semi-prepared state. At all levels of the industry there is increasing demand for conformity to specifications and continuity of supply. The "Quality" system has been employed informally by the vast majority of restaurateurs over the centuries and still works effectively today. Among corporately-owned restaurants, however, quality is achieved through more formal structures. Detailed specifications are drawn for each food item and there is a greater emphasis on partially processed

or prepared foods which are frequently supplied in a frozen state. A growing number of corporately-owned restaurants now operate just-in-time systems similar to those operated by the manufacturing industry.

## INDUSTRY STRUCTURE

### Companies

While becoming increasingly dominated by big chains, as growth in the fast food and take-away sector outpaces average growth, all EU countries continue to offer an enormous range of family run restaurants and cafes that are central to the appeal and character of the industry. The increase in market share and overall market growth of the chains has, however, been at the expense of the traditional independently-run operations. An Economist Intelligence Report, "Eating Out in the United Kingdom" estimated that the restaurant market was becoming increasingly concentrated.

The sector includes chains of restaurants, often owned and operated by conglomerates, and also embraces the fast food subsector which is largely controlled by USA companies operating through local franchises. The largest catering group in the EU, McDonald's, fits this profile perfectly. Fast food restaurant chains are both multiple retailers and a production enterprise. In both these facets of their activities they have similarities with multinational multiple retailers and with multinational manufacturing enterprises. Like the retailers, expansion across national borders has occurred first and most substantially in the wealthiest EU Member States.

The most significant group of restaurants, which represents more than 90 % of the sector across the EU, is family-owned and employs less than ten people, some of whom may be casual or part time employees. Family-owned restaurants span the full spectrum of dining out in Europe from simple take-away "fish and chips" shops in the United Kingdom to the award-winning restaurants of the famous French chef-patrons. The local family restaurant often offers dishes based on local or regional cuisine. More and more, this cuisine is offered outside its country or region of origin. It is no longer unusual

to find, for instance, restaurants serving Italian cuisine in France, Greek restaurants in the United Kingdom or French restaurants in Germany. A trend throughout Europe has also been the success of restaurants offering regional cuisine outside of their own regions, for instance Tuscan dishes in Veneto or the cuisine of Andalusia in Catalonia. Similarly, many upmarket French and Italian restaurants are adopting more adventurous menus featuring regional dishes and their influence is filtering down to more mainstream European restaurants.

The gourmet segment of the market is dominated by family-owned restaurants and in most Member States it is the personality, reputation and skill of the patron who may be the chef or the maitre d' hotel on which the success of the enterprise is based. Many such family-owned restaurants at the top end of the market are relatively large concerns employing up to 100 people and some, like the Roux Brothers in the United Kingdom and Paul Bocuse in France, have developed ancillary enterprises. More typical even at this level, however, is the restaurant serving 50 dinners each evening, owned and operated by a single proprietor and employing a staff of around 20.

Corporations and chains are rare in gourmet dining, except in the context of hotels. Many four and five star hotels of Europe offer at least one restaurant serving gourmet food. The scale and variety of the food offered in hotels is also expanding. More hotels are now operating ethnic restaurants in addition to the cuisine of their region, an international menu and informal dining in brasserie and coffee shop styles.

### Strategies

Investment by corporations has been most obvious towards the lower end of the market, particularly in the areas of popular catering, transport catering and fast food. Groups like Forte's Little Chef (United Kingdom), GIB (DK), Quick (F), GfnBAB (D) and Autogrill (I) have developed successful chains of restaurants close to motorways and associated restaurants can also be found in towns and cities. These chains tend to be national rather than transnational and a dominant EU-wide restaurant chain has yet to emerge.

A transnational restaurant chain may emerge through activities in other sectors such as retailing or hotels. Forte's "Little Chef" is expanding alongside the hotel group's hotel joint ventures in Italy, Spain and Ireland. Supermarkets and department stores already operate large chains of cafeteria style restaurants in France, Germany, Benelux, United Kingdom and Italy. The expansion of these stores within the Community would lead to the expansion of their restaurants also. Karstadt, Hertie and Kaufhof operate large restaurant chains in Germany and the Casino supermarket chain operates the largest group of restaurants in France. Another large scale retailer involved in restaurants includes GB Inno-BM of Belgium. In addition, individual restaurateurs have opened restaurants offering their own national or regional cuisine in larger cities of Member States. EU capitals for instance are locations for restaurants in the style of virtually all Member States.

Investment by corporations from outside of the EU has been an increasingly important phenomenon since the early 1980s. This has been confined almost entirely to the fast food sector and has been spearheaded by the USA chain, McDonald's, which had 1 808 outlets in Europe at the end of 1993. Other chains which originated in the USA like Burger King, Kentucky Fried Chicken and Pizza Hut have also been making an impact on this segment of the market - Burger King and Pizza Hut are now owned by the United Kingdom companies, Grand Metropolitan and Whitbread, respectively.

Popularity of fast food and fast service can be attributed to the European acceptance of American dining culture, particularly among young people; to the expertise of the American chains in the areas of product development, location of outlets, staff training, consistency in quality; and, to changing living patterns in Europe. The principal food products served in this sector include hamburgers, chicken, pizza, pastry, fish and potatoes. Entrepreneurs in each Member State have established national and regional fast food chains which compete with the US-originating franchised outlets. In this area France, for example, has achieved considerable success with groups like Quick, La Brioche Dorée, La Croissanterie and Pomme de Pain.

Investment in the EU restaurant sector has also come from entrepreneurs from outside of the EU opening "ethnic" restaurants. Thousands of restaurants owned by immigrants and offering Chinese, Indian, Thai, Vietnamese, Argentinean, Indonesian and other cuisines scattered throughout the Community, are seeing their market share increase.

### Impact of the Single Market

The removal of barriers to movement within the EU and the creation of the Single Market has had an indirect effect on the hotel sector. The free movement of goods, capital and services had an almost negligible effect on this sector. The measures which have been most relevant are those ensuring the free movement of people, this constituting the mainstay of the tourism sector. Increased intra-EU business flows for instance have assisted business travel. However, this free movement of people has not fully materialised yet and, when it does, it will be more in the framework of the Schengen Convention than of the Single Market. It must also be remembered that the hotel sector already operated on a tran-

snational basis long before the Internal Market programme was launched.

There remains important distortion to travel due to differences in VAT rates across Member States. Hotel and restaurant services have not been fully incorporated in the lower VAT bands, and much is left up to the individual Member States. Hotel services are included in the lower band of VAT at the discretion of the Member States. This situation may, however, change in the near future with the setting up of a definite VAT regime.

In the meantime, negative impacts on the hotel sector through loss of competitiveness due to VAT rate against non-EU countries have materialised. According to all major sources on tourism (e.g. World Tourism Organisation, OECD, European Travel Commission, etc...) while tourism in Europe is growing, it is growing at a much slower pace than the rest of the world. Europe has the lowest growth rate for tourism in the world and is below the international average. Europe has also lost approximately 10% of its market share of international tourism over the last 10 years.

The industry remains concerned about the increasing regulatory burden being placed through developments in consumer, social and environmental legislation. Social legislation and the issue of atypical workers also affects this sector to a very large degree.

### REGIONAL DISTRIBUTION

Restaurants are ubiquitous in Europe. Many restaurants at the upper end of the market are often found in relatively remote rural areas; an aspect which may serve to improve their "charm". In many cases location is a key factor, both in terms of the ambience it may lend to the overall "dining" experience, as in high quality restaurants or in terms of the throughput it helps generate.

In general, concentration and level of competition is related to population densities. Cities and larger towns have more restaurants per capita than do villages and rural areas. An exception lies in areas of tourism interest which tend to have a large number of restaurants competing for tourism business, although some may operate on a seasonal basis.

### REGULATIONS

There are a wide variety of national and EU regulations impacting on the restaurant trade. The most important include compliance with hygiene regulations and certification by local health authorities, regulations relating to working conditions; and, in some cases, the granting of a licence to sell alcohol. In some Member States restaurants must also comply with local and national regulations on the protection of the environment. Hygiene regulations across the EU are in the process of being harmonised, and the harmonisation of qualifications is improving worker mobility. In addition, EU labour legislation is constantly impacting on conditions of work. Harmonisation of VAT rates (and excise duties on alcohol) will also have differential impacts on restaurants across the Community over the next five years. Restaurant services are not included in the list of goods and services to which Member States may apply a reduced rate of VAT. However, the Member States that were applying a reduced rate to restaurant services at 1 January 1991 are allowed to continue to do so at least until the end of 1996.

The Directive on the hygiene of foodstuffs (93/43/EEC) was adopted in June 1993. Standards of hygiene are set out in the annex to the Directive together with suggestions of ways in which Member States can assist firms in achieving these standards. Firstly, it is recommended that ISO 9000 quality standards be promoted within the EU. Secondly, it is recommended that codes of practice for food hygiene be drawn up

for particular sectors, in order to assist firms and individuals in fulfilling their legal obligations, as set out in the annex. It is envisaged that these codes of practice may eventually be harmonised at an EU level. Thirdly, the use of the HACCP (Hazard Analysis and Critical Control Points) system is to be encouraged among those who have legal obligations in relation to food hygiene. Finally, it is important to remark that the HACCP system has been highly criticised as impossible to implement in SMEs, which make up the bulk of the restaurant sector.

A number of National Associations representing the sector are lobbying to have the lower rate of VAT applicable to all restaurant services within the EU after 1996.

## **OUTLOOK**

The restaurant sector in the EU grew throughout the 1980s and despite a slowdown in recent years overall growth is likely to continue during the 1990s. With most EU Member States well recovered from the recession which commenced in late 1990, accelerating demand for restaurant services can be expected in the short-term. With economic prospects remaining bright into the medium term, the outlook for the restaurant trade is similarly good. Increased spending on eating out, somewhat above the level of GDP growth, is expected. The EIU predict GDP growth in western Europe to average 2.5 % over the 1995-99 period.

Growth in intra-EC travel and in the number of visitors from outside the EU will increase demand for restaurant facilities. Reflecting an increased emphasis on quality and higher value-added tourism, restaurant expenditures per tourist should increase. More short-breaks and second holidays should contribute to increased trips and restaurant expenditures among domestic tourists in north Member States; and, international tourism revenues in the Mediterranean Member States should continue showing strong signs of growth similar to 1994.

While a growing share of household expenditure was devoted to eating out during the 1980s, this trend may have run its course in some of the more developed Member States. Disparities in Gross Domestic Product (GDP) and private consumption expenditure growth rates will create higher levels of demand for restaurant services in those Member States whose economies grow fastest.

Employment growth is expected to be below that of turnover. The level of automation will increase, motivated by cost-cutting, service improvement and problems with attracting staff. Restaurateurs are also likely to seek other service innovations reducing labour usage.

National growth rates will also be affected by the prevailing tradition of dining in restaurants, which varies widely across EU Member States. Social attitudes towards eating out are gradually changing and as the EU becomes more integrated, the dining tradition is likely to spread. Different segments will also grow to varying extents across Member States.

Countries with an emerging youth population will also see more rapid growth in fast service and fast food restaurants and those with an ageing population will see more growth in health food and leisure style restaurants. Changing demographics, social patterns and tastes will also offer opportunities for restaurants to increase sales for home deliveries, although this may have some impact on traditional sales. As more people move into urban areas there will be fewer family meals, greater consumption of snacks and small meals and more dining in restaurants as a leisure activity.

# Hotels

## NACE 665

The hotel sector comprises a disparate variety of establishments in terms of size and range of services provided. Tourists and business travellers form two distinctly different markets for hotel services, both of which are now recovering strongly having slumped in 1991 and 1992. Fragmentation of demand in recent years has resulted in growth of both affiliated hotels providing a uniform product at different price/quality levels, and of hotels striving to differentiate their product. Concentration in the industry is growing as large hotel chains increase market share, although this increase should not be a source of concern to competition authorities. In response, smaller hotels are increasingly joining voluntary associations. The outlook is for modest growth during the mid-1990s.

### INDUSTRY PROFILE

#### Description of the sector

The hotel sector comprises establishments which vary widely both in terms of size and services provided. At one end of the scale there are small, single location, family run enterprises providing accommodation services and at the other are large hotels, frequently part of a chain, operated in a highly professional manner and providing a wide range of services. Such services might include restaurant and banqueting, public bar services, health and leisure facilities, foreign exchange facilities, shopping facilities, business secretarial services and conference facilities. The number of hotels supplying accommodation only is now relatively small, with a discernible trend towards larger establishments providing a broader range of services. As a result, the extent to which the business of hotels impinges on other service sectors is increasing.

Official statistics on hotel turnover and value-added in different EU countries do not exist. Nor are there consistent definitions

of hotels and similar establishments across countries, making aggregations and inter-country comparisons difficult.

Eurostat data indicates that the hotel industry is most important in Italy and Germany, although definition differences suggest care in making any comparisons. For example, France has fewer enterprises and hotel employees than Germany, but has considerably more bed-places.

#### Recent trends

Official employment data in the hotel industry is only available for eight of the twelve Member States. The trend in overall employment is upward reflecting industry growth and the limited possibilities for capital substitution. The overall growth in total employment masks a decline in the number of self-employed persons, reflecting growth rates of larger chain operations at the expense of smaller traditional hotels.

Despite definition differences, a trend increase in the volume of turnover in accommodation services, between 1987 and 1992, is evident from guest flows in most Member States. However, the strength and volatility of this growth varied across Member States. Spain was the only Member State to experience a decrease in hotel guest nights between 1987 and 1992. Increases in northern Member States were, on average, higher than in Mediterranean countries. The trend in non-resident guest nights differed from that in total guest nights in most Member States. While Belgium, France, Ireland and Portugal all recorded sharp growth in guest nights from non-residents between 1985 and 1992, falls were recorded in Spain and Italy. In value terms, however, turnover is unlikely to have risen since 1990 because many hotels have been forced to reduce tariffs to maintain occupancy levels.

Analysis of available bed nights indicates an increase in the supply capacity of the industry. The number of bed places increased in all Member States over the 1985 to 1992 period showing a continuation of the trend in the first half of the decade. The increase in available capacity was less evident in Italy where growth was only 4 %; while, Denmark, West Germany, Greece, Spain and Portugal all experienced increases in excess of 20 %.

The increase in the number of beds and bedrooms was against a background of a slight decline in the number of hotel and

Source: Eurostat; Mercure

similar establishments. This reflects the industry trend towards larger units. Capacity also increased faster than guest flows, while occupancy rates in the hotel industry fell sharply in 1991. They were above 60 % in 1989 and 1990 in each of the eleven EU Member States surveyed by Pannell Kerr Forster (PKF), ranging from 62 % in Luxembourg in 1989 to 79 % in Italy. However, in 1991 they fell in all Member States and have remained low. Low occupancy rates are particularly evident, in Spain (53 %), Portugal (54 %), Belgium (60 %) and France (60 %) during 1993.

Data collected by PKF on average room rates across different European countries places France's hotels as the most expensive; although as discussed later, patterns in EU capitals reflect different factors. Prices in EFTA countries tended in general to be higher than in the EU with particularly high average rates in Austria and Switzerland.

Price levels and changes in the EU's capital cities, however, reflect local supply and demand imbalances and local property prices. Analysis by the Economist Intelligence Unit (EIU) indicates that the prices of hotels fell in most Member States in response to lower demand between 1990 and 1993; after having risen sharply in the late 1980s. Reflecting lower prices and falling occupancy rates profit levels also declined in 1991 and 1992.

### International comparison

Horwath International's analysis of the overall performance of hotels by global regions indicates that income before fixed charges per available room and revenue per room were highest

in Europe in 1992. However, Horwath data is most pertinent to chains.

### Foreign trade

Available data on hotel nights does not facilitate a breakdown into intra-EU and extra-EU "exports" and "imports." Most Member States distinguish between resident and non-resident guest nights. Over the second half of the 1980s, the strongest growth in most Member States was non-resident guest nights. However, a slowdown in international tourism growth in the early 1990s, particularly in 1991, has contributed to a decrease in non-resident guest nights in a number of Member States. While official data for 1994 is not yet available, growth in non-resident nights increased rapidly.

## MARKET FORCES

### Demand

The most important consumers of hotel services are tourists, although their importance varies across Member States. For example, Horwath International's hotel survey indicates, that business travellers are of much greater importance in Germany and the United Kingdom.

The commencement of the Gulf War in mid-1990 to the end of 1993 was one of the most difficult periods in the recent history of the European hotel industry. In addition to the war's impact on international travel, recession in Europe and the United States combined to depress the tourist and business accommodation markets. The downturn in demand for hotel

bed-nights also had a depressing effect on rates. As hotels strove to maintain occupancy rates the gap between officially published "rack" rates and "achieved" rates widened. As economic growth in most European economies began to pick up, demand growth recovered strongly in 1994.

The distinction between tourist and business market demand is important as they are affected by different factors. While both are strongly affected by the general level of economic activity, business travellers, and in particular the conference market, are more sensitive to economic downturns than tourists. International and domestic business demand is higher in northern Member States. Recent analysis by stockbrokers, Kleinwort Benson Securities, in the EIU's Travel and Tourism Analyst, suggests the importance of service industries and the level of concentration are important components of the demand for domestic business travel. Large service firms tend to have a greater number of branches than their manufacturing counterparts and, thus, generate substantial travel. Closer integration of the EU Internal Market, and subsequent cross-border expansions, will continue to increase the importance of inter-EU business travel.

Traditionally, business travellers are less price sensitive than tourists but become more price conscious during economic downturns. This has been very evident in recent years and may have led to a permanent shift in attitudes towards corporate travel budgets. The implications go beyond seeking lower cost hotel deals. Often, the economic rationale for foreign trips is more carefully scrutinised and cheaper alternatives such as video-conferencing, and greater use of the electronic communication techniques are examined. Technological developments will also aid business travel though. Smart cards and bio-metric technologies are being refined to enable frequent business travellers to save time at international airports. However, Visa International's September 1994 Corporate Travel Survey indicates that a majority of business travellers, in all ten countries surveyed, would like to reduce the number of business trips they take, but they were also strongly of the opinion that one-to-one meetings were invaluable and would not be replaced by video-conferencing. A similar conclusion was reached by a 1994 EIU report on Business Travel which suggested that technology would be most useful in terms of follow-up but would never "act as a wholly acceptable substitute for the introductory meeting or concluding meeting at the end of a business arrangement".

Income levels are an important determinant of overall tourism demand. In more prosperous northern Member States second annual holidays are now commonplace while in the southern Member States international tourism has only recently grown. This reflects rising incomes and increased leisure time arising

from shorter working hours. Increased frequency of holiday-taking spreads seasonal tourist flows and favours hotels relative to the other popular forms of accommodation. In addition, with increased female participation in the workforce and a tendency towards smaller families, a growing proportion of European households have two incomes and higher levels of disposable income.

The relative importance of international versus domestic demand varies widely across Member States. The tourist attractions of France, Greece, Italy, Portugal, Spain and to a lesser extent the United Kingdom and Ireland attract substantial numbers of foreign hotel-guests. Traditional factors, such as climate and income levels affect the habits of domestic holiday-makers across Member States with relatively greater usage of hotel accommodation in northern Europe. A slight reversal of the traditional north to south tourism flows was evident in recent years reflecting increased international holiday-taking by southern Europeans and the declining relative importance of sun and beach holidays. Both trends should boost hotel demand somewhat at the expense of other accommodation. However, having revamped their product and broadened the range of attractions, Mediterranean sun destinations are successfully regaining market share and demand rose sharply in 1993 and 1994. Bad weather in Northern Europe and currency devaluation also helped kick-start demand for Mediterranean destinations.

Long distance travellers are much more likely to use hotel accommodation and in particular hotels at the upper end of the market, while tourists from EFTA countries are more likely to use budget or non-hotel accommodation. Initial tourist flows from eastern Europe may also favour non-hotel accommodation. An ageing European population and the continued importance of business travel will help maintain demand for hotels at the upper end of the price-quality range, but such hotels will be adversely affected by trends towards cheaper and independently organised holidays. However, not all independent tourists seek budget accommodation and many hotels at the upper end of the market are cooperating with other suppliers and adapting their product offer to attract the more lucrative segments of this market.

### Supply and competition

Economic power is important in negotiations between the industry and upstream suppliers, such as major tour operators, but the need to maintain goodwill and quality standards generally tempers excessive exercising of power. Similarly, the emergence of anti-competitive practices through increasing vertical integration is less likely because of the volatility of the tourism demand, the "contestable" nature of the industry

and the high degree of inter-dependence between its various segments. Characteristics of the hotel industry affecting competition include: ease of entry and exit, the often localised nature of competition and competition between segments within the industry and non-hotel establishments supplying similar services. These factors ensure that, in general, monopolistic positions are rarely attained: exceptional hotels at specific locations, such as The Gleneagles in Scotland, can maintain excess margins. In addition, in 1992 only 14 % of hotel rooms in the EU were publicly traded companies, indicating concentration remains low despite the recent growth of chains. Thus, increasing competition through mergers of large chains in the European market is not a cause for significant concern for competition authorities.

The nature of the hotel industry is such that imbalances between supply and demand are generally localised in either time or space and invariably lead to variations in prices and in profit levels. Surpluses and shortages in "time" are most common. With high fixed overheads, the marginal cost of selling an extra room is low and hoteliers throughout Europe respond to falling demand by reducing prices to maintain occupancy levels. Thus, the downturn in tourism demand over the last two years resulted in good deals for consumers but substantial losses for many hotels. In addition, high levels of investment during the late 1980s in increasing capacity or in refurbishment left many hotels financially ill-equipped for the subsequent downturn. Re-possession reached a record high during 1991 in the United Kingdom. In 1993, the high profile quoted companies Queens Moat Houses (UK), Resort Hotels (UK), Ciga (I) and Fimpar (I) had their share quotations suspended and Forte (UK) cut its dividend for the first time in 20 years. Accor (F) maintained its dividend despite a 42 % drop in after-tax profits. Increasing demand in some Member States, such as the UK in 1993, and more generally in 1994 is rectifying this demand-supply imbalance. Occupancy rates are increasing sharply and price growth should follow in 1995.

Seasonal variations in demand for hotel rooms typically result in lower prices (or additional value-added in terms of special incentives) in many rural and resort hotels in the off-season. Many urban hotels are also capitalising on the growing short break market to boost overall occupancy in hotels which are filled during the week by business travellers. Capacity imbalances also result in profit variations around normal margins. In other cases, time and location supply constraints place strong upward pressure on prices; for example, major sporting events like the Olympic Games.

Reflecting weak demand, hotel prices, particularly in the moderate/comfortable category, fell during 1991 and 1992, picking up in some cities in 1993. Price variations vary widely re-

vealing different supply and demand conditions, but trends in all capital cities (except Berlin) reflect a divergence between the boom 1985-90 period and the stagnant 1990-93 period. For example, EIU data indicates the price of a single room in the moderate/comfortable category in Madrid rose more than threefold in 1985-90, but remained static in 1990-93. Price levels and price changes in cities reflect local supply and demand imbalances, with local property prices having the greatest effect on hotel prices. The sharp differences across cities is evident in that the average tariff for a room in a similar hotel in Greece fell (in current ECU) even in the boom 1985-90 period.

During the 1980s operating profits were generally higher in chains, i.e. affiliated hotels, than in their independent counterparts. However, the importance of scale is recognised by many small hotels and increasing numbers are becoming affiliated to voluntary associations or franchising.

EU hotels cannot compete with most extra-EU counterparts on price alone. The labour intensive nature of the industry ensures that hotels in developing countries have a strong competitive advantage. EU hotels are often reliant on the tourism strengths of their location and other quality factors. A wider range of facilities, better quality and other local attractions are important differentiation factors against the cheaper prices of East European countries. The cost of travel to many non-EU destinations is also a factor, as demonstrated by the increasing popularity of Asian locations. Reductions in the cost of long distance travel can be expected to divert more tourists from competing EU resorts.

### Production process

Services provided by hotels vary widely across the industry. At one extreme hotels may simply provide accommodation, although this is quite rare. More commonplace is a mixture of accommodation, restaurant food and retailing of alcoholic beverages. However, the variety of services may also include banqueting, health and leisure facilities, a variety of business services, shopping, foreign exchange facilities, conference facilities, laundry facilities and touring services.

The hotel industry is a service industry where most of the service offered is based on labour intensive methods. In particular, it involves substantial use of part-time and female workers. This labour intensity is creating problems on two fronts. Firstly, it is a major and increasingly expensive cost item, and secondly, attraction plus retention is a problem. As a result, increased automation is apparent, particularly in northern Member States where problems with labour retention and the attraction of new workers are sharpest. A recent survey at Oxford Brookes University highlights conditions of em-

**Table 6: Hotels**

ployment, perceived lack of prospects and attractions of competing employment opportunities as key factors discouraging young people, particularly women, from entering the hotel industry.

The introduction of the 5 day or 40 hour week, night shift compensation, with weekends and holidays to enjoy, lure people away from labour intensive jobs with unsociable hours. Many hotels and chains have introduced innovative programmes to tackle recruitment and retention problems. Their intent is to enable personnel to move within the industry with clear career paths and to improve cooperation with schools in terms of curricula and candidate selection. While the Single Market process is increasing the reservoir of labour available to the hotel industry, greater mobility and higher expectations may accentuate staff retention problems.

Technological developments have led to some employment substitution effects. For example, in some hotels guests now check themselves in. In general, however, increased use of technology, yield management and CRS, front office systems, in-house entertainment, and improved kitchen equipment contribute to greater skill requirements for hotel staff rather than displacement. However, "fear" of such techniques remains an impediment at some levels of the industry. The proportion of automated bookings from CRS relative to telephone reservations is still very low in Europe compared to the US but such applications are gaining ground as hotels become increasingly appreciative of the potential they offer for improving management efficiency and profit margins. Some major chains have introduced innovations to encourage CRS bookings - Utell, Marriott and Kempinski for example, have each established different schemes related to faster or guaranteed

commission payments. Use of yield management techniques, which apply basic economic principles to pricing and controlling room inventory to maximise revenues, is also facilitated by technological advancement. The techniques enable the anticipation of late demand and the offer of an appropriate number of rooms at the higher rates these guests are willing to pay. Yield management systems are also useful for market information, such as knowledge of repeat customers' preferences, identifying clients, and deducing crucial factors affecting decisions.

Driven by economic developments, the spread of large chains, the growing complexity of the industry's market and the availability of sophisticated management information systems, there is a growing trend towards more professional management in the industry. This is reflected in strategies for labour saving, such as the increasing number of hotels offering buffet breakfasts.

## INDUSTRY STRUCTURE

### Companies

Overall the hotel industry is fragmented but the importance of large hotel chains has increased considerably over the last decade. While these chains have brought a degree of homogeneity to the industry in many European countries, the structure and importance of the industry differs across Member States. In terms of bed places offered, there is considerable concentration among the chains. The top ten chains operating in Europe provide as much capacity as the next forty chains combined. It should be noted, however, that while the incidence of branded chain hotels is increasing, in some cases these

are run by independent hoteliers on a franchise basis. Pressure for increased size comes from economies of scale in marketing, greater ability to meet the trend towards market segmentation with a complete range of differentiated services and advantages in covering a range of major destinations in any specific area. The strength of the chain to invest in CRS is another factor which will shape the industry in the coming decade; although advances in technology, competition among CRS companies, improved user-friendliness and the advantages of these systems will increasingly see smaller hotels availing of CRS.

In identifying the world's top hotels, the magazine "Hotels" distinguishes between three different types of hotel companies: corporate chains, with a strong brand identification, professional hotel management companies (HMCs) and voluntary chains and associations. There is overlap between these categories. For example, Best Western, a voluntary group is included among the corporate chains because of strong brand image, while many of the larger corporate chains have their own HMCs which may run the hotels of other groups in certain locations. Each of the top five corporate chains franchise part of their room stock. The five top HMCs in the world have Hilton (USA), Sheraton (USA), Radisson (USA), Marriott (USA) and Days Inn (USA) among their portfolios.

Other forms of affiliation such as leasing and joint ventures are currently being explored as a means of expansion by several chains, including Accor (F) and Forte (UK). Forte, for example, currently has joint ventures in Ireland (with Aer Lingus), in Italy (with Agip) and in Spain (with Repsol), while Accor has several joint ventures with Ifil (I). Accor's strategic alliance with Carlson (USA) is likely to bring flow-on synergism with the hotel chain. Radisson and Sol (E) have also established a joint venture with German tour operator, ITS, to develop a Primasol budget brand.

By global standards the top EU hotel companies are not as large as North American-based chains, but they are larger than their Asian counterparts. The 1994 listing of the world's top corporate chains in 1993, by the magazine "Hotels," included eight North American-based chains in the top ten, although the second largest corporate chain, Holiday Inns, is owned by a United Kingdom brewing conglomerate, Bass Plc. Similarly, the top ten second tier management companies listed by "Hotels" included only one EU company, the troubled Queens Moat Houses Plc. However, reflecting the continued importance of small hotels in Europe the "Hotels" listing of voluntary chains and associations had seven EU-based companies, among the top ten in the world. The top hotel company in the EU in 1992 was Accor (F) with 250 000 rooms, well ahead of its nearest rival Forte (UK) who had 79 000 rooms. However, Forte narrowed the gap during 1994 with the purchase of the Meridien chain from Air France.

### Strategies

The most important developments in the hotel industry in recent years have been the expansion of the chains/voluntary associations and segmentation of hotel properties into branded products each aimed at specific clientele. While different levels

of service and quality across hotels has always been a feature of the industry, segmentation within the major hotel chains has resulted in increasingly distinctive products. It is also argued that too many brands within some chains may lead to customer confusion. Segmentation in Europe is not as advanced as in the United States but has increased substantially, to the extent that nearly all major hotel chains now have a range of differently specified products. For example, the French-based Accor, Europe's largest chain with a presence in nine Member States, has a highly-developed set of branded products, ranging from the four-star Sofitel (F) to the one-star Formule 1 (F) and budget chain Motel 6 (F).

The fastest growing segment of the market is the budget and "no-frills" establishment, a format which is well developed in France and spreading to other EU Member States. Forte's joint ventures, for example, have all been aimed at expansion in budget brands. Their joint venture with Repsol (a Spanish petrol company) is to construct up to 100 Travelodges along Spanish motorways. Likewise, the French group Bajen and the Spanish group Sagas have plans for 50 motorway motels. Greater economic cohesion within the EU alongside greater cost consciousness among business travellers and demand from East and Central Europe are expected to contribute to increased demand for low-cost no-frills establishments. Along with Formule 1, other budget and no-frills chains include the French sister companies Campanile and Premiere Classe, Forte's Travelodges and Holiday Inn Express hotels. However, segmentation is not solely based on simple price/quality features, resort hotels and hotels specialising in the growing conference market are also considerations.

Consistent delivery of good service, particularly for business travellers, is the key element to maintaining loyalty as repeat business is the most cost-effective way of generating profits. Marketing, sometimes in partnership with other hotels or upstream services, is a key strategy element in generating new business, but as articulated by Thomas W Storey, Executive vice-president of Radisson Hotels International "We've calculated it costs 15 USD to get a new trial guest and 2.50 USD to get a repeat guest".

Due to different travelling objectives, business travellers and long distance travellers are distinct from the leisure traveller. The discussion on demand trends in the industry suggests that there is need for a wide range of products to keep pace with the increasingly diverse forms of demand. The more a hotel can differentiate itself from its neighbour, for example by reflecting the special character of its surroundings, the more it is likely to appeal to the discerning guest. Similarly, with the growing importance of short break holidays many hotels are becoming the central element in a package of accommodation and leisure activities designed to attract short-break guests, particularly in the off-season. Many resort and medium-sized hotels are also adding attractions such as fitness centres and other forms of all-weather entertainment.

Catering for new and alternative forms of tourism, such as activity holidays, also requires many hotels to re-think their strategy vis-à-vis non-hotel accommodation. Evolving pack-

ages to attract these new tourism market segments may involve coordination with other tourism and leisure facilities in the locality and other forms of accommodation. Cooperation between hotel groups is also a feature. For example, in order to improve its marketing in Europe, Radisson has cooperated with SAS (S) hotels, Mövenpick Hotels (D) and Concorde Hotels (F). Similarly, cooperation between smaller hotels has resulted in segmentation, generally with a stronger leisure dimension, through the formation, or expansion of existing voluntary chains.

While the top hotel groups in the EU are predominantly EU owned, in general, large hotel chains are international in character. Two of the top chains, Hilton and Holiday Inns, originated in the US, were recently purchased by United Kingdom companies. The political and economic changes related to 1992 and German re-unification should have a positive "ripple" effect on hotel investment, although the ongoing recession has dampened investment at the present time. There is probably already a sufficient number of hotels in most major EU locations to cater for increases in demand and most investment will be in the form of conversions and extensions of existing properties. While the flow of tourists to less well-recognised "tourist areas", particularly rural areas, is expected to grow, much of the increased capacity required will be met by non-hotel accommodation.

The twin trends of expansion and globalisation of hotel chains have been evident in Europe over the last decade. In addition to economies of scale these trends are also driven by the perception that much business travel is global and that travel service companies and accommodation providers need to provide the same services, irrespective of location. Whether this perception is correct remains to be seen. As with tourism demand, there is little doubt that many international business

travellers will gravitate towards accommodation providers with whom they are familiar and whose standards they are comfortable with. According to Inter-Continental's European vice-president Michael Stajdel, "the fastest growth area for hotel bookings is through global distribution systems." Nevertheless, there are dangers in such a strategy as the bulk of business travellers are still of domestic origin, even in international capitals and gateway cities. Furthermore, as shown by the Visa survey, business travellers from different countries have strikingly different views on what their priority travel requirements are.

Discernible trends indicate take-overs are the preferred expansion mode, as current players seek further economies of scale and/or expansion into new markets. The economic downturn resulted in a temporary slowdown in merger activities, but with more properties coming on the market activity levels are increasing. For example, Forte's take-over of Meridien during 1994; successfully fending off a bid by Accor. The sale of the Ciga chain in Italy also indicates expansion tendencies among leading hotel groups - Forte, Accor, Hyatt, Marriott and ITT Sheraton all expressed interest at various stages, with Sheraton finally gaining control. Prior to the recent slowdown, a feature of merger activities was extra-EU hotel chains, particularly from the US and Japan, seeking to expand in Europe. These chains include the US-based Marriott Corporation, ITT Sheraton, Ritz-Carlton, Holiday Inns, Hilton Hotels Corporation and Radisson and Far East chains such as Nikko (JPN), Seibu Saison (JPN) and Aoki (JPN). The trend is partially based on "globalisation" strategies: although US chains are also encouraged by saturation in their domestic market. The nature of the European hotel market and its "modus operandi" is a major constraining factor for US chains. To date they have been most successful in gateway cities rather

than locations which attract mainly domestic business. Not all US expansions into Europe are aimed at international business travellers though. Holiday Inns plans to expand the US budget chain Holiday Inns Express into Europe and to build 20-100 premises; depending on performance over the next five years. In general, and with a long term view, Japanese investment has tended to aim for vertical expansion - hotels, restaurants, leisure facilities - rather than a significant market share in a particular subsector.

EU-based chains rapidly expanded across national borders during the second half of the 1980s in anticipation of increasing integration of the EU. This expansion slowed somewhat in the early 1990s as recession choked off investment, but has resumed over the last two years at a moderate pace. Increasing investment from large chains is unlikely to threaten the com-

petitive position of the many small, independent hotels and restaurants that create the uniqueness of European tourism. These small, independent hotels should be able to establish themselves in their own profitable niche.

Retaining traditional ambience and intimacy with their clientele are important marketing characteristics, but small hotels should also pay adequate regard to modern marketing, technological and management practices. These practices may include investment to upgrade quality, and cooperation with other tourism enterprises and other hotels in promotion, reservation systems and information systems. For example, national and international voluntary chains are expanding membership. Small Luxury Hotels of the World aims to double membership to 200 by the end of 1995, while Family Hotels Federation in the Netherlands was recently formed with the

key objective of competing better with one to three-star chains. Cooperation can, however, take a number of forms. The simplest is combined marketing in one brochure under a single brand, but with each hotel maintaining autonomy. Another form may involve common CRS and shared payment systems. Franchising is a common form of joint branding, while trademark licensing is another. Some chains insist on exclusivity, while others, such as Logis de France, allow affiliation to more than one grouping. Cooperation can also involve joint purchasing, such as Hotusa (E) which has 650 hotels and restaurants in its purchasing pool and intends to expand into other EU Member States.

Airport locations provide prime locations for both expansion and the development of new hotels, although increasing emphasis on high-speed rail links should draw both business and leisure travel from the airlines, suggesting that railhead locations will also see new investment. A number of continental railhead hotels have already been upgraded or tied in with railway travel. InterCity (D) hotels are marketed, but not owned, by the German railways and tie-ups are being developed between Wagonlits night sleeper passengers and Accor's railhead hotels. Improved road transport networks, particularly in the EU's Objective 1 regions, will also provide scope for investment in motorway hotels. Continued growth in business and leisure travel will stimulate new investment in hotels at large business parks and in resort areas. Increased investment in budget hotels may also see traditional European heavy construction giving way to prefabricated units - bedrooms for Forte's Travelodges are factory built and assembled on site.

Investment funds are being funnelled to East and Central Europe where there is a supply deficiency, particularly of three star hotels. Investment may be diverted from EU countries, although it is expected that the bulk of the diversion will be from developing countries, with the exception of Asia. Another concern is that although freer mobility of capital may encourage large-scale investors, small operators may continue to be hampered by the reluctance of banks and other financiers. This will add to the concentration of the industry and the weakening of the independents, although a number of countries have developed incentive schemes to remedy this problem, either by providing finance as such or by guaranteeing finance. Mechanisms to guarantee borrowing are par-

ticularly prevalent in Germany, but also exist in Portugal and Italy.

## REGIONAL DISTRIBUTION

Venue availability has traditionally been considered the most important element governing the supply of hotel services. In general, hotel location follows demand rather than stimulating it, although there are exceptions. Hotels are predominantly located in cities, specialising in business travellers, and in resort areas, specialising in tourist traffic. These factors have led to significant variations in the distribution of hotels both across and within Member States. For example, the largest hotel in the EU is located in the Canary Islands.

## ENVIRONMENT

To date, regulatory pressure on the hotel industry with regard to environmental issues has not been extensive. HOTREC has identified three pieces of legislation that could have an impact, albeit indirectly, on the hotel sector. These are:

- Environmental Impact Assessment
- Packaging and Packaging Waste
- Eco-Audit Scheme

As regards any legislation on civil liability for environmental damage, its impact on the hotel sector will necessarily depend upon the eventual content of such legislation.

There are three major pieces of environmental legislation which affect the hotel industry: the requirement for an environmental impact assessment, which is required for large projects; liability for damage caused by waste; and, the obligation to clean up contaminated land. The latter two are not yet in effect and, in general, their impact will not be excessive. However, there is an expectation that pressure may increase on requirements for improved waste management and consideration to how hotel structures blend in with their surroundings.

The Fifth Environmental Action Programme has identified Tourism as one of the five priority areas. HOTREC firmly

believes that a sound environment is vital to the hotel industry, and it has formulated its position with regard to the environment on the following basis:

- The development and dissemination of better environmental management tools specific to the industry is crucial. But it is essential to keep in mind that most of the enterprises in the hotel sector are SMEs. Therefore the tools need to be adapted to them: they must be easy to access and imply no additional cost. The tolls should be developed with the double aim of protecting the environment and reducing cost.
- The hotel industry is ready to collaborate with the Commission in order to develop the most appropriate approach to the environment. This approach must be built taking in consideration three main points: first, actions must be taken and determined at the most appropriate level, be it the local regional, national or European level; second, actions should be as much as possible on a voluntary basis; actions should be adjusted to the size of enterprises.

The IHA has identified the environment as a key tourism asset and warns of stringent regulations if hoteliers do not work to improve their environmental records. They also point out that hotels may save on costs and gain in consumer goodwill by improving their environmental awareness. The World Travel and Tourism Council has a Green Globe Initiative while the IHA presents an annual "environmental award" in association with American Express. IHA also drew up twelve environmental resolutions in 1992. These resolutions include care in planning and designing new projects, energy conservation, waste management, emission of pollutants and sensitivity towards ecological habitats, local populations and culture/heritage issues.

As far as environmental management schemes are concerned, at least eight European national associations members of HOTREC have developed such schemes and more than twenty large European hotels or hotel chains are known to implement them.

Environmental policies can be improved. In particular, the construction of new hotels in terms of energy conserving design, materials chosen, location and blending with surroundings. For existing hotels there is considerable scope for improved waste management both through recycling and energy conservation. Computer-based management systems are contributing to better control of costs including those with environmental implications. Demand size management (DSM), for example, is being used to control expenditures on energy costs and to extract more out of existing facilities. Attention to such details has been motivated by escalating power plant construction costs, excessive lead time to build new plants, as well as, the public's increasing environmental concerns. German tourists are particularly environmentally conscious and TUI (D) is developing an extensive database which will enable its travel agents to ascertain the "greenness" of over 5 000 hotels. The company has developed a special hotel checklist containing minimum standards and hotels with a high enough environmental quality rating gain a special brochure symbol. Consequently, hotel groups are cooperating to promote good environmental practice. Hilton (USA), Inter-Continental Hotels, Marriott (USA), Meridien (USA), Ramada (USA) and Sheraton (USA) are among a number of groups which recently signed an environmental charter for the industry covering areas such as waste management, product purchasing, air quality, energy conservation and noise pollution. The creation of a European "tourism and environment" prize by the European Commission in co-operation with the Member States is intended to help raise awareness throughout the sector of environmental issues either created by, or that have an impact on the tourism industry. The most successful experiences and good practices will be identified as models

for widespread promotion in the hope that they will repeated by others.

## REGULATIONS

Hotels are affected by a wide variety of regulations (local, national and EU) relating to health and safety, hygiene, sale of alcohol, planning permission and consumer protection. At the EU level a range of regulations indirectly affect the hotel industry. These include the directive on Package Travel, Package Holidays and Package Tours (90/314/EEC). The directive concerning package travel, package holidays and package tours is intended to give consumers of the various types of holiday packages across the EU a minimum level of protection and information provision while at the same time assist the establishment of a European internal market of package tour services. Within this framework, it has been left to the Member States to implement measures to achieve these objectives.

Directive 90/314/EEC stipulates, in article 5, that the organiser and/or retailer party to the contract is liable to the consumer for the proper performance of the obligations arising from the contract, which includes adequate provision of safety measures in hotels (without prejudice to the right of the organiser to pursue other supplies of services). The result is that those in the industry responsible for organising tours are applying pressure and calling for more binding regulations on hotel safety.

The industry is directly affected by the 1986 Council Recommendations on fire safety in hotels (86/666/EEC), specifically aimed at a particular segment of the industry.

Regulations on competition policy, particularly on abuse of a dominant position and state aid, also potentially affect the hotel industry. However, the hotel sector is generally regarded as competitive and has not been the subject of attention from competition authorities. With regard to state aid, the hotel industry in a number of Member States, most notably southern Member States, receives state aid for infra-structural investment. This has not been contested by other sectors or hotel interests in other Member States who are often partly funded by the EU's European Regional Development Fund. This financial support is regarded as regional aid and, as such, allowable under existing regulations. The state itself is also involved in the hotel industry in some Member States, either directly or through state-owned airlines, although the incidence of state ownership is decreasing as these hotel chains are identified as candidates for full, or partial as in the case of Spain's Paradores, privatisation.

Initially, proposed changes on VAT harmonisation would have increased hotel prices and reduced competitiveness relative to extra-EU destinations. This was a worrying prospect for Mediterranean Member States whose hotel prices were also under pressure from other areas of prospective EU legislation, particularly in relation to working conditions. Furthermore, these Member States face direct competition from non-EU Mediterranean destinations such as Cyprus, Turkey, Malta and north African countries. Swayed by these and other factors, hotel services are now included among a list of goods and services to which the Member States can apply a reduced rate of VAT. Spain and Italy have used this opportunity to lower VAT rates on five-star hotels to the same level as is applied to the rest of the industry.

Finally, HOTREC has identified over 70 measures of Community origin likely to have an impact on the HORECA sector. These were outlined in August 1994 in an internal publication "EU developments of interest to the HORECA sector".

## OUTLOOK

The steady growth of the European hotel industry in the 1980s gave way to three years of stagnant demand, declining occupancy levels and falling "achieved" rates in the early 1990s. This slowdown was only temporary and reflected the underlying volatility of the demand base. Recovery, which became apparent in the UK in 1993, is now spreading to the rest of the EU. Over the next decade, global demand for both tourist and business accommodation will continue to grow. Factors contributing to growth over the next three years are: a sharp recovery in the level of economic activity in most EU economies; increased trip frequency and improved seasonal spread, pushing up room-occupancy, capacity utilisation, achieved rates and profits; more active retired people with high levels of disposable income, increasing demand for hotel accommodation; and increased business travel as a result of both closer European integration and more service-oriented industries in mainland Europe.

Cost conscious business travellers and the EU's declining share of global tourism revenue will temper growth rates, although increasing tourism expenditures by southern and eastern Europeans and arrivals from the emerging tourism markets of South-east Asia will help counterbalance the drift to extra-EU destinations. The EU hotel industry will also face stiff competition from alternative forms of accommodation and from more adventurous and demanding tourists. Value for money is another emerging criteria among EU tourists and business travellers but adoption of new technology should enable hotels to provide better service and more targeted marketing while keeping costs from rising; although there will be pressure on labour costs from both a regulatory end and from dwindling supply. Growth in guest nights should remain steady, at 3 % per annum, over the next three years.

The industry is represented at the EU level by: Confederation of National Hotels and Restaurant Associations in the EC (HOTREC). Address: 111 Blvd Anspach Bte 4, B-1000 Brussels; tel: (32 2) 513 6323; fax: (32 2) 513 8954.

# Other accommodation

## NACE 667

The non-hotel accommodation sector consists of a wide variety of types and sizes of establishments. Some subsectors, such as camping, hostels and caravan sites, are dominated by smaller operators and have highly seasonal demand. Other sub-sectors, holiday villages, timeshares and integrated resorts, are less seasonal and are predominantly owned by major companies. Demand is influenced by economic trends. Growth slowed in recent years, though it is picking up in 1994. Concentration within the industry is very low and the range of products in terms of cost and quality is diverse. There is little regulatory pressure and many smaller establishments are unrecorded and operate without constraints. Overall rapid growth is expected during the 1990s. Areas where new products have been developed will fare better than more traditional establishments.

### INDUSTRY PROFILE

#### Description of the sector

The non-hotel accommodation sector encompasses a wide variety of establishments in terms of type, size and services provided. This sector includes camping-sites, caravan parks, hostels, guest houses, bed & breakfast, social tourism establishments, rural tourism establishments, apartments, second homes, timeshares and integrated resort developments. Services offered by this sector range from simple accommodation with basic amenities at the low end, to integrated resorts with restaurants, bars, shopping malls and health and leisure facilities at the high end. The former overlaps with the hotel sector at its lower end of the market while the latter competes with high and mid-range hotels. The services and facilities provided within the non-hotel accommodation sector vary widely. For example, camp-sites may provide restaurants, bars, swimming pools and other leisure amenities or just the basic facilities.

#### Recent trends

Due to the diversity and size of the sector, official statistics on turnover and value-added in different EU countries are very limited. The use of different definitions of other accommodation

throughout the EU also makes it difficult to make comparisons and obtain main indicators for this sector. This is reflected in Eurostat data which shows that turnover in the Netherlands is significantly higher than in any other Member State, including Germany which has nearly twice as many establishments. The Netherlands also ranks highest in terms of the number of persons employed, including self-employed.

Eurostat data on the number of employees shows that even after a marked decline, Spain has the highest number of employees. In Germany and the Netherlands, the other main employee markets, there has been consistent growth in the number of employees in the 1990s.

Eurostat data also provides detailed information on camping and tourist village accommodation establishments. However, there is only limited data on other categories such as holiday dwellings and social tourism establishments. Much of the data on camping and tourist villages is based on classified campsites and, therefore, underestimates the number of establishments and bed places. Furthermore, available data, mainly relating to the supply of establishments, provides very few official statistics on realised demand. The European Federation of Camp Site Organisations (EFCO), which has 14 000 members operating holiday park enterprises in the EU Member States of Norway, Switzerland and Sweden, indicated that 1994 was one of the best seasons on record for campsites in Spain, Italy and the South of France. In addition, while growth in Greece was affected by the troubles in the former Yugoslavia, which reduced access from northern Europe, their domestic camping market improved. Across northern Europe the market was variable with some operators reporting very good seasons and others poor seasons.

Available data shows that Member States reflect varying tendencies of non-hotel accommodation availability and preferences. France, followed by the United Kingdom, Italy and Germany have the largest number of camping and tourist village establishments, while Spain has the largest number of holiday dwellings. However, this figure must be treated with caution as it includes a large number of small establishments. Germany has the largest number of social tourism establishments.

While the paucity of the data hinders cross sector comparisons, Eurostat data indicates that most of the bed places provided by the non-hotel accommodation sector are located in campsites and tourist villages. France provides the largest number of bed places followed by Italy and the United Kingdom.

With regard to social tourism accommodation, it is difficult to gauge developments on an EU wide scale. This type of accommodation is made available through social tourism schemes for people who are unable, generally for financial reasons e.g. pensioners, large families and the handicapped, to go on holidays.

Eurostat data on the number of bed places in camping and tourist villages indicates that this sub-category of the other accommodation sector is most important for France followed by Italy. Excluding the strong growth in Italy, the capacity of this sector in the EU has remained largely static in the 1990s. According to the European Federation of Camp Site Organisations (EFCO) this is due to considerable resistance from local planning authorities to the extension of camping facilities. Comparable information for Denmark is not available and data for Portugal and Greece are seriously under-recorded. Eurostat data on social tourism establishments suggests Germany and the UK are the leading providers, although they may not be capturing all the establishments. France is generally regarded as the leader in the provision of this form of accommodation. Villages Vacances Familles (F), for example, provides around 67 000 bed-places.

Self-catering accommodation, which includes rented flats, villas, chalets, cottages and single rooms completely furnished, is reported to represent the largest subsector of non-hotel accommodation. A large proportion, perhaps 50 %, of self catering accommodation is let unofficially. The data that does exist suggests France, Spain, Italy, Greece and Portugal lead in the provision of such accommodation.

In 1993 approximately 760 000 European families constituting some 2.5 million holidaymakers, travelled on timeshare holidays. Europeans bought some 220 000 weeks of timeshare in over 1 100 holiday resorts. The greatest number of timeshares are situated in Spain followed by Portugal. Both of these markets have shown very strong growth in the 1990s. This category also includes gîtes which are generally rural properties let as holiday homes. France has the greatest number of gîtes followed by Germany and Italy. While Spain has a relatively small number of gîtes it has over 90 000 officially classified furnished flats. In the United Kingdom, Ireland and Germany bed and breakfast accommodation is very popular. Often their existence is unrecorded. Similarly, the international edition of the Fifth Report on Italian Tourism calculates that the number of resident and non-resident bednights in Italy is double officially reported figures because of under-reporting from the holiday rental and owner-occupied holiday home market.

Timeshare ownership grew sharply in the five years to 1993. The UK, which has traditionally dominated the timeshare market in terms of ownership, has grown most in absolute terms,

although all major EU Member States have experienced rapid growth in ownership.

Integrated resort developments are common, but the popular formats differ. In Spain, France, Portugal, Italy and Greece most integrated resorts are aimed at the upper-end of the market. They have high quality standards which attract these markets and have associated activities, such as golf, tennis and entertainment. They may be self-catering or food may be provided. In the United Kingdom, "holiday camps" such as the Haven, Butlins and Pontins chains are popular and are primarily aimed at the family market. They provide a wide range of activities and leisure pursuits and have been moving upmarket in recent years. In northern EU countries, resort complexes located close to conurbations, targeting the short break market, are most common. The main operators are Centre Parcs (NL), Dorint (D), Gran Dorado (NL) and Sun Parks (B). Most of these operators have spread into neighbouring countries, including the UK.

There are over 1 600 youth hostels registered with the International Youth Hostel Federation (IYHF) in the EU and a further 1 160 in other European countries. Nearly 40 % of IYHF hostels are in Germany.

There was a decline in the number of overnights spent at IYHF hostels in the EU between 1992 and 1993. In 1993 nearly 19 million nights were spent in hostels of which over one quarter were by foreign visitors. The main EU markets for youth hostel accommodation by foreign visitors, Germany, the UK and France accounted for over 2.7 million overnights. German, British and Polish IYHF hostels are predominantly used by the domestic market. According to the IYHF there has been a sharp increase in the number of cheap accommodations available to budget travellers which has resulted in poor standards of non-Youth Hostel Association accommodation. However, as a result, plans to implement youth hostel standards and common practices have been approved, which should increase the quality of youth hostel accommodation as well as the level of regulation.

A useful indicator of the markets for youth travel is the sales of student travel (ISIC) cards. Demand for these cards is consistently greatest from Germany, the United Kingdom, Spain and Ireland. In 1993 there was continued growth in the sales of ISIC cards in all of these main markets except Spain. Student travel, invariably users of non-hotel accommodation, is one of the biggest growth areas and is relatively recession-proof. Sales of Student Air Travel Association tickets almost doubled between 1988/89 and 1991/92 from 634 000 to 1 243 000 tickets.

### International comparison

Usage patterns of non-hotel accommodation in the EFTA countries are comparable to those of the EU states. EFTA countries

generally have high standards of accommodation with Nordic countries, particularly Sweden, noted for chalet style accommodation located in forest surroundings. Though no EU comparable data is available for the US, the US touring market is very large. Americans have pioneered the recreational vehicle market and standards and levels of provision for mobile tourists in the US are very high.

Europe contains one in four of the world's timeshare resorts and nearly one-fifth of the world's timeshare owners live in Europe. This form of holiday accommodation is most popular in North America and Australia and almost non-existent in the less developed areas of the world. However, the liberation of the former Eastern bloc countries has led to rapid growth in the number of people in the Czech Republic, Hungary, Poland, Russia and the Baltic states buying timeshares; mainly at Spanish resorts.

### Foreign trade

There is insufficient data to ascertain a breakdown of non-hotel bed nights in terms of "imports" and "exports". Even if this data were available, the large number of establishments that are unrecorded would undermine its accuracy. The proportion of "camping tourists" from outside each Member State is typically in the range 30 % to 40 %. The ratio in Greece and Luxembourg is believed to be considerably higher.

Excluding youth travellers and those visiting friends and relatives (VFR), long distance tourists to Europe are infrequent users of non-hotel accommodation. The same applies to European tourists travelling to far away destinations. Non-hotel accommodation is popular with East European tourists visiting EU Member States, although it is not as common as might be expected given their income constraints. According to a report on outbound east European travel in the Economist Intelligence Unit's "Travel and Tourism Analyst," over half of the visitors to Austria from Poland, Hungary and the Czech Republic, used hotel accommodation, albeit mainly two-stars hotels.

## MARKET FORCES

### Demand

Demand for non-hotel accommodation is strongly linked to tourism demand. Most non-hotel accommodation users are leisure travellers. With the exception of niches developing in direct competition with hotels, such as serviced apartments, business travellers generally use non-hotel accommodation only when hotel accommodation is unavailable. The low level

of business demand results from the nature of the accommodation which is generally booked well in advance, by the week rather than the day, and because it is the lower end of the accommodation market.

Increasing incomes and discretionary leisure time are predominant factors in determining the amount and type of travel and use of other accommodation. Both disposable income and available leisure time increased in the EU Member States during the 1980s stimulating the demand for other accommodation. Available leisure time expanded over the last two decades as improvements in working conditions led to longer holidays and shorter working weeks, although this trend has decreased in recent years. Much of the demand for other accommodation, particularly camp-sites and rented accommodation, comes from family groups. In other cases, family based demand may relate to budgetary constraints which preclude the use of hotels.

There is a large domestic component in the demand for other accommodation. For a variety of reasons, including income levels, the weather and the attractiveness of their own country as a tourist destination, nationals of the southern Member States of Greece, Portugal, Spain, Italy, and France are more likely to holiday in their own country. In the higher income northern European countries, particularly Germany, the United Kingdom and the Benelux countries, there is higher demand for foreign holidays as travellers seek better weather and cheaper holidays. Rented accommodation should be distinguished from domestic VFR and second homes. Second home ownership is very high in Denmark, France and Italy, particularly when you consider extended family members who use the core members' home free of charge. In Denmark, the self-catering rental market to non-residents (mainly Germans and Dutch, but also eastern Europeans) is very important as a flow-on effect from second home ownership.

The demand for non-hotel accommodation is highly seasonal in nature. It is essentially limited to the warmer months, although winter sports generate demand for self-catering accommodation, particularly in the French Alps. Increased awareness in leisure, health and fitness of Europeans has encouraged growth in activity and sporting holidays. Approximately 10 % of all holidays taken in Europe are built around a specific activity or sport. This seasonality results partly from the nature of the product. Thus, camping and caravanning holidays are more suited to the summer months. Institutional factors, such as school holidays, are also responsible for seasonality. All-weather holiday parks, in the style developed by Sun Parks and Center Parcs provide facilities such as sub-

tropical swimming pools, saunas and high standards of catering which generate high occupancy levels throughout the year. Such parks are also tailored to the growing popularity of short-break holidays.

The demand for camp-site accommodation is strongly correlated with the use of cars as a transport mode. European Travel Monitor data indicates that car usage for international travel is most popular in Luxembourg, the Netherlands, Germany and Belgium. Few international tourists from Ireland, Greece and the United Kingdom use a car for even part of their travel, which indicates a lower demand for other accommodation. The opening of the channel tunnel will stimulate international car and rail travel between the United Kingdom and mainland Europe, which should in turn increase demand for the non-hotel accommodation industry. However, a few factors, such as the weather and rabies laws, a high proportion of caravan and camping holidaymakers bring their pets with them, may deter some holiday traffic from mainland Europe.

Use of other accommodation often depends on travellers' national tendencies. At present, British tourists typically do not use non-hotel accommodation when travelling abroad. Holiday villas and apartments are the exception. An article in the Economist Intelligence Unit's "Travel and Tourism Analyst" indicated only 3 % of UK holidaymakers travelling abroad used caravan or camping-sites in 1992, while 48 % seek hotels, 24 % seek villas/apartments accommodation and a further 18 % visit homes of relatives. In contrast, a third of West German holidaymakers in 1991/92 used hotels, while nearly 10 % used camping or caravan sites. Similarly, the growth in the share of continental European tourists in Ireland has resulted in substantial growth in demand for non-hotel accommodation: total visitors to non-hotel accommodation by overseas tourists increased by 26 % between 1990 and 1993.

The demand for social tourism accommodation is most prevalent in France and Belgium. This subsidised travel works by either providing holiday vouchers or aid for constructing tourist facilities. In France, vouchers are distributed by the Agence Nationale pour les Chèques-Vacances (ANCV). The objective of the scheme is to assist lower-paid employees in going on holiday with their families. These vouchers are accepted by over 30 000 establishments and more than 4 million French people, or 1 million employees and their families, benefited from the programme in 1992. Even though the number of people benefiting from the scheme is growing at around 37 % a year, there is still only 7 % take-up by those entitled to participate and only 5-6 % participation by larger employers.

In 1992, 413 million French francs, or 36 % of the total expenditure, was spent on non-hotel accommodation. Over 50 % of this was spent on social tourism establishments, 30 % on rural gîtes and the remainder on camping and caravanning. There is still potential for growth in social tourism since there is a latent demand for this type of holiday and the associated accommodation. Unlike demand for other non-hotel accommodation, social tourism holiday demand is less dependent on the factors determining growth and trends in tourism expenditures and more dependent on institutional factors. In practice, the institutions in many Member States, including France are becoming less willing to finance social tourism and groups such as VVF and Renouvea are becoming increasingly indistinguishable from budget tour operators and holiday village operators.

Spain has adopted a different approach. Whereas French social tourism is largely family-oriented, Spain subsidises off-season holidays by pensioners. A limited number of travel agency chains are picked each year to operate the scheme on the basis of a competitive tender. The 1994/95 budget is 40 million ECU for 360 000 holidays spread over eight months. A 1994 study by Price Waterhouse showed that the programme is largely self-financing through savings on unemployment pay for the tourist industry workers who are kept in full-year employment by the scheme. The study estimated that more than 20 000 jobs are protected by the scheme. Extension of social tourism to all EU countries would be beneficial both to the hotel and "other accommodation" sectors.

The rapid growth in short break and weekend holidays may be positive for some non-hotel subsectors while the same growth may have negative repercussions for other subsectors. Generally, most non-hotel accommodation establishments are poorly equipped to cater to the short break market, and would not attract the higher income groups that can afford second holidays. In addition, growth in short breaks is generally in the off-season, which is unsuitable for many "weather dependent" forms of non-hotel accommodation. If anything, growth in short breaks has contributed to a shortening of the duration of main summer holidays. Thus, the demand for caravan parks, campsites, chalets and holiday apartments is adversely affected by the trend towards more frequent holiday breaks. Integrated resorts, on the other hand, have benefited from growth in the short break market.

The demand from East European countries for other accommodation is low, but increasing. Tourism flows from these countries are likely to increase as their economies improve.

The low income levels in these countries will lead to a higher proportion of holiday makers using budget accommodation such as camp-sites. In addition, the demand for timeshare accommodation by East European countries is expected to increase as exchange organisations enable the purchase to be made in domestic currencies.

The majority of EU holidaymakers travel to the seaside, but these holidays are weather dependent and often seasonal. Many traditional resorts have tried to extend the season by improving their all-weather facilities, with hotels being the main beneficiaries. Nearly a quarter of Europeans spend their holiday in the countryside, which tends to be less weather dependent. As a result, rural tourism has shown stronger growth than sun and beach tourism. In France, where rural tourism is promoted by the government, 80 % of visitors travel independently, 20 % are foreigners, and 30 % are on short breaks.

### Supply and competition

The supply structure of non-hotel accommodation varies dramatically across segments of the industry. Integrated resorts and timeshare developments tend to be capital intensive with organised management structures. Similarly, apartment and villa establishments tend to be capital intensive with many of them marketed through travel agents as part of package holidays. At the lower end of the scale, camp-sites and caravan parks tend to be less capital intensive, while temporary accommodation in bed and breakfast establishment may be provided by altering the use of existing buildings rather than constructing new ones. Barriers to entry in the integrated resort and timeshare markets exist in terms of the high set up costs and the long lead in time associated with purpose built resorts. At the lower end of the market, especially camp-sites and caravan parks, the set up costs are much lower.

The supply of other accommodation tends to be seasonal in nature. A number of caravan sites and non-hotel accommodation establishments operate at full capacity in the summer while providing limited or no accommodation in the winter. This results in over capacity for much of the year and shortages at peak times. In contrast, integrated resorts, theme parks and some timeshare accommodation are provided all year round and significant price differentials are used to spread the demand.

The supply of social tourism accommodation is dependant on state (and in some cases Church, employer and trade-union) funding. Such funding is being cut back, at least in real terms, and many establishments are in need of modernisation and upgrading. As this funding is cut any element of unfair subsidised competition with the commercial accommodation sector is reduced. Traditionally, the degree of competitive overlap

was regarded as marginal as social tourism accommodation was originally designed to stimulate latent demand among those who cannot afford holidays rather than diverting existing holiday-makers. However, this is changing.

A number of non-hotel establishments provide similar services to hotels and compete with hotels at all ends of the market. Thus, tourists might be faced with the choice of a hotel or self-catering apartment, while businessmen are increasingly choosing between hotels and serviced apartments. Competition within the bed and breakfast market has led to improved quality and more direct competition with hotels.

Tourists in the non-hotel accommodation sector are clearly becoming more demanding and expect higher standards of comfort and facilities: e.g. sanitation, catering and sports facilities. In France, for example, around a fifth of camp-sites have a swimming pool and/or at least one tennis court. The trend is to improve the quality of the facilities and services supplied. However, there is still considerable divergence within Member States.

Competition in the non-hotel accommodation sector varies between Member States. In some Member States the market tends to be mainly domestic and the consumers choose between different regions, while southern Member States tend to attract a higher proportion of foreign visitors. It is estimated that nearly 70 % of camp-site users in Greece are from abroad. Thus, there is an element of intra-sector competition, par-

ticularly between other accommodation situated in coastal areas, where the foreign tourists are sun seekers and less concerned by the cultural and heritage aspects of their holiday. There is also direct competition between hotels and apartments in the package holiday market to Mediterranean resort destinations.

### Production process

The services provided by non-hotel accommodation vary widely across the industry. At one extreme camp-sites and caravan parks may provide a pitch or area of land, as well as, basic amenities, while integrated resorts often have restaurants, bars, shops, and health and leisure facilities. The variety of facilities and services being provided means that the production process differs significantly throughout the industry.

Camp-sites and caravan parks are the most land intensive. With regard to labour, the industry is generally not as labour intensive as the hotel industry because there are fewer services offered; and, they often come with an element of self-catering. Many of the workers tend to be part-time, for example at camp-sites and ski resorts, and in the smaller establishments, such as bed and breakfast, family and female labour is used. The integrated resorts tend to be more labour intensive and the skills are similar to those in the hotel industry.

The majority of the establishments are not technology intensive. Some sectors such as integrated resorts, apartments and villas, which are marketed as part of a package holiday, use computer reservation systems (CRS). Many small operators rely on local advertising or links through tourist agencies. Smaller pensions and bed and breakfasts rely upon guide books and literature rather than depending on travel agents.

## INDUSTRY STRUCTURE

### Companies

The pattern of camp-site and caravan park ownership varies within the EU. In France, municipal authorities have traditionally been a major force in the ownership of camp-sites. Recently, however, the private sector has increased its presence

and in 1991 owned 54 % of sites and 60 % of pitches. Privately owned sites are overwhelmingly in the hands of small business people typically running just one facility, although some of these may operate a number of facilities within a region. The industry is fragmented and dominated by a large number of small enterprises. There are a number of larger players who run organised camp-sites where the camping equipment is provided on site. For example, Haven Europe, a subsidiary of the Rank Organisation which also owns the Butlins holiday resorts, offers 47 parks in Spain and France varying in size from under 250 to over 500 pitches. Similarly, Keycamp holidays offers 100 camp-sites throughout Europe, including mobile homes. Both of these operators have increased the number of campsites they offer between 1992 and 1994 by 25 %.

The integrated resort sector of the non-hotel accommodation industry has developed over the last 10 to 15 years. This represents a much more concentrated sector. The leading developers of health and leisure centres have been Dorint in Germany, Gran Dorado in Germany and Benelux, Sun Parks in Benelux, Center Pares in Benelux, France and the United Kingdom and Pontins and Butlins in the United Kingdom and Ireland. Centre Pares and Pontins are both owned by Scottish and Newcastle Breweries (UK). The concept is highly developed in the Netherlands where the market is dominated by Center Pares with seven parks. In 1990 there were over 400 000 villa rentals and nearly 2.1 million visitors to the Benelux properties. Demand is also expected to grow in the medium term: for example, Center Pares is building its first park in Germany with 600 bungalows and Sun Parks plans to increase the number of their parks in the next two to three years.

Club Med is the largest upmarket tourism product designed for activity holidays. It is based on a system of holiday villages. Club Med currently has around 100 holiday villages with a capacity of close to 68 000 beds in 33 countries around the world. The number of villages in Europe has fallen since 1991 with the closure of villages in Yugoslavia, Switzerland and Spain. Other villages include Valtur in Italy and tour-operator-owned holiday villages at leisure resorts (including at non-seaside rural and mountain resorts, particularly in Austria and Switzerland). The biggest in this field is TUI, with its

Source: International Youth Hostel Federation

Robinson Club and Bauerndoerfer chains, but other large German operators are all active in this area. TUI markets its Robinson Clubs through other operators as well.

Despite a drop in the number of villages there has only been a 2 % drop in Club Med's sales between 1991-93. Declines in the larger French, German and Belgian markets were countered by sales growth in Turkey (86 %), the Netherlands (29 %) and Spain (22 %).

The Euro Disney resort in France is the largest theme park in Europe and offers non-hotel accommodation, including 14 rustic lodge sites with over 1 000 rooms and 400 wooden cabins. France has a further 35 recreational parks and 30 aqua parks. Most European theme parks are geared to the day trip market and generally do not include accommodation. The arrival of Euro Disney is focusing the attention of some theme parks on the short break market as a supplement to their traditional day-trip customers.

Social tourism initiatives tend to be concentrated in Belgium and France. The VVF (Villages Vacances Familles) in France provides subsidised accommodation and has a capacity of 186 villages with a total of 67 000 beds and an annual turnover of 190 million FF. VVF was largely instrumental in setting

up Euro-villages, which now has members in France, Belgium, Germany, Switzerland, Italy, Spain and Portugal.

### Strategies

The general strategy within the other accommodation industry has been to improve the quality of the accommodation and facilities. Camp-sites now offer swimming pools, sporting facilities and even cinemas and discos.

The strategy in the more sophisticated integrated resorts has been to transfer the ambience and environment of tropical resorts to northern European locations. These resorts tend to be of a higher quality than the traditional resorts with swimming pools, tennis courts, restaurants and comfortable accommodation. They also tend to be more activity based with numerous sporting and leisure facilities, and, most importantly, are independent of the vagaries of the weather. The primary target group is families with small children. Club Med's management has attributed their poor performance in recent years to price and have developed a series of special offers effectively allowing clients to opt for the basic package without the traditional free sports/full board.

The success of the timeshare establishments is largely due to their ability to offer exchange location. This initiative means

that the owner does not have to return to the same resort every year. They are able to exchange their accommodation for another resort by using the services of the exchange companies. In any one year approximately 40 % of timeshare owners swap their timeshare and visit a different resort. The majority of timeshare resorts are affiliated with one of the two major exchange companies, RCI (Resort Condominiums International) or II (Interval International).

At the lower end of the market efforts are being made to tailor youth hostel facilities to the needs of various different groups, instead of serving all customers with the same product. Rent-a-Hostel, which aims at using Youth Hostels out of season, offers groups and families the opportunity to rent a hostel for themselves. As a result, they increased growth in turnover in 1993. Hostelling International has introduced the first computerised advance booking system "IBN" for youth hostel accommodation. The network of youth hostels using this new system is expanding.

### Impact of the Single Market

The overall impact of the Single European Market (SEM) on non-hotel accommodation is likely to have been positive, although given the diversity of types of establishments within the sector this statement cannot be regarded as definitive. While holiday apartment complexes, timeshare resorts and integrated resorts all benefited from an SEM induced increase in travel, they are adversely affected by consumer protection legislation relating to package holidays, distance selling and timeshares, and by requirements for environmental impact assessment for large developments. These considerations are of less importance at the other end of the market, i.e. for rural and social tourism establishments, including camping and caravanning sites, although with the bulk of their demand base being domestic holidaymakers these sub-sectors benefit less from increases in cross-border travel. Rural tourism and social tourism also stand to benefit from initiatives at an EU level designed to directly encourage the development of these types of holidays. Infrastructure improvements, including "trans-European" networks, also benefit this sector.

## REGIONAL DISTRIBUTION

Location of other accommodation establishments has followed demand rather than leading it. Unlike hotels, other accommodation tends not to be concentrated in major cities but is located away from these centres. This reflects the close ties with tourism traffic and, in some cases, the industry's dependence on climatic factors. Distribution of other accommodation establishments varies from country to country and depends upon the nature of demand and the type of establishment. Camping and caravan sites, and to a lesser extent second homes and timeshare accommodation, are generally located in coastal areas.

Non-hotel accommodation not located near the coast is generally in rural, rather than urban, areas. These include caravan and camp-sites, as well as, farmhouse accommodation. Integrated resorts in northern Europe are not as dependent on natural features for their location since they are activity based and are generally self contained. An exception is Center Parcs which tends to be located in rural and forest areas. Northern European integrated resorts do, however, take account of local population structures in planning their locations. In southern Europe, integrated resorts tend to be mainly situated in coastal areas.

## ENVIRONMENT

In general, the non-hotel accommodation sector has developed without major damage to the environment. Many of the sub-categories such as rural tourism, camping and caravanning are dependent upon their location and environment as a major selling point. However, the growth of overnight parking of motorhomes, caravans and tents in the countryside outside designated campsites is a growing problem. This type of wild camping is associated with refuse and waste, as well as, a decline in the amenity of sites of natural beauty. Research in Spain indicates that this form of camping amongst motorhome owners increased by 47 % in 1991. Although land intensive, most forms of non-hotel accommodation, gîtes, farmhouses, camp-sites and small hostels tend to be less intrusive on the landscape than hotels. Since many other accommodation users are independent travellers there tends to be a high proportion of car usage associated with this type of accommodation. A green paper from the EU indicates that the use of cars as opposed to rail or bus increases congestion, produces more pollution and is a less efficient use of energy. At 25 % occupancy levels railway uses less than half as much energy per passenger kilometre as small engine cars. There may be scope to develop alternative modes of transport or

to spread the peak season so that some of the negative environmental impacts associated with the car are reduced.

Under EU legislation an environmental impact assessment is required for large infrastructure projects. Since many of the non-hotel accommodation establishments are either small in nature or not capital intensive this is unlikely to have an impact on these areas of the industry. However, there may be a need to increase environmental awareness in the development of integrated resorts and timeshare resorts. Since these resorts benefit from a clean environment it is in the interest of developers to ensure that any new developments blend in with their surroundings. The construction of new establishments might also be controlled in terms of density, materials chosen, location and more sensitivity to the regions heritage and natural/historic environment.

One area where the non-hotel sector has had a detrimental impact on the environment is in overcrowded holiday resorts where a large number of apartment blocks are crammed into coastal locations. These types of resorts are often linked to package tours. Examples can be found on the Costa del Sol in Spain, in the Algarve in Portugal, as well as, on a number of Greek Islands. These problems are now being addressed, particularly in Spain.

## REGULATIONS

National and local regulations concerning issues such as fire services, safety, food hygiene, etc. cover all forms of non-hotel accommodation. There are also specific regulations covering individual subsectors. Those affecting caravan parks and camp-sites vary across Member States but tend to cover the use of the parks in terms of the maximum number of pitches, the minimum size of the site, adequate drainage of the site, access to and within the site, car parking provision associated with the site, as well as, toilet and water facilities. Regulations generally limit the proportion of fixed facilities that may be allocated to holiday parks, 15-20 % is a typical ratio. It is attractive to the operator to develop fixed facilities, since they bring higher rent and profits. There are a large number of parks which cater to fixed facilities markets, like caravan and mobile home owners who usually pay an annual rent for the site. These parks are not operated in the same way as touring or tourist parks since they are not open to tourists. They are, however, subject to similar regulations. EFCO highlights the phenomena of unregulated use of caravan and camping accommodation or "wild camping" as the greatest threat to the camp/caravan site industry. According to EFCO this practice manifests itself in the establishment of unofficial and

unlicensed campsites and the use of land outside licensed holiday parks on beaches and in car parks.

Some of the larger accommodation providers within the other accommodation industry are affected indirectly by EU regulations. The EU Package Travel Directive will affect suppliers of apartments, villas, chalets or other accommodation as part of inclusive tour packages. The Directive makes tour operators liable if customers are not satisfied with their accommodation or if facilities are not a true reflection of those advertised. The threat of liability faced by tour operators will lead to the imposition of stricter safety criteria on providers of activity holidays and a consequent increase in the prices of these types of holidays.

Consumer legislation on access to computer reservation systems (CRS) will involve the tightening of advertising standards and may affect the way in which package holidays incorporating other accommodation products are sold. As far as the time share directive is concerned, one of the problems is that of the law applicable to the contract, because the Rome Convention on the Law Applicable to Contractual Obligations (1980) can not cover all forms of timesharing. The directive only stipulates that the purchaser can not be deprived of the protection afforded by the directive if the immovable property concerned is situated within the territory of a Member State; this gap is filled by the fact that Member States are entitled to prohibit the sale, within their territories, of timeshare rights through a contract that does not include all the protection elements included in the directive, independently of whether the immovable property concerned is located in a Member State or not.

The main components of the Directive are unchanged since it was proposed and include that it is prohibitive to ask for a deposit and the consumer has the right to demand a contract in his/her own language. Other changes to the Directive are that consumers may unconditionally withdraw from a contract, without giving any reason, within ten days; and an extension of the list of conditions under which the consumer has the right to end the contract within three months. The implementation of the directive should be done before April 1997, though a number of Member States are expected to do it well before that date.

While the most important aspect of the Directive from the consumers' viewpoint is probably the introduction of a "cooling-off period", the timeshare industry has indicated that the ban on taking a deposit will be most harmful to the industry. Without the commitment from the potential buyer that a deposit implies, it will be harder for timeshare marketers to judge sales levels and this may lead to an increase in prices.

Regulations on the harmonisation of VAT, may increase the price of non-hotel accommodation. For example, most Member States charge VAT on campsites of 4-6.5 % with the exception of Denmark (25 %) and the UK (17.5 %). However, from 1996 the minimum level may be 15 % leading to a loss of price competitiveness. In the short term this is unlikely to be a major issue because, like the hotel sector, the rate of VAT applied over the transitional period can be at a reduced rate fixed by national authorities. Although the non-hotel accommodation sector is not particularly labour intensive, the seasonal nature of this sector suggests that EU employment legislation introducing greater protection for temporary, or seasonal, workers will push up costs.

## OUTLOOK

It is difficult to provide an overall outlook for a diverse and disparate sector like non-hotel accommodation. Demand for non-hotel accommodation grew steadily over the last decade in France, Spain, Greece and Italy but has remained static in Germany and the Netherlands. There is also variation within different sectors. For example, lower growth in the traditional

**Table 13: Other accommodation**

Turnover	6.0	5.0
Employment	3.0	2.0

Source: Fitzpatrick Associates, Economic Consultants

holiday resorts of Spain and Portugal, against strong growth in integrated resorts in northern Europe. While new legislation covering the timeshare industry is likely to restrict growth in the short-term, medium-term forecasts are buoyant, with spending on leisure likely to grow faster than consumer spending. There will also be an increase in the number of typical timeshare buyers, e.g. active and affluent people aged 44 and over. The number of timeshare owners is forecast to grow from approximately three-quarters of a million in 1993 to around 1.5 million by the year 2000, with the German and Nordic markets having the greatest potential. Another potential area of growth lies in the provision of suitable other accommodation for the disabled. According to a recent report for Tourism for All in Europe, there is potential demand for some 8 million people travelling abroad and 15 million taking domestic trips.

Over the next decade global demand for tourist accommodation will continue to grow at a moderate pace. Increased leisure time and disposable income coupled with more diverse products will lead to an overall increase in demand. How non-hotel subsectors will fare is less predictable. Growth in short breaks will adversely affect accommodation primarily designed for good weather conditions (camping, caravanning, chalets etc.) but, will boost integrated resort developments. Growing demand from East Europe will favour less costly forms of accommodation and trends towards rural and mountain tourism will have a positive impact. Student travel will also continue to grow. The general movement away from traditional resort holidays may adversely affect some subsectors of the industry, but increased growth will result from the shift towards more independent holidays and the demand for more adventurous holidays.

The shift towards new, higher quality and year round products is likely to continue. The use of CRS and the development of activity and theme holidays around non-hotel accommodation packages will attract new clientele and ensure that value for money is maintained without a loss in quality. Growth in guest nights in the medium term will be strengthened by improved economic conditions.

# Recreation parks

*The recreation parks sector covers a wide range of tourist and leisure attractions with overlap between subsectors increasing. This monograph mainly applies to amusement parks. Based on comparisons with North America, the European market for amusement parks has not yet reached maturity and there is considerable growth potential. Potential demand in Northern Europe has been stimulated by the arrival of EuroDisney and there are also strong prospects for growth in the "all weather" parks in southern Member States. Ownership of large parks is consolidating as a number of firms grow through acquisition, including through the expansion of USA firms. Large parks may harm the environment in a variety of ways, from noise pollution and scenic intrusion to attracting a high volume of motorised transport. The impact of technological developments such as virtual reality are currently uncertain, but in the medium term attendance numbers and revenues should continue to increase.*

## INDUSTRY PROFILE

### Description of the sector

The recreation parks sector includes a wide variety of establishments in terms of size, style and services offered. They vary from theme parks, other amusement parks and water parks, through holiday camps, to zoological gardens and safari parks. Taken literally, municipal parks and nature reserves would be included within the definition also. An important element of the recreation parks sector is non-permanent or travelling "enterprises" which often offer many of the same attractions as those available at permanent sites. Holiday camps, such as those operated by Pontins in the United Kingdom, and indoor resorts, like Centre Parcs, will not be addressed in this monograph, but are discussed under NACE 667, "Other accommodation."

Variety in scale and orientation among individual operations reflects the constant evolution which takes place within the industry due to changing technology and consumer tastes. A number of key characteristics can be identified which distinguish recreation parks from other facilities. A recreation park constitutes a visitor destination in its own right and offers a range of attractions which are often, but not always, for a single standard admission fee. Many recreation parks close in off-peak periods, although this is becoming less the norm. Zoos, however, usually remain open year round.

The level of overlap with other tourism sectors depends on the size of the operation. Non-admission revenue sources such as restaurants and retail outlets are estimated to account for approximately 45 % of the total revenue of large theme parks and amusement parks. Only a few large parks operate hotels or other forms of accommodation (caravan parks, self-catering, etc.). At the other end of the market, smaller parks do not provide accommodation and generate a smaller proportion of revenue from non-admission sources. Nevertheless, receipts from restaurants and retailing, particularly of park-related merchandise, are still important to the smaller parks. Considerable overlap is evident in the case of EuroDisney. EuroDisney is now the largest restaurant owner in France, with sales of over 30 million meals a year; and, if developed as planned, the site will have a third as many hotel rooms as the area surrounding Paris.

The geographic distribution of the industry is influenced by park size, with large parks generally located a small distance from major urban concentrations and smaller parks providing an important part of flanking attractions, which are increasingly required in traditional resorts; particularly seaside des-

tinations. While recreation parks are to be found in all EU Member States, the largest parks are situated in France, Germany, Belgium, the Netherlands and the United Kingdom.

It is difficult to obtain reliable data on the recreation parks sector, even though it generates very substantial levels of turnover and employment. As of yet, no official statistics exist. The information that does exist is patchy, and is unlikely to cover more than a particular segment of the recreation parks sector.

In 1991, approximately 300 zoos and aquaria were members of regional and/or national zoo associations in Europe (including non-EU states and some former Soviet Union states) and zoo attendance was estimated at 125 million, approximately one fifth of total global attendance. Of the EU Member States, zoo attendance is much more popular in Germany than in the other eleven countries.

Membership of organisations such as Europarks (European Federation of Leisure Parks) and IAAPA (International Association of Amusement Parks and Attractions) provides some data on major theme parks. However, little data exists on smaller theme and amusement parks. Overall, Europarks estimates annual attendance at all parks was around 120 million in 1990, while employment was estimated to be between 30 000 and 50 000. These estimates pre-date the opening of EuroDisney which is likely to have added a further 10 % to these figures. Including EuroDisney and the smaller parks, total revenue is likely to have been nearly 1.5 billion ECU in 1992.

### Recent trends

The popularity of zoos and safari parks among day trippers has fallen considerably in most EU countries over the past decade. Consequently, some have experienced financial difficulties, shut downs (particularly in the UK and to a lesser extent in Germany) or diversified. In the United Kingdom, for example, Windsor Safari Park was rescued from receivership by Legoland (DK), the London Zoo was hit by financial difficulties, while Chessington World of Adventure (UK) and Flamingoland (UK) developed from zoo-based attractions into theme parks.

However, there are examples of successful zoos (notably in the Netherlands) which adapted to the new market situation - by changing their formula or theme - and which could record a growth of attendance.

In general, the number of major amusement parks in the EU and the average size of parks have increased in the last five years. In particular, American style theme parks are enjoying a boom period. Despite the recession, IAAPA data indicates

a 5.6 % rise in visitor numbers to Western European theme parks over the 1991-93 period. Similarly, a survey by the Economist Intelligence Unit (EIU) indicates attendances at major European parks rose by 32 % between 1985 and 1992. Coupled with the increase in the number of parks, it is evident that there has been growth in the industry. The arrival of EuroDisney also gave a boost to theme park attendances without a substantial adverse impact to rival theme parks. On the contrary, the EIU analysis indicated many parks prospered through the raising of the sector's public profile.

In 1994, however, most parks in the EU were confronted with a loss, as attendance fell (varying from 3 % to 15 %) following a cold spring and an unusually hot summer. At the same time, most parks reported an increase in visitors' per capita spending.

Large scale amusement parks have existed in Europe for many years. Tivoli Gardens (DK) in Copenhagen, for instance, was opened in 1843 and remains one of Europe's largest recreation parks. The opening of Disneyland (USA) in California in 1955, however, marked a departure in the kind of product on offer. Since then, theme parks have spread rapidly throughout the developed world. In Europe, a number of new developments came about in the late 1980s, particularly in France. The most prominent was EuroDisney (USA), whose advent has had a considerable impact on the size and structure of the sector.

In 1994, France proved to be a special case. EuroDisney attendance fell by some 10 %, while on the other hand the other French parks seemed to recover from the arrival of EuroDisney to regain their previous attendance levels: Parc Asterix went up by 30 % and Futuroscope by 35 %.

### International comparison

The standard reference point for international comparisons of recreational parks and, especially theme parks, is the North

American market, which is the largest in the world. There was a major boom in theme park attendance in the United States during the 1970s, with the market growing at a lower, but steady rate in the 1980s. During the latter period a number of major operating companies moved out of the market, with control of major theme parks passing to a smaller number of large companies. In the USA, new initiatives have tended to either concentrate on smaller parks serving niche markets, such as waterparks, or extensions or variations to existing products; particularly the addition of new high-profile attractions.

Theme parks are a very important element of the USA domestic and international tourism product. Around one in four North Americans visited a theme park in 1993, many of them more than once, and total visitor numbers exceeded those of all major sports events. Growth in attendances in the USA fell slightly (1.5 %) in 1992 but increased substantially (61 %) in 1993. In Europe, the proportion of visitors is much lower as are expenditures per capita in amusement parks.

Admission revenues accounted for over half of all revenues, excluding accommodation, in major European amusement parks in 1993, compared to under 40 % in other world regions surveyed by IAAPA. The difference reflects both higher admission charges in Europe and a greater reliance on a "pay-one-price" (pop) admission, whereafter all rides are free of charge. However, while European general admission prices are the highest they have much more price differentiation in off-peak periods. There is also a lower expenditure on ancillary products in European theme parks, a fact which has contributed to EuroDisney's well-publicised difficulties.

The Japanese experience of sharp growth in the 1980s closely reflects that of Europe. Disney, for example, opened a park in Tokyo in 1983, and a number of other major theme parks were opened in the late 1980s. As in Europe, the Japanese and other Pacific Rim markets are not yet regarded as having

**Table 3: Recreation parks**  
**Average year-end attendance by world region (1)**

(thousands)	1991	1992	1993
Western Europe	708.7	727.0	748.5

matured. They experienced strong attendance growth in 1992, but witnessed a 2.8 % decline in 1993.

### Foreign trade

Recreation parks are primarily a tourist product, where domestic tourists are more important than their international counterparts. However, the international attraction potential of recreation parks does differ significantly. A number of such parks, EuroDisney being the most obvious example, are international attractions which generate substantial cross-border tourism in their own right. Other major recreation parks could be classified as flagship attractions, meaning that they form an integral part of a group of tourism products which attract tourists to a particular country or area. In many cases these recreation parks also attract international excursionists, particularly in northern Europe. A trend enhanced by the abolition of border controls in 1993, reveals that consumers are increasingly willing to make cross-border trips to attend recreation parks. Smaller types of recreation parks are more common as flanking attractions and are becoming more important at traditional seaside resorts frequented by international tourists.

USA theme parks are important in attracting European tourists. In particular, utilising the major flagship attraction of Disneyworld (USA), Florida has developed a critical mass of theme parks and other attractions to draw visitors. Many holiday packages to Florida include a week at a beach resort and a week in Orlando, where many of Florida's main attractions are centred. Disneyworld estimates that United Kingdom visitors to their park outnumbered those from the state of Florida in 1991. Anheuser-Busch (USA) also plans to expand their reach into Europe with sales missions to Germany and the United Kingdom during 1993.

The majority of owners in the European recreation parks industry operate a single park. Cross-border expansions and joint ventures are, however, becoming more common. The scale of investment required for a theme park in the 1990s means that most investments are now financed by large operators and conglomerates who are less adverse to direct foreign investment than the traditional family owners who were prominent in the sector in the past. Reflecting the popularity of USA-style theme parks, the largest recent inward investment to the EU has been Walt Disney's EuroDisney park outside of Paris. In addition, a major park is currently being constructed outside Barcelona as part of a joint venture involving Spanish, UK and USA partners. Also, Warner Bros. plans to open a film theme park in Germany which will open in 1996.

in particular, have changed substantially since the beginning of the 1980s. Although demand has stabilised, and in some cases has grown, zoos have lost considerable market share in recent decades. Similarly, attendance at safari parks has plunged since the 1970s when they were very popular. Pleasant weather is generally good news for recreation parks as most of their attractions are outdoors, even though it also increases the popularity of beaches, scenic areas, public monuments and other less expensive leisure pursuits. However, 1994 proved that sunny weather is not at all the best for parks: at least in northern Europe, light cloudy weather seems to be preferred for visits to parks.

Poor economic conditions adversely affect all leisure expenditure, especially the higher priced amusement parks which compete with much cheaper, and often free, competitors such as beaches and scenery. In addition, ancillary expenditure within the "pay-one-price" parks falls during recessions. However, a counterbalancing effect of poor economic conditions is that people tend to skip long distance holidays in favour of short breaks or day trips in the surrounding regions (which increases park attendance).

Traditionally amusement parks were either a day trip attraction or part of an overall package of attractions for visitors at resort destinations, particularly seaside resorts. Factors influencing demand for day trips include: the distance which the customer has to travel; alternatives such as seaside resorts and national monuments; consumer preferences; children's desire to visit a park; climate; and cost. The most important demand determinants are: proximity; fun-rides; little waiting-time; weather; cost; and family atmosphere. Proximity is particularly important. The catchment area of a park is usually considered to lie within a 150-200 kilometres (maximum 2 hours of travel) radius of the park itself. Major theme park developments in recent years have located at non-resort destinations with catchment population as a key determinant. The rule of thumb suggested by the English Tourist Board for a park hoping to attract around 1 million visitors annually is a "two hour drive of 12 million residents or one hour drive of a major holiday destination and also two hours of 5-6 million residents". The private car is by far the most significant mode of transport in this sector and the abolition of border controls in 1993 has increased the willingness of consumers to take day trips outside their own Member State.

More recently, demand has broadened beyond the day trip market. Following the USA example, a number of theme parks are marketing themselves as short break destinations. Short breaks represent major growth areas within the overall tourist market. Helped by EuroDisney's boost to their profile, major European theme parks are exploiting the short break market. For example, De Efteling (NL) has opened a hotel in 1993 and is building self-catering accommodation and a golf course; Alton Towers (UK) is planning hotel accommodation nearby; Europa Park (D) is constructing an Andalucian style hotel in its new Spanish-theme area; and Parc Asterix (F) and Fu-

## MARKET FORCES

### Demand

Consumer demand for recreation parks is volatile. Major factors contributing to this volatility are changing consumer tastes, the weather and economic conditions. Consumer tastes,

**Table 4: Recreation parks**  
**Average admission charges by world region, 1993 (1)**

	General admission charge (ECU)		Parks charging an admission fee (%)	Admission fees as share of gross revenues (%)	Revenues generated per visitor (ECU) (2)
	Child	Adult			
Western Europe	8.2	9.7	87	55	8.9
USA	6.4	8.1	55	35	5.6
Pacific Rim	5.6	9.5	88	38	13.9
Americas	5.5	8.8	48	38	6.5

(1) Covers parks participating in IAAPA survey

(2) Excluding admission price

Source: IAAPA

troscope (F) promote their parks as short break destinations alongside EuroDisney.

The central elements of any amusement park are the number, quality and variety of attractions it offers. These attractions are generally united by a common theme or set of themes. Variety is extremely important as clients vary from young children to adolescents through to senior citizens, and there must be a sufficient range to hold the attention of each group throughout the day. The perception that theme parks are primarily for children is somewhat misplaced, although family groups do form the backbone of demand. The proportion of children to adults varies widely across different parks. Parks are also increasingly attracting groups through organised tours ranging from school trips to business conferences. The average stay at a European park tends to be around 6 hours, although this figure varies widely. In the case of EuroDisney the aim is to provide sufficient attractions to entertain for more than a day and hence attract short break and repeat visitors.

Ancillary factors contributing to visitor satisfaction are becoming increasingly important as tourists become more sophisticated and demanding in relation to quality. These include: landscaping of sites, absence of litter, cleanliness of toilets and other facilities, maintenance of gardens and green areas, simplicity and clarity of information, attitudes and friendliness of staff, and ample provision of rest and picnic areas. EuroDisney's attention to quality factors has put increasing pressure on major European parks to do likewise.

As demographics change and the European population ages, the emphasis is shifting from white-knuckle (meaning frightening) rides towards more family oriented entertainment. Nevertheless, constantly updating rides and attractions with more recent and more thrilling replacements remains the primary, and increasingly costly, method of freshening the appeal of theme parks. The UK industry for example, marketed 1994 as "the year of the roller coaster," highlighting a range of new high profile attractions introduced at various theme parks.

In the USA, but also in Europe, there is an ongoing change which combines entertainment and education through themes such as dinosaurs, simulations such as earthquakes or participative rides such as a traffic school. Customer participation and education are two major themes which zoos have been focusing upon in recent years. As a result, they have become important centres for environmental education, which helps distinguish them from other recreation or theme parks.

European amusement parks experience sharp seasonal variations in demand, although they are still among the most visited of tourist attractions. EuroDisney attracted substantially more visitors than any other attraction in the EU during 1993. Similarly, Alton Towers (UK) and Blackpool Pleasure Beach (UK) were the most visited United Kingdom attractions charging admission and not charging admission, respectively.

### Supply and competition

The number of recreation parks in Europe has increased over the last decade. Indeed, some of the demand for theme parks has been supply driven as evidenced at a macro level by the strong net impact of EuroDisney and at a micro level by the strong promotion of new state-of-the-art rides. However, expansion has not been uniform and amusement parks have enjoyed far greater growth than zoos, aquaria and safari parks. In fact, there have been a small number of closures in the latter subsectors, although their prospects have improved with better marketing and infrastructure improvements, such as restaurants, shops, and, in particular, the presentation of animals. A number of new amusement parks have opened in recent years, especially in France, with most incorporating specific themes. The advent of EuroDisney raised the profile of amusement parks and encouraged better product quality, particularly in presentation. This is especially the case in the United Kingdom, Germany, Denmark and the Benelux countries where

an already high concentration of parks leaves little room for greenfield investment.

Greenfield investment in amusement parks is a relatively high risk activity. The capital costs of investment are high and demand is difficult to predict. Factors which contribute to demand uncertainty include: the specialised nature of the amusement park business, the wide range of lower priced leisure attractions, the seasonality and weather sensitivity of demand, and the varied age profiles of consumers to whom it must appeal. A recent addition to the associated risks is environmental pressure which increases the difficulties and delays in obtaining planning permission.

Reflecting these risks there have been a number of high-profile failures in recent years, the publicised financial difficulties of EuroDisney being the most well known. The operating performance of some of the recently opened French and Dutch parks has been below expectations and a number have closed or changed hands. Part of the problem is that the operation of these parks is seasonal with little consideration in their design for all-weather attractions. Weather proofing amusement parks is very costly. Thus, investments from private sources and from financial institutions have been difficult to attract and may become more difficult for the next few years.

The recreation park sector is both land and capital intensive. In addition to the land required for the recreation park itself, space is required for parking. This has also contributed to environmental problems with greenfield investments. The capital costs of building new parks makes the acquisition and expansion of existing parks more attractive for companies seeking to enter the market or to expand their base of operations. This is already leading to mergers and take-overs with older operators selling out to new theme park owners. For example, the Walibi (B) has expanded considerably in recent years through the acquisition of new parks in France and the Netherlands, the Tussaud (UK) group has grown substantially in the United Kingdom and is now entering the Spanish market, and Lego (UK) is establishing in the United Kingdom. Overall, there is a trend towards consolidation, although the strength and tight ownership control of many parks suggests that consolidation will not reach the levels currently pertaining in the USA.

### Production process

Given the diversity of packages offered to the consumer, the production process varies greatly, depending on the type of park involved. As such there are a wide variety of different ride types, varying from kiddie rides through roller coasters to simulators, live entertainment and mini golf. The majority of parks also rely on return visits, so there is a constant need to update and renew the attractions available. Parks whose main focus is white-knuckle rides and similar attractions are generally obliged to invest in new equipment on a regular basis, usually every two to three years. Another approach is to bring in attractions from other operators for a limited period.

Technological progress will effect major changes in the production process over the remainder of the 1990s. Virtual reality machines, which give participants a heightened sensual awareness of a fantasy environment, represent a potential threat to the industry's current structure. These products are considerably cheaper than conventional rides and, once installed, can be readily changed and developed at a lower cost to the park. This could conceivably lead to more parks being built at a lower cost, or the addition of high quality excitement to attractions offered by smaller parks.

Recreation parks are important employers of both skilled and unskilled workers. Permanent core staff are generally well qualified. They include administrative and marketing staff and skilled workers such as carpenters, painters, electricians, mechanics and specialised designers. In the case of zoos and aquaria the requisite qualifications are even higher. A high

Source: IAAPA

proportion of seasonal staff are, however, relatively unskilled. According to a recent report in the German trade magazine, "Amusement Industrie," the ratio of permanent to seasonal staff is around 1:4 to 1:5. A limited 1993 survey conducted for the Economist Intelligence Unit indicates a variation around a similar ratio. IAAPA estimates for world regions indicates a slightly lower ratio with the average park in its survey employing 265 seasonal staff compared to 84 full-time. Reflecting capital intensity of leisure park operations, the "Amusement Industrie" report suggested that, in 1989, the average capital spent per full-time employee was around 70 000 ECU.

Professionalism and good park management are also very important elements in the overall mix of factors which produce the recreation park service. With increased emphasis on satisfying more demanding and sophisticated customers the need for an appropriately good management response will increase.

## INDUSTRY STRUCTURE

### Companies

In the European recreation parks sector, unlike the USA, comparatively few park owners control more than one park and most companies are family-owned and controlled. However, this is changing. In the United Kingdom, the Tussaud (Pearson), Granada and Gibb groups continue to expand, while in France, investments in the late 1980s were primarily financed and driven by conglomerates of large leisure companies. Elsewhere in Europe, firms expanding through the acquisition of existing parks or through new construction include Walibi (B), Tivoli (DK), Lego (DK) and some of the major USA companies. While Tivoli Gardens (DK) in Copenhagen differs from most theme parks, the company has expanded across Europe using a mixture of more traditional amusement attractions and its original formula, emphasising music and flowers. Tivoli is involved in: a Rhine side Park near Düsseldorf, a Hans Christen Andersen fairy tale theme park in Odense Denmark and a project in Japan.

It is still uncertain whether Europe will follow the USA structure where, although there are a large number of smaller parks, the major theme parks are primarily controlled by four large firms; Disney, Anheuser Busch, KECO, and Six Flags. However, with the North American market regarded as saturated, USA companies are now focusing on Europe. For example, EuroDisney is already in operation with ambitious and well publicised expansion plans. Anheuser Busch (USA) is involved in a joint venture to build a new theme park near Barcelona. Six Flags (USA) is said to be considering a theme park in Marbella in southern Spain, and Time-Warner (USA) plans a major park in Germany. The link between film and other media and the development of parks is noteworthy for firms holding property rights to leisure "icons" (Disney, Paramount, Time, Warner and Universal Studios) which are all becoming involved in the industry.

The availability of European Regional Development Fund (ERDF) money through Structural Funds is boosting investment in smaller scale recreation parks in some areas of the EU. Countries such as Greece, Portugal and Ireland do not have the population density or the required transport infrastructures to justify major theme parks, but have made considerable use of ERDF money to leverage investment for small scale developments. For example, Celtworld in the seaside resort of Tramore in the south of Ireland is regarded as a flagship attraction but is very small in comparison to the major theme parks discussed in this report. The Irish also have provision in their Operational Programme for Tourism for expenditure on "flagship" projects with a theme park as one of the targets.

### Strategies

As with the European tourism market in general, the recreation parks industry is being shaped by advances in communications and changes in consumer tastes. Some of the older recreation park types such as zoos, safari parks and traditional holiday camps have experienced mixed fortunes during the post-war period. These attractions have adapted to changed circumstances and are currently retaining their market share. Many zoos, for example, are currently expanding marketing activities

and enjoying improved visitor numbers as a result. Others have diversified their appeal through the addition of shows and rides, while a number have gone further and re-emerged as full-fledged amusement parks.

At present, most parks are idle throughout the winter; although the increasing popularity of indoor and water-based attractions has widened the possibilities for extending the season. This development is both demand and supply driven. Increased demand for short breaks in the off-season is a recent feature of the tourism sector, coinciding with the aim of park operators to increase levels of utilisation of their investment. In addition to extending the season, some parks have tested the market with Christmas and New Year opening periods. Also, many recreation parks are increasingly turning to the corporate sector to boost demand during off-peak periods.

The advent of EuroDisney and the impact which it is likely to have on raising standards will require investment in software areas such as staff training and presentation formats. Theme parks will need to concentrate on improving the less desirable aspects of their product like: adverse environmental effects, misinformation or confused facts relating to themes and staff attitudes to customers.

### Impact of the Single Market

Overall, the impact of the Single Market to date has been negligible as those measures which would have had the greatest impact on the recreation parks sector remain largely unimplemented. These include fiscal harmonisation, safety regulations and movements towards a single currency. Freer movement of people and goods across borders has helped, in particular in those Member States where crossborder travel to recreation parks is most important - Belgium, France, Germany and the Netherlands - and where the barriers were largely eliminated through the Schengen agreement. Developments

in labour legislation, particularly in relation to atypical workers, is a major concern in the sector as a very substantial proportion of those employed are temporary or part-time workers. Some of the larger park companies have expanded across the EU, but this is more reflective of an overall trend towards international expansion than a direct consequence of the Internal Market programme.

### REGIONAL DISTRIBUTION

While smaller operations are located throughout the EU, larger parks are located in northern Europe near the major population centres. Unlike the USA, European parks are rarely located in traditional holiday areas. However, this is less true of the United Kingdom where traditional resorts such as Blackpool, Margate, Skegness, Southsea and Great Yarmouth all have large recreation parks, while other major parks such as Alton Towers, Thorpe Park and Chessington World of Adventure are located in non-resort sites.

Attempts have been made to capitalise on the more suitable climate of southern Europe, with the development of a number of smaller parks; especially water parks. The use of ERDF money is contributing to such developments. With the exception of EuroDisney, recent and planned major greenfield investments in amusement parks are in southern Member States. Rural areas are also attracting smaller, culture-based theme parks often with relatively less importance on rides and more emphasis on shows or activities with audience participation.

### ENVIRONMENT

The size of most large theme parks and the volumes of car visitors which they attract can have negative environmental

consequences for the areas in which they locate. For large land areas there is a trade-off between sites which impact on residential areas and those which are located in green belt areas and may have an adverse impact on natural habitats, local woodlands etc. Similarly, there may be opposition on the basis that large scale man-made attractions are a blight on the landscape and have detrimental effects on local communities in terms of traffic problems, litter, noise and loss of privacy.

Following EU regulations, such developments require Environmental Impact Assessments, although it is also in the interests of major parks to consider the relationship between their park and the local environment. In a market which is increasingly sensitive to quality and environmental factors, the advantage of a sympathetic landscape in surrounding areas and on approach roads is important. The parks themselves, and their representative organisation, Europarks, are very aware of the adverse impact which heavy reliance on car based visitors can have on the environment. Thus, Europarks has endeavoured to cooperate with national governments to improve accessibility by public transport to their member parks.

While nature themes are common among theme parks in Europe, in particular those which have evolved from zoos or safari parks, strict ecological or environmental themes are not common in major theme parks. This may be an area for future development. This trend is currently visible in the indoor resort sector, with environmental friendliness and harmony with nature being an important feature of Center Parcs' resorts.

Greater concern for the environmental impact of major theme parks, particularly greenfield operations, has pushed outward the time required to move from planning to completion. Extensions of existing theme parks can also be delayed. Indeed, to the extent that some theme parks have evolved through a sequence of smaller planning applications, the environmental problems of sequential increases in the volume of intrusive noise and traffic congestion are greater upon residential areas which were previously unthreatened by the initial small development plans.

## REGULATIONS

All theme parks are the subject of national legislation in relation to safety and local planning laws. As all major parks are also involved in ancillary activities, such as food service, they are subject to relevant legislation in the areas of hygiene, certification by health authorities and, in some cases, licences to sell alcohol. Employment legislation is also particularly important. Developments at the EU level in a number of these areas and in the areas of environmental policy, consumer protection and competition policy are also relevant. In the area of food hygiene, the EU adopted the Directive on the Hygiene of Foodstuffs (93/43 EEC) in June 1993 and Member States are required to incorporate its provisions by January 1996.

Concerning zoos, there exists a Commission proposal for husbandry standards in zoos (COM (91) 0177 final) laying down minimum standards for the accommodation and care of animals in zoos.

EU regulations in relation to employment are viewed as particularly important. The general thrust of EU-based proposals has been to improve conditions of work for employees and, in particular, to equalise the entitlements of part-time and temporary workers with their full-time counterparts. In a number of northern Member States work conditions for recreation park employees are already relatively high and there is little concern about the impact of existing and proposed EU legislation, or the principles of the Social Chapter of the Treaty of Maastricht. However, this is not the case in all Member States, particularly in southern Europe and in the United Kingdom.

The Directive on Package Travel, Package Holidays and Package Tours (90/314/EEC) which came into effect in January 1993, is of considerable relevance to those recreation parks which rely on coach tours and other forms of organised travel. This Directive is also significant to EuroDisney and parks whose expansion plans include addition of accommodation facilities. However, with most recreation parks relying on independently organised day trips the impact of the Package Holiday Directive will not be as far-reaching as it is for hotels, travel agents and tour operators.

Recreation parks are included on the list of products and services which Member States can levy a reduced rate of VAT. French and Belgian theme parks benefit from relatively low rates of VAT, 5.5 % and 6 % respectively, in comparison to competitors in Germany, the Netherlands and the United Kingdom, which are all over 15 %. Rates in Spain, Portugal, Greece and Italy are also relatively low, but their distance from the high VAT northern Member States reduces distortive trade impacts.

Safety regulations are dealt with at state or regional levels, although the EU has considered introducing a Directive in this area. However, Member States such as the Netherlands, France and Belgium generally already follow German standards, particularly in the manufacture of machinery. Thus, reasonably uniform standards already exist in northern Europe. Recreation parks will be affected if the draft Directive on product liability in services, which shifts the burden of proof in "service" liability cases from the consumer to the producer, is adopted. Disputes will arise because it will be up to the supplier of services to ensure that reasonable precautions have been taken to prevent damage or injury to the consumer or his or her property. Another Directive that might influence this sector is the draft Directive on distance selling.

## OUTLOOK

Given the diversity of the recreation parks sector, its prospects for growth are best analysed in terms of its constituent sub-sectors. As suggested above, the outlook for zoos and safari parks has improved, at least in the sense that they are no longer declining rapidly and that operators are coming up with fresh ideas to enhance their products. They are also making good use of ancillary attractions and shows to enhance their appeal. In addition, the combination of environmental education and recreation has stimulated public interest in zoos.

The amusement park market in Europe is generally regarded as not yet mature. Visits to amusement parks per capita in the USA are estimated to be over twice that of Europe. Continued investment in additional facilities by major parks and the building of new parks suggests the industry agrees with this assessment. That EuroDisney's overall impact has, on average, benefited other recreation parks is also supportive of this thesis. Attendances are estimated to have fallen at most parks during 1994 (4 % overall); however, expansion is expected in the medium term. Economic recovery in Europe should also lead to accelerated growth in the short-term.

The cost of admission to parks varies widely across the EU and also differs within Member States, depending on the overall quality of particular theme parks. Pressure on admission prices should be mitigated by further demand growth resulting from a trend increase and the economic recovery. However, encouraged by high admission prices at EuroDisney, some parks will seek to improve their quality and increase their admission prices. Others will maintain or reduce existing prices to provide affordable family entertainment. Almost all parks will seek to increase revenue through ancillary activities.

The overlap between zoos, aquaria, safari parks and theme parks is likely to increase. However, while the trend in recent years has been to expand or re-orient their operations into theme parks, over the medium term, changes are likely to

occur in the other direction. Nature themes in attractions will increase together with the emphasis on education and customer participation. This will be apparent through growth in "shows" featuring animals, more children's zoos and botanical gardens. However, EAZA and its members do not support this trend as they require high husbandry standards for zoological collections. A report on theme parks in the 21st Century in "Parkworld" magazine suggests that as competition for theme park visitors will come from zoos, aquaria and museums, parks will adopt these types of attractions as an integral part of their product. Thus, exhibits of art, live craft demonstrations, dance theatres and other cultural-based attractions will become more common. These changes in emphasis will help attract a greater proportion of older visitors, an important consideration in the EU where family sizes have contracted and the population structure is ageing.

Extending opening hours and incorporating more evening and night time attractions is also likely to become more common as parks tailor their product to suit demographic trends. Reflecting a more sophisticated and demanding consumer, a greater awareness of environmental considerations, landscaping and improved staff attitudes towards customers will occur. While theme parks will increasingly educate as well as entertain, the latter will remain their primary function.

The impact of technology as a key determinant of the future of theme parks is more difficult to envisage. Virtual reality and simulation technologies are increasingly directed at leisure applications, reflecting a fall-off in demand from military sources. These technologies provide experiences which impact through visual, aural, touch and smell sensations, placing "riders" in a "virtual world" where imaginary adventures closely approximate reality. The potential for revamping the appeal of theme parks through improved attractions will expand as new technologies contribute to equally thrilling but cheaper attractions. Some of the existing appeal of the larger theme parks is based on the high capital cost of the most thrilling rides and there is a danger that falling prices, as a result of technological advances, may reduce this competitive advantage. Experimental virtual reality arcades have opened in Japan and North America, while SEGA (USA) has announced plans for 50 such arcades. Smaller and cheaper, but equally exciting, rides will also make it increasingly easy for other leisure emporia such as family entertainment centres (FECs) attached to shopping malls and other recreation centres to incorporate theme park style attractions. Technological developments do raise the threat that the theme park bubble will burst but this is unlikely in the foreseeable future.

# Travel services

## NACE 771

*The emergence from recession of most EU Member States during 1993 and into 1994 provided a welcome turning point for the travel services' branch of the travel and tourism industry (although the effects of recession have been less negative than in most other industries). Recovery in demand for tourist travel is evident and medium term growth will remain strong, driven by an improved international economic environment and increased outbound travel in southern European Member States. As travellers become more sophisticated in their demands, the inclusive tour package (IT) is losing favour to individually tailored products, although this shift in the nature of demand is not leading to any significant bypassing of the travel services sector. The demand for tailored and modular travel products is, on the other hand, leading a number of groups in related services, such as hotels, airlines and ferry companies, to compete with the travel services business more directly than in the past. IT is also leading to growth in acquisitions and mergers as travel service businesses integrate with related services. Cross-border expansion within the EU and into central Europe is also increasing. In both the business and leisure travel markets, value for money is the overriding demand factor, but customers are not prepared to sacrifice quality. On the contrary, quality expectations are rising.*

### INDUSTRY PROFILE

#### Description of the sector

The distinction between the various activities of the travel and tourism industry is often blurred. Operations and activities of the travel services branch are indistinguishable from other related sectors of the industry; e.g. retail travel agencies, tour operators, ground handling services and even car rentals. Since car rental is covered in another monograph, it will only be briefly discussed in this chapter. There is considerable vertical integration in the European travel industry. Hotels, airlines and other transportation companies can and do have their own tour operating subsidiaries, developing either fully inclusive tour packages or partial package arrangements to help fill airline seats or hotel rooms. Travel agencies are being integrated with hotel operations, particularly where the target is the business travel market. In the leisure market, tour operators are increasingly vertically integrated with travel agencies and leisure airlines.

Moreover, the majority of travellers, whether business or leisure, do not use the services of tour operators or travel agents to make their travel arrangements. They either book their transportation directly with airlines and other suppliers, or travel by private car; the dominant mode of transportation in Europe. A significant share of hotel and other accommodation reservations are also made directly. In addition, other organisations provide part of the services available from companies in the travel services' branch. These include motoring associations, tourist offices and non-profit bodies, such as trade unions, clubs, company staff associations and media groups. In some EU states, there are "social tourism" organisations which provide low cost holidays.

Difficulties in evaluating the core sector activities are compounded by the fact that many companies do not release operating figures, let alone consolidated results. The level of disclosure is improving, although comparisons should still be treated with caution because of underlying differences in accounting principles. Figures on the number of packages sold, of passengers, tickets issued or volume of sales, number of employees or number of agency outlets are all sometimes

used as measures of the level of activity, but all have shortcomings. For example, passenger figures in relation to travel agency sales cannot be readily equated with the number of holidays sold by travel agents, since the real value of the agent's sale is only the commission. Employment poses further problems, since employment in the tour operating and ground handling service sectors is highly seasonal and, therefore, fluctuates widely with no common conversion factors for part-time to full-time jobs.

The distinction between business and leisure travellers has always been difficult to identify and is becoming increasingly muted with the disappearance of border controls. Balance of payments data are generally used to measure the currency flows generated by travel and tourism, but provide an inaccurate measure since data collection methodology and analysis vary widely from country to country. With ongoing liberalisation of exchange controls, it is even less useful.

Profiles of the leading travel and tourism groups in the travel services sector illustrates that the industry is not built on a combination of the three sectors (tour operating, retail travel and ground handling) nor even with an emphasis on one or two of them. In fact, only one of the top ten groups in the industry, in the EU, is wholly focused on this sector. On a Member State basis the density of travel agencies is highest in Germany and lowest in France.

#### Recent trends

According to some estimates, in 1993 half of outbound trips involved some kind of booking through the travel trade. About 25 % were fully inclusive tour packages (ITs), usually off-the-shelf programmes developed by tour operators and 23 % were trips involving either part package arrangements, transportation and/or accommodation booked through a retail travel agent. An additional 18 % were arrangements for transportation or accommodation booked directly with suppliers. The remainder were fully independent trips with no pre-booked arrangements.

Relative market share varies widely but, in general, the share of fully inclusive package tour arrangements has been declining since the late-1980s; in favour of partly booked trips. However, this trend appears to have been arrested. The Mediterranean Member States are regaining market share, as are inclusive package tour holidays. The major reason for this has been the devaluation of both the Spanish peseta and of the Italian lira, which had a significant impact on sales of tour packages to these destinations. Also, this could well be a blip in long-term trends as people return to tried and tested destinations closer to home in times of economic recession, rather than further afield for their holidays.

Airline ticket sales channelled through IATA's (International Air Transport Organisation) Bank Settlement Plan (BSP) also provide an indication of the use of travel agents. The net sales volume of airline tickets issued by the BSP around the world in 1993 was 49.5 billion ECU. In Europe countries generating the highest sales volume through BSP were the United Kingdom and Germany. The decision by IATA to broaden the customer base of the BSPs and to encourage participation by other travel industry service suppliers such as railways, shipping lines, car rental companies, etc. means the figures are not totally reflective of travel agency sales alone.

European Community Travel Agency Association (ECTAA) data on turnover in travel agencies and tour operating enterprises, indicates that turnover was highest in Denmark and Germany between 1991 and 1993, while turnover in Belgium, the Netherlands and United Kingdom declined. Given the stagnant demand in the travel services industry the results cast some doubt on year to year consistency, possibly arising from changes in membership of national associations.

Data on travel agency operations do not always distinguish between wholesaling and retailing activities. Figures released by ECTAA indicate that the retail travel agency sector is slowly expanding, although the trend in some Member States suggests inconsistencies in year to year figures.

Analysis of travel agency sales of airline tickets indicates growth both in the value and the number of locations in the majority of EU Member States. The apparent increase in the number of travel agencies has been accompanied by growth in employment in some Member States. Again, however, inconsistencies in the data and their variance from trends in overall tourist and business travel demand in recent years suggest institutional and organisational changes may be responsible for the some of the trends.

The economic uncertainties, and associated loss of consumer confidence, which marked 1991 and 1992 started to dissipate in 1993 and are being virtually eradicated in 1994. World-wide, 1993 was a relatively successful year for the travel and tourism industry with international arrivals up 4 %, and tourism receipts up 9 %, on 1992. However, performance varied sharply from one market and one destination to another and growth was not as evident in Europe throughout 1993, although demand for travel started to pick-up in the latter stages of the year. While the leisure market sector recovered in the United Kingdom and is reviving in mainland Europe, it was still a difficult year for the industry given low yields and the loss of buying power in major source markets. However, 1994 is providing the turning point the industry had hoped for.

While leisure travel has grown, greater confidence in the economic outlook has not fully translated to resurgent business travel demand. A continuing excess of airline seat capacity made pricing competitive and has flowed back into some increase in demand for travel services. Indications from the travel trade suggest that businesses are reducing trip duration's, sometimes to day-return trips to save on costs. A "book your own" trend is emerging in some large corporations, while more stringent travel budgeting policies are being introduced in others and altered arrangements with travel agents such as a management fee approach are cutting business travel costs and travel service commissions.

## International comparison

Europe attracted 59.3 % of world-wide international visitor arrivals in 1993, or 296.5 million, up 2 % on 1992. International tourist receipts rose by 6 % over the same period to 139 billion ECU, equivalent to 50 % of the world total. EU countries recorded a fall in receipts and in guest nights. EFTA countries, in contrast, showed modest rises in both receipts and guest nights but a slight fall in international arrivals. While East Europe showed strong increases in arrivals and overnight stays, receipts stagnated.

Despite continued growth in arrivals and revenues, Europe's relative share of world tourism has been declining since the early 1960s. While data from the World Tourism Organisation (WTO) indicates that western Europe's share rose between 1980 and 1985, it fell back rapidly over the latter half of the decade. In the 1990s, Europe's share of international arrivals and receipts continues to fall steadily. The main reason for the decline in the EU market share is the rapid increase in tourism from the pacific region, which inevitably benefits that region more than the more distant Europe.

## MARKET FORCES

### Demand

Final consumers of travel service products are those who take holidays, visit friends and relatives or who travel on business (although there can be intermediaries, such as clubs and associations, or corporations).

Each year 60 % of Europeans take at least one trip a year away from home. The level of trip-taking varies widely from country to country, ranging from as high as 87 % in Iceland to 51 % in Portugal, and still lower in the countries of East Europe. The proportion of Europeans who take a leisure or business trip abroad (inter-EU) tends to be considerably lower. The average share of all Europeans who travel abroad is around 26 %, although the level of travel abroad is actually higher than domestic travel in some markets, notably Belgium, Luxembourg, the Netherlands and Germany. Domestic travel tends to decline in favour of foreign travel as the market becomes more travel experienced.

Source: ECTAA

The level of trip-taking is very much affected by income, age, education and social status. When incomes rise travelling tends not to be limited to just one trip per year. In addition, business travel is usually much more frequent than leisure travel. In the less mature European markets, the cost of travel is also an important deterrent to foreign holidays, especially for markets located great distances from popular holiday destinations, like Greece and Portugal.

Most business travellers use the services of the travel trade, at least for airline travel, though it is fairly common for corporations to deal directly with hotel chains when they can get a better deal for room accommodation, and with the railways and car rental companies for ground transportation. New technology is opening up the tourism industry, as well as improving communications. This has both negative and positive effects. As it becomes easier for people to book their own travel directly with airlines, hotels and other suppliers the impact on travel service firms is generally negative. Access via-Minitel-type systems not only to airline reservations but also to hotel accommodation and increasing applications for "smart cards" are examples of how technology facilitates access for consumers. Video-conferencing and at-airport automated ticket issue are other technology-driven innovations which impact negatively on the sector. Examples of positive impacts of technological developments include: travel agents are better able to respond to the increasing demand for tailor-made products; multimedia presentations enhance sales promotions; in-agency terminals for customers to buy their own tickets improve efficiency; and CRS developments enable the issue of immediate tickets, rather than vouchers, for entertainment events. While dedicated software enables access to information on travel and accommodation only travel agents and airlines can issue tickets. This has helped maintain the role of travel agents in the face of technological developments but, in the medium term, there may be pressure for allowing large corporations access to blank tickets.

Use of a travel agent depends heavily on how clients plan to travel, what type of accommodation they will use and whether they speak the language and/or are familiar with the destination country. The majority of domestic holidays bypass the travel services branch completely, with people travelling by car to their destination and staying with family, friends, in their own or rented holiday accommodation.

The crucial variables affecting demand for travel and for travel services are price, security, health standards and economic trends. The on-going economic recovery through the EU will crucially influence both expenditure and destination choice over the next few years. The different taxes on travel, notably

on air travel, and exchange rate fluctuations are also important influences.

Increased airline liberalisation theoretically allows greater access to markets by a greater number of carriers and should put downward pressure on fares. However, on many routes it is difficult to see fares falling substantially. The increasing liberalisation of air transport in Europe has been reflected in sharp passenger traffic growth since the mid 1980s. The effects of this growth, and the competitive fares which helped drive it, are apparent in the financial strain on some airlines and in delays at airports. Current indications are that flight delays are reducing, a trend helped by major airport upgrades and increased capacity.

Health risks and environmental damage are also examples of factors affecting tourism demand. There have been increasing concerns over dirty beaches and polluted bathing waters in the Mediterranean and other popular tourist resort areas. Some travellers (particularly in Germany, where environmental sensitivity is high) have shunned tour operators and destinations that have received bad publicity over their environmental record. High investment in water and sanitary services in Mediterranean Member States (co-financed by the EU's Structural Funds and the Cohesion Fund) is improving matters. The importance of "quality" factors in general and the environment in particular has increased considerably in recent years.

A wide range of new products and programmes have been introduced on the market over the last few years in Europe. These have helped to stimulate travel and tourism to less developed regions and to encourage a better off-season utilisation of facilities. However, most new products are targeted at people who already travel at least once a year away from home for holidays or other leisure purposes. Few have addressed the issue of people not travelling at all and the proportion of Europe's population that does not travel has changed very little. Fast growth in short breaks, trips of one to three nights, evident in the late 1980s slowed during the early 1990s. This reflects the impact of the economic downturn and a cut back on travel frequency and concentration on main annual holidays. However, there are signs of a pick-up in this market in 1994. The bulk of short break travel does not use the travel services' branch, but there has been strong growth in the commercial sector. Tour operators, airlines and hotel groups have all launched their own programmes. Rural and urban tourism have also registered above average growth in the last couple of years, both in domestic and international markets. In general, travellers are becoming more adventurous and activity oriented.

### Supply and competition

Supply is in general more than adequate to meet demand. The suppliers of the travel and tourism industry, e.g. airlines, hotels, etc., are cyclical industries and this can have repercussions on the availability of seats and rooms, particularly at peak seasons. Consumers are in a buyer's market and this is reflected in price-setting and margins.

Demand for travel services is met by tour operators and/or retail travel agents. Travel services can cover a wide range of products, not just transportation tickets and hotel reservations. Car rental, theatre and restaurant bookings, visas, the provision of travellers' cheques, travel insurance and foreign currency are all part of the package of services offered. Car rental bookings may be handled by travel agents or directly by suppliers. There is an increasing trend for major tour operators to have a preferential relationship with a single car rental company. The tour operator is effectively a wholesaler combining travel, accommodation and ground handling services in a single package. The increasing independence and sophistication of leisure travellers are reflected in the product range. There are also increasing expectations for these services, in terms of price advantages and quality. For corporate travellers, travel service firms also handle demand for travel to conferences, trade exhibitions and fairs, and incentive travel.

The travel and tourism industry is highly price sensitive in most EU states, though this appears to be less true in countries where the industry is more fragmented. Price/quality trade-offs are also not the same for all groups and all nationalities. Pressure on prices comes from the nature of the demand, but also from the nature of the production process. The industry gains pricing advantages from bulk buying. But, it has to ensure that once it has factored in its own operational costs, staffing, catalogue production, advertising, computer reservation systems, and travel agents' commissions the end result is a product which is still competitive with the product the consumer could put together on their own.

The conventional travel agency faces competition not only from new entrants, such as hotel chains and airlines, but also from tour operators who sell direct (by mail) and from clubs and associations acting as travel organisers where local legislation allows. These have been sources of competition for some time. As consumer knowledge of travel increases - and need for travel agency advice decreases, selling by mail order firms and through supermarkets is increasing.

Foreign competition is not really an issue, although there are an increasing number of examples of tour operators establishing themselves in the traveller's destination country. The Japanese in Europe are one example. Asian airlines have also introduced competitively priced products in European markets to their own destinations, but these are not a major source of competition.

There is an attempt by all operators to keep price increases to a minimum in a highly competitive market. They achieve this through bulk buying of seats and rooms, in some cases, owning several stages in the production process; and, by switching more capacity to, and promoting more heavily, lower cost destinations.

Vertical integration is particularly marked in the United Kingdom and Germany, but is found in all the other major countries as well. In the United Kingdom integration among the largest companies involves travel retailing, tour operating and leisure airline operation. In Germany, there are two models: travel retailing, tour operating and hotel operation or these three together plus airline operation. In France, these models co-exist with the retail travel and hotels model adopted by Accor and its strategic ally, Carlson (USA).

The United Kingdom and Germany are the only countries where the competition authorities have paid any consistent attention to the tourist industry. Concerns about the build-up of dominant positions by the major players have become a constraint on expansion in Germany. Exclusive distribution arrangements between tour operators and travel agents, which had been the subject of Cartel Office and court scrutiny, ceased in late 1994.

In the United Kingdom, on the other hand, no merger in this sector has ever been turned down or constrained, even though the market shares of the largest players are greater than those of any other European operator. The Office of Fair Trading in the UK looked at vertical integration of tour operators and travel agencies in 1993/94 and concluded that there were no grounds for concern. As of late 1994, it appeared this finding would be appealed to European Union authorities by smaller operators and agents.

### Production process

The main capital employed is access to computerised reservation systems (CRS), except in cases where the travel company owns its own aircraft or accommodation. The cost of

these can range from a few thousand ECU to tens of millions, depending on the solution adopted. There is constant pressure to upgrade technology. Leading operators aim to provide real time connections with the consumer through travel agents (or their own sales outlets) with instant confirmation of bookings. In addition to the costs of CRS access, hardware costs and expenses for dedicated data lines, travel agencies in some Member States also require substantial finance for government "loading" schemes.

Investment in automation from the outset is essential, but relative to other industries the cost of tooling-up is still low and many start-up operations are run single-handed. Thus, barriers to entry are low in the travel services industry. Overall the industry is labour intensive despite the increasing need for large groups to invest heavily in computerisation. Franchising is increasingly being adopted by retail travel agents to minimise the cost of expansion.

Where travel services spill over into other sectors, they become more capital intensive. This is true where travel service providers enter the hotel/hospitality industry which requires investment in land and buildings (though here too franchising is growing). In addition, hotel sector operations are increasingly capital-intensive with, in extreme cases, fully automated check-in and staff on duty only a few hours a day at some budget hotels.

When tour operators become their own transport operators, particularly in aviation, the industry becomes capital intensive and the needs of the airline often dominate the strategy of the tour operator.

The industry requires a range of technical skills. These vary across the sector from familiarity with the information technology applications for counter staff through to language skills for tour representatives in destination markets. Customer care skills are required throughout the sector, while quality management is as crucial as in other industries. The industry attracts labour because of its glamorous image and the perceived possibility of free or low cost foreign travel. Labour turnover tends to be high as this perception is not realised, or the realisation is not sufficient to compensate for the disadvantages of the job. Major travel agencies train their own staff, however much training is either on the job, through familiarisation trips to destinations or on courses run by tour operators. There is, however, a growing recognition of the need for higher standards of service, and several initiatives are being undertaken by tourism training establishments, national tourist of-

fices and the EU to raise awareness of the issue and to provide more comprehensive customer-orientated training programmes.

Product innovation in the business travel sector takes the form of products which, above all, improve comfort, speed of service and of travel, and flexibility at competitive prices. One significant development in the industry in the last five years has been the formation of networks among business travel specialists as an alternative route to international expansion. EU travel agents are prominent members of these. Among these are Business Travel International (BTI), Internet, Global Travel Management, First Travel Management International, the Woodside Travel Trust and World Independent Network (WIN).

Innovations in the leisure sector product (through tour operators and travel agencies) are broadly similar, i.e. improvements in relative levels of comfort, speed of service and travel and of flexibility, although leisure travellers are more willing to trade these off for the sake of a competitive price. There is constant innovation through the addition of new accommodation, new destinations and new products, such as short breaks, one-day plane trips, new theme parks, sporting and cultural events. Similar product innovation approaches apply to the incentive and conference segments of the business travel market. Frequent flyer programmes for business travellers, air mile programmes for business and leisure travellers, tour operator-issued credit cards and credit facilities for leisure travellers are all product innovations which are growing in importance.

## INDUSTRY STRUCTURE

### Companies

There are no composite figures on the turnover of the travel services branch, nor on employment or number of companies. It is clear, however, that the sector is growing in the EU as a whole. Recession is now receding. This was felt in 1993 and again in a strong recovery (in part exchange-rate induced), in major destination markets, such as Italy and Spain, in the summer of 1994. Growth in outbound leisure travel from these two countries and from the former East Germany, all of which are emerging outbound origins, has contributed to the EU-wide expansion. Expansion into central Europe, particularly by German and French travel service firms, has also contributed significantly to the industry's growth. A further factor in ex-

(1) Estimate  
Source: ECTAA

pansion is the recovery in business travel as economies pick up. However, the corporate travel market has become more price-sensitive and has been trading down to economy air fares and less luxurious accommodation.

Travel agencies and many tour operators are members of trade associations, but travel agency membership may be by branch or by parent company, so the figures are not homogenous. The EU travel agents' association, ECTAA, is formed by national associations. The European Tour Operators Association (ETOA) represents mainly inbound interests, and the International Federation of Tour Operators (IFTO), represents entirely outbound interests.

There has been a marked concentration at the top of the European travel and tourism industry in the last five years. The pace of mergers and acquisitions has been rapid in virtually every EU country and cross-border acquisitions are on the increase. Over the last decade, there has been a clear move in the retail travel industry to regard leisure and business travel as separate markets and for companies to handle either one or the other. Major developments in 1993 and 1994 (first nine months) included: acquisition of a significant stake in TUI (D) by the WestLB bank which is the majority shareholder in LTU (D), Thomas Cook and a significant shareholder in First Choice (UK); restructuring of DER's (D) holdings in the ABR and Rominger travel agencies to make it one agency and to give it a greater stake in TUI; the forging of a retail travel alliance between Wagonlits, part of the Accor Group (F), and Carlson the largest US retail travel agency; the takeover of SAS Leisure (S), the number three Scandinavian travel business, by Airtours (UK); and, the sale of the business travel divisions of Thomas Cook to American Express (US).

Concentration has not necessarily meant increased concentration in individual national market segments. Frequently, it is the result of creating an integrated business. The response of middle-level and niche players to this concentration, increasing vertical integration and strategic alliances has been to explore forms of cooperation, e.g. franchising, trademark licensing, pooled purchasing or European interest groupings. Their goal is to retain their independence but still achieve economies of scale. The international networks of the business travel companies are a similar response to the global challenge of the largest international groups.

The leading companies generally sell all types of travel, subject to their chosen specialisation in business or leisure. But there are a number of specialists in the middle reaches of the industry selling solely to specific markets; e.g. 55-plus age group, young people and students, religious travel, long haul destinations, short breaks or cultural travel. There are also a number

of non-profit organisations which are significant players in package travel. The largest of these is Villages Vacances Familiales (VVF) in France. Others are the Deutsches Familienwerk in Germany, Loisirs et Vacances in Belgium and IGS in Spain.

A number of the major travel companies are directly or ultimately owned or controlled by public sector enterprises. The largest are DER (owned by the German railways), the DSB travel agency chain (owned by the Danish railways) and CIT in Italy (owned by the Italian Railways). As most European airlines are still state-controlled, the public sector ultimately has an interest in leisure tourism through these as well. Air France (F), Iberia (E), Lufthansa (D), Sabena (B), Luxair (L), Olympic (GR) TAP (P) and Alitalia (I) all have significant tour operating interests and/or travel agency interests. The picture of who chooses to invest in this sector of the industry is also varied. TUI is controlled by a group of travel agencies (including DER); Wagonlits is owned by a hotel group (Accor); Thomson and Havas Tourisme are owned by media-related operations; and NUR is owned by retailing chain Karstadt (which also has its own travel agency chain). In addition, ITS is owned by the retailer Kaufhof and Hotelplan is owned by the retailer Migros. Retailers find synergies through the travel agency side of the tourism business. Publicly-quoted companies are few, with Club Méditerranée, Airtours and First Choice.

### Strategies

With the relatively constant pattern of concentration, there has been considerable change at the top in the travel service industry over the last five years. This has largely been as a result of acquisitions, many of them cross-border. Viajes El Corte Ingles is the only company in the top twenty not to have made a major acquisition nor to have had any significant change in its shareholder make-up or strike a material strategic alliance over the last decade. There has been no consensus on strategies, however. Of the top 20 travel and tourism companies in Table 7, nineteen combine tour operating and retail travel agency businesses. But, the relative emphasis placed on one or the other varies. For some companies, the two arms do not work as an integrated structure in which one supports the other. A second emerging trend is to work through a combination of owned agencies or 50 %-owned agencies with an owner-manager and/or franchising. The strategy is even more varied when it comes to hotel and airline ownership. Eleven of the top twenty have an airline as an integral part of their operation or have a shareholder connection. Thirteen own destination hotels on a significant scale.

Source: European Travel Commission

Outside of Germany and southern Europe, growth in the domestic markets of the leading companies has been slowing, particularly for tour operators. This has only been partially compensated for by an increase in the number of short-break holidays. The slowdown has been both in growth in tourism numbers and in spending. Both business and leisure travellers have become more cost-conscious and sales figures are also under pressure from price competition. Consequently, companies are seeking productivity gains, opportunities in the growth markets, particularly Spain, and synergies in neighbouring markets or markets with a cultural or linguistic affinity. This is true of German companies in Benelux, Austria and the rest of central Europe; of French companies moving into Spain (in particular Wagonlit through the strengthening of its position in Viajes Ecuador); of Belgian companies operating in France, the Netherlands and the United Kingdom; Dutch companies moving into Belgium; United Kingdom companies crossing the channel, the North and Irish Seas; and, the leading Spanish company exploiting the synergies of being a major destination for United Kingdom and Irish tourists by operating out of the United Kingdom and Irish leisure markets.

In Italy, on the other hand, successful expansion has essentially been organic and domestic-based, with fresh injections of capital coming from domestic sources. However, even though north European firms have been moving south, several firms in south Europe have been expanding so rapidly that they seem likely to number among the leading European companies in the near future. Grupo Viajes Iberia of Spain and Alpitour of Italy are among them. The industry remains dominated by European companies. American Express is the key exception to the rule.

The vertical and horizontal integration which characterises the travel services sector has been ongoing for nearly a decade and has accelerated over the last five years. That a number of companies are operating as tour operators, retail travel agencies and ground handling agents (inbound operators) in a number of Member States highlights the fact that regulation is not a barrier to entry. However, a key difficulty facing cross-border expansion is cultural barriers which complicate the transplanting of the travel product between some Member States. Local preferences to be considered are: language, tastes in food, eating hours, accommodation standard and type, transport mix and quality. These are highly variable from country to country. Significantly, travel agencies, who allow the consumer to select their product, have expanded across EU borders much faster than tour operators.

### Impact of the Single Market

The Package Travel Directive is the single piece of legislation that had the most impact on the operating environment for travel services. A globally positive assessment of the creation of the Single Market on the travel services sector is, however, partly offset by difficulties in selling travel packages to consumers outside the EU who are worried about the compliance costs of consumer protection legislation. On the other hand, transport liberalisation, both for air and for coach travel and

the free movement of people, have been beneficial to this sector. Further dismantling of barriers in this area is seen as a priority.

Surviving differences in VAT rates are felt to be a source of distortion. High levels of indirect taxation, not just VAT but also local taxes on tourism, are seen as negative incentives stifling the development of the industry, while zero-rating of export sales favours non-EU destinations. A single currency would be very beneficial not just for the operators but for their customers.

Future priorities include a level playing field for airlines, (i.e. close scrutiny of state aids), dismantling of restrictive practices affecting the industry, (e.g. in ground handling at airports), hotel safety and infrastructure improvements allied with an environmentally sound approach.

### REGIONAL DISTRIBUTION

Travel agencies are invariably located in urban areas, both small and large but with a higher density in larger cities. On the other hand, inbound tour operators are generally found in major cities, while ground handling operations tend to be located at gateway cities and major tourist resorts.

Many of the medium sized firms only have a regional catchment area. Specialists in some segments, such as coach holidays, can operate profitably from a local base. The products of the industry are available throughout the EU. Although there are areas where the density of travel agencies is lower, this is not a major issue. Many tour operator products are available by mail and bookings can be made directly by phone and through view data systems. This method of distribution is especially popular in France and is expected to become more widespread as view data ownership expands throughout the EU.

### ENVIRONMENT

There is evidence that consumers are becoming increasingly sensitive to the impact of travel and tourism on the environment, although this is not yet true in all countries. In Germany, where the package travel markets are well developed and consumers are particularly eco-conscious, it is now common for large companies to appoint executives responsible for environmental policy and for monitoring of the destination hotels' energy conservation and environmental practices. Hotels which do not comply with basic minimum standards can be struck off a tour operator's hotel listing. In addition, the pressure on a number of Mediterranean resorts to improve their ancillary services and infra-structure represented a mixture of direct pressure from stagnating demand and encouragement from tour operators.

Although travellers are more aware of the impact of tourism on the destinations they visit, this has not yet translated into apparent concern over the type of transportation chosen to

travel on holiday. Tour operators may also supply clients with guidelines on preserving and protecting the local environment at holiday destinations.

Major tour operators also work behind the scenes, particularly in developing countries, to help local authorities plan sustainable resort development. Thomson has also been heavily involved in encouraging the restructuring of some of the Balearic islands' mature resorts. IFTO is involved in the ECO-MOST project, which aims at developing sustainable tourism. The main regulatory pressures inside the EU come from environmental impact assessment or land use requirements for tourism developments. Regulations on night flying also affect the industry.

Trade associations are also becoming increasingly active in the environmental field. The new Green Globe concept launched during 1994 by the WTTC (World Travel and Tourism Council) has already attracted widespread support from industry associations and tourism companies. It will provide a universally recognised insignia displayed by tourism enterprises in all industry sectors which become part of the scheme. The aim of the scheme is to raise awareness of environmental issues and to provide advice and training.

## REGULATIONS

There are major regulatory differences in areas such as consumer protection, conditions of market access, competition

policy, availability of state aid, and attitudes to monopolies and mergers. The EU is addressing a number of these issues through the Directive on Package Travel, Package Holidays and Package Tours (90/314/EEC). This Directive came into force on January 1, 1993, but its impact was only starting to make itself felt in 1994. The effects will impact EU companies differently, reflecting variation in national laws prior to implementation. The Directive is intended as a start towards harmonising the varying national situations, while leaving the Member States discretion in the implementation process.

Other potentially important issues are the future of duty-free sales on intra-EU flights and ships and the imposition of VAT on the industry's products. Implementation of the former has been postponed until July 1999. It is still not clear what the eventual outcome will be in relation to indirect taxes, in particular in relation to VAT on intra-EU travel. Airline deregulation/liberalisation has a potentially beneficial impact, at least in theory. However, practical problems exist including the weak financial position of many of Europe's major airlines. An array of other regulations ranging from environmental limits on resort developments to other aspects of transport policy also have implications for the travel trade and are discussed more fully in the overview chapter.

As a result of the diversity of the tourism industry, a wide range of EU directives and regulations, including many which are not specifically tourism-orientated, affect day-to-day operations of companies. These include technical specifications (e.g. CO<sub>2</sub> emissions), consumer legislation, transport policy, social legislation, indirect taxation, etc.

## OUTLOOK

The average holidaymaker's yearning for sunshine and an inexpensive vacation will ensure the traditional Mediterranean resorts continue to top the popularity lists. Yet the two- to three-week inclusive package holiday (IT) geared to lying on a beach in the sun will not be enough to satisfy the market's increasingly sophisticated demands. This holiday will have its place, provided destinations remain abreast of demands for higher quality, greater environmental awareness and flanking attractions and activities. Recognising changing tastes, many traditional resort areas have restructured and re-packaged their product and this investment will have to continue, indeed accelerate. Rural tourism will be a major beneficiary of the search for new and less crowded destinations and for self-catering rather than all-inclusive holidays. The increasing demand for self-catering holidays reflects both growing independence on the part of the average holidaymaker and a way of keeping down costs.

IT sales to the EU leisure traveller will continue to grow through the addition of new destinations and through strong growth in long-haul destinations, city breaks and travel by the 55-plus age group. The ageing of the population in most EU member states will have a significant impact on travel demand, particularly in countries where this market segment already has the holiday habit. Some of the greatest changes in the market are likely to be not so much demographic as psychological in nature. Personal values, such as having fun, relaxation and self-fulfilment, are becoming more important. New products and programmes introduced in response to changing demographics, social patterns and tastes may stimulate travel to less developed regions and encourage better off-season utilisation of facilities. Member States, helped by the European Regional Development Fund (ERDF) and European Agriculture Guarantee and Guidance Fund (EAGGF) incentives, are increasingly developing the tourism potential of non-traditional tourism areas.

Choice of destination will also be influenced by capacity restraints and bottlenecks in destination countries and on transport routes. This will be mitigated to some extent by pricing,

which encourages travellers to take their trip off-season, and by major infrastructure projects, such as the Channel Tunnel and the Trans-European Networks. A constraint will arise in some destinations from fears about capacity in terms of environmental impact and local population reaction. There will also be a trend on the part of these destinations to target only high yield visitors.

Increasing leisure time, due to a shorter work week, more part-time employment and more flexible working hours, will stimulate demand for travel and use of the travel services' sector. Increased traffic through Europe's regional airports shows that air travel is finally starting to filter down to the masses. However, there is still an estimated 40 % of Europeans who do not travel at all. A significant share of non-travellers probably would like to travel if there were no economic or timetable constraints. A number of new products need to be developed and measures taken, either by local or national governments, to stimulate this sector of the population. There is, however, a potential conflict between this objective and environmental considerations.

The future success of individual companies in the sector will depend largely on their ability to meet the need for new products, as well as changing demands from increasingly sophisticated European travellers. This, in turn, is likely to be linked to their ability to stay ahead of technological developments in the field and strengthen their presence throughout the EU by acquisitions, mergers and other collaborative ventures. Concentration within the industry will continue in order to achieve economies of scale and to exploit air traffic deregulation to the maximum. The division between business and leisure travel specialisation will accentuate. Small and medium-sized businesses will concentrate on niche markets and alliances with

like-minded businesses both horizontally and vertically, developing distinct market positions based on service and market knowledge rather than price. Business travellers and, in particular, corporate travel departments will also become more discerning in a search to cut costs. Some will look at bypassing travel agencies and dealing directly with suppliers. They will also make increasing use of non-travel alternatives, e.g. video-conferencing, e-mail and voice mail. Greater scrutiny of traditional forms of business travel will, to some extent, be compensated for by the growing globalisation of business and growth in incentive travel.

Market demand is becoming more difficult for the travel services sector to meet. Well-informed travellers seeking greater value for money, more variety and greater flexibility expect travel agents to improve on what they can package themselves. Technological advancements are increasingly enabling consumers to bypass travel agents and book their holidays directly with airlines or large suppliers of tourism services.

Growth in 1994 was quite strong as EU countries began to emerge out of recession. Ongoing strengthening of the international economic environment during 1995 will lead to further growth in tourism expenditure in the medium-term. Overall, average annual growth of 4 % in turnover is expected over the 1994-98 period. Employment growth will be somewhat lower, because like other tourism sectors travel service workers are poorly paid, and new inducements to retain and attract quality staff are required.

## Overview

### NACE 7

The transport sector faces good medium term prospects due to the progressive recovery of European economies. Increasing European integration will lead to more interaction between the economies of the Member States and thus to more demand for transport services. Common policies for transport will help create and maintain a competitive environment, but at the same time will encourage an increasing number of merger and alliances as firms strive to maintain their competitive positions. Expansion of various networks is continuing but large investments are still required to alleviate congestion problems in some major corridors. These investments, provided that they actually materialise, will create the conditions and opportunities for integration, a modal shift and the emergence of new services, including value added services based on transport telematics. In the short term, however, growth in transport will continue to be unbalanced as road will continue to gain market shares at the expense of other inland transport modes, both for passengers and freight.

## INDUSTRY PROFILE

### Description of the sector

The transport services industry is primarily engaged in the conveyance of goods and passengers either directly or indirectly. Direct involvement relates to the actual conveyance of goods and passengers by various modes of transport. Indirect involvement relates to such services as handling when changing modes, traffic guidance, travel arrangement, freight brokerage, storage, etc.

NACE 7, the transport and communications industry, comprises the following two-digit classes:

- NACE 71: railway transport;
- NACE 72: other land transport, including urban transport, road transport and pipeline transport;

- NACE 73: inland waterway transport;
- NACE 74: sea transport and coastal shipping;
- NACE 75: air transport;
- NACE 76: supporting services to transport, including inland waterway ports, sea ports and airports;
- NACE 77: travel agents, freight brokers, storage and warehousing;
- NACE 79: communications, including postal and telecommunication services.

Note that it is important to distinguish statistics related to the transport industry (e.g. value added or employment) from statistics related to transport traffic (generally measured in tonne/km or passenger/km). Statistics related to the transport industry capture transport services marketed to third parties but generally exclude transport services produced by economic units for their own consumption. By contrast, statistics measuring transport traffic in physical units usually cover both types of activity. In the case of road transport, own account is far from negligible. For example, companies active in manufacturing regularly transport on their own account, as they do not want to rely on external transport services and own account represents about a third of road freight traffic in tonne/km. Similarly, in family households, the use of the private car is not in itself an economic activity but it accounts for about 80 % of total EU passenger traffic in passenger/km.

Consequently, the interpretation of statistics can sometimes lead to paradoxical results, and the problem should be kept in mind.

Of the subsector telecommunications and postal services (NACE 79), only postal and express services are covered in this chapter, telecommunications being covered in another chapter. However, statistics on communications provided in this monograph cover telecommunications as well and postal and express services.

### Recent trends

Total gross value added at market prices generated by the EU transport industry amounted to 212 billion ECU in 1992, which is 4.1 % of EU GDP (communications and own account transport not included). This share has remained relatively stable since the early 1980s. In real terms, annual growth in value added has averaged 2.5 % since the beginning of the 1980s, which is slightly faster than growth in real GDP (2.3 %). Spurred by progressive liberalisation and the completion of the Internal Market, the sector experienced particularly fast growth during the late 1980s. The situation deteriorated progressively in the early 1990s, reaching a bottom in 1993 with a slight decrease in real production.

Depending on geographical factors, but also on structural factors such as the degree of liberalisation or the share of own account, the importance of the transport sector varies considerably by Member State (Table 2). In Germany, Spain, France, Ireland and Portugal transport's share of GDP is below the EU average, whilst for Belgium, the Netherlands, Denmark and Greece the share in national GDP is substantially larger than the EU average.

Turning to employment, the transport services sector accounted for 4.3 % of the EU labour force in 1992, which represents slightly more than 6 million jobs. In addition, employment in telecom and postal services totalled 2.4 million. Employment in transport services increased moderately during most of the late 1980s and early 1990s, but this progression owes much to the rapid growth in value added observed over the period which more than outweighed sustained productivity gains. The transport sector has consistently improved productivity since the beginning of the 1980s. Productivity gains have fluctuated considerably from one year to the other, generally following the business cycle, i.e. increasing faster during expansion periods. However, the long term trend is toward a more than 2 % annual increase in real productivity, which is quite high compared to most of the other service sectors and which leaves limited room for increases in employment given the sector's long term growth. Consequently, the transport sector though it does generate employment, has a much poorer record in terms of job creation than most of the other service sectors.

Inland transport services, the total of rail, road and inland waterways, account for 65.4 % of total employment in transport alone (i.e. excluding communications). Sea and air transport take a share of 8.6 %. Indirect transport services, the supporting services and other auxiliary services have a share in the sector's total employment of 26 %.

The trend in national and urban/suburban passenger transport has favoured the private car, which has become the primary mode of transport. Since the early 1970s, traffic by private cars has increased continuously, on average by more than 3 % annually. This mode now accounts for 83 % of total inland traffic, leaving the balance to railways (about 7 %) and buses and coaches (about 10 %). The continuous loss of market shares from rail and busses to private cars is presenting a number of problems for the environment, particularly congestion and atmospheric pollution. Public transport - rail and bus - tends to compete poorly with the mobility advantages of the private car (except in densely populated and congested areas), and suffers from a competitive disadvantage on the price front, insofar as the cost of using a car poorly reflects the environmental and social costs linked to that transport mode.

For international long distance passenger transport, air transport has become the most important mode for both business travel and tourism, particularly as the time wasted on travel represents a very real opportunity cost to the business traveller and as the demand for leisure has favoured longer distances.

In spite of a dramatic slump in 1991, passenger traffic by EU airlines has surged by more than 7.5 % annually over the past seven years. Fast growth has caused congestion problems in the airways and at airports, which are currently being addressed Community-wide within the EU. However high speed rail services are becoming very competitive for medium range distances (around 300-500 kilometres).

The bulk of freight transport is road haulage. Based on 1990 data, road accounts for 74 % of total inland traffic measured in tonne/km, the rest being shipped by rail (16 %) and inland waterways (10 %). Maritime transport accounts for about 30 % of goods movements between Member States. Road haulage has benefited significantly from increasing integration within the Union. Since it is highly flexible, it can quickly take advantage of changes in industrial structure and new demand requirements. New forms of production organisation, such as just-in-time, are particularly demanding in terms of transport flexibility and have considerably favoured road haulage. Furthermore, rail and inland waterways have suffered from the sluggish growth of their core activity, the transport of bulk goods. These two modes do have opportunities, however, in unitised cargo (containers).

Another trend is the increasing importance of air freight transport services, albeit its overall market share remains low. Especially in the field of high value goods and perishable goods, air transport has a competitive advantage with its high speed of conveyance. This service is currently being integrated more and more with express service companies.

### International comparison

Table 3 provides a comparison of value added in transport and communications in the EU, the USA and Japan. The contribution of transport and communications to GDP is fairly similar in the three regions, at about 6 %, though the absence of recent data in the case of the US makes such a comparison a little awkward. In 1992, value added in the sector totalled 316 billion ECU in the EU, a considerably higher level than in Japan (177 billion). However, in per capita terms the value added is far higher in Japan (1 427 ECU) than in the EU (910 ECU).

## MARKET FORCES

### Demand

The demand for transport depends on economic and social developments within the Community. Growth in transport demand tends to depend on growth in GDP, albeit disproportionately, hence accelerating GDP growth does have a more than proportionate effect on transport activity and vice versa for decelerating GDP growth rates.

In addition to the general level of economic activity, demand for transport also depends on other factors such as structural changes in the manufacturing sector, the completion of the Internal Market, changes in living modes and liberalisation. The relocation of manufacturing (usually to non-urban areas) and the dispersal of economic activity has had a concomitant effect on good and passenger movements. The trend towards very flexible production methods (JIT) have led to lower stocks which in turn have required more frequent deliveries and lower volumes. The rapid growth in the services sector has multiplied the demand for professional mobility over all distances. The completion of the Internal Market, by spurring intra-EU trade and by allowing the restructuring of manufacturing production around larger production units, has also contributed to increased demand for freight transport. As to passenger transport, the urban spread and the development of mega-cities have boosted the demand for commuting whereas leisure transport has benefited from continuous reduction in barriers to mobility in the Union.

Demand for transport is usually decomposed by transport modes both for passenger and freight movements. Over the past twenty years, growth in these various segments has been far from uniform. Since the early 1970s, growth in passenger traffic has been slightly faster than growth in real GDP, averaging 3.2 % annually between 1970 and 1992. On the other hand, growth in freight traffic has been slightly slower than growth in GDP, averaging 2.0 % annually over the same period. Passenger transport is characterised by faster than average growth in traffic by private cars and particularly fast growth in air traffic. As to freight transport, road has increased its share of inland transport markedly at the expense of both rail and inland waterways. Rail has experienced an overall decline in traffic since the beginning of the 1970s while traffic in inland waterways has hardly increased over the same period.

The demand for road transport, both passenger and freight, has been dramatically affected by the demand for increased mobility and flexibility where the door to door concept has acted as competitive edge unmatched over shorter distances by any of the other modes. On longer distances, road transport for freight still allows for door to door delivery without transshipment that is usually required for rail and inland waterway freight. In addition, the competitiveness of road compared to other freight transport modes has largely benefited from the general liberalisation trend which has taken place in Europe and which has simultaneously improved efficiency and reduced prices in road haulage.

The development and the increasing complexity of transport and logistic operations have led many companies to outsource more of these activities to professional transport operators in order to minimise costs. As a result, the demand for professional transport services has been growing faster than total freight traffic which, as already explained above, also covers

own-account transport. Furthermore, professional transport operators are somewhat moving out of the simple transport function to supply more complex logistics and warehousing services, a trend which further raises the value added by the sector.

### Supply and competition

The major impacts on aggregate supply are changes in infrastructure, changes in equipment technology, policy measures to encourage one mode over another or with another, and liberalisation.

Infrastructure has impacts on all the various modes. For road transport, freight and passenger, quality and availability of roads are crucial, particularly on inter-city routes for freight and on inner city and urban congestion for both freight and passengers. For all rail, improvements in the network, including both network additions and the viability of high speed networks are key components. For air transport, congestion at some airports at peak loads is a serious problem, which coupled with an air traffic control system that requires substantial investment to operate efficiently, causes a real problem for the sector to supply services efficiently and cost effectively. For inland waterway, there is a real limit to infrastructure investment, although links to eastern Europe are slated for improvement. Overall, the supply of transport services is increasingly hampered by serious bottlenecks at some points of the European network. Recognising both the infrastructure shortage and the importance of an effective transport system for the EU economy, the EU Commission has proposed the development of a trans-European transport network covering all transport modes including combined transport. Corresponding infrastructure investments have been estimated at 400 billion ECU by the year 2010 (COM(94) 106 final).

Changes in equipment technology and infrastructures have had the most impact on air, road and rail transport. In air transport, vast strides have been made in supplying efficient air transport at a cost that has in real terms declined on aggregate over the last few years. For road freight, improvements in truck design and efficiency have allowed a real reduction in operating costs and higher volume per load movements. For passengers, the effect has been less noticeable as changes in technology have allowed some efficiency gains, but these latter have been outweighed by larger numbers of single oc-

cupancy movements. Investment in higher quality track and rolling stock for rail has allowed efficiency gains and also in some cases induced additional traffic, both passenger and freight - the drawback to freight still remains inflexibility and transshipment at point of loading and unloading.

Competition between modes has meant that overall road transport, specifically passenger cars and road freight, has gained share at the expense of other modes. In particular, cars have taken share from rail for short to medium length journeys and share from urban/suburban public transport for short journeys in and between urban and inner city areas. Road freight has taken share from rail, and to a lesser extent from inland waterway. Air travel for leisure and business has gained share from rail and coach for medium to long distances within the Union.

Several segments of the transport sector have traditionally been heavily regulated through price controls and entry restrictions. The increasing recognition of the ensuing losses in efficiency and high prices, together with the necessity to liberalise intra-EU international transport to complete the Internal Market, have fostered a general liberalisation trend which has however so far essentially affected road freight and air transport. By spurring efficiency and lessening prices of a given transport sector, liberalisation also shifts the relative competitiveness of transport modes.

Another issue, which could impact considerably the structure of the transport sector but which has so far translated in very few policy measures, is the mis-pricing of the various transport modes. Competition between modes is distorted by the fact that the prices of some modes, essentially road, do not fully reflect their environmental and social costs (air pollution, congestion etc.). The result is a loss of welfare for the community as a whole. However, the issue remains quite controversial insofar as no real consensus has so far emerged as to the magnitude of these environmental and social costs.

## INDUSTRY STRUCTURE

### Companies

The sector is characterised by large differences in the importance of state ownership depending on the transport mode considered. Road freight and private cars (including taxi serv-

ices) are completely dominated by private ownership, with only isolated case of concentration - typically in a geographical area - and by definition private cars are privately owned. Rail, including urban/suburban services, is dominated by public ownership. Air transport has been dominated by 'flag carrying' airlines that have tended to be owned by the state, and on balance most of the major airlines in the Community still remain in the hands of the state. However, there are numerous medium to small sized airlines that are privately (this includes quoted companies) owned and within this sub-sector there is a low degree of concentration. Inland waterways are dominated by small privately owned firms, often of one barge or ship. Maritime transport is largely privately owned.

### Strategies

Strategies developed by transport companies in the Union are largely dominated by the necessity to adapt to two major trends: increasing privatisation and enhanced competition. The degree of these trends strategies varies according to the sectors considered. In road transport, particularly road freight, the move has been to increase competition between firms in different Member States by deregulating intra-EU international transport, by gradually allowing cabotage and by liberalising domestic supply in most of the Member States. In air transport, the liberalisation of the market within the Community in 1993 and the lifting of all restrictions on cabotage by 1997 has meant that many of the flag carriers that still remain state owned will gradually be moved into the private sector and that competition will force more alliances and mergers and acquisitions as companies seek to minimise costs and maximise revenues, and expand their access to markets of critical size in order to compete effectively. Spearheaded by the United Kingdom, a limited number of Member States is progressively moving towards the privatisation of their rail operator. However, changes in the structure of the rail industry will generally take place only slowly as rail tends to be viewed as a quasi-public good as the supply of rail services is in the public interest. The EU has introduced limited open-access and the accounting separation of the provision of infrastructure services from the provision of rolling services. Nonetheless, for rail operators competition essentially stems from other transport modes rather than from other rail operators. As to inland waterways and maritime services, privatisation is a less important issue as these sectors are already largely privately owned. Further deregulation will take place in the coming years but this can only have limited impact as the two sectors have traditionally been quite competitive

### Impact of the Single Market

The completion of the Single Market had a major impact on the transport services sectors, both directly and indirectly. The elimination of controls at internal frontiers facilitated intra-EU movement of passengers and freight and reduced time wasted in administrative formalities. For several transport modes, the liberalisation of access and prices has considerably modified industry structure and brought about more efficient and cheaper services. Free access has generally fostered entry by start-up companies, but has also opened new perspectives for larger operators which have frequently reacted by increasing size through M&As and alliances. In general, liberalisation has allowed the sector to take more advantage of the main indirect benefit of the Internal Market, namely increased demand due to increased cross-border mobility, additional intra-EU trade and faster GDP growth in the EU economies. However, the 1992 programme has unevenly affected transport modes. Some of them were not really concerned from the beginning, either because they were already largely liberalised (inland waterways) or because most of their activity takes place extra-EU (maritime shipping). In other cases, mainly rail, the integration process has been much slower both in terms of liberalisation and in terms of technical harmonisation. The next priorities thus include a strengthening of the integration process for those modes which are still behind. Another remaining barrier is the lack of a level playing field in terms of inter-modal competition. Some transport modes benefit from an unfair competitive advantage insofar as their costs do not reflect the total social and environmental costs generated by their activity.

### TECHNOLOGICAL PROGRESS

In all subsectors of the transport and communications industry, progress in technology and possible economic and social benefits are substantial. It relates to the following items:

- the development of new information and communications technology ("telematics"), leading to new communication and value added services;
- the application of telematics enables considerable improvements in transport service quality. Key quality items such as vehicle monitoring, goods and parcel tracking, container handling, traffic management, travel information, route guidance, automatic fee collection, fleet management, driver assistance, etc. have improved due to advanced applications

of information and communication technology and Electronic Data Interchange (EDI);

- several research programs, such as DRIVE (Dedicated Road Infrastructure for Vehicle safety in Europe), EURET (Research and Technological Development Programme in the field of Transport), both contained in the second Community RTD Framework Programme, telematics Applied to Transport of the third Framework programme as well as activities outside the Community framework such as the Prometheus (1989-94) EUREKA programme examining advanced telematic systems for the motor industry, and EATCHIP (European Air Traffic Control Harmonisation and Integration Programme) of Eurocontrol have been carried out with the purpose of improving traffic safety, the impact on the environment and integrating approaches to increase transport efficiency on an European basis;
- energy efficiency and reduction of exhaust emissions and to a lesser extent other forms of nuisance such as noise.

The potential of the application of these emerging innovative technologies on the creation of value added services and on the stimulation of economic growth is significant, as the various communications of the Commission on the information society and the two European Councils conclusions in Corfu and Essen have highlighted. In addition, the Commission in its communication on telematics applications for transport in

Europe (COM(91)469) has set an outline action plan for the best approach to re-deploy telematics systems.

## ENVIRONMENT

Transport is the dominant source for certain types of air pollutants: in particular, transport is estimated to be responsible for about 80 % of carbon monoxide emissions in the EC. For nitrogen oxides and hydrocarbons, estimates indicate that transport causes between 50 % and 60 % of all man-made emissions, and furthermore it produces 40 % of all emitted particulates. Another major pollutant is lead, which is discharged by internal combustion engines using leaded gasoline (dominated by cars and light vans).

In 1992 the European Commission published a Green Paper on The Impact of Transport on the Environment - a community strategy for sustainable mobility. This Green Paper was a milestone in attempting to look at the issues of the impact of transport on the environment from a global perspective taking into account the inter-relationship of transport and economic welfare and the relationships between the various transport modes. Although the Paper focused on atmospheric pollution, it also covered, in some depth, the other forms of pollution or nuisance that are often skated over in considerations of transport. In particular, it discussed the impact of

noise on the environment, water pollution (inland and maritime) from the effects of transport, soil impacts, vibration, land use and intrusion, congestion and the risks inherent in transporting dangerous goods.

In assessing the impacts of transport on the environment, the Paper concludes that operational pollution is the critical issue for all transport sectors, with the main culprits being the road, sea and air sectors. Land use and intrusion was ranked second in importance (particularly the one caused by the road and rail sectors). Congestion interestingly was ranked third although it restricts mobility and contributes to atmospheric pollution. This third place was largely due to congestion tending to be prevalent only in inner-city and densely populated urban areas and in terms of the whole picture had less impact. Bottom of the ranking was the transport of dangerous goods, although politically sensitive, due largely to the small quantities moved within the EU compared to the volumes of other goods.

The Paper also sought to provide possible measures and research programmes for discussion on a common strategy based on a global approach requiring different types of initiatives. The essence of the Paper is to ensure that transport continues to fulfil expectations in terms of its contribution to social welfare, economic cohesion and growth whilst minimising its impact on all aspects of the environment. Within this global approach to strategy were outlines of various approaches that could be made or adopted to achieve these ends.

## REGULATIONS

Most of the EU transport market is currently regulated on a national basis and therefore relatively fragmented. In 1985, a ruling of the European Court obliged the Council to work out a common transport policy along the same liberal lines that hold for the rest of the economy under the rules of the EC.

The implementation of the common transport policy involves two elements:

- freedom to provide services and eliminate competition distortions;
- improvement of infrastructure and production means.

The latter element relates to large investments in infrastructure and new innovations in means of transport as the Community contributes to a number of infrastructure-related projects, which are dominated by the high-speed rail network. However, the Community programme has limited funds, and there are a number of projects important to the Community that are not funded by the Community: e.g. the Channel Tunnel, the Trans-European Motorway, the construction of the Rhine-Main-Danube Canal and the Bælt Link in Denmark.

Innovation in transport is dominated by European R&D programmes aimed at traffic safety, reductions in energy consumption and in exhaust emissions and at adding new telematics-based services. Also, the harmonisation of technical standards continues as part of general harmonisation in the Single Market.

In terms of broad policy issues on transport in the Community, the Commission published a White Paper on The Future Development of the Common Transport Policy at the end of 1992 (COM(92)494). This communication from the Commission is a crucial tool in setting out the issues that need to be discussed as it seeks to set out a global approach to transport issues enabling due consideration of all views before the launch of particular initiatives. It recognises the importance of each transport mode in the global picture, and seeks to balance transport policy in terms of its impact on the environment with sustainable mobility for the Community as a whole. The communication enlarges on the major issues of modal dise-

quilibria, capacity constraints, system and network developments, environmental issues, safety, and social issues.

Whilst the desire to create a Common Transport Policy that maximises all requirements is existent, there are a number of regulations and policies that are mode specific and in general these are designed to tie into the master plan. The important regulations by mode are entered into more detail in the following relevant monographs. However some of the more important ones are summarised below. The major changes in regulations have been aimed at stimulating competition by removing artificial and regulatory barriers.

In terms of freedom to provide services and eliminate distortions of competition, the Commission has produced several communications on the establishment of the conditions for cabotage, with the most progress being achieved on intra-EU road transport. Bilateral authorisations for transport between countries were replaced by EU permits at the beginning of 1993 with an elimination of all quotas.

As to inland waterways, there is relatively unhindered competition on the Rhine River, but initiatives are being taken to extend this to other waterways. Initiatives have also been taken to allow cabotage: each ship with an EU-flag is allowed to provide services within other Member States. This will increase competition on the European waterways.

The railway directives of June 1991 and July 1994 aimed at giving limited access to the national railway networks. The directives were designed to encourage the national railway companies to form international alliances for both passenger and freight services under single management structures, and to allow a measure of free access to the entire EU railway system for private companies involved in combined transport.

As regards the shipping market, in December 1992 the transport ministers adopted a regulation liberalising maritime cabotage within the EU. The regulation entered into force January the 1st 1993, but includes several temporary exemptions such as island cabotage in the Mediterranean.

Since 1987, European airlines have been subject to a process of deregulation, which has taken place in three stages. The third stage became operational on the 1st January 1993. Although it is the most far-reaching package so far, the programme did not bring about a totally deregulated EU air transport market in 1993. It still includes some safeguards on issues such as free settlement of fares and also a transition period for the introduction of cabotage. Cabotage will only be introduced in April 1997. In the meantime conditional cabotage is allowed.

In the field of regulation aimed at environmental protection, measures concentrate on emissions of exhaust gases and particulates. The general aim is to reduce the burden for the environment caused by the transport sector. The standards for carbon monoxide (established in 1985) depend on engine size and became effective during the 1988 to 1993 period. One of the consequences of this policy is the use of three-way catalytic converters in gasoline-fuelled automobiles. Also, aeroplane engines will have to conform to Stage III regulations on noise and emissions by early next century.

Policies in passenger transport aim at reducing private car use to the benefit of public transport. This is being done to alleviate congestion problems on the networks in and between major conurbations in the EU. Additionally, it is beneficial to environmental protection initiatives.

## OUTLOOK

The prospects for the EU transport industry remain quite positive. Growth in demand for transport services is gathering speed as European economies progressively emerge from their worst post-war slump. A number of factors will act as additional

spur. Increasing European integration will continue to fuel transport demand, both in terms of the volumes of goods and passengers and in terms of the distances to be covered. Industries externalising their activities of transport and logistics in order to minimise costs will act as a fillip to the growth in professional transport services. The opening up of the East European economies will also contribute, although, during the initial period of economic restructuring, only marginal growth in transport demand may occur. Also, transport services suppliers from these countries will be limited in their ability to compete with EU companies.

Growth prospects differ depending on transport modes considered. Rail transport faces only moderate growth and will continue to lose market shares to road though passenger transport is expected to grow faster than freight transport. Road passenger transport is likely to exceed average growth rates as private car use and ownership has not yet reached a maximum. Road freight transport will grow much faster due to the liberalised market and new opportunities, although tighter environmental regulations will act as a counter force. Inland waterways transport will maintain its upward trend with small rates of growth. Seaborne trade is expected to grow slowly in the short term, but faster in the medium to long term: recovery in long-term depressed markets such as steel and iron will be very gradual. The outlook for air transport is very positive as advances in managing congestion through improvements in air traffic control and investment in additional airport capacity at the more congested airports takes place. Also the upward trend in real personal disposable incomes will act to buoy the trend.

Large investments in infrastructure are currently being undertaken or planned in order to extend the network capacity of the various transport modes, as some existing networks are operating at or above capacity level. This will create new transport possibilities which are necessary for the growing integration of the EU market. This effect can be increased by the deployment of transport telematics tolls and services.

The Common Transport Policy, which aims at liberalising and harmonising the EU transport market, will improve the industry's efficiency. This will enhance competition and improve the quality of service offered.

Written by: DRI Europe

# Railway transport

## NACE 71

Most of the European railway networks are controlled by single national operators, which precludes competition between individual railways companies and between railway companies and private firms. To increase competition and profitability, several countries have initiated more or less ambitious privatisation plans for their railway. In the framework of the Common Transport Policy, the competitiveness of the railway sector should be improved by the possibility of more accurate reflection of the real cost burdens the various modes impose. Also competitiveness will be enhanced by continuing investment in trans-European networks and the progressive emergence of an integrated European network, particularly for high-speed railways but also for combined transport and for conventional railways.

### INDUSTRY PROFILE

#### Description of the sector

This sector includes units that are exclusively or primarily engaged in the transport of passengers and goods by rail. It also includes the equipment and facilities required to provide this transport, including private railway lines.

However, it does not include: railway networks solely or primarily serving a single town or city (NACE 721.1); locomotive, carriage and wagon repair workshops (NACE 362.3); local units of railway enterprises which operate regular bus or motor coach services (NACE 721.2); and the operation of sleeping-car and dining-car services (NACE 666).

#### Recent trends

Rail passenger traffic has remained relatively constant during the 1980s, growing by hardly more than 1 % annually over the decade. Similar growth rates were registered in 1991 and 1992 at 1.8 %, but recessionary pressures in the EU took a heavy toll in 1993 causing a 3.1 % reduction in traffic to 234 billion passenger-kilometres.

For the individual Member States, only Germany and Ireland reported growth in traffic (2.5 % and 3.9 % respectively) whilst a number of member States suffered serious drops in traffic, such as Greece (-13.9 %), France (-7.1 %), Spain (-5.5 %) or Portugal (-5.2 %).

Recent developments for freight traffic are still more gloomy. Traffic measured in tonne-kilometres declined by an average 1 % annually over the 1980s. The situation further deteriorated in 1992 and 1993, with a 6.2 % and a 7.9 % drop. However, the overall decline in traffic has been somewhat compensated by a partial structural shift in cargo carried away from low value added dense products to higher value products, often carried in containers or on road units (combined road/rail traffic). Estimates put the recent growth of this latter type of traffic at around 7.5 % per year and its share in total rail freight transport increased from 7.5 % in 1985 to about 13 % in 1992.

The only Member States to record freight traffic growth in 1993 was Luxembourg (+1.7 %). Two Member States reported double digit losses, Spain (-15.7 %) and United Kingdom (-11.2 %). Most of the others suffered from declines in traffic in the 5-9 % region.

Intra-EU rail freight traffic is dominated by four Member States, Belgium, Germany, France and Italy which between them account for over 80 % of intra-EU rail freight. The major intra-EU flows are between Italy and France, Belgium

Figure 1: Railways  
Development of financial result in EU railways

(1) Excluding España (RENFE)  
Source: UIC

and Luxembourg, Belgium and Germany, Germany and France, Germany and the Netherlands and between France and Belgium. These flows account for one-third of total intra-EU rail freight traffic.

Employment in European railways has declined continuously since the beginning of the 1980s, by close to 3 % annually, which corresponds to a reduction in workforce by close to one third between 1980 and 1993. The pruning process intensified in 1993 with a 4.2 % reduction in employment and a total labour force falling short of 880 000.

#### International comparison

Table 5 reveals the significant differences between the railways in the EU, Japan and the USA. Although the data for comparison is in some cases dated, it does enable a useful comparison. The US railway is heavily dominated by freight traffic, with only a relative small number of passenger-kilometres, as freight is moved over long distances in a country which is sparsely populated between the major cities or population centres. Japan by contrast is dominated by passenger traffic, due to the heavy population concentrations in many parts of the country and extreme road traffic congestion. Falling between the two is the EU with a fairly even divide between freight and passenger.

The approximate length of railway line available in the EU (excluding eastern Germany) is 121 000 kilometres, which is substantially more than Japan at 20 000 kilometres and half that of the USA at 243 000 kilometres. Given the different nature of the railways in these three countries, it is difficult to use a labour productivity measure, however, the comparison of the number of workers employed per kilometre of track shows that the differences in structure are enormous. The USA employs less than 1 worker per kilometre, the EU 7 and Japan almost 10. This confirms the strong correlation between employment and the type of traffic, i.e. the higher the passenger share of total traffic the more staff required.

### MARKET FORCES

#### Demand

Demand for rail services is divided into passenger and freight. Passenger demand is composed by leisure travel and business travel. The largest portion of business demand is daily com-

**Table 1: Railway transport

Source: UIC

muting between the workplace and home. The demand for commuting places peak load strains on the network services at the start and end of the working day. Leisure demand does not have the same daily peak impact, but does have seasonal peak impacts, for instance at Easter or Christmas. Within the two passenger demand segments are sub-segments that depend on the distance travelled. Typically, these subdivisions are split into three: intra-urban, inter-urban/city domestic and inter-urban/city international.

Freight demand does not have the same time sensitive profile as passenger, as freight trains can be run to meet demand during non-passenger peak times, which is often at night.

The industry in the EU has undergone a structural change away from the traditional intensive rail user industries such as coal and steel, on which rail was particularly dependant. This has affected the rail freight industry severely. Also, part of the changing structure has meant that technical and organisational developments in other industries (just-in-time stock management and sophisticated distribution networks) has accelerated demand for quick, flexible and predictable deliveries of relatively small quantities of cargoes. These developments have been detrimental to rail transport, because of its perceived relative inflexibility and high transshipment costs. Moreover, lack of integrated, inter-border co-ordination has not helped the demand for international rail transport, although, the advent of the Single Market has eased much of intra-EU border delays.

### Supply and competition

Rail competes with all other transport modes, road (car, truck and bus) for both long and short haul freight and passenger journeys, air for some passenger routes and inland waterway for some bulk freight. Increased private car ownership with the concomitant ability of car drivers and passengers being able to travel door to door without changing mode has affected passenger rail traffic negatively. Surveys of travellers have indicated that for business commuting, travelling speed and convenience are rated the most important factors in the mode choice decision. This priority is much less important for shorter distance (50 to 300 kilometres) leisure travel, where price comes higher up the list. Rail tends to win share in instances where it can complement other modes by providing almost seamless travel, for instance rail to metro, and where road traffic congestion is bad enough to negate the convenience factor of door to door travel.

In competing with air travel, the development of high-speed rail services has provided an opportunity to divert traffic from air to rail. Air traffic's comparative advantage over rail transport i.e. speed, is under pressure on some routes in the EU as over shorter distances the flight time is only a minor portion of total journey time which is compounded by increasing congestion in airports and air corridors. The train, which is traditionally less expensive than flying, can become particularly attractive for journeys between 300 and 600 kilometres.

For example, on the stretch Paris-Lyon, air traffic's share of passenger traffic on that route declined from 30 % to 9 % after the introduction of the TGV. Moreover, in some EU countries, policy is aimed at positively influencing the demand for rail transport. Current concern with congested roads, airports and airspace, as well as with pollution due to road and air traffic, are underlying this change in policy.

Passenger pricing for rail travel is usually worked on a per-kilometre basis and tends to be uniform in mainland EU, hence the longer the journey, the higher the price. However, prices from BR in the United Kingdom are not uniform, especially for the captive commuter belt surrounding London where prices are much higher than proportionate travel elsewhere in the UK.

For cargo, rail has the distinct advantage in its ability to move large volumes of freight in a single unit between specific points over short, medium and long distances. However, rail's share of freight traffic has declined over the last two decades. In the early 1970s the share of freight moved by rail was around 30 %, but by the end of the 1980s it had declined to just over 16 %. This loss of share is attributable to the increase in movement of freight by road, as road can move cargo from point to point, whereas rail freight requires modal symbiosis as the many cargoes need to be transported to and from rail freight terminals.

In 1992, the aggregate for labour costs in rail were over 60 % of total operating costs and subsidies came to close to 30 % of the operating revenue of the EU railways. At the same time, the EU railway companies suffered a joint loss of 6.3 billion ECU. The dominant contributors to this deficit were the German (west) and Italian railways with a combined loss of ECU 5.8 billion, or more than 90 %.

## INDUSTRY STRUCTURE

### Companies

The top four rail companies in terms of network length are the SNCF in France (33 400 kilometres of track), DB in western Germany (27 100 kilometres), BR in the United Kingdom (16 600) and FS in Italy (16 100). These four combined have 75 % of the available track in the EU. At the other end of the scale is CFL in Luxembourg with 270 kilometres and the next smallest is CIE in Ireland with just over 1 900 kilometres.

Most of the national EU railway networks are controlled by single national operators. Rail transport services in the Member States can be characterised, to varying extents, by state regulation, the importance of non-commercial obligations and political objectives. Large subsidies from the state generally cover operating losses and/or investment. The nature of the system has so far largely precluded competition between railway companies or free market across national boundaries.

### Strategies

The various railway companies in the EU have been collaborating to improve both international passenger and freight services. The strategy for international passenger services has been to provide day-train services under the brand name of "EuroCity" in order to harmonise the service provided by the participating companies, and night services under the "EuroNight" banner, which are designed to provide uniform services with three categories of comfort. International freight services in containers (refrigerated and non-refrigerated) have come under the auspices of Intercontainer-Interfrigo (ICF), which provides the logistics and networks to move containers throughout Europe. ICF is owned by 27 railway companies in Europe.

In order to increase competition and profitability some Member States - Germany, the Netherlands and the UK - are in varying stages in the process of privatising their railways. In the UK, the unbundling of British Rail started in May 1994. Ultimately,

the break-up of the rail monopoly is expected to create a host of private companies including Railtrack the owner of the tracks and of the stations, Railfreight Distribution which will handle intermodal and international traffic, three freight operators, 25 franchisee supplying passenger services, three rolling stock companies as well as a number of rolling stock maintenance companies. The system will be capped by two regulatory bodies, a competition watchdog and an organisation in charge of awarding the franchises.

In the Netherlands, the plan is to privatise the Dutch Railways in 2000. The Dutch railways expect passenger traffic to double by the year 2010 and have been investing in equipment and infrastructure improvements to meet the current growth in demand and future requirements.

The privatisation plan of the German railways started in January 1994 with the transformation of Deutsche Bahn, a department of the German administration, into Deutsche Bahn AG a private-sector holding company. Within three years, the

activities of DB AG will be reorganised into three independent subsidiaries in charge of passenger services, freight services and infrastructure. The infrastructure company has started charging the passenger and freight operators for the use of the tracks and access to the network for independent companies is planned in the near future (in order to comply with Directive 91/440). However, the restructuring process of the German railway is only in a preliminary stage and privatisation remains a long term objective.

One of the major pressures on most of the EU rail companies is their historic debt burdens. Huge debts have been incurred as railways have invested in the infrastructure and equipment required to provide the levels of service demanded by both customers and the fulfilment of a public service obligation. High interest rates coupled with steep competition that reduced revenues has compounded the problems. Some of the EU railways have had their debt burdens substantially reduced (BR in the UK and DB AG in Germany) and/or rescheduled. However, the companies and their associations are lobbying for government commitment and assistance to reduce the debt burdens as there is still a long way to go in the EU before

many of the rail companies could be considered as 'going concerns'.

### Impact of the Single Market

So far, the impact of the Internal Market on rail transport remains somewhat mixed. The sector has benefited from the removal of border controls, as well as from renewed international transport as a result of increased cross-border mobility and a surge in intra-EU trade. Besides, the directives on public procurement are beginning to translate into some downward pressures on cost as competition between suppliers of rail equipment intensifies. On the negative side, the Internal Market has indirectly curtailed the competitiveness of rail compared to other transport modes. The liberalisation of air transport and road haulage has fostered the efficiency and curbed the cost of these two modes, thereby amplifying modal imbalances. In the long run, some of the handicaps of rail should be lifted once the Internal Market is fully implemented. As explained in more detail in the section on Regulations, the EU is progressively introducing a more liberalised framework for the supply of rail services which should ultimately lead to in-

creased efficiency. Another aspect is the lack of harmonisation of equipment and infrastructure across Europe, a problem which is solved only slowly, partly owing to the cost of the process. Last but not least, in the case of competition with road, rail suffers from an unfair handicap to the extent that the price of road transport does not reflect its true social and environmental costs. The competitiveness of rail therefore partly hinges on the future shape of the EU environmental policy.

## ENVIRONMENT

Rail impacts the environment principally through air pollution, noise and land-use. Pollution into the atmosphere is both direct caused by emissions from diesel engines, and indirect from the power stations that generate electricity for trains using electrified track. The impact of noise is particularly acute in urban areas, although track tends to be placed in areas of lowest population density. In addition, track that is forced to go through densely populated areas is often placed in a way that minimises the noise, for instance in cuttings.

Although rail does cause atmospheric pollution, it is the most environmental-friendly form of transport. At full capacity both rail and buses have the lowest consumption of energy per passenger-kilometre than other forms of transport. Intercity and urban trains consume in the region of 0.3 MJ of primary energy per passenger-kilometre at 100 % occupancy compared to between 0.6-1.1 MJ for cars. High speed trains consume around 0.7 MJ compared to almost 1.5 MJ for a Boeing 727. Even at low occupancy rates rail consumes less energy per passenger kilometre than most other forms of transport (the exception being bus). The difference for freight is not so marked, as bulk rail freight traffic is estimated to consume 0.6 MJ per tonne-kilometre, whereas the equivalent figure for an articulated truck at 100 % capacity utilisation is about 0.7 MJ. However, trucks rarely have 100 % capacity utilisation as this implies that both the outbound and inbound journeys are full. Hence, assuming a capacity utilisation for trucks of around 50-75 %, energy consumption is around 1-1.5 MJ per tonne-kilometre for an articulated vehicle.

Electric traction could also allow different energy sources to be used, for instance gas generation rather than coal, which would further reduce the impact of rail. In practice, however, railways tend to buy their electricity from national grids and hence cannot choose the method of generation.

## REGULATIONS

In July 1991, the EU Transport Ministers agreed upon a directive (91/440) setting some guidelines to improve the efficiency of the railways and encourage their adaptation to market conditions by widening access and separating infrastructure management from infrastructure usage as much as possible. In particular, national railway monopolies have to account separately for infrastructure and operating costs in order to allow transparent charging for infrastructure use by newcomers and to prohibit cross-subsidies between the two functions. The directive also includes limited open-access to the rail network by allowing international groupings of railway undertakings to use the network for international transport between the States of establishment of these undertakings. Individual railways undertakings are also allowed to have access to the networks of the other Member States but only for international combined transport operations.

In July 1994 the principles set out in the 1991 directive were put in concrete form with the adoption, by the European Council, of two new regulations setting out formal rules for the licensing of railway undertakings and for the allocation of infrastructure capacity and charging of infrastructure fees. On November 21, 1994 the Council has adopted a common position on both regulations. The two directives should be further examined by the Parliament early 1995.

The Commission's White Paper on The Future Development of the Common Transport Policy (COM(92)494), that was adopted by the Council in December 1992, has important implications for the rail industry, as one of its cornerstones is the ability to stimulate modal shifts. Policy instruments that encourage modal shifts tend to favour modes that are viewed as having the most favourable balance between positive economic development and minimal environmental impact. Rail is considered to be the most serious contender for meeting both objectives within a global transport plan. By 1st January 1995 the Commission has to report to the Council on further measures needed to develop railways in the Community.

In late 1989, the Union Internationale de Chemins de fer (UIC) launched the P.A.R.I.S. (Pricing, Accounting and Rolling Stock Interchange Simplification) in order to set about increasing international rail competitiveness and revenues in passenger traffic. Within the recommendations was the possibility to revamp the prevailing price structure. It is deemed as rigid, complex and unable to respond to specific market conditions and it also makes revenue accounting and settlement

slow and inefficient. Further rolling stock interchange rules would be simplified and more geared to market conditions. The programme consisted of two stages. The first stage ended in September 1990. Recommendations on pricing, accounting and international route management were submitted and ratified in October 1990. Then the second phase was launched, including the implementation of the recommendations from the first stage and to come to further recommendations.

## **THE TRANS-EUROPEAN TRANSPORT NETWORK**

The development of a Trans-European Network (TEN) in the area of transport constitutes the cornerstone of the European policy in terms of transport infrastructure. In 1990 the European Council gave a favourable reception to a master-plan for high speed railways. This was followed by the adoption of three new master-plans in October 1993, for combined transport, roads and inland waterways. The Maastricht Treaty, which came into force in November 1993, gave an additional impetus to the European policy with respect to transport infrastructure. Article 129 B of the Treaty states that "the Community shall contribute to the establishment and development of trans-European networks in the areas of transport, telecommunications and energy infrastructure". The importance of transport networks has also been reassessed in the White Paper on Growth, Competitiveness and Employment released in December 1993. In this context, the development of an efficient transport network is seen as a fundamental factor of Europe's competitiveness. The White Paper identifies 26 priority projects in the field of transport. These projects correspond to an estimated 82 billion ECU investment of which rail takes the lion's share (close to 54 billion ECU). In July 1994, the Commission proposed guidelines for the development of a trans-European transport network. Contrary to previous master-plans, these guidelines cover all transport modes.

There are now 22 projects, 10 of which are rail or rail & road transport projects. In the case of rail, the proposal sets out a 26 700 km network for high speed trains (including 12 500 km of new lines for speed exceeding 250 km/h and 12 500 km of upgraded lines for speed of about 200 km/h, together with 1 700 km of interconnection lines) which would provide a link between the main European cities. The proposed total rail network covers 70 000 km, including 47 000 km of conventional tracks of which 23 000 would be essentially used for combined transport services. Projects of interest would be those which remove bottlenecks in centrally-located countries and those which improve access to peripheral countries as well as to airports and seaports.

A recent event which is expected to rejuvenate the European rail network is the opening of the Channel Tunnel in 1994. The tunnel will allow rail to compete with other modes both for passengers and for freight. In the case of passengers, high speed trains will cut the journey time between Paris and London to about three hours and to a planned two and half hours by the beginning of next century when the high speed line connecting London to the tunnel is completed. In addition to the traditional leisure traffic, rail is therefore also expected to capture a large share of business travel across the Channel thereby competing both with ferries and airlines. As to freight, the connection of the British rail network to the continent spells renewed competitiveness for rail which, before that, was seriously hampered by the limited length of most of the freight journeys in the UK (road is a more economical mode for shorter trips). British Rail expects annual rail freight traffic to surge from the current two million tonnes to 9 million tonnes by about 2000.

## **OUTLOOK**

Rail's future share in the (growing) European transport services market will depend on its ability to meet customers requirements concerning speed and flexibility and the effects of the Common Transport Policy.

The prospects for rail passenger traffic are for positive growth of 2.5 % in the short to medium term. A breakdown of this figure among subsectors reveals that stronger growth is expected in urban rail transport and long-distance high speed rail services, while there should be a decline in the regional and inter-regional rail services, covering distances between 50 and 300 km. Improved railway services and increasing congestion in other modes will help favour rail transport. The high-profile high-speed rail services will continue to contribute to positive customer awareness as well as continuing to compete with air traffic on distances between 300 and 600 kilometres.

In the short and medium term, rail freight will continue to lose market share to road due to its relative inflexibility and as the modal relative cost structure favours road haulage, but in terms of volumes moved, rail will see some marginal growth. In the longer term, the integration of the European railway system and deregulation of the EU railway market will help garner some of the share back onto rail. Also, within the framework of the Common Transport Policy, measures that genuinely reflect the real costs of each mode will act as fillip to rail.

The entry of the three new Member States will not affect radically the present EU scenario for rail transport. One should nevertheless mention that the accession of Austria, which greatly favours rail transport versus road transport, might be marginally beneficial for the sector. Also, two of the Trans-European Network projects are of particular importance to Sweden and Finland - the Nordic Triangle and the Øresund fixed link.

Cost and debt pressures will continue to force rationalisation within the industry, which will have further negative implications for employment. The planned privatisations of the railways in Germany, the Netherlands and the UK will exacerbate the decline. Privatisation of the Bundesbahn is estimated to cause over 30 000 job losses.

Written by: DRI Europe

The industry is represented at the EU level by: Community of European Railways (CER). Address: Rue des Colonies 2, B-1000 Brussels; tel: (32 2) 525 3050; fax: (32 2) 512 5231.

# Public transport

## NACE 721

Though the most recent statistics point to a weakening in the use of urban public transport in recent years, the sector's long term prospect remain good. Increasing environmental concern and increasing congestion are leading many countries to consider policies which favour public transport at the expense of the private car. Substantial investments continue to be made to improve public transport services, both in the provision of new equipment and infrastructure and in modernising and improving existing vehicles and infrastructure. The tendency to privatise particular segments of public transport will continue.

### INDUSTRY PROFILE

#### Description of the sector

Public transport (NACE 721) consists of city underground, surface and elevated railways; tramways, regular bus and motor coach services. The NACE classification distinguishes two subgroups:

- NACE 721.1 - city underground, surface and elevated railways, i.e. units exclusively or primarily engaged in the transport of passengers by electric rail services solely or primarily serving a single city or town.
- NACE 721.2 - tramway, regular bus and motor coach services, i.e. units exclusively or primarily engaged in the operation of city, suburban and inter-city tramways, bus and motor coach services insofar as they are operated as regular or special services.

Regular services provide for the regular transport of passengers on scheduled routes and follow a fixed timetable; they normally only pick up and set down passengers at stops marked on their routes. Special regular services cater for specific categories of persons to the exclusion of other passengers (e.g. workers, school children and air line passengers).

Public transport can be analysed either by mode (rail, tramways and buses) or by type of services (e.g. city centre, suburban,

park-and-ride services). It should be noted that inter-city rail and road services represent a quite different market. This monograph is therefore restricted to urban transport in a multi-modal approach. Inter-city services are covered in the monographs on rail and road passenger transport included in this chapter.

#### Recent trends

Reliable statistics for the sector are relatively sparse. The tables provided in this monograph are based on several sources. The International Union of Public Transport (UITP) collects traffic statistics on urban transport (all modes included) for the major urban areas in Europe. In addition, Eurostat provides a set of employment and turnover data. However, these data are based on NACE 721 and their coverage is therefore somewhat wider than urban public transport as inter-city regular bus and coach services are also included.

Based on Eurostat data, public transport accounts for about 10-15 % of the total labour force in the transport sector.

In 1992, the number of passenger journeys in major urban areas in Europe was just short of 25 billion. Germany had the greatest number of passenger journeys (close to 7.9 billion passenger journeys), followed by the UK (4.4 billion) and France (4.3 billion).

The relative importance of different modes in terms of the share of passenger trips and of the total vehicle fleet is indicated in Table 2. Bus services are the most widespread mode in public transport in the EU, and about 90 % of all transport systems. Measured in terms of fleet size, route length and number of routes, the larger operating bus systems are to be found in the large European cities like Paris, Athens, Rome, Madrid, and London.

### MARKET FORCES

#### Demand

The principal journey purposes for which public transport is used are:

- journeys to and from work;
- journeys between home and education;
- shopping;

- personal business;
- visiting friends and relatives.

The demand for public transport is dependent on the overall state of the economy, the availability and price of alternatives, its own price and service level and quality.

Over the past 30 years, increasing incomes have led to higher levels of private car ownership. Owing to its flexibility, the private car is a very strong competitor with public transport and many journeys which were previously made by public transport are now being made in the private car. It is likely that a large proportion of the loss in public transport patronage results from transfer to the car. The transfer to the private car, by necessitating reductions in service frequency and increasing traffic congestion (which has a disproportionate effect on the reliability and cost of bus operation) has created a vicious circle making public transport still less attractive. Furthermore, increasing personal mobility as a result of the private car has meant that many services and facilities are now located where they are easy to serve by car but not by public transport. This has created a captive market for the car which public transport finds difficult to penetrate. Counting both urban and non-urban transport, travel by private cars now represents more than 80 % of total inland surface travel (i.e. rail, buses and private cars) in terms of passenger kilometres travelled.

Increasing traffic congestion and, more recently, increasing concern with the environmental impact of traffic have led many countries to consider policies which would increase the use of public transport at the expense of the car. Policies adopted have varied from direct control of private car traffic (for example in some Italian cities) or the stringent control of parking through increased investment in public transport in order to expand supply and improve quality, subsidisation of public transport operating costs, and allocation of road space for the exclusive use of public transport vehicles. It is likely that these measures will continue throughout the EU and will in some countries be strengthened by direct charging for the use of road space which is already practised in Stockholm and Oslo. Overall, these measures will, over the next 10 to 20 years, lead to an increase in the demand for public transport.

As indicated in Table 3, the 120 million people living in the EU's largest cities completed close to 25 billion journeys in 1992. In providing an estimate for service coverage, Table 3 shows the ratio of passenger kilometres per head of population served in the various EU countries. These ratios should be viewed with some caution as local or national circumstances can influence the indicators substantially, but they nevertheless provide a useful broad overview of the level of demand. The ratios indicate that broadly the number of public transport passenger kilometres per head of population is fairly similar

across the EU, the exceptions being Belgium (low) and Portugal (high).

### Supply and competition

The supply of public transport is generally analysed by mode:

- bus and coach
- light rail/tramway
- heavy rail

Within each mode a number of distinctions can be made in relation to the type of vehicle and type of service provided. In general buses provide short distance urban services on which average journey length is quite short and peak hour passenger flows are high. Such services are usually operated with high capacity vehicles, with a large proportion of standing capacity (although sometimes - UK, Ireland and Berlin - double-deck vehicles may be used) and multiple entrances/exits.

The traditional street operating tramway with stops at similar distances to bus stops is now being supplemented by light rail services which can either run on segregated track like conventional railways or on-street. One of the main differences is that the light-rail services will often have much less frequent stations reflecting their affinity with longer-distance suburban rail services.

There is also a wide variety of heavy rail services. In many conurbations (for example London, Paris) there are extensive networks of specialist underground metro services. These operate high frequency services, vehicles with similar seating characteristics to bus services and which are confined to relatively short distance/suburban travel. As well as this there are many networks of surface railways conveying passengers for up to 100 kilometres distance from the major conurbation centres. These services are typically used by commuters and have highly peaked demand characteristics. On the longer distance routes the level of comfort and equipment in the trains may approach that offered by long distance trains.

Apart from the operation of the services themselves, two other aspects of service provision are critical for the marketing of public transport: information, and fare collection.

### Passenger information

Public transport operators have to convey information to existing and potential passengers about timetables and schedules. As buses and to a lesser extent tramways are susceptible to random variations and deviations from schedule as a result of traffic congestion, and for various reasons similar occurrences can happen on rail networks, there is a growing trend towards provision of real time information to passengers at stops and stations. This has been largely developed on rail systems but is now being extended to bus systems, particularly with the advent of geographical positioning systems which allow the location of individual buses to be accurately determined within a central computer system. There will be major developments within this area over the next 5 years. The rapid development of information technology - e.g. the anticipated connection of many homes and most offices to the information superhighway - should make radical improvements possible in the presentation and dissemination of information to potential customers.

### Fare collection

Other major developments concern fare collection systems. In most Member States the fare structure for urban services is very simple with a flat-fare or a series of zonal fares with substantial discounts for purchasing period passes or multi-journey tickets which are sold off the vehicle. In a number of instances, drivers have no direct involvement with fare collection or ticket checking. However, such systems can be prone to abuse and there is now a growing trend towards using forms of automatic ticket checking using either mag-

netically encoded tickets or, more recently, smart cards (i.e. cards with magnetic strips or micro-chips on which a number of "units" are stored). This will open up the possibility of pre-purchasing a given value of travel and using it up on service run by any of the operators subscribing to the scheme over a period of time. This will not only provide greater flexibility for the passenger but will allow operators to increase revenue by comparison with e.g. the yield from conventional (e.g. weekly or monthly) travel passes. Such a system has already been implemented in Hong Kong and is now being successfully tested in London and in Manchester in the UK. Both cities have taken the decision in principle to introduce system wide smart cards.

### Competition

The most effective and demanding competition for public transport has for a long period been provided by the private car. Within the sector, however - although there has to be a measure of competition between modes - operation has traditionally been tightly regulated, whether on the basis of direct provision by local or central government, or of an exclusive concession or contract being granted to an individual operator for a network of routes.

Public transport however is now being increasingly subjected to competition as a means of stimulating improvements in services and reductions in costs. Competitive arrangements may range from: (a), at the minimum, the contracting out of individual activities such as cleaning and maintenance, through (b) "management only" contracts, in which vehicles and installations remain the property of the authorities and (c) contracts under which the operator owns the vehicles and possibly other assets, and where different tenderers compete on the basis of the net or gross cost of providing the service to (d) to full "on-the-road" competition, where operators are left free to operate whatever services they wish, without public subsidy, subject only to limited restrictions in regard to e.g. safety. The number of firms capable of tendering depends both on the extent of the risk they are required to bear (e.g. the assets they require to deploy) and the scale of operation: it will be easier for small companies to bid for the operation of single routes, in particular an inter-city route, or to attempt to compete "on the road", than to take over the operation of a whole system.

Public transport's ability to compete with the private car, however, depends heavily on its ability to provide an effective network to try to minimise its disadvantages, compared with the car, which offers an "anytime, anywhere" service. This

demands an element of collaboration between routes and between modes in e.g. ensuring the maximum geographic coverage, in making the best use of the relative speed of rail and the accessibility offered by bus, in coordinating timetables to minimise waiting times, and in simplifying ticketing and information arrangements. Forms of competition which disrupt these facilities are likely to be counter-productive.

### Investment

The ability of public transport to continue to attract passengers and to fulfil its potential role in tackling the problems of congestion and environmental degradation due to the growth in private car use depend heavily on investment - investment in extending networks, in improving the quality of service, in carrying out the basic heavy renewal works which are essential to maintain services. Investment requirements are generally far greater for rail than for bus services.

Large investments continue to be made in public transportation. Total investments in urban rail systems (both underground and light rail) through the 1990s is expected to be around 30 billion ECU. Large programmes exist in France (e.g. extension of the RER network in Paris, new systems in Strasbourg and Rouen), Germany (integrating eastern German networks), United Kingdom (e.g. extension of the Jubilee Line in London and the Metrolink in Manchester, light rails in Birmingham, Sheffield and Bristol) and Italy (e.g. underground in Naples). Even in Greece and Portugal (Athens and Lisbon) major metro schemes largely funded by the EU are under way in a bid to reduce the problems of congestion and pollution.

### Supply of public transport

Table 3 presents some indications of supply of public transport in the EU Member States. For all modes in major urban areas, the number of vehicle-kilometres per capita served indicates a relatively high service provision in countries like Denmark, Ireland and the United Kingdom. The figures indicate that populations in major urban areas in these countries have over 40 vehicle-kilometres per annum per person. Relatively low service levels per capita occur in Germany, Italy and Portugal (the lowest). These figures do to some degree reflect differing population densities and should be viewed cautiously.

## INDUSTRY STRUCTURE

In general, the majority of public transport operations are in public sector ownership although there are a number of ex-

ceptions - where services are provided by privately-owned companies working under contract either to public sector companies or direct to local authorities (as in France, and, to some extent, the UK).

This situation has arisen for a number of reasons, in particular the perceived need initially to control a de facto private monopoly and subsequently to maintain through the public purse a level of service and/or low fares which could not be offered without the intervention of the authorities. In some cities indeed comprehensive utility organisations have been created covering transport, gas, electricity and water supply.

Relations between the authorities and the providers of public transport services are now changing radically however with the prime object of reducing the costs to the taxpayer. The changes include:

- introducing or extending competition for the provision of services which is involving private sector operations,
- a more structured and formal contract between public authorities and transport operators which often means separating the latter into specific legal entities.

The situation in each country is as follows.

### Belgium

The responsibility for public transportation by bus lies with the three regional governments of Flanders, Brussels and Wallonia. The former national bus company and urban public transport companies are now organised into regional companies owned by the regional governments. In the Walloon region five local subsidiaries operate under four to six year management contracts. The regional authority decides fare levels and the allocation of subsidies to operating companies. It also co-ordinates various activities such as ordering vehicles, a common statute for personnel, common services between operating companies, etc. Operating companies determine timetables and can decide on subcontracting operations externally.

### Denmark

Danish county councils (except Aarhus and Fyn where the local authority is responsible) have created regional transport companies for the management of all regular public transport within the area. In general, these companies organise, plan and market the services offered. Operations are generally licensed out to (mostly private) companies. Revenues go to

the regional transport company; deficits are financed by the county council.

In the Capital Region (Copenhagen and surroundings) the situation is different. A new law came into force on January 1st, 1990 engaging the Capital Region Public Transport Company in general transport planning, the maintenance of the network and integration of fare structures with those of the railways. Currently it is putting bus services out to tender under long term contracts.

Other local rail services are operated under agreements with local authorities. Agreements relate to service levels to be provided and fares and subsidies to finance the services. A particular example is the metro service in Copenhagen.

### Germany

Local and regional authorities in Germany control and co-ordinate public transportation solely by determining routes and fare systems and deciding on the licensing of services to private companies. In practice companies active in this field cooperate extensively with each other. Licences can apply to all modes of transport, but the period of validity can vary. Subcontracting to other operators is allowed. In principle, fares must be set at a level which covers costs. Where this is not possible, subsidisation will be defined by the authorities. The Federal Government is investigating the possibility of deregulation.

Competition between bus and rail has always been strictly avoided. The Deutsche Bundesbahn itself operates various rural bus services through its subsidiary Geschäftsbereich Bahnbus (GBB; split in 25 regional companies) as a replacement for former rail services.

In former East Germany, public authorities were heavily involved in public transport operations. The situation is currently changing towards the present system in the western part of Germany.

### France

In the Ile de France area (Paris and the surrounding area) the Syndicat des Transport Parisiens governs the main operators (RATP and SNCF) together with a further 80 small operators. The STP defines policies, route coverage and revenue structure (fares versus subsidisation). Existing services cannot be transferred from one operator to another although operators are allowed to sub-contract services to other companies. For new services, operators are selected on the basis of a tendering process.

In urban areas outside Paris "conurbation authorities" are responsible for controlling local transport, determining routes, service pattern and fares levels, and granting a single operator the right to provide services throughout the area covered on a fixed term contract. Elsewhere, the provision of bus transport is the responsibility of the départements, which buy in services under contract from private operators.

In the past contracts were often renewed automatically, but they are now subject to competitive tender. Most of the operators on the market are owned by one of three major private or semi-private groups: Transexel, Transcet, and CGFTE.

Local railway services, although operated by the national operator SNCF, are in many cases now specified by the regions in which they run, although a proposal to create a corresponding regionally based financing system has not yet been implemented". for some pilot regions

### Greece

Greek regional and local bus transportation is controlled by the regional prefectures. They grant public transport licences to co-operative associations in the regions. A co-operative consists of individual bus owners providing buses and drivers, and revenue collection staff for fare collection. In Athens,

Source: UITP

three government-owned bus companies run the public transportation services within the city under the control of the separate public body OAS. Thessaloniki and Rhodes have systems slightly different from the prevailing system in the country. In Thessaloniki, a private operator has a licence of 21 years duration to operate services; in Rhodes city a municipal operator runs the services in the city proper under the supervision of the prefecture.

### Spain

Spanish authorities, usually the municipal council, grant concessions of between 8 and at maximum 20 years for the operation of a network of scheduled local bus services. The authorities determine the route structure and fare levels. Special regular services are allowed on condition that they do not compete with scheduled services.

Urban transport is provided by 185 companies, of which 28 are municipally owned and three are labour co-operatives. Private companies also operate in 129 of the 134 small sized towns (less than 100 000 inhabitants). In four of the five large cities (population above 0.5 million) the municipalities operate public transport themselves.

In inter-urban bus services, regional authorities grant concession rights to private operators. In cases the service crosses the regional boundary, the concession is granted by the national government. Concession conditions are generally the same as those for urban transport.

Passenger services by rail are mainly provided by the state railways RENFE. In some regions, however, the regional government owns the network. Sometimes services are provided by way of a concession to a private operator using this network. Metro services (Barcelona, Madrid and Valencia) are provided by either state owned or municipally-owned organisations.

### Ireland

Irish public transport is operated by the state-owned holding company CIE. This company owns three subsidiaries: Dublin Buses for bus services in the Dublin city region, Provincial Buses (Bus Eireann) for inter-urban and rural services and local services in the two major towns outside Dublin, and the Railways for all rail services including the rapid transit line in Dublin. The government is currently considering introducing competition in the provision of transport services. A new authority is likely to be created for putting individual services out to tender and issuing licences.

### Italy

Public transport in Italy is governed by a concession system. In general, concessions are granted for long periods under monopoly conditions. In larger cities, the concession usually goes to the (generally municipally-owned) local public transport company. Regional authorities let long term franchises for longer-distance services and services in rural areas. In some cases, national authorities issue concessions for inter-regional and other long-distance services. These concessions

can be granted to any operator, either private or publicly owned. The body issuing the concession usually determines services, timetables and fares.

### Luxembourg

In Luxembourg four networks exist in public transportation. These are:

- Luxembourg City Buses (AVL) for local and out of town services in the city of Luxembourg under the control of the city government;
- RGTR: a number of private operators providing bus services under the control of the Ministry of Transport;
- bus networks in the cantons of Esch-sur-Alzette under the control of a syndicate of cantonal authorities;
- CFL: the railway company provides not only rail services but also bus services on former railway links and on routes determined by the Ministry of Transport.

The controlling body is the Ministry of Transport. It determines fares, timetables and services, co-ordinates the provision of

services throughout the country and grants 10-year concessions to operators with automatic renewal.

### Portugal

Most public transport in Portugal is provided by public sector companies. Some local and regional bus services are in private hands under a concession agreement granted by national or local government. In 1990, a law was passed to deregulate public transportation.

In Lisbon, Oporto and Coimbra, services are provided by companies owned by the municipality. For Lisbon and Oporto committees have been established to control the implementation of a public transport plan designed to regulate the public transport system in the area.

In the rest of the country, the government strives for complete deregulation by imposing only qualitative restrictions in licences for operators. Control over maximum fares is retained. Local authorities are authorised to supplement the network with subsidised services.

## Netherlands

In the Netherlands public transport has until now been generally provided by operators who have been granted exclusive rights under the Passenger Transport Act. Seven major cities operate their own bus services. As an experiment however two further cities have invited tenders for the operation of their networks, as a result of which their systems are now being operated by an American company under 5-year contract. In 4 other cities, services are provided by 80 %-owned regional subsidiaries of the state-owned holding company VSN, working under 10-year contracts which are automatically renewed. These regional subsidiaries also provide inter-urban and regional transport, under the control of the Ministry of Transport.

Since 1988 private operators have had the right to compete on inter-urban services - although this has led to the establishment of only a handful of new routes, none of which competes directly with existing routes.

Although the Ministry of Transport is persisting with its policy of encouraging the development of public transport, it is seeking to increase efficiency and reduce subsidies by increasing resort to competition. Proposals are at present being considered to create 35 areas covering the whole country, the operation of public transport in each area being subject to competitive tender."

## United Kingdom

The UK is unusual in that, outside London and Northern Ireland, most bus services are provided by privately owned companies competing freely on the road with no intervention from the authorities apart from ensuring basic safety standards and that the rules of competition are observed. There is no control over fares or networks and services. Where however the county authorities (or in the major conurbations the Passenger Transport Executives) consider that the resulting services do not adequately meet social needs - e.g., at the extreme ends of the day, or in rural areas they may buy in services from private operators following a tendering process. In London, services are operated as part of a co-ordinated network

with individual private sector operators competing for contracts to operate individual routes or sometimes groups of routes for periods of 3 to 5 years. Similar arrangements have been adopted in Northern Ireland.

Rail services are also in the process of privatisation. A separate track authority has been formed and the operations of British Rail has now been split into 25 separate operating companies. The franchises to operate the services provided by these companies will be let by a competitive tendering process over the next 2-3 years. Meanwhile such supporting activities as track and signal maintenance and the leasing and maintenance of rolling stock are being put out to tender.

## Impact of the Single Market

As a result of the opening up of public procurement (see section on regulations), the Single Market has begun to spur cross-border competition between operators of public transport, which is modifying the structure of the industry. In a number of places there has already been increased competition, which has been accompanied by restructuring. This in turn has led to an increase in company size and in concentration, while subsequent productivity gains have negatively affected employment. This process can be expected to continue progressively across the Union. Decline of public transport has particularly affected those types of employment (local jobs, "proximity" less qualified employment) targeted by the Delors report.

On the other hand, whereas the completion of the Internal Market has significantly modified competition within the public transport sector, it has also intensified existing imbalances in competition between transport modes. Compared to its more direct competitor, i.e. private car, public transport suffers from a serious competitive disadvantage to the extent that the actual cost of usage of private car is far lower than its true social and environmental cost. These costs should include use of scarce urban land (for moving vehicles and for parking), cost of road accidents to society, health effects of exhaust gases particularly in urban areas, increase in CO2 levels in the at-

mosphere and disruption of urban quality of life by automobile related infrastructures and activity. The EU environmental policy has so far failed to correct the situation. Other measures of the Internal Market, such as the harmonisation of taxes on private cars, have brought about a strain on the pro-public transport policies of Member States such as Denmark which had put serious fiscal disincentives on the use of private cars. Finally, the too timid internationalisation of rail services has further accentuated the imbalances.

---

## ENVIRONMENT

---

In urban and inner-city areas, the congestion and environmental degradation - pollution, noise, visual intrusion - caused by the use of motor vehicles are now recognised as major problems. Increasingly public transport is seen as the most cost-effective means of combating these problems. National and regional government and the European Commission are all developing strategies to reduce the environment impact of traffic, and in most cases those policies include the increased use of public transport. Policies to discourage private transport use include increasing the tax burden on cars and fuel (yielding revenues which could be used for subsidising public transportation operations and investment), providing park-and-ride schemes, charging increased premiums for parking in inner-city areas and allowing only residential parking in suburban areas. Close attention is also being given to the possibility of introducing road pricing.

Although a comparison on a per vehicle basis between buses and private cars shows that a bus produces more NO<sub>x</sub>, HC, CO<sub>2</sub>, SO<sub>2</sub> and particulates (but less CO) than the average petrol-engined car, in terms of emissions and energy consumption per passenger and per passenger kilometre the bus is considered the most environmentally friendly transport mode. A bus carrying 25 passengers will produce, per passenger kilometre, only 67 % of the NO<sub>x</sub>, 8 % of the hydrocarbons, and 16 % of the CO<sub>2</sub> emissions produced per passenger kilometre for a car carrying a single passenger. Suburban electrical rail services are estimated to consume substantially less primary energy per passenger-kilometre, at any occupancy over 25 %, than private cars but marginally more than a bus. In addition, if transfer of traffic to buses can be achieved in such a way - as with most park and ride schemes - as to reduce traffic congestion, then the remaining vehicles will be able to operate more efficiently, leading to a further reduction in emissions and in fuel consumption.

In its Green Paper on the Urban Environment the European Commission has suggested the following actions:

- encourage city authorities to incorporate public transport and road construction into their plans for land use and transportation;
- promote innovation in public transport, environmental-friendly vehicles and advanced traffic management systems by way of contributing to the cost of pilot projects and monitoring their effects;
- encourage EU-wide exchange of information in urban traffic management to maximise the benefits of a wide range of experiences;
- consider in detail the potential for using economic instruments in private car transport such as road pricing and pay-tolls for the right to enter city centres.

---

## REGULATIONS

---

As a major employer in a labour-intensive business, public transport is heavily affected by the wide variety of legislation regarding health and safety and employees' rights which have been passed in recent years by the institutions of the EU. It is also strongly affected by legislation regarding consumer

rights (e.g. the Unfair Contract Terms Directive, which in many cases outlaws clauses restricting the operator's liability in the case of accident). Legislation on the protection of the environment - in particular emissions from motor vehicles - is also having an important impact. The recent individual pieces of EU legislation which are having a marked effect on public transport operators include the Procurement Directive for Utilities (93/38/EEC) and the Directive on the Development of Railways (91/440).

The Procurement Directive for Utilities has obliged all operators in the public sector to seek tenders Europe-wide for works (over 5m ECU), and supplies and services (over 0.4m ECU), leading - albeit at some cost in additional administration - to the prospect of increased competition in the supply of goods and services consumed. At the same time the legislation on services means that the placing of contracts for public transport services must themselves be the subject of a Europe-wide tendering process, leading to an opening up of an increasing number of services to competition between operators.

The legislation also makes it obligatory for operators to refer to European standards, where available, in specifying goods and services purchased. Notwithstanding the commercial advantages of standardisation, this holds out the possibility of difficulties in specifying vehicles and equipment required for specific services with non-standard infrastructure or unusual physical or market requirements.

The Directive on the Development of Railways separates the accounting of main line rail infrastructure and operations. In those countries which choose to include local rail systems within the scope of this directive, and where inter-working is physically possible, it could present new opportunities for working local rail services over main line systems - although with the drawback that existing services operated in this manner could find themselves in increased competition for paths with longer distance services.

New legislation currently progressing through the EU institutions is likely however to have a much more marked effect on public transport. Directives which are likely to have a major impact include the Working Hours Directive, new directives on vehicle dimensions and bus construction and interoperability for high speed and conventional rail.

If the general Working Hours Directive (93/104) were extended to public transport in its present form, the costs of meeting such features as a minimum 11-hour daily rest period could result in additional labour costs of up to 5 % for many public transport operators (source: UITP).

Current proposals in the area vehicle of type approval could place serious restrictions on flexibility in bus design and operation, making it impracticable e.g. to use double-deck vehicles or small minibuses, or to obtain multi-purpose vehicles suitable for operation on routes which combine city, suburban and inter-urban characteristics.

Increased railway interoperability potentially offers new possibilities for the expansion of local rail services over main line systems in the long-term. Whether this is practicable depends however on the specifications adopted. If high speed specifications are extended to tracks currently used by local rail services, very heavy expenditure would be required to adapt local rail services so that even existing inter-working can be maintained.

The White Paper produced by the Commission at the end of 1992 on The Future Development of the Common Transport Policy (COM 92/494) has initiated a global approach and hence providing a framework for policy that integrates all modes. The White Paper is one of the most important documents from the Commission on transport issues and the discussions and negotiations that it has started will have far reaching impact on all modes of transport in the Community.

One result of the White Paper in the long run is likely to be to substantially encourage public transport.

The 1993 "Delors" White Paper on Growth, Competitiveness, and Employment is also of profound importance for public transport: the paper highlights in particular the urgent need to improve the operation of labour markets, to tackle social exclusion, to combat environmental degradation and develop a new pattern of sustainable development. Almost all these problems are pre-eminently urban phenomena, and the development of urban public transport is essential if these challenges are to be met.

---

## OUTLOOK

---

Despite improvements in the private car (e.g. reduced emissions, electronic control) which are likely to reduce emissions and to increase road capacity, the car will continue to pose mounting problems for society: the delays and waste caused by congestion; the increasing social exclusion of those without access to a car (who are likely to increase in number with the rising average age of the population), the unpleasantness and danger of urban areas in which the car dominates, growing suburban sprawl coupled with decaying city centres.

There is moreover a mounting groundswell of opinion in favour of the environment and against new road building, to the extent that in many major cities new road construction has become politically impossible. This is coupled with a growing recognition among the public and planners that improved public transport is essential if cities are to become habitable again.

The problem, however, is how to make it attractive to the individual traveller to choose public transport in preference to the private car - and thus how to fund the public transport improvements which are required.

The introduction of road pricing - now being pursued in a number of EU states, as well as in EU-wide research programmes - provides the most promising long-term solution. It would both reduce congestion (allowing buses to offer a more attractive service and reducing their operating costs) and permit fares to be increased to cover a larger share of costs as well as providing a large source of direct income which could be reinvested in public transport. Many of the benefits of road pricing (which still presents considerable technical and political difficulties) could however be achieved simply by controlling and increasing the price of parking in urban areas.

Increasing taxes on motor fuel, coupled with the allocation of some of the proceeds (as in Germany) to funding public transport, could achieve some of the benefits of road pricing. Meanwhile other sources of funding can draw on the benefits which public transport creates for third parties, in particular employers (note the Versement Transport paid by employers in French cities) and property owners (note the tax proposed by the City of London to fund public transport improvements). Meanwhile even direct investment by government is likely to be self-financing if viewed globally, taking account of the effect of transport improvements on earnings, unemployment, and rents, and the corresponding impact on tax revenue.

At the same time major steps are being taken to improve the management of public transport to improve the quality of service and reduce its costs, in particular through the rapidly spreading practice of tendering bus services (which can result in savings exceeding 20 %). This will complement the impact of new investment, as an increasing number of cities are turning to new light rail and metro systems, and existing systems are being upgraded with faster and more comfortable rolling stock and modernised stations. Particularly important will be the further integration of public transport systems with other modes of transport through e.g. park and ride and new links to airports, coupled with radical improvements in information and simplified systems of payment.

Essentially, Europe now faces a clear choice: either to allow its cities to continue to develop along American lines. Or to seek to revive its city centres and urban life. This can only be achieved through greater use of public transport. The techniques now exist to provide ease of mobility in cities with a greatly reduced impact on the environment. It is a question only of political will as to whether the right turning will be taken.

Written by: UITP and DRI Europe

The industry is represented at the EU level by: International Union of Public Transport (UITP). Address: Avenue de l'Uruguay 19, B-1050 Brussels; tel: (32 2) 673 6100; fax: (32 2) 660 1072.

# Road passenger transport

The road passenger transport sector is composed of regular and occasional bus services. This monograph focuses on inter-city services whereas urban bus services are covered in the monograph on public transport. The private car remains the most important competitor for this mode for short and long distances, followed by rail and air for medium to long distances. Enterprises in the coach sector are continuing to invest in upgrading equipment in order to attract new business and maintain existing business.

## INDUSTRY PROFILE

### Description of the sector

In general, road passenger transport refers to bus and coach services provided both within urban areas and between cities. However, urban and non-urban road transport correspond to distinct services, satisfying different consumption needs. Hence, given that urban bus services are covered in the monograph on public transport, the present monograph will be, as much as possible, restricted to inter-city bus and coach services.

Inter-city bus and coach services cover basically regular and occasional services. Following the more refined distinction made by the European Commission, the sector may be broken down into the three following segments:

- regular services whereby passengers are picked up and set down at specified intervals and at predetermined stopping points,
- shuttle services whereby groups of passengers assembled in advance are carried from a single area of departure to a single area of destination and are carried back to the place of departure,
- and occasional services, which cover all the services which are neither regular nor shuttle services.

Regular services also include special services such as the carriage of workers between home and work place, the carriage of pupils between home and school etc. Occasional services essentially fulfil tourist needs whereas shuttle services constitute an intermediate category depending on whether ac-

commodation is included or not. Shuttle services with accommodation are essentially tourism services and therefore close to occasional services whereas shuttle services without accommodation are closer to regular services.

The NACE classification handles the road transport sector in a somewhat unsatisfactory way. NACE 722 covers all forms of road passenger transport except regular bus services and so includes occasional motor coach services but also taxis services and chauffeur-driven hire cars. NACE 721.2 covers regular services but makes no distinction between urban and inter-city services and also includes tramway services. In short, the NACE classification distinguishes between regular and non-regular services but not between urban and inter-city services. In addition, bus services are systematically merged in larger categories including additional services such as taxis, tramways etc.

### Recent trends

The analysis of road passenger transport suffers from an inadequate statistical coverage. At the EU level, two types of statistics are available. Eurostat supplies some industry data based on the NACE classification whose shortcomings have been highlighted above. These data also remain somewhat difficult to compare across countries and have therefore not been used hereafter. The European conference of Ministers of Transports (ECMT) releases statistics in physical units (passenger/km or number of buses) which, however, do not break down total bus services into urban and inter-city services. The analysis of recent trends in traffic, carried out hereafter, is based on ECMT data and therefore covers both urban and inter-city bus and coach services.

Between 1986 and 1992, estimated growth in total EU traffic by bus and coaches (i.e. including urban services) averaged 2 % annually, a relatively modest increase compared to total passenger traffic (i.e. rail, road and private cars) which is estimated to have expanded by more than 3.5 % annually over the same period. During the second half of the 1980s the development of bus and coach transport differed significantly from country to country. Portugal, Italy, Spain, and the Netherlands have all reported growth rates exceeding 3 % between 1986 and 1992. Past trends were much less positive in countries such as Denmark and France which reported quasi-stagnation in traffic (less than 1 % average annual growth) over the same period, and even quite dismal in the case of countries such as the United Kingdom which suffered an actual decline in traffic.

(1) Estimate

Source: Eurostat; Transport Yearbook; IRF; World Road Statistics

Comparing traffic levels across countries, Italy is the unquestionable European leader with a number of passenger/km which is more than 15 % higher than in Germany (including the Eastern Länder) and about twice as high as in the United Kingdom and in France. In 1992 Spain became the fourth largest Member State with a bus traffic exceeding that of France for the first time. Differences in traffic levels between countries reflect differences in population size but also differences in the level of development and in the national policies towards the private car. Hence, the most developed Member States tend to have the lowest per capita bus traffic (e.g. Germany, France and the UK) though national policies towards the private car and public transport can have an extremely strong impact as in the case of Denmark where a particularly unfavourable tax treatment of cars results in the highest (and by far) traffic per capita ratio.

### International comparison

Estimates of the stock of buses and coaches point to similar slow growth in the USA, Japan and in the EU. In the USA and in the EU the stock increased by 1.2 % annually over the 1986-92 period, whereas a similar average growth rate was registered in Japan for the 1986-91 period. In the USA, among other factors, the intense price competition among American airlines has caused people to favour air transport instead of coach services, and in Japan high-speed inter-city rail services provide a competitive edge over coach services.

## MARKET FORCES

### Demand

The demand for extensive private mobility, arising from the desire to travel door to door with maximum flexibility, the absence in some countries of adequate alternative public transport and rising real personal disposable incomes have been the main factors behind the extensive growth in private car ownership and use. This has meant that growth in passenger road use has been largely in private cars. Substantial excise duties on fuel prices have barely influenced car ownership and car use as the user perceives the additional incremental cost as minuscule compared to the improvement in mobile efficiency.

In most EU countries, transport by private cars has been increasing faster than overall mobility, in part fuelled by house-

holds owning more than one vehicle. In the traditionally lower car density countries in southern EU, Greece, Portugal and Spain, car ownership and use will continue to grow and outpace demand for public transport.

A significant proportion of the sector is coach services for tourism. Tourist coach services in combination with accommodation arrangements (inclusive tours) is popular among lower and medium income households and among senior citizens. Operators, however, are trying to attract other market segments by offering high quality services on long-haul routes. This aspect of public road transport is important for the tourist industry as it provides a convenient and predictable leisure schedule that is extremely cost efficient.

### Supply and competition

Contrary to urban busses, inter-city busses and coaches usually have seats for all the anticipated passengers and therefore carry a smaller number of passengers for similar vehicle sizes. The long distance services typically use luxury coaches with a high level of interior furnishing and amenities.

The cost of entry of new operators into bus and coach services has historically been low - typically the purchase of equipment and insurance - but due to regulation overhang, the number of new entrants is still limited in some EU countries. Also, entry of new operators is subject to EU directives on access to the profession (condition of financial standing, good repute and professional competence). For non-regular services competition between firms is muted as they provide similar services and also due to the low number of competitors for particular holiday schedules. The major competition comes from other modes of transport, typically the private car, rail and air.

Over longer distances added competition, from improvements in domestic rail networks and the introduction (and extension) of high-speed trains in some Member States threatens the road transporters. However, the experience of the TGV in France over the last ten years indicates that high-speed trains slightly stimulate overall demand for transport services and have mainly tended to take market share from regional air services.

In terms of passenger safety, buses and coaches have significantly less passengers and drivers killed or seriously injured (KSI) per passenger-kilometre compared to cars. On average, it works out at about 1 to 18. Nonetheless there are still

demands to improve safety for coaches, including such measures as compulsory wearing of seat-belts and in some Member States improvements in the road worthiness of the vehicles.

## INDUSTRY STRUCTURE

The regular services sub-sector varies considerably from one Member State to the other. In general the sector is fragmented with a large number of operators with fleets of varying size and although some very large operators exist, the majority of the enterprises are small-sized. Hence the sector is generally considered unconcentrated. In the occasional services sub-sector, the variance between Member States is significant, with some Member States having a dominant carrier, whilst in the others the reverse is true. Medium and large sized operators tend to work more in the international market, in contrast with smaller companies which operate in national and regional markets.

Amongst the larger operators in the EU markets are National Express in the United Kingdom, De Jong Inratours and Beuk in the Netherlands, ALSA and Iberbus in Spain, GTI in France and Deutsche Touring (subsidiary of the German railways) in Germany. Most of these firms also offer regular services. Also, for international European coach operations some 40 operators of international regular services are members of Eurolines. This consortium allows co-operation and efficiency in arranging and pooling service schedules as well as sharing the costs of marketing. Another such organisation is Europabus, which operates in Germany.

The greater part of the investments made by enterprises is for replacement of depreciated vehicles. Particularly in the longer distance market, the intensifying competition and customer expectations on quality standards forces enterprises to operate with high-quality buses and coaches with a broad variety of modern features (e.g. air conditioning, air pressure suspension systems, video facilities, catering etc.).

### Impact of the Single Market

The completion of the Internal Market has positively influenced road passenger transport. The liberalisation of international intra-EU non-regular services and the progressive freedom of cabotage have created new opportunities for operators and somewhat unleashed competitive forces. Larger operators are reacting to the new environment by expanding their foreign activities and by increasing their size. More intense competition has, however, put pressure on profits and wages. In addition to easier access to the market, international transport operators have directly benefited from the removal of border checks which, in the case of non-regular services, entailed relatively burdensome administrative formalities. Overall, the sector has benefited from renewed demand owing to increased cross-border mobility and to the supply of more adequate services. Only few barriers remain to be lifted for the completion of the Internal Market, but existing discrepancies in the enforcement of EU regulations remain a problem.

## ENVIRONMENT

A comparison on a vehicle to vehicle basis between coaches and private cars shows that a bus produces more NO<sub>x</sub>, HC, CO<sub>2</sub>, SO<sub>2</sub> and particulates (but less CO) than the average petrol-engined car. However, in terms of emissions and energy consumption per passenger and per passenger kilometre the bus is considered the most environmentally friendly transport mode. According to the Commission's Green Paper on the Impact of Transport on the Environment, during a non-urban utilisation a bus requires on average 13 passengers to one passenger in a petrol-engined car to equate NO<sub>x</sub> emission, 2 passengers to equate HC emission and 7 passengers to equate CO<sub>2</sub> emission. Concerning, CO<sub>2</sub> emissions, which has become a central concern because of the Greenhouse effect, buses

and coaches (both urban and non-urban) are estimated to contribute only 1.6 % of the total in the EU, compared to 55.4 % for private cars. This small contribution partly mirrors the low share of busses and coaches in total passenger transport but also the superiority of busses and coaches in terms of energy consumption per passenger. When comparing a standard inter-city train with a standard bus at similar occupancy rates, bus and rail services post nearly similar primary energy consumption per passenger kilometre. Both modes consume substantially less primary energy than cars (diesel or petrol) and aeroplanes at similar occupancy rates, however the superiority of buses and rail decreases somewhat when occupancy rates increase.

## REGULATIONS

The EU legislation has established three types of international bus services: occasional, shuttle and regular services. As far as national bus transport is concerned, the categories of service vary from country to country and within certain Member States there is no category of shuttle services.

International regular services are subject to similar rules as those which apply to national services (timetables, set routes and prices). As to non-regular services, the EU Council of Transport Ministers has adopted in 1992 the regulation on the freedom to provide intra-EU international services for road transport by coach and bus. Under this regulation, an authorisation is no longer required for most occasional services and for shuttle services if accommodation is included (inclusive tours). For regular services and shuttle services without accommodation, however, authorisation is still required.

In 1992, the EU Council also adopted a regulation on the conditions under which non-resident carriers may operate national road passenger transport within a Member State. Since January 1 1993, freedom of cabotage allows operators to provide certain non-regular services under the same conditions as resident carriers. Though only closed-door tours presently enjoy freedom of cabotage, other non-regular services will be liberalised as from January 1, 1996.

The degree of regulation of bus and coach services varies greatly between Member States. Certain Member States, such as the United Kingdom, have a very liberal system, where basically only qualitative controls govern the operation of a service (Transport Act). The Netherlands also have a relatively free system (Passenger Transport Law) for non-regular operations but regular bus services remain strictly regulated. In Spain, the 1987 LOTT legislation prescribes very detailed provisions governing all road passenger transport.

Furthermore, a Directive (on the admission to the occupation of road passenger transport operators in national and international transport operations) has come into force on 1 January 1990, strengthening the existing provisions for becoming a passenger transport operator. In particular, it specifies precise minimum financial requirements to ensure the viability of existing and potential operators and it makes the passing of a written examination compulsory for new entrants.

The legal framework concerning intra-community bus transport is established by Regulation 684/92 containing provisions on regular, shuttle, occasional and own-account transport. Freedom to provide services affects regular and non-regular services.

The White Paper produced by the Commission at the end of 1992 on The Future Development of the Common Transport Policy (COM 92/494) has started the ball rolling in terms of a global approach to viewing all modes of transport simultaneously and hence providing a frame work for policy that integrates all modes. One result the White Paper may provide in the long run is to favour public road transport; however,

the approach will be cautious so as to minimise the effects of sudden changes in policy and hence mobility.

---

## OUTLOOK

---

Growth in inter-city bus traffic will be lower than overall mobility, as private car use is yet to reach its maximum. Policy instruments from national governments, local authorities and potentially the European Commission to discourage private car traffic in order to reduce road congestion and air pollution by cars, are not likely to have significant consequences for the ownership and use of private cars in the short term. This is especially the case, as mentioned earlier, for habitual car owners and users who have a substantial tolerance for mechanisms involving increase taxes and fuel excise. The opening up of Eastern Europe has and will further expand tourist destinations for coaches. Investments in high-speed trains is not expected to threaten the road passenger transport in the short term.

# Road freight transport

## NACE 723

Road freight is the dominant sector in the movement of cargoes within the Union, accounting for close to three quarters of inland transport. The sector has suffered from a protracted recession since 1990. It is so far keeping its competitive edge compared to other transport modes, helped in that by the completion of the Single Market which is improving the sector's efficiency and fostering growth of intra-EU traffic. However, in the coming years, growth in road freight will be hindered to some extent by increasing congestion and a lack of investment in road infrastructure. In addition, public authorities are increasingly considering road freight in a global framework where environmental and other social costs are fully taken into account when comparing different transport modes.

### INDUSTRY PROFILE

#### Description of the sector

The goods transport sector includes units exclusively or primarily engaged in the transportation of goods - regular or otherwise - by trucks and vans or similar vehicles e.g. trailers, semi-trailers, road tankers, removal vans, articulated vehicles and truck-trailer combinations.

#### Recent trends

After the buoyant second half of the 1980s, during which growth in total road freight traffic measured in tonne averaged 3.5 % in the EU, the sector entered into more difficult times in beginning of the 1990s. In 1990 and 1991 total freight traffic declined by about 2 % annually. Estimates for 1992 point to an apparent strong recovery with 5 % growth. However, the recovery is entirely accounted for by a 22 % surge in German domestic traffic. Germany excluded the European recovery turns into another year of recession with a more than 2.5 % decline in traffic.

Thanks to the development of intra-EU trade, international road freight traffic grew faster than domestic traffic during the second half of the 1980s, expanding on average by about 8 % per year. The trend continued during the early 1990s when sustained growth in international transport somewhat compensated the recession in domestic transport.

Turning to the performance of individual countries in 1992, most of the Member States reported a drop in total traffic

with particularly dramatic results in the case of Portugal (-12 %) and Greece (-15 %). Apart from Germany, only Denmark, Italy and the Netherlands have experienced a rise in traffic.

International road transport can be analysed either in terms of traffic flows as in Tables 4 and 5 or in terms of shipments made by vehicles registered in the country considered. Based on the latter concept, the Netherlands are the leading European country in terms of international road transport, accounting for close to a quarter of all international shipments by European hauliers. They are followed by Germany (20 %), France (17 %) and Belgium (17 %).

### MARKET FORCES

#### Demand

Road freight generally offers an efficient and facile method of transporting and distributing goods to wholesalers, retailers and consumers. The level of economic activity is a major component in the demand for road freight, and there is a strong correlation between growth in economic development and growth in the demand for road freight, both internationally and domestically. On average, European road freight transport measured in tonne-km expanded faster than real GDP over the past two decades. In tonnes lifted growth was slower than GDP, indicating that an increase in average distance travelled accounted for much of the sector's past growth.

Road freight's largest customer sectors are machinery and other manufactured goods, manufactured minerals and building materials, and food and drink products. In tonnes lifted these three sectors account for about three quarters of the cargo shipped by road. Manufactured minerals and building materials are predominantly transported over short distances and therefore represent more than 45 % of domestic road transport in Europe when measured in tonnes. However, when considering domestic and international transport in tonne-km, machinery and other manufactured goods becomes the largest customer.

Though this effect remains difficult to quantify, the advent of the Single Market has proved beneficial for demand for international road freight transport. In addition to an increase in intra-EU trade, demand has also benefited from a set of factors specific to the road freight sector. The removal of trade barriers has entailed an increase in intra-EU trade for a given amount of EU production both because it has allowed companies to ship goods which were previously too difficult or too costly to export and as a consequence of the restructuring of the European manufacturing industry triggered by the In-

Source: Eurostat: Carriage of goods

ternal Market. The latter effect entails the progressive rationalisation of the European industry around larger production and distribution units as well as increasing trans-border sourcing. The ensuing increase in distances between consumers and suppliers translates into additional demand for the transport sector.

As to the factors specific to road transport, the Single Market is improving the efficiency with which goods can be shipped by road. The deregulation of international transport is fuelling competition between European road transport companies, an effect which is amplified by the progressive deregulation of national road transport in many Member States. Competition fosters innovation and encourages road transport companies to upgrade their services in order to meet developments in demand by shifting from general goods transport to a wide range of specialised and sophisticated transport services. Hauliers tend to be increasingly engaged in distribution and logistics activities as well as in physical transport. Increased competition and the pressure to innovate is also entailing a process of concentration and co-operation. On the other hand an increase in the demand for specific services offers prospects for specialisation.

A major extra-EU market to use the road goods transport service from the EU is Eastern and Central Europe. However, eastern European countries have been unable to cope with the resulting substantial increase in road traffic. Estimates put the average additional time required to travel a specific distance in Eastern and Central Europe compared to the equivalent A road in western Europe at 20 %. Road maintenance, upgrading and the construction of new motorways will be required to ease congestion and to ensure rapid flows of goods and passengers. Implementation of these measures require both considerable investment and time. The TEM (Trans-European Motorway), prepared and carried out under supervision of UN, has the objective of ensuring the construction of an integrated Pan European road system. However, the TEM-project is not expected to be realised before the turn of the century.

The use of information and communication technologies, e.g. Electronic Data Interchange, Tracking and Tracing systems, will act as a fillip for market growth, as the services offered by the players in the road goods transport market can provide better quality (e.g. Just In Time, reliability, flexibility and probability of damage) and/or cover a far wider range of destinations thanks to efficiency improvements.

### Supply and competition

Road goods transport is able to supply a flexible range of services that moves a wide range of products over a very

broad geographic area. One of the cornerstones of road goods transport's competitive position vis-à-vis rail and inland waterways is this geographic flexibility. For short haul movement of goods, road goods transport has a distinct advantage. It is typically on long haul point to point bulk services, where rail can collect from point of initial loading and delivers to point of final discharge, that rail offers its most competitive threat to road goods transport. Overall, services supplied by inland waterways and rail suffer from a lack of competitiveness both in terms of quality (flexibility, reliability etc.) and in terms of price. Over the past two decades modal competition has therefore largely turned to the advantage of road. If transport by pipelines is excluded, the share of road in EU inland transport continuously increased from slightly over 55 % in 1970 to 74 % in 1990. Over the same period the share of the two competing modes (i.e. rail and inland waterways) declined continuously, rail being somewhat more severely hit than inland waterways.

In addition to the road goods transport industry, there is 'own-account', which is a company transporting its own products in its own fleet. In the last few years there has been a noticeable trend for companies using own-account transport to downsize their fleets and move to using third party transportation. The observed increase in the share of 'hire and reward' compared to 'own-account' is in line with the more general trend towards an more outsourcing of non-core activities in the European industry. It is also a consequence of enhanced competition between hauliers and the associated decrease in cost and improvement in quality and complexity of road transport services. The emergence of large transport operators providing complete logistics services is a strong incentive to outsource part or the whole of the logistic function. However, in some cases the frontier between 'own-account' and 'hire and reward' becomes somewhat blurred because of the emergence of professional transporters operating dedicated fleets for large retail chains or manufacturing companies requiring specialised trucks such as oil tankers.

The enforcement of regulations on driving and rest hours have still to be improved in the Union. This, coupled with variations on hours kept at loading and discharge areas can severely affect the logistics and scheduling of road freight movement. Additionally, permissible weights for particular truck and trailer types, which vary from country to country in Europe, have an indirect impact on cross-border movements, although there is now conformity in the Union.

Liberalisation is another important area of transport policy which will continue to affect the supply side in several ways. Firstly, as discussed above, trade between Member States and

thus intra-EU road traffic will continue to increase. Secondly, the deregulation of international transport and the progressive introduction of cabotage will continue to strengthen competition between hauliers from different countries, pushing freight rates downwards. This in turn will benefit the industry as more cargo will be diverted to road. However, it remains somewhat difficult to evaluate the respective effect on freight rates of the Union liberalisation of international intra-EU transport and of ongoing domestic deregulation. The EU liberalisation process only concerns international transport and cabotage, i.e. the right by a foreign haulier to pick up and deliver ship cargo between to points within the domestic country. Nevertheless, the prospect of increased competitive pressures by foreign companies both in the international market and in the domestic market as a consequence of cabotage has led most of those Member States which still imposed strict regulations on their domestic road freight services to start up a liberalisation process in order to boost the competitiveness of their own transport industry.

Comparison of market shares confirms the strong competitive position which the Netherlands hold in intra-EU road freight, in relative as well as in absolute terms. Belgium also is well placed on the intra-EU market. The intra-EU market shares of Germany and France are also high, but compared to their national traffic their contribution to intra-EU traffic is of minor importance. Spain is the only other country where intra-EU traffic is significant to the sector.

### Production process

The production process is relatively straightforward. Cargo is collected en masse at point of origin, or it is consolidated by a transport firm. The consolidation may involve collecting small parcels of freight from many different locations using smaller vehicles before transshipment for the major stage of the journey. Delivery of a large single cargo is to point of destination, where it may be used in its entirety or broken down into smaller parcels for onward delivery. A consolidated cargo is delivered to a point where it can be distributed or it is distributed on by the vehicle used for the major journey leg.

## INDUSTRY STRUCTURE

### Companies

The market is fragmented into many small transport companies. In some EU countries, the number of road transport firms is gradually declining, indicating a tendency towards some co-operation between companies or concentration in the sector. However, the barriers to entry in road freight are minimal due to low initial capital requirement and also minimal product differentiation, hence, liberalisation is expected to foster entry and substantial concentration is unlikely. To some extent, the industry will evolve towards a two segments structure with a large number of small companies providing simple transport services and a limited number of larger operators providing more sophisticated logistics services. Companies

in the first segment will benefit from limited economies of scale and will essentially compete in prices while companies in the second segment will take advantage of economies of scale or of scope to provide complex services where quality will become as important as price.

Member States differ considerably in the number of hauliers, the evolution of this number, and the distinction made between own account transport and transport for hire and reward. However, broadly, there is a degree of inter-relation between country size and number of companies. The main exception are Spain and Italy, which have an unusually high number of enterprises. Traditionally, Member States have had different market access rules for long distance and short distance goods transport respectively, however, as harmonisation progresses this will be less apparent.

### Strategies

Investment in expanding road infrastructure has not matched the development in road use. The growth in the number of cars, trucks and vans has exceeded the capabilities of some road networks. This in turn is causing serious problems for road maintenance, congestion, and technical and operational logistics. The lack of sufficient investments in road infrastructures becomes a serious threat to the goods transport sector. Governments are essentially monopoly suppliers of roads, and this is reflected in their investment decisions. Low investment in roads mirrors increasing strains on public finance but also increasing awareness of environmental issues. Besides, investment in infrastructure in some areas of congestion will do little to relieve the problem. European authorities also acknowledge capacity problems in the in road network. The trans-European road network (TERN) covers 58 000 km of which 43 000 km of existing roads to upgrade and 15 000 km of new links to build by 2004. However, the TERN looks somewhat pale compared to the trans-European rail network which covers 70 000 km and the EU Commission recognises that environmental considerations set constraints to the possible extensions of the road network.

Competition from rail may increase due to additional investment in railway transport, particularly investment in the improvement of the overall quality of railroad transport. The major investment of the Channel tunnel and the link between Sweden and Denmark will also lead to changes in transport flows and logistic locations.

### Impact of the Single Market

The completion of the Internal Market has strongly affected both the supply of and the demand for road transport services. The liberalisation of international intra-EU transport and the progressive introduction of cabotage have seriously spurred competition in the sector. Several Member States have reacted to the prospect of increased competitive pressures, both on the international market and on the domestic market as a result of cabotage, by adopting more liberal policies for their domestic transport market, thereby amplifying the initial effect of the Single Market. Though the sector has benefited from

the removal of border controls, which constituted a heavy cost burden, liberalisation and increased competition have translated into serious pressures on profits and wages. The Internal Market has also modified the structure of the sector, with an increase in the size of the larger operators needing to expand their geographical coverage to provide truly European services, and the simultaneous entry of a large number of small operators as a result of easier access to the market. On the demand side, the increased integration of European economies has fostered intra-EU trade and therefore demand for international road transport services. Only few barriers remain to be lifted for the completion of the Internal Market, but existing discrepancies in the enforcement of EU regulations remain a problem.

## ENVIRONMENT

Road goods transport is coming under substantial pressure from concerns over the environment. Road traffic is responsible for a large contribution to air pollution. Among the major air pollutants are: Sulphur dioxide (SO<sub>2</sub>), Nitrogen oxides (NO<sub>x</sub>), Carbon monoxide (CO), Particulates (Aerosols), Lead (Pb) and Carbon dioxide (CO<sub>2</sub>). Both gasoline-driven and diesel vehicles emit carbon monoxide, hydrocarbons, nitrogen oxides and carbon dioxide, though diesel vehicles emit CO and NO<sub>x</sub> at lower rates. Furthermore, gasoline vehicles emit lead, and diesel vehicles emit SO<sub>2</sub> and particulates.

Whilst most emissions are produced by private cars, the emission of particulates originate mainly from diesel engines - important for freight traffic. New EU standards for heavy vehicle emissions, Euro I and Euro II, will reduce emissions by these vehicles by 55-65 %, except for CO<sub>2</sub>. In the short term, there is no expected major technological revolution in engine design that will substantially reduce emissions. Hence, a major option is to ensure that the effect on the environment is costed correctly. The Commission is reviewing options on how to cost this effect, for instance through a proposed tax on energy and carbon. This could be used to stabilise the emissions of the greenhouse gas CO<sub>2</sub> over the coming decade, with emissions in 2000 remaining at the level recorded in 1990. It is important to note that the proposed CO<sub>2</sub> tax does not appear to find unanimous approval by Member States.

## REGULATIONS

The issue of authorisations, the fixing of tariffs and driving times, the imposing of technical standards and taxes on motor

vehicles, are actions that can affect the supply side of the market, for instance, the number of vehicles on the road. As to intra-EU international road transport, all bilateral authorisations and EU quotas have been replaced by EU authorisations since January 1st 1993. Permission to enter the market now depends on qualitative criteria and all quantitative restrictions have been lifted except for a safeguard clause which includes a crisis mechanism in case of serious market disturbances. On January 1st 1990, the old tariff system for international journeys within the EU was replaced with free price fixing.

As to cabotage, restricted market access started in July 1990 with the introduction of a limited number of cabotage licences. End of 1992, 18 000 such licences, each valid two months, were in operation. In June 1993, European transport ministers agreed upon an extension of the number of licences to 30 000 beginning of 1994 and an annual 30 % increase thereafter. The agreement also includes full freedom of cabotage as of July 1998.

Fiscal harmonisation is another important element of the EU policy towards road transport. During the same June 1993 Council, transport ministers agreed upon a minimum vehicle tax to be introduced in January 1995 and reached an understanding concerning infrastructure charging by allowing Member States to introduce road tolls or user charges. The new regulation allows Belgium, Denmark, Germany, Luxembourg and the Netherlands to proceed with their plan to introduce a common user charge system beginning of 1995. All hauliers, irrespective of their nationality, will have to purchase the so-called Euro-vignette in order to use the road network of the participating countries. Proceeds of the charge will be allocated between countries on the basis of predefined calculation rules.

By improved co-ordination, the EU is trying to improve the observance of social measures, i.e. to extend its span of control, to prevent drivers from neglecting the measure dating from November 1985 which regulates their hours of driving.

Other EU measures that may affect the road transport of goods are associated with the EU policy concerning environment and infrastructure. The Communication from the Commission in the form of a white paper entitled *The Future Development of the Common Transport Policy (COM(92)494)*, of December 1992 seeks to set out a global approach to transport issues enabling due consideration of all views before the launch of particular initiatives. It recognises the importance of road transport in the global picture, and seeks to balance transport policy

in terms of its impact on the environment with sustainable mobility for the Union as a whole. The communication enlarges on the major issues of modal disequilibria, capacity constraints, system and network developments, environmental issues, safety, and social issues.

---

## OUTLOOK

---

The liberalisation and harmonisation of the EU transport market, the resumption of positive economic growth and the continuing move towards fast and flexible transport will affect both the volume of total transport and modal choice. Environmental regulation, Eastern and Central Europe, investments in road transport and other modes of transport and information and communication technology are other important aspects.

For road transport operators, the European integration will continue to produce some general advantages such as an increased transport volume, more third-country transport, less empty return loads, simplified foreign settlement, and co-operation with foreign transport operators. Intra-EU traffic will grow significantly faster than national traffic, as the effects of the Single Market act as boost to the sector. Meagre investment in infrastructure will, in some cases, act as brake on the efficient expansion of road goods transport. However, investment in infrastructure in some areas of congestion will do little to relieve the problem.

The use of new information and communication technologies will act as fillip for the transport companies as developments in this field have undergone rapid improvements in recent years.

# Inland waterways transport

## NACE 73

During the past five years, the EU inland waterways transport industry has been affected by overcapacity problems and structural bottlenecks which have hampered the development of an equilibrium between demand and supply in the sector. Scrapping policies at the Community level have made some progress in improving the situation, to the point that these measures have been extended and hardened.

There are prospects of increasing demand (especially in the transport of hazardous goods and unitised cargoes) for inland shipping, which is rightly considered as one of the most environment-friendly and cheap modes of transport.

### INDUSTRY PROFILE

#### Description of the sector

NACE 73 includes units exclusively or primarily engaged in the transportation of passengers and goods on rivers, canals, lakes, lagoons and within river ports. Tugs and push boats operating on inland waterways also belong to this NACE group.

The largest portion of inland waterway transport consists of companies operating ships of various sizes to convey goods throughout Europe on the available inland waterway network. As passenger transportation is limited to a few ferry boats across rivers and boats for river cruises, this part of the sector is very small and will not be considered in this monograph. Most inland shipping operates with unscheduled services, and operations using fixed schedules are very rare.

Inland waterways goods transport is usually divided into liquid or dry cargo, according to the type of goods transported.

Next to companies operating ships as their primary activity (professional transport), there are companies active in manufacturing that operate ships on their own account (own account transport).

#### Recent trends

In terms of tonnage transported in 1992, the country with the largest volume is the Netherlands with over 260 million tonnes. Germany ranks second with a total tonnage of about 230 million. Belgium follows in third place with about 89 million tonnes and France is in fourth position with 71 million tonnes. Tonnage transported in Luxembourg exceeded 10 million tonnes in 1992. In the other EU countries, inland shipping is a marginal activity. In the United Kingdom and Italy, only

Figure 1: Inland waterways transport  
Distribution of EU fleet in number of vessels, 1992

(1) 1990

Source: Eurostat: Transport Yearbook

domestic shipping takes place; in Greece, Portugal, Spain and Denmark, inland shipping is virtually non-existent.

When measuring transport activity of inland shipping in terms of tonne-kilometres, the ranking changes. Germany takes by far first position followed by the Netherlands. France ranks third and Belgium fourth. Although the Netherlands has a greater length of navigable waterways in use than Germany, these comprise mostly of canals, whereas Germany has substantial lengths of arterial navigable rivers in use (3 000 kilometres). Also, the majority of inland shipping activity is accounted for by goods transported on the Rhine (622 navigable kilometres in Germany). Nearly 300 million tonnes are transported annually on this main artery of inland transportation for the European continent. Hence, the combination of the traffic density on the Rhine and Germany's greater stretches of arterial waterways provide the higher tonne-kilometre result for Germany. The river is the most important connection between the large ports in the Le Havre-Hamburg range (e.g. Rotterdam and Antwerp) and the European hinterland.

National differences occur when looking at the distribution of goods transport by type of traffic. In some countries, such as France, domestic transport is overwhelming (about half of inland shipping is composed by national traffic). At the other extreme, about the totality of inland waterways transport in Luxembourg is represented by transit traffic. In the Netherlands, exports dominate inland waterway transport with about 45 % of inland shipping, whereas only 19 % is represented

by imports. In Germany, the situation is reversed, with about 40 % of inland shipping due to imports and around 20 % is due to exports. In Belgium, imports represent close to half of total inland shipping and exports account for 27 % (measured in tonnes).

Most of inland waterways transport throughout Europe takes place within the EU. Transport to and from non-EU countries mainly relates to transport links with Switzerland (Rhine) and the East European countries along the Danube and the Elbe rivers.

Over the period 1987-92, the tonnage transported in the EU has been decreasing in the Netherlands and Belgium (-4.4 % and -5.2 % respectively), while increases were recorded in France (16.1 %) and Luxembourg (23.6 %). No figures are available for Germany.

## MARKET FORCES

### Demand

Inland shipping specialises in the transport of large quantities of bulk products, such as sand, ores, coal, chemicals, and oil. These are clearly divided into dry and liquid bulks. The larger volumes of goods transported are petroleum products (16 %), iron ore, iron and steel waste, etc. (13 %) and the largest group, crude and manufactured minerals, (33 %). In practically all countries, crude and manufactured minerals are the most important cargoes.

Over the years, demand growth in inland shipping had been fairly limited. In other types of transportation, such as road transport, growth rates of demand have been much higher. The major factor underlying this disparity in demand for inland waterway compared to other modes is that demand has been dominated by types of cargoes such as traditional bulk products used as inputs for traditional industries (e.g. refineries, steel industries, chemical plants), where growth rates of industrial activity have been either moderate or declining.

Another factor which has restricted over time demand for inland waterway transport services is undoubtedly the limited possibility of interconnections between national networks. This is mainly due to the limited capacity of some waterways: for example, 60 % of the French waterway network is accessible only to vessels of less than 400 tonnes.

The cost structures of these industries have supported the requirement for inexpensive transportation for bulk goods, where the transportation costs can sometimes exceed the raw material costs.

There has been a structural tendency to reduce the volumes of goods to be transported. This has been done by transferring the initial processing of raw materials to the origin. As a result, total tonnage of raw materials has declined and the tonnage of processed materials increased. However, this increase of semi-processed and processed cargo has not fully compensated for the decrease in raw materials.

Another problem on the demand side is that there is a tendency for monopsony power: demand is with a limited number of

large industries, which are able to exchange information on the inland shipping market. In the Netherlands, for example, the transport of sand and gravel has been controlled by a cartel of sand and gravel traders and producers. Furthermore, some industries have arranged long-term transport contracts with shipping companies at guaranteed prices. In addition, some industries have their own vessels (own account shipping). They only need to employ additional (independent) vessels to meet peaks in their transport demand.

On the positive side, inland waterway transport can represent a valuable and environment-friendly alternative to road and rail transport, at least in countries where the network allows it. For example, the car factory Ford-Werke in Cologne has recently announced that about 70 % of the cars produced will be transported to distribution terminals by inland waterway ships.

Another tendency is that inland shipping has become important for the transportation of dangerous cargoes, such as highly poisonous or explosive chemical products. These substances require a high level of safety standards from the transporters.

### Supply and competition

Inland shipping is capable of meeting the industry's requirements for bulk transportation which is cheap, energy-efficient, safe and reliable. A key advantage offered by inland waterways in comparison to other modes of transport is the relatively low burden for the environment since the energy use per tonne is very low. From a cost perspective, inland waterways transport is also advantageous: by way of example, in 1989 in Germany the cost of transporting one tonne per kilometre has been calculated at 3.3 pfennig for inland waterways, compared to 12.3 pfennig for railways and 23.3 pfennig for road transport.

The EU inland waterways fleet is dominated by the Netherlands in terms of both number of vessels and carrying capacity. In 1992, Dutch vessels accounted for more than half of ships

in the EU, followed by Germany with about one fifth of the total. The same figures are roughly applicable to the two countries in terms of carrying capacity.

The fleet is characterised by the existence of a large number of private owners mostly operating only one vessel, often with the owner's family living on board. These ships are generally old and of small size, and are not demolished as the owners operate at or below economic cost prices, accepting very little or even negative returns (hence the strong social aspect characterising the activity). Large shipping companies exploiting fleets of 20 to 100 vessels mainly operate on the Rhine and its branches.

The existence of small family-owned vessels which have not yet been scrapped and the introduction of modern large sized vessels has caused a structural imbalance between supply and demand. Overcapacity, therefore, has become a structural phenomenon in inland shipping. During the 1980s, overcapacity was estimated at some 20 % of the EU fleet.

Overcapacity has been blamed for its negative impact on the evolution of prices on the free market. Price regulating and cargo sharing systems were introduced, basically to guarantee ship owners a minimum income.

### Impact of the Single Market

The Rhine market, which represents about 75-80% of total inland waterways transport in the EU, was deregulated more than century before the completion of the Single Market. As a result, the Internal Market programme could only have little incidence on a sector which was already largely competitive. One of the few measures which had a noticeable impact is the suppression of border controls. On the other hand, the recent liberalisation of cabotage has not added much to existing competitive pressures. In the long run, the EU environmental policy is an aspect of the Internal Market which could seriously modify the sector's prospects. From an environmental standpoint, inland waterways constitute the safest transport mode

**Table 5: Inland waterways transport

for freight. However, inter-modal competition remains seriously distorted by the fact that environmental aspects are not reflected in modal costs. The competitiveness of inland waterways transport would therefore strongly benefit from measures aiming at a better internalisation of environmental costs.

## REGULATIONS

The action of the EU institutions in the field of inland waterway transport has been characterised by two main aims: the liberalisation of the sector and the reduction of overcapacity.

It is important to stress that a large part of EU legislation in the sector of inland waterways is not applied in countries with a closed canal network, i.e. that is not connected to other EU Member States.

Concerning liberalisation, the first relevant legislative measure taken at EU level has been the Council Regulation (EEC) 3921/91 of 16 December 1991 on inland waterway cabotage. From 1 January 1993 onwards, companies from one EU Member State can carry out national and international inland waterway transport operations in any other Member State. France and Germany were allowed some restrictions on cabotage until 1 January 1995.

In June 1994 the Commission presented to the Transport Council a report on the organisation of the inland waterway market, focusing in particular on the so-called "tour-de-rôle" (in-turn) tariff and charter system.

Under this system, carriers inscribe themselves in special "availability lists". According to their rank in the list, carriers can choose to undertake a transport service among those which are put on offer and for which they fulfil the requirements. In case of no choice by the carrier, their place in the list does not get lost. The "tour-de-rôle" guarantees minimum revenue to vessel-owners, and at the same time clearly hampers competition in the sector and reduces the commercial freedom of clients of the service.

The "tour-de-rôle" system is used in Belgium, France and the Netherlands, and affects altogether about 11 % of total cargo in the EU. However, its incidence is far greater at national level: it is estimated that this system affects about 50 % of total cargo in Belgium, 31 % in France and 18 % in the Netherlands.

On the other hand, the Rhine market which represents about three quarters of total inland waterway traffic in the EU is free. The Act of Mannheim of 1868 guarantees free shipping on the Rhine and its arteries for all ships with flags belonging to countries signatory to the Act (Germany, France, the Netherlands, Switzerland, Belgium, and the United Kingdom).

France already aims at abolishing the system after a six years' transition period. On its part, the EU Commission proposes to gradually make the system more flexible by exempting

**Figure 2: Inland waterways transport**

(1) Based on tonnes

(2) 1990

Source: Eurostat: Transport Yearbook

certain goods, increasing the possibility to conclude free contracts and by abolishing the obligation to use this system.

To remedy overcapacity problems, Council Regulation (EEC) No. 1101/89 of 27 April 1989 (subsequently amended by Regulations (EEC) 3690/92 and (EEC) 3433/93) was introduced to implement structural improvements in inland waterways transport. It created two set of measures:

- the granting of premiums to reduce the capacity of the active inland waterways fleet; and
- curbs on investment in extra vessels in the course of the co-ordinated scrapping scheme.

The main elements of the EU scrapping scheme for inland waterways are:

- Member States whose tonnage of inland fleet exceeds 100 000 tonnes have each set up a scrapping fund. Vessels from other Member States that operate on the shared network have to adhere to one of these scrapping schemes.
- The total active fleet registered and operating in the Member States is subject to the scrapping scheme. There are a limited number of detailed exceptions.
- New tonnage is only allowed on one of two conditions: (a) equivalent old tonnage is scrapped to match the new tonnage; or (b) a premium is required equivalent to the

scrapping premium for the type of vessel brought into operation, which is paid into the scrapping fund.

- Vessel owners paid annual contributions to the scrapping fund based on the tonnage and types of their vessels. Governments have provided interest free loans to the scrapping funds, repayable over a number of years. Transfers between "rich" and "poor" scrapping funds ensure that amortisation periods in all states are identical.

Scrapping activity in 1990-1992 took more than 2 000 dry cargo vessels out of the fleet with a carrying capacity of 1.1 million tonnes; additionally, 260 tanker vessels with a carrying capacity of 260 000 tonnes and 30 000 kilowatts of push boat capacity were removed. Total expenditure to achieve this is estimated to have reached 104 million ECU. The scrapping scheme has achieved a measure of stability between demand and supply, and has been extended beyond the original five years life for another five years. Recently, the conditions for bringing new vessels into operation have been made stricter: shipowners now have to scrap (or to pay for the scrapping of) 1.5 tonnes for each new tonne of new capacity they put into service.

The European Commission has also been active on the front of the harmonisation of criteria for issuing boatmaster certificates. A proposal of directive concerning this issue has been presented to the Council on 8 September 1994.

## THE NETWORK

The network for inland waterway transport in the EU extends itself for about 17 000 km, of which however only about the half can be used by vessels of more than 1 000 tons. Moreover, the connections between different national networks is very limited.

In effect, the so-called EU inland waterway network only includes the rivers and canals of Germany, the Netherlands, France, Belgium and Luxembourg. In the remaining Member States, infrastructure for waterway transport is either absent / insufficient (e.g. the United Kingdom) or disconnected from the European network (e.g. Italy and Spain).

Four major axis can be identified in the European inland waterway network:

First comes the Rhine, being navigable over a distance of 887 km from Basle in Switzerland to the North Sea at Rotterdam. This is the true backbone of the EU waterway system.

Furthermore, a coherent network has been created by waterways navigable for units with a loading capacity from 1 350 to 10 000 tonnes (pushed convoys on the Rhine and certain other sections) which covers most of Germany, the Netherlands, Belgium, Luxembourg and the northern and eastern frontier zones of France.

This network has been recently extended to Eastern Europe thanks to the opening of the Rhine-Main-Danube Canal, the second major inland waterway axis. Since its opening in 1992, this canal has exceeded initial expectations on volumes, and reached 4.2 million tonnes of cargo in its first year of operation.

The third major axis is known as East-West, and is formed by the rivers Elbe, Weser and Ems. Together with other canals such as the Mittelland canal, the axis basically unites some Northern regions of Germany with the new Länder. The Dutch government has recently expressed interest in the construction of the Twente-Mittelland canal, which would greatly improve inland waterway communications between Germany and the Netherlands, by avoiding vessels a diversion via the Rhine and the Weser-Datteln and Dortmund-Ems canals. On the other side, the German government has announced a programme to finance the restructuring of the Berlin-Spandau canal to improve inland waterway transport to and from the city of Berlin.

The fourth major axis is called North-South and serves the regions of Belgium, the Netherlands and France which are not connected to the Rhine. The main rivers of this axis are the Meuse, the Schelde, the Lys and the Sambre.

Although no major bottlenecks exist, investments in new infrastructure continue to be necessary. Increasing ship size requires enlargement of locks and canals, the deepening of waterways and adaptation of inland water ports. Modern navigation facilities are also needed along the waterways.

## OUTLOOK

Demand for inland waterway transport is likely to maintain an upward trend at moderate growth rates. In view of economic integration, transport demand among Member States will increase in terms of both volume and distance to the benefit also of inland waterways. In the field of hazardous goods transport and unitised cargoes, inland waterways are likely to gain.

The developments in Eastern Europe will affect traffic in two ways. Firstly, positive developments will emanate from Ger-

man unification and the opening up of the Eastern European economies. New market opportunities and intensifying trade will occur, but in the short term these effects will be limited. Secondly, negative developments may occur as fleets from East European countries enter West European markets, especially via the Rhine-Main-Danube canal. There is evidence that the low-priced Polish operators have almost driven out German competition on the Polish-German trades. In this case the German Transport Ministry has been negotiating with Poland to seek a 50:50 cargo share with minimum freight rates, and recently introduced a licensing system to enforce the agreement.

Concerning capacity, the EU scrapping system is likely to continue its initial successes. Together with the present trends in demand, equilibrium between demand and supply will be closer to realisation.

# Shipping

## NACE 74

The EU shipping industry is moving into a stage of advanced maturity, where the number of players will be dominated by increasing concentration in the top ranks, supported by a number of small niche players in specialised trades. Expectations are for the largest companies to continue to expand by acquisition and alliances, with fewer operators around by the end of the century. In the global liner industry, an EU company has remained in top position, while the EU liner industry gains an addition position in the top twenty ranking. The gradual recovery of some of the major trading power houses and developments within the EU will contribute to further improvements of trade, although the impact on the EU shipping industry is potentially mixed. Developments within the EU concern further deregulation of the EU shipping market and the effects of a shipping policy aimed at achieving an efficient and competitive EU shipping industry. European liner companies are increasingly becoming multi-modal operators and expanding distribution networks via purchases or alliances to meet customer requirements for inter-modal transport and value added services. The tanker and dry bulk fleets are continuing to be dominated by older tonnage and will have to undergo significant renewal in the 1990s if scrapping accelerates. The EU cruise industry is growing and looks to expand significantly over the next few years as real disposable incomes increase.

### INDUSTRY PROFILE

#### Description of the sector

The sector includes units exclusively or primarily engaged in the transportation of passengers and goods in sea-going and coastal vessels and units engaged in the operation of sea-going tugs. Deep-sea transport refers to shipping on long sea routes; and, coastal shipping or short-sea shipping refers to the conveyance of passengers and goods between national or European ports, including those on the Black Sea, the Mediterranean and Moroccan Atlantic.

Within the merchant shipping industry, cargo is usually analysed in sectors, which are dry bulk, tanker (also known as liquid bulk) and liner (typically scheduled services with consolidated cargo from many shippers). These sectors are further subdivided: dry into major dry bulks, such as grain, and minor dry bulks, such as bauxite; tanker into crude and products

(or dirty and clean) and gas carriers; and, liner into container and non-container (or general cargo). Usually tanker and dry bulk is dominated by tramp (non-scheduled) services. There are also specialised vessels that do not necessarily fit into any of these categories, such as refrigerated ships, forest product carriers, car carriers, steel product carriers and combination carriers. The situation is further complicated by non-standard operations. For example, it is possible to have a tramp operator moving containers, or a scheduled operator moving bulk coal, and some vessels can be used for conveying more than one commodity type, such as a gas carrier used for 'clean' oil products.

#### Recent trends

Growth rates derived from Table 2 indicate that, during the period 1986 and 1992, world seaborne trade achieved an average annual growth rate of 4.7 % in tonne-miles; however, the growth rate decelerated over the last three years to average 3.3 %. The various sectors of seaborne trade have shown similar development patterns over 1986 to 1992, although their pace of development varied widely. During this period, most of the sectors averaged rates of around 4 % per year; the two exceptions being iron ore (averaging only 2.1 %) and crude oil (7.3 %). The picture for the sectors' rates of growth for the period 1990-92 was not so rosy, with both iron ore (-2.2 %) and oil products (-0.6 %) recording declines but, despite a slowdown in its development, crude oil managed to maintain strong growth at 6.3 %.

#### Dry bulk and tanker

The dry bulk and tanker sectors form the largest part of seaborne trade in volume terms. In 1992, liquid bulk's (crude and products) share was 47 %; and the three main dry bulk commodities (coal, grain and iron ore) accounted for 27.5 %. Thus, the three major dry bulks and the tanker sectors account for almost three quarters of world trade in tonne-miles. In terms of tonnes, SS&Y Research estimates that total dry bulk trade in grain, coal and ore declined by 1.3 % in 1993. Estimates put about one-fifth of the world's bulk traffic (in tonnes) as originating from or arriving in Europe during 1993 and the overwhelming portion of these flows (94 %) were inbound.

The iron ore trade depends predominately on the steel industry, and to a lesser extent so does the coal trade. In 1993 world steel production trade rose by a modest 0.4 %; its first increase in four years. Surprisingly, the growth in 1993 was not from the traditional countries of Japan or the EU but was realised due to import growth from PR China and South Korea. It is expected that PR China will remain the leading generator of import growth for the iron ore trade until the end of the 1990s. As a result of the increased import demand from the PR China the EU saw a minimal increase of 0.2 % in its crude steel production. However, within the EU there were significant changes among individual producers of crude steel. Germany experienced a 5.3 % decline in production, while Italy, Spain and the United Kingdom all increased production in 1993. This had concomitant effects on iron ore shipments. Estimates for iron ore trade in the EU indicate a 7.4 % decline in 1993. Imports of iron ore from Australia, one of the EU's main external suppliers of iron ore by sea, reported a 15 % decline in trade with the EU for 1993.

The seaborne coal trade experienced a substantial reduction in volume for 1993, declining by 6 % from 1992. The reason for the decline is due to the substantial decrease in demand from the EU. EU production decreased by 16 % and its share of coal imports likewise declined by 18 %. However, for the dry bulk trade as a whole, DRI's Industry Consulting Group indicates that 1994 will provide a modest upturn, primarily from continued demand in the Far Eastern and Japanese markets.

Grain trades (wheat and coarse grain) decreased by about 8 % in 1993-94 (grain years are reported July to June) reaching their lowest level since 1986. Of the five primary exporters of grain (US, Canada, Australia, Argentina and EU), only Australia had an increase for the period. Total grain trade exports increased in Australia by 24.0 % while declining in the US (17.4 %), Canada (6.9 %), Argentina (11.1 %) and the EU (15.0 %).

Intermediate dry bulks (bauxite, alumina and phosphate rock) have had mixed fortunes over the last few years. In 1993 overall aluminium production rose by 1.4 % while in the EU production continued its five year downward trend with volumes falling by 2.5 % in 1993. The major factors causing this decline in production are aluminium production has been shifting to low price energy producing countries and low-priced imports from the CIS and Eastern Europe, which the European Commission has countered by imposing limits on these imports. The downward trend of phosphate rock imports into the EU also continued for 1993. On the other hand, alumina production increased by 4.1 % on the year.

Minor bulks, amongst which are steel products, pig iron, ferrous scrap, fertilisers (sulphur and potash), agricultural products (soya, rice and sugar), coke and cement, have experienced mixed results in trade for 1993. EU imports of third-country steel products rose by only 4.2 % in 1993 to approximately 12.5 million tonnes, while exports are estimated to have increased, according to the European Commission, some 40 % to around 26.5 million tonnes. This trade has been dominated by various trade disputes, the most important of which is the anti-dumping duties imposed by the US, which threaten some 1 million tonnes of EU exports. However, as of mid-1993

the threat has been removed with the US International Trade Commission's dismissal of the majority of the disputes. The latest data (through 1992) for pig iron indicates that world imports have fallen by almost 45 % since 1990. Preliminary estimates for pig iron in 1993 do, however, reveal a gradual improvement in trade as Japanese and South Korean imports increase. Total world ferrous scrap imports increased by 10.2 % in 1992 with the EU representing approximately 56 % of the trade. The EU trade of fertilisers (dominated by imports) continued to decline in 1993 as demand remained low. As a result, both sulphur and potash imports into the EU declined. Total world trade in soya beans for 1993/94 declined by 3 % over the period; primarily due to floods in the US, the world's main exporter. However, the US floods presented an opportunity for both Brazil and Argentina to release their extra supplies of soya for export. EU imports in soya bean trade for 1993/94 are expected to be 14.2 million tonnes representing roughly 50 % of the world soya trade of 28.6 million tonnes. However, current growth in the soya import trade is essentially coming from Asia. The global sugar trade experienced a dramatic decline of 13 % in 1993 mainly due to a 39 % reduction in Cuban exports. Western Europe imports of coke declined by 6 % in 1993 emphasising the weakness of its steel industry. Luxembourg, the United Kingdom and France were the only countries to show marginal increases of coke imports for the period. Finally, imports to Europe of petroleum coke increased strongly in 1993 (20 %) following a decline in 1992, with the majority of the demand coming from Italy, Belgium, Spain and the Netherlands.

In the tanker trades, EU imports of crude oil products remained stable in comparison to 1992 levels, averaging 10.0 million

barrels per day while products declined by 0.1 % mb/d to 3.4 mb/d in 1993. The major crude oil tanker trades were in general positive, with the Arabian Gulf States supplying 13.41 mb/d, Africa declining slightly to 2.54 mb/d, while the North Sea and Russian supplies also increased to 3.33 and 1.65 mb/d respectively. The largest portion of total EU imports of products is intra-EU trade (2.75 mb/d in 1993). However, total products imports recorded a decline of 1.9 % in 1993 as EU refinery capacity utilisation continued to be high (a trend caused by the Gulf War) as imported crudes were refined within the Community. ]

In the gas carrier segment, the major sources of LNG for the EU are Algeria and Libya to the EU. In 1992, Algeria's exports of LNG to the EU are estimated to have been almost 14 million tonnes, the major importers (in quantity) being France, Belgium, Spain and Italy. Libya exported 1.23 million tonnes to its major trading EU LNG trading partner Spain in 1992. The EU is the second largest importer of LPG after Japan, followed closely by South Korea. Total LPG exports for 1993 were 35 million tonnes. Extra-EU imports of LPG are estimated to have dropped by some 15 % in 1992, reflecting increased intra-EU trade.

#### Liner trades

The liner trades are dominated by movements of goods in containers. An analysis of the container trades is an excellent indicator for overall liner trades, with the proviso that there is a trend in the industry to move more liner-propensive commodities into container. Hence, although liner trades are already dominated by containers, container penetration is increasing. In 1993, the total volume moved in containers on the major trades increased by 3.1 % twenty-foot equivalent units.

The growth in demand for liner shipping averaged around 9 percent in 1980 to 1985, slipping slightly to around 6 % in 1985 to 1990, and around 4.7 % on average in the last three years. In recent years, the major growth has been in the intra-Asian market which now accounts for over 12 % of world trade. Deep-sea liner trade into Northern Europe grew by about 4 % in 1992, and declined by 4.4 % in 1993. On out-bound trade, growth in 1992 was fairly strong at 4 % and for 1993 growth was maintained at 3.8 %. The inbound liner trades for Southern Europe steadily increased up to 1992 but in 1993 inbound trade declined by 6 %. The outbound liner trades have maintained growth with an increase of 10 % in 1993.

#### Cruise shipping

Cruise shipping has grown considerably in the last ten years, predominately fuelled by the demand in the United States. However, growth is also expanding in Europe, albeit at a

slower pace, with more cruises available to places previously difficult to enter - for instance the territorial waters of the Warsaw Pact.

## MARKET FORCES

### Demand

In general terms, both manufacturers and retailers need a reliable and continuous flow of products at a reasonable price. Regarding major bulk commodities, which are inputs in the oil refineries (crude oil), the iron and steel industry (iron ore, coal and petroleum coke) and electric power plants (steam coal), the customers are largely in control of the flows to secure their regular supplies. They operate on a global scale.

For general and containerised cargo, customers are moving increasingly toward a global strategy, particularly with just-in-time inventory control, and global purchasing options that mean that purchase can be made from suppliers providing the lowest unit cost for similar goods. Additionally, there is increasing pressure from shippers on the shipping companies as these customers require door-to-door delivery at prices usually associated with port-to-port deliveries. Shippers are under significant pressure to reduce costs and improve time-to-market product delivery, hence it is becoming much more important for shipping companies to provide responsive, flexible, cost efficient and dependable services.

### Supply and competition

The shipping industry is very fragmented, ranging from major diversified shipping companies with liner, dry bulk and tanker operations and hundreds of vessels to one-vessel captain-owners. There are large producers who carry their own cargoes, for instance in the banana and car trades, and there are owners specialised in bulk shipping or solely in the rental or leasing of ships.

### Short sea trades

The European short-sea trades, including the intra-EU seaborne trade, still have the characteristics of regional markets. Mediterranean trade comprises largely national traffic (own-national flagged vessels) and international traffic between the Mediterranean and North African countries. Therefore, in these trades there is imperfect competition. By contrast, in and around the North Sea, there is fierce competition between short-sea carriers due to open trade to all flags. Germany, the Netherlands and Denmark dominate the international short-sea trades.

Short-sea owners dominate specialised trades under European flags because many owners of larger vessels have opted out of the trade under these flags. Specialised trades include chemical vessels, liquid-gas tankers, reefer trade, car carriers, the

carriage of heavy lifts, and chartered containers. Markets for liquid-gas and reefer trades are much less volatile than those for tankers and bulk carriers, because owners either charter their vessels to the traders or join freight pools.

#### Deep sea trades

Regarding general cargo North-South trades with developing countries (particularly those in Africa and Latin America), conference trade has often been divided in accordance with the 40:40:20 formula of the UNCTAD Code. According to the formula the two national carriers in the trade each have a 40 % share with the remaining 20 % divided among cross traders. The UNCTAD Code applies to conference cargoes only, but some developing countries are attempting to bring their whole liner trade within the scope of the Code. This would enable them to regulate the share of non-conference lines, generally referred to as outsiders. As far as the EU is concerned, the shares obtained by EU lines within a conference on the basis of the UNCTAD code are redistributed on the terms of Regulation no 954/79, the 'so-called' Brussels package.

Many liner companies, both conference members and outsiders, are operating on the principal East-West routes. Although the world's largest container operators are involved on this routes, trade market shares of more than 10 % are rarely achieved. Most of the shares are in the range of 2 % to 9 %. Furthermore, in the relevant North-South trade, the shares vary from 10 % to 20 %. Consequently, no single liner company dominates the trade. It is a very competitive market which is enhanced by the prevailing excess capacity in the liner industry.

To cope with the fierce competition as well as to meet the ever increasing needs of the clients, some carriers are aiming at providing global operations. The creation of the Single EU Market has further encouraged the concept of globalisation

as a spur for greater penetration. Globalisation involves "one-stop shopping" (i.e. door-to-door transport) and "no sweat arrangements". One-stop shopping refers to geographical coverage of the transport service; and, no sweat arrangements refer to the so-called value added services (i.e. integrated transport and ancillary services).

#### Fleet and capacity developments

A comparison of fleets by vessel types to carrying capacity reveals differences in growth. Between 1990 and 1993 the average world development of crude and product dedicated tankers increased by 8.4 % in dead-weight (DWT) and 9.3 % in numbers of vessels. For dry bulk products, the dry bulk and combination carrier fleet averaged a 3.9 % increase in DWT and only a 0.7 % increase in the number of vessels. The relative increase in the capacity of the dry bulk fleet has put substantial downward pressure on freight rates in 1993. Indications for 1994 are for a positive improvement in these rates, but they are still below the levels of 1991. The rates in the liner trade have also been under pressure from excess capacity. The rapid increase in container capacity in relation to the development of "other commodities" has enhanced rather than relieved the pressure on the rates. Excess capacity is expected to continue in the liner industry with no let up in container over-capacity. The liner fleet is relatively young and active, so there are no extensive scrapping programmes. Although the older liner vessels are considered too small and inefficient for the main east/west arterial trades, they are useful in feeder trades and in supporting secondary services, thus there has not been a significant withdrawal from the market.

Between 1990 and the 1993, the number of vessels over 300 grt in the world's merchant fleet increased by 1551 vessels, or a 4.7 % increase in growth. However, the relative growth of carrying capacity (DWT) and container capacity (TEU) was higher. In particular, the growth of container capacity

was quite significant, averaging 6.3 % per year. During the past two years, the development of both the world fleet and capacity have accelerated and although their development varied considerably, the container fleet increased fastest.

In 1993, the world container fleet stood at 8.1 million TEU, of which 4.4 million was owned by the carriers and 3.6 million by container lessors. Container production in 1993 was down 17.4 % to 950 million from 1.15 million TEUs in 1992. Companies adopted an expansive approach as they ordered significant numbers of containers in early 1992 in anticipation of accelerating demand for trade in containerised commodities. In 1993 the owned carriers added more capacity (13.2 %) in comparison to leased capacity (11.5 %). This was a significant reversal from 1992 where leased capacity increased by 20.5 % and owned capacity increased by only 13.7 %. The slowdown in container demand has forced price reductions in some container types, with dry containers averaging a 7 % drop in prices.

EU fleet development has not kept pace with the world fleet. Unlike the world fleet, the number of vessels with EU Member State flag decreased by almost 300 vessels over the period from 1990 to 1993 a 5.7 % decline; although the capacity in DWTs has increased marginally by 2.4 %. However the USA and Japan have also faced declines in their merchant fleet over this period. For example, in the USA, the number of ships declined by 8.4 %, while container capacity increased only marginally by 0.3 %. Contrary to developments in the EU, the USA and Japan, the "other" countries (open registry) flag categories showed significant growth in both their fleets (8.9 %) and their fleet capacity (11.4 %). Part of the explanation for these figures is the move of some EU carriers to flag out their vessels in order to reduce costs.

With the exception of Denmark, France, Luxembourg and the Netherlands the merchant fleet of all Member States declined over the period 1990 to 1993. The substantial increases in the Danish and Luxembourg fleets are due largely to formation of a second Danish register - the Danish International Register (DIS) - and the introduction of the Luxembourg register that have allowed cost-effective movements from other flags into these registers. In particular, Belgium's fleet declined substantially (67 %) as most of its private fleet was transferred to Luxembourg. Other countries facing considerable reduction in their fleets were Spain (31.7 %) and the United Kingdom (28.4 %). Only two countries, Spain and the United Kingdom, had a decline in their container capacity (TEU) for the period 1990 to 1993. In the remaining Member States, container capacity (TEU) increased substantially in Denmark (34 %), the Netherlands (29.1 %) and Portugal (35.3 %). However, aggregate container capacity in the EU registered fleet increased from 1990 to 1993 by roughly 2100 thousand DWTs.

In 1993, Greece had the largest share in the EU fleet, 27.5 % of the vessels and 49.4 % of the DWT, due to the large number of bulkers and tankers owned and operated by Greek concerns. Greece is followed at some distance by Italy with 15.4 % of the vessels but only 10.8 % of DWT, due to a large number of smaller vessels on their registry. The differences in the fleet structure of the Member States are clearly presented in Table 7. More than half of the fleet in Luxembourg and Greece is comprised of tankers and bulk carriers; in contrast to Denmark, Germany, Spain, Ireland, the Netherlands and Portugal where general cargo and container vessels account for more than half of their respective fleets. For the EU as a whole and Japan, general cargo vessels hold the greater share. In the USA, tankers are the main vessel type.

National governments and the European Commission want to maintain an EU fleet not only for strategic and commercial reasons but also because of its contribution to Member States' economies in terms of income, employment and balance of payments. Employment of EU nationals has decreased from about 250 000 crew members in 1980 to about 108 000 in 1993. The decrease has been mainly due to the movement of owners and operators away from EU flags to open registers where there are less stringent manning conditions and costs tend to be lower. In 1993, EU nationals made up 85 % of the total employed in the EU shipping industry. This share varies considerably by Member State, e.g. it is relatively low in the Netherlands, where it is 67.3 %; in comparison with France and Italy where the percentages are 93 and 96 % respectively.

## INDUSTRY STRUCTURE

### Companies

#### Tanker and bulk

In the EU, the tanker trades are dominated by time charters of tankers plying specific routes and ships owned and managed by the major oil conglomerates. The bulk trades are formed of three distinct groups, time charters, the single cargo same route and tramp vessels, where the vessel location and voyage depends on cargo availability.

#### Liner

The liner industry is moving from the product life cycle stage of maturity to advanced maturity, where customer sophistication is high, product differentiation is low and concentration substantially increases. Hence, in this final stage of the life cycle, the two types of carriers that will survive are the first

**Table 8: Shipping

Source: ISL Bremen

tier carriers with established multi-modal presence and the niche operators that trade in speciality trades. Most companies in-between these two extremes are likely either to disappear or merge over the coming decade.

Towards the end of the third quarter of 1994 the aggregate capacity in service of the top 20 container carriers totalled 1.8 million TEU, representing 46.2 % of the world's total available slots. The share of the top 20 liner companies has been increasing steadily: it was 43.7 % in 1993, against 32 % in 1982.

Traditionally the Asian carriers have dominated the rankings and continue to do so. However, an EU line, Maersk Line, has remained in first place. The Asian carriers dominate the top 20 with 10 carriers, of which 3 are now in the top 5. These 10 carriers together accounted for 911 762 slots, slightly over half of the top 20 operating capacity. Sea-Land and APL

represent the US in the top 20 with an aggregated operating capacity of 223 643 TEU or 12.4 % of capacity (in 1993 it was 13.6 %). Apart from ZIM Israel Navigation and the Mediterranean Shipping Company, the remaining operators are from the EU. The EU lines now occupy six places among the top 20 and their aggregate operating capacity was 563 826 TEU or 31.3 % of capacity, which is substantial gain in share from the 1993 result of 27 %. The two major EU ranking changes from 1993 were DSR-Senator Lines move from 20th position to 8th by adding 15 ships increasing their capacity by 48 455 TEU and the addition this year of Compagnie Maritime d'Affretement from France into 20th position.

#### Cruise shipping

Cruise shipping is dominated by the US, which accounts for some 85 % of the world cruise industry. The US industry has expanded by almost 10 % per year for the last few years,

with passengers up from 1.43 million in 1980 to 3.86 million in 1991. However, as the industry comes under increasing pressure to advance safety standards, it will see some structural change in the major players. At least half of the fleet is over 20 years old, and the latest regulations from the IMO will accelerate the division between the major groups with modern tonnage and the 'others'. Also, the demand for cruises has undergone a shift away from longer cruises to those of 3 to 5 days, which should act as fillip to the EU cruise industry which has tended to specialise in short-sea cruises. Increasing concentration in the industry will mean a bipolar orientation towards the major players and the much smaller specialist operators.

### Strategies

In the last two to three years, there has been a major shift in the operation structure of the liner carriers. Historically, there have been a small number of global carriers, with many companies operating in just one or two of the three major trades and niche operators filling the smaller trades. However, increased globalisation has led to acquisitions and alliances.

The response of the major EU liner carriers to the global and European challenge has been very different. Nedlloyd and P&O have built up large transport networks and restructured them in line with the growing importance of intra-European trade. Container logistics on a world-wide scale and inland activities (storage, distribution and transport) on a European scale are underlying Nedlloyd's policy, which aims at being present throughout the whole transport chain with the view to providing a full logistic package. In 1988, therefore, Nedlloyd Road Cargo, Nedlloyd Air Cargo and Nedlloyd Lines Agencies were established. In addition, acquisitions were obtained in countries like Germany and the United Kingdom. On more of a world-wide scale, Nedlloyd, American President Lines (APL), Mitsui OSK Lines (MOL) and Orient Overseas Container Line (OOCL) are establishing a new co-operative agreement for transpacific trade.

P&O has followed a similar multi-modal policy. It has invested in key areas of surface transport industries and follows a strategy of acquisition. Furthermore, it developed P&O European Transport Services (POETS), grouping together European haulage and distribution activities. P&O, together with Maersk and Sea-Land, has also moved into the growing Mediterranean hub market. In addition, P&O Australia and Sea-Land have recently formed a joint venture with the Port Authority of Vostochniy (Russia), the primary Trans-Siberian railbridge port. It has also been investing substantially in Chinese ports.

Unlike P&O and Nedlloyd, CMBT, Bolore and Hapag-Lloyd continued to focus on their core transport activity and enhanced operations for their deep-sea service clients. CMBT (largely owned by CMB Group) has taken steps to become a leading door-to-door operator for the European market. Its deep-sea strategy is concentrated on North-South traffic. Hapag-Lloyd concentrates on intercontinental door-to-door transport, al-

though they currently provide some distribution in Europe for Far Eastern clients and have continued to sub-contract many inland modal movements for cost-efficiency reasons.

As for non-European carriers, Sea-Land's activities have acquired a truly European dimension. For haulage on European roads, Sea-Land used a joint venture with Frans Maas as part of a policy of forming alliances to enter the EU market. 'K' Line, the Japanese carrier, recently announced the formation of a global alliance with Hyundai Merchant Marine.

The number of conferences, capacity sharing agreements and alliances continues to grow as companies try to come to terms with over-capacity.

### Impact of the Single Market

In general, measures pertaining to the Single Market programme have had a positive though limited impact on the shipping industry. The largest share of the sector's activity is accounted for by extra-EU trade, and therefore falls outside the scope of the Internal Market. In this context, the benefits of the Internal Market may have been largely indirect, through faster growth in European GDP and therefore additional trade. The most important direct effect of the Internal Market is the progressive liberalisation of intra-EU shipping and the introduction of cabotage. As to the EU environmental policy, further progress is required for establishing a level playing field in terms of inter-modal competition. Presently, shipping cannot fully capitalise on its environmental advantages because the prices of other modes, primarily road, do not reflect associated social and environmental costs.

### ENVIRONMENT

Increasing pressure is being brought to bear on EU (and non-EU) shipping companies in the areas of environment and safety. In its communication "A Common Policy on Safe Seas", the Commission expressed the main points of its future policy. In addition the Council, in its resolution of 8 June 1993, fully supported the Commission and the measures outlined in action programme@HEADING 6 = Starting from the observation that although adequate international rules exist to cover many aspects, often ships are not constructed, maintained or operated up to those standards, the action programme from the Commission is based upon a coherent package of measures including:

- measures to establish a convergent implementation of existing international rules in the Community;
- measures to ensure a tighter and more effective control of ships, regardless of their flag, by the State of the port;
- measures to promote coherent and harmonised development of navigational aids and traffic surveillance infrastructure, bringing maritime safety into the electronic age;

- measures to support international organisations enabling them to strengthen their primary role in international standard-setting.

The Council has formally adopted the first (out of two) directive on mandatory reporting by ships carrying dangerous/polluting goods, the directives on common criteria for ship inspection and certification bodies, and on qualification and training of seafarers, the regulation on segregated ballast tankers, and has reached a common position on a directive concerning controls of ships by the States of the port (PSC), in view of its formal adoption expected in Spring 1995.

Many other proposals are to follow soon, regarding safe management code for Ro-Ro passenger ferries, non-convention vessels, fishing vessels, marine equipment, licence regime for passenger vessels and a system of recovering costs of aid to navigation from users.

Estimates put pollution from maritime transport at 12 % of the total pollution entering the sea and the average loss of life at sea is around 1000 per year. The major problem has been and will continue to be one of enforcement.

CFCs continue to be an issue in the refrigerated industry, as production of the more damaging ones are phased out globally. Within the industry the forerunner substitute to CFC12(R12) appears to be HFC(134a). This is impacting the industry for refrigerated containers and the purpose built refrigerated vessels, as equipment needs to be changed over the next few years to allow for the use of the CFC substitutes.

## REGULATIONS

Governments have offered throughout the years incentives to owners to keep their vessels under national flags. Nevertheless, an increasing number of vessels owned by EU nationals have been transferred to open registers. Initially, these registers were used to avoid tax liability but, in the last few years, cost reduction (particularly of manning costs) has been the main motive. The main open registers are those of Liberia, Panama and Cyprus. Some cost-saving measures have been made by governments, such as investment allowances and government-supported research to advance automation and innovation, to help EU owners with high labour costs under national flags.

Some countries have tried to mitigate the owners' plight further by creating offshore registers or similar schemes which may allow wider employment of foreigners at lower wages and of nationals at reduced levels of taxation. Denmark introduced a separate international register for Danish vessels, and Germany authorised a similar scheme in 1989.

These initiatives have now been followed with a proposal from the European Commission to introduce positive measures through EUROS as a Community ship register. EUROS would operate in parallel to the existing national registers (i.e. certain vessels already entered on national registers could as an option of the ship owner also be registered in EUROS), in which case such ship owners may be entitled to financial and fiscal benefits with a view to improving their competitive position.

The past decline of tonnage under EU flags due to the relative high cost position vis-à-vis more liberal registers, external relations to remedy protectionist practices and other distortions underlies the development of an EU shipping policy. A start on such a policy was made in 1986, when the Council adopted four major shipping regulations: 4055/86, 4056/86, 4057/86 and 4058/86. These regulations focus on liberalisation, protectionist and competition practices, which refer both to non-EU countries and EU Member States. The principles underlying these regulations are fair and free competition.

The main purpose of regulation 4056/86/EEC was to lay down rules for the application of the competition rules in international maritime transport and aims to ensure that competition in international maritime transport services from or to one or more Community ports is not unduly distorted through restrictive practices, while avoiding excessive regulation of the market. It applies to international maritime transport services other than tramp vessels. The regulation granting a group exemption to liner conferences vis-à-vis the EU competition rules was aimed at stability, guaranteeing regular and reliable services to transport users.

Regulation 4057/86/EEC is designed to deter unfair pricing practices in maritime transport; through continuous underpricing practices of some non-EU countries. These practices are detrimental to the competitiveness of EU ship owners in international liner shipping. The regulation allows for a redressive duty to be imposed on the foreign ship owners concerned.

Source: Containerisation International Yearbook

Regulation 4058/86/EEC is aimed at safeguarding free access to cargoes in ocean trade. The regulation provides for a procedure to be applied when certain trade practices by a non-EU country threaten to restrict free market access by Member States' shipping companies.

Regulation 4055/86/EEC applies the principle of freedom to provide services to maritime transport both between Member States and between Member States and non-EU countries. This regulation provides for the phasing out or adaptation to Community legislation of agreements between a Member State and a non-EU country containing cargo sharing clauses and of unilateral national restrictions on the carriage of goods wholly, or partly, preserved to the national flag. This practice could seriously affect the trading interests of all countries by substantially increasing transport costs. Adjustment to Community law of agreements concerning trades not governed by the United Nations code of conduct was to be completed by 1 January 1993.

Further mention should be made of the deregulation of the EU shipping market, implying the freedom of cabotage (i.e.

the freedom of a shipping company established in one Member State to operate on the domestic market of all the other Member States). In December 1992, the EU Transport Ministers adopted the regulation applying freedom to provide services to maritime transport within Member States. The text provides for a series of derogations for different trades in certain areas of the Community.

The following maritime transport services carried out in the Mediterranean and along the coast of Spain, Portugal and France are temporarily exempted from the implementation of the regulation:

- cruise services, until 1 January 1995;
- the transport of strategic goods (oil, oil products and drinking water), until 1 January 1997;
- services by ships smaller than 650 GT, until 1 January 1998;
- regular passenger and ferry services, until 1999.

Island cabotage in the Mediterranean and cabotage with regard to the Canary, Azores and Madeira archipelagos, Ceuta and Melilla, the French islands along the Atlantic coast and the French overseas departments is also exempted until 1 January 1999. This derogation extends for Greece until 1 January 2004 for regular passenger and ferry services and services provided by vessels less than 650 GT. In those areas outside the geographical scope of the above mentioned derogations, liberalisation was completed as from 1 January 1993.

An issue that has gained significant prominence in the last twelve months has been the application of the EU competition rules to maritime transport. Investigations by the Directorate for Competition (DG IV) found that some EU lines had been acting uncompetitively, particularly in the North-South trades, by breaching Articles 85 and 86 of the Treaty of Rome and regulation 4056/86. On October 1994, the Commission found that capacity management agreements, as practised in the North Atlantic trade, violate Article 85 of the Treaty.

With the growing trend of vertical transport integration, the European Commission's, June 1994, issuance of its "Maritime Transport Report" addressing intermodal operations within the EU may significantly impact on conference carriers. In its decision of 21 December 1994, the Commission found that price fixing on the inland leg through conferences is illegal under EU competition rules. As of June, the Commission is recommending that conference carriers begin to initiate joint inland operations, with regard to multimodal pricing, which will not adverse impact upon shippers and which would promote more open competition.

Finally, the new EU banana policy which came into effect on 1 July 1993 has imposed a new set of quotas on banana imports into the EU. Bananas are estimated to have about a 40 % share of refrigerated trade; hence there are dedicated operators, terminals and distribution services for bananas, and the impact of the tariffs may be significant on EU consumers, as producer and shippers pass on the tariffs to consumers in the form of higher prices. It is too early to assess the impact of the new tariff regime on the banana shippers, except to note that the new regulations, as much as the previously preferred status of some exporters, cause distortions in the market.

## OUTLOOK

Global developments will continue to fuel growth in world sea-borne trade. The trend of continued growth in the Far East/Asian markets in both demand and global sea-borne trade are expected to continue and will impact on the future development of global alliances and conference growth.

Although developments within the EU will improve trading conditions, the outlook for the EU shipping industry is mixed. "Europe 1992" and the resulting gradual deregulation of the EU shipping market coupled with improving economic growth in the EU will provide an increase in the Community's share of world trade. The four regulations adopted by the Council of Ministers at the end of 1986 and recent discussions on the future of the Common Transport Policy, aimed at increasing the competitiveness of the EU shipping industry towards non-EU countries which apply unfair trading practices, may contribute to less protectionism. The aim of the Commission to achieve an efficient and competitive EU shipping industry should also enable EU ship owners to regain a major role in world shipping using ships registered in the EU. The proposed EUROS register should contribute to that end. However, the downside is that the EU shipping companies are facing and will face increasing competition from lower unit cost carriers such as those from the Far East. This may result in a reduction in the EU shipping industry and more global alliances, as the export of cargo is viewed as more important to the growth of the Community on the world stage rather than the growth of the shipping industry per se. Increased competition should

reduce the price of traded goods through lower transport costs and hence EU exports and imports will have lower wholesale prices.

A large part of the tanker and bulk fleets will have to be renewed in the 1990s as the existing fleet becomes increasingly aged, which may entail problems in private financing, given the risks and the huge amounts involved. The availability of both finance and reputable ship owners in Europe will help the EU to play a larger role in bulk transport. The vessels involved in merchant shipping will be of proven design, with the exception of double-hulled tankers and hatchless container ships, but there will be a tendency towards larger container vessels.

The development of the world economy and implementation of the measures aimed at increasing the competitiveness of the EU fleet are expected to have the greatest impact in the medium-term. Total carrying capacity is expected to increase at a much slower pace than container capacity: Container penetration in the liner trades continues to grow and most of the prospective growth is expected in the liner sector.

Employment of EU nationals in the EU shipping industry is expected to continue to decline as shipping companies continue to flag out, although the EUROS register, if and when approved by the Council of Ministers, may contribute to halting or even reversing this trend.

# Air transport

## NACE 75

Air transport is starting to move out of the financial doldrums caused by the recent economic weakness of some of the major trading blocs and the Gulf War. Deregulation has spurred competition within existing airlines in the EU and will prompt both an increasing number of privatisations of the traditional EU state carriers and allow airlines to consolidate operations through mergers and alliances. These will act as a spur for the globally oriented airlines to improve their competitive position vis-à-vis the airlines from the other major geographical blocs. Hence, although in the short term the pain of the adjustment process will continue, a leaner, fitter and aggressive industry will emerge.

### INDUSTRY PROFILE

#### Description of the sector

The air transport industry comprises enterprises which are exclusively or primarily engaged in the transport of passengers and goods by air on scheduled or chartered services as well as helicopter and air taxi services, local pleasure flight operators, etc. Air transport also includes the town offices of airline companies.

Air traffic (excluding military) is usually divided into commercial and general aviation. Commercial aviation consists of passenger travel, both charter and scheduled, and air freight, which includes air freight on freighter aircraft, combination passenger/freight aircraft and freight in the hold of passenger aircraft, and air courier and mail services. General aviation includes private use of planes and air taxi services.

This monograph will focus on the commercial aviation sub-sector, with particular emphasis on the major airlines of the EU Member States. Unless otherwise specified, statistical information mentioned in the text refers to scheduled traffic for the large EU carriers. These statistics therefore do not cover two important segments of the industry, namely regional airlines and charters.

#### Recent trends

Average growth rates in demand for air transport during the latter period of the last decade were healthy, with an average annual growth rate of 7.7 % for passenger-kilometres and 8.9 % for tonne-kilometres (freight) for the period 1985 to 1990. During the same period employment grew by some 3 % per year. This rate of growth was due to the positive economic growth experienced by the countries served by EU airlines, both within the EU and externally. However, the industry experienced a severe and unexpected downturn in 1991. This downturn was due to recessionary pressures emanating from the US and the United Kingdom and the weakening of economic growth in other major European countries. In addition, the downturn was exacerbated by the effects of the Gulf War with the result that between 1990 and 1991 passenger-kilometres declined by 4.7 %, and tonne-kilometres by 2.9 %. EU air transport staged a recovery in 1992, driven largely by the improving economic environment in the United States and in the Far East as well as price cutting and fierce competition between airlines. Growth on 1991 was 13.8 % for passenger-kilometres and 3.2 % for tonne-kilometres. However, much of this growth corresponded to a catch up effect. Compared to the level of traffic reached in 1990, growth in 1992 reduces to a more usual 8.5 % for passengers and a weak 0.2 % for freight. Notwithstanding a worsening of the economic climate in all major EU countries except in the UK, freight transport recovered strongly in 1993 with a 7.8 %

increase in tonne-kilometres. In the meantime, passenger traffic continued to register healthy growth (7.3 %).

Recent indicators issued by the Association of European Airlines point to particularly sustained traffic in 1994 which is likely to turn out as one of the best growth years in 15 years. Over the nine months to September, passenger and freight traffic increased by 8.3 % and 13.1 % respectively compared to the same period the year before. These figures should only be used as broad indicators, as there are definitional differences to those shown in Table 2.

Surging aircraft orders in the late 1980s have combined with slowing traffic growth in the early 1990s to generate serious overcapacity and intense competition. Resulting low fares, together with low load factors, have taken a heavy toll on European airlines. Between 1990 and 1992, AEA carriers accumulated losses of 3.5 billion ECU and provisional figures for 1993 point to another significant loss in the 1.8 to 1.9 billion ECU region. However, preliminary results for the second quarter of 1994, indicate that the situation is at last im-

proving, at least for those carriers which have made the most sweeping cost cutting efforts in the recent past.

Growth in the EU's regional airlines' traffic has been over 2 time greater than the industry average over the last six years. Even in 1991, during the trough of the recession, traffic expanded by 10 % (number of passengers). Growth in 1992 and 1993 reached 16 % and 14.2 % respectively and preliminary data show a 14 % growth for the first half of 1994 compared to the same period the year before. The regional fleets have also been undergoing a change, with a steady increase in average aircraft size. The share of aircraft of more than 40 seats has increased continuously in recent years. In addition, more than 50 % of the regional fleet is under six years old giving it one of the younger aggregate fleets.

#### International comparison

Figure 1 shows the relative sizes of the aggregates of the EC, US and Far East airlines. It includes domestic traffic, and hence the US airlines account for more passenger-kilometres than the EU and the Far East combined, and also more than double the EC.

Table 6 provides a ranking of world carriers based on aggregated domestic and international passenger traffic. The top ten world airlines include two EU airlines and two Far Eastern carriers but no less than six US airlines. The top four carriers are all American and the largest European airline, British Airways, only comes in fifth position. Table 6 also provides a clear picture of the level of dependence the EU airlines have on international travel demand. The proportion of international travel in total travel for the EU airlines belonging to the top 20 is 89 %, compared to 31 % for the US airlines. The corresponding figure for the Far East airlines is closer to that of the EU at 77 %.

#### MARKET FORCES

##### Demand

At the aggregate level, changes in the demand for air travel are highly dependent on the growth prospects for the world economy. There is a very strong relationship between air transport demand and trade, which in turn is driven by the level of economic activity. However, the major components of air travel (i.e. business, leisure and cargo) respond to different

pressures. Air travel for business purposes is primarily driven by activities that require face-to-face contact. Leisure travel is dependant on the levels and growth of real personal disposable income and available leisure time, whilst air freight depends largely on international trade. Hence periods of economic growth or recession can impact air travel significantly: for instance, in a period of strong economic growth business expands generating more business travel, real incomes increase generating growth in leisure travel and trade improvements generate more air freight. In addition, patterns of leisure travel have changed due to increasing available leisure time and income allowing for a greater proportion of major holidays to involve long distance travel, as well as short breaks that require flights.

In the recent years, enhanced competition between airlines has also underscored the impact of cuts in fares on travel demand. Whereas leisure demand has long been known to be sensitive to prices, the recession of the early 1990s has made most companies more cost conscious as to their travel budgets. Whereas the forthcoming recovery should ease some of the pressure on business travel budgets, it seems unlikely that business travellers will completely renew with their pre-1990 behaviours. Many companies have indeed realised that some of the business trips could be easily replaced by phone calls and that significant cost cutting could be made by downgrading from the business to the economy class, particularly on short-haul flights.

### Supply and competition

Most of the EU 'flag carriers' provide global services, whilst the small to medium sized EU airlines concentrate on predominantly intra-European services (British Midland and Luxair), specific inter-continental services (Virgin Atlantic Airways) or niche point to point routes. However the small to medium sized carriers do have alliances and equity partnerships that allow them access to much larger and global route structures. Within the EU the scheduled airlines are increasingly competing on a level playing field due to de-regulation. However, as many of these airlines are providing some form or another of global offering to passengers, they face severe competition from the major airlines of other geographic regions

that are also global in nature. The main competition comes from the US 'megs' and the Far Eastern airlines. In addition, EU schedule services continue to face competition from the EU charter carriers.

However, one longer term direct effect that European de-regulation may have is on the charter industry. Prior to de-regulation the charter industry was able to offer point to point services for leisure travel at a substantially lower unit price and cost than the scheduled carriers. On the price issue, it was the double approval regime that helped the scheduled airlines to maintain potentially artificially high fares, whilst the charter airlines were pricing on cost equated levels. The charters were able to do this as they were in essence wholesaler's offering direct flights, whilst scheduled services were typically retailers. Charters could also match supply to the seasonal peaks and troughs of demand that was typically leisure dominated. The so-called third EU package on air transport liberalisation entails more or less complete free pricing for intra-EU scheduled traffic so that some of the intra-EU charter traffic may decline as the scheduled carriers take some of the traditional leisure traffic away from the charterers. In addition, the distinction between charter and scheduled services becomes increasingly blurred as carriers may choose to operate scheduled as well as non-scheduled services between EU airports. Charter services also increasingly look like retail services as they are now allowed to appear on Computer Reservation Systems (CRS) and tickets can be purchased by the public in the same manner as scheduled services. In general, charter operators affirm their commitment to remaining the major suppliers of wholesale passenger air services meeting point to point seasonal demand and whereas there may be a decline in intra-EU charter traffic, charter traffic from within the EU to destinations outside the EU, where the current bilateral agreements continue, will strengthen.

A number of studies undertaken in the late 1980s comparing the efficiencies of the European airlines with those of the USA (and, in some cases, with the Eastern carriers) highlighted some interesting conclusions. Three inter-related factors have stood out as crucial to the relative efficiencies of airlines, namely the operating regulatory environment, the structure of airline operations and labour costs. Issues such as fuel

costs or scale economies do not appear to be highly relevant. Many of the large airlines are active in the spot oil market, and hence fuel costs are more or less an even field. Size tends to bring some benefits such as large scale marketing, with particular emphasis on frequent flyer programmes, or a better co-ordination of schedules and airport capacity utilisation. However, scale economies do not confer some magic status on cost management, as the demise of some of the largest airlines has shown, i.e. Pan Am and TWA.

Some of the Far Eastern carriers fare well in efficiency comparisons as they operate in capacity constrained markets with long stage lengths and a low-cost workforce.

The studies also looked at competitive issues for labour, as this is presently the most controllable cost and typically the European airline staff, in particular cabin and cockpit crew, are more highly paid than their US and Eastern counterparts. This higher wage burden on the European airlines is not offset

by higher productivity. In fact, the US and Eastern airlines appear to have a higher average degree of productivity than their European counterparts. This is one indication that the European carriers still have a long way to go before they match the productivity levels of their major competitors.

In particular, a communication by the EU Commission (COM(94) 218 final) states that, in 1992, physical productivity of European carriers was more than 20 % lower than the levels achieved by US carriers. Furthermore competitive disadvantages incurred by European airlines are not restricted to labour costs but also include user costs such as infrastructure charges, air traffic control charges and congestion costs. Compared to US competitors, European carriers also have to face higher costs in terms of equipment both because of exchange rate risks (aerospace equipment is traditionally billed in USD) and a less favourable tax-lease treatment.

## INDUSTRY STRUCTURE

### Companies

#### Scheduled passenger services

In the EU there is typically a three tier structure in scheduled air passenger transport defined by numbers of routes and age of operation. The first tier includes those carriers that have been and still are the so-called "flag carriers". The second tier consists of the carriers that operate reasonably large networks, either within the EU or internationally or both (for instance British Midland). The third tier comprises the regional carriers, such as ATI in Italy or Air Inter in France, and the tiny niche point-to-point airlines, i.e. Orient Air, which operates from Waterford, Ireland to Gloucester, England via Dublin. However, in scheduled international and domestic services, the EU air transport industry is dominated by the small number of flag carriers. The ownership structure for the flag carriers in 1994 is presented in Table 9. The dominant four flag carriers share 70 % of the services operated by the EU flag carriers in terms of passenger-kilometres (including domestic scheduled services).

This would indicate that the scheduled EU carriers are dominated by the 'flag' carriers, however, although the figures indicate that the industry could be considered concentrated, the number of EU airlines actually in operation is substantial. IATA lists 35 airlines operating scheduled passenger services. The European Regional Airlines Association (ERA) lists another 20 regional airlines that are not included in the IATA list. The regional airlines account for 1 in 7 of intra-Community passengers on scheduled services. Also, the regionals operate a fleet of over 600 aircraft in the Community. There are also a number of much smaller regional airlines operating that are not members of either organisation. Hence, excluding freight only operators and the non-member airlines there are 109 scheduled passenger airlines operating in the Community.

#### Charter passenger services

The EU hosts 35 specialised charter operators. In addition, some of the schedule carriers operate charter services directly or through subsidiaries. The importance of these charter operators is pinpointed by ACE, the European Community's Independent Airline Association, which estimates that 60 % of international revenue passenger-kilometres performed in Europe by the combined membership of ACE and AEA are performed by ACE members. Also, its members employ almost 20 000 staff (1992 figure).

#### Air freight services

Air freight is often referred to as the poor cousin in the air transport industry. This misnomer is due to the lack of accurate and substantive data on the sector, coupled with the market being a mainly buyer market. Though the trend is changing progressively, scheduled passenger airlines are still extremely reliant on the freight forwarders to fill up the cargo holds on scheduled routes. Often, the amount of cargo space is finalised at the last moment when the final number of passengers on the flight is known, usually an hour or so before departure. There are, however, very good early estimates of available cargo space based either on maximum passenger capacity and/or bookings for the flight. The scheduled freight carrier, whether independent or a subsidiary of a scheduled airline, typically has a scheduled route for cargo on dedicated freighter aircraft.

Amongst the EU carrier members of the AEA, the air freight sector is dominated by two airlines, Air France and Lufthansa, which together account for almost half of the recorded market. British Airways and KLM follow in third and fourth place. Comparing the revenues for scheduled passenger traffic with freight traffic, freight accounts for just over 14 % of revenue.

#### Strategies

There are three dominant strategies observable in the EU at present, of varying degrees of importance and influence. These are privatisation of national flag carriers and the associated

**Table 9: Air transport

issue of state subsidies, the formation of alliances and, less importantly, the formation of start-ups and expansion of the small regionals.

On balance in the European industry, it will be the process of privatisation, which is encouraged by de-regulation, that will have the largest aggregate impact on the industry. Government subsidies to flag carriers to cover operating losses will be severely restricted in the new environment. Airlines will have to operate profitably in order to survive, and this in turn will require a change in the corporate environment with, in particular, increased flexibility and the ability to react more swiftly to a changing competitive environment. An example of the differing abilities of the first tier carriers to react to changing circumstances is illustrated by some of the carriers reactions to contain costs during the recent downturn. British Airways reacted very rapidly to the downturn by reducing employment levels in 1991 by some 12 %, whereas, amongst the larger state owned carriers the reaction was either much weaker or contrary to expectations, with Air France reducing employment by 1.2 % and Lufthansa increasing employment by 4.2 %. It was only in 1992, that these two carriers reacted more strongly.

Privatisation will have a substantial impact on employment: for instance, in the run-up to privatisation British Airways reduced staffing by one third through a programme of voluntary reduction and early retirement schemes. This amounted to almost 20 000 employees. Similarly, the partial privatisation of Lufthansa in September 1994 which will scale down the state share in the airline's equity to 35 %, was preceded by a restructuring programme which, within one-and-a-half year, brought about a 17 % in cut in the payroll and a 31 % surge in productivity.

The most rapid transformation of the industry structure is taking place through alliances, both within the EU and globally. These alliances take a number of forms, from equity investment to code-sharing agreements. Typically equity alliances involve an EU airline purchasing minority stakes in other airlines, for instance, British Airways currently owns 24.6 % of USAir, 25 % of Qantas, 49 % of Deutsche BA, 49.9 % of TAT, 40 % of the Plimsoll Line, and 31 % of Air Russia, as well as absorbing Dan Air in October 1992.

Shared equity stakes could follow the pattern of the abandoned 'Alcazar' alliance between Scandinavian Airlines System (SAS), KLM Royal Dutch Airlines, Swissair and Austrian Airlines. These four medium sized airlines announced plans

in April 1993 to set-up a jointly owned company with SAS, KLM and Swissair owning 30 % of the equity each and Austrian taking the remaining 10 %. The joint venture would have had a single management structure and balance sheet. The new company would have matched the individual European majors in size and passengers, and would not be too far behind the US 'mega-carriers'. The agreement failed mainly because airlines did not agree on the choice of a US partner. Longer term expectations are that the four airlines will now form mergers or allied operations with other EU or non-EU airlines as their individual markets are considered by them to be too small to compete globally. This example provides a clear insight into the difficulty of forming strategic partnerships based on equity investment.

The alliance between Lufthansa and United provides a typical example non-equity alliances. The agreement includes ticket code-sharing, collaboration on frequent flyer programmes and marketing, and some sharing of airport facilities. Essentially, it will allow Lufthansa access to the 200 cities served by United. Many European airlines are now involved in similar agreements. Iberia has set up a commercial collaboration with United. Delta has reached a set of bilateral agreements with Sabena, Virgin and Austrian Airlines. Air France has joined forces with Air Canada and Alitalia is cooperating with Continental.

Non equity alliances as well as many M&As operations, such as BA's partial equity purchase of USAir, KLM's stake in Northwest and Delta and Swissair's cross-shareholding, are largely motivated by the need of a partnership between US and European carriers. For US carriers collaboration allows the entry into the newly liberalised Single European market while, for European carriers, collaboration entails access to the world's largest domestic airline market.

Increasing concentration in the airline industry, particularly through alliances, continues to dominate strategic thinking in Europe, especially following the third package. Many of these alliance involve code-sharing and block-space agreements. Code-sharing provides a seamless flight that may involve two or more airlines (usually two) and potentially a change of aircraft. The advantage of the code-share is that it shows up on CRS as a single flight and hence appears before flight combinations with two or more flight numbers. Blockspacing is where airlines add their code to another carrier's flight and vice versa, where the two carriers have blocked space on the flight of the other carrier.

The liberalisation of the EU skies, discussed below, has allowed the smaller niche regional carriers to expand services where previously route rights and slots were hard to come. In addition the regulations on start-ups should foster additional point to point small airlines, as they take away some of the competitive edge previously held by other airlines through prior legislation. The question is whether European skies will experience a pattern similar to that observed in the US where one of the most striking upshot of deregulation has been the emergence of new low-cost airlines offering now-frills services on short and medium-haul routes. In the US, these new competitors have driven traditional carriers into costly price wars and triggered another round of restructuring in the industry. In some cases, traditional carriers have even reacted with the creation of their own low-cost subsidiaries. To some extent, the phenomenon is also spreading in Europe but several factors will limit its extension. Several flag carriers have anticipated these developments, setting up their own low-cost subsidiary. Besides, entry into European skies remains limited by a set of structural hurdles such as congestion at the biggest airports, subsidies to state-owned airlines and competition by high speed rail on small to medium-haul routes.

### Frequent flyer programme

Frequent Flyer Programmes (FFPs) are used as a competitive tool by airlines to win frequent travellers by providing rewards for flights taken on a particular airline or groups of airlines. These rewards usually take the form of points which count towards free flights, ticket upgrades, leisure travel and holidays, amongst others. Many airlines view FFPs as defensive, in order to maintain competitiveness and existing customer base rather than gain additional custom. The programmes have two advantages for the airlines in that they provide a useful marketing tool for matching customer requirements more exactly and developing new marketing strategies, and since they are usually restricted they enable airlines to balance loads on flights. The major drawback are the costs associated with administering the programmes and providing the rewards. The airlines in the EU have introduced FFPs cautiously and with a large variation in the levels of rewards.

Several changes have been observed recently. More airlines are now rewarding the lowest fare leisure traveller compared to the original requirement of business or fully flexible economy tickets. Hence, airlines are keen to fill up the back of

the aircraft on a marginal cost basis. There also appears to be indications of an FFP competition, as airlines have been increasing rewards, in some cases doubling them. Finally, business travellers seem to be shifting their priorities when joining a FFP, attaching more importance to being at the head of the waiting list for overbooked flights than to earning free flights.

Though the number of members of the major EU airlines' programmes is still tiny compared to the US, membership in FFPs are on an upward trend and more than 85 % of business travellers now belong to a frequent flyer scheme.

### Impact of the Single Market

For the airline industry, the most important aspect of the Internal Market has been the liberalisation of air transport services. By freeing entry, capacity and fares within the European market, liberalisation is bound to have an important impact on the structure of the sector. However, this effect will only materialise progressively and, at the moment, only a relatively small number of M&A operations or start-ups may be directly attributed to the Internal Market. The impact of liberalisation has so far been quite different depending on the type of airlines considered. Charter airlines, which have long operated in a competitive environment, have until now been much less affected than other airlines. By contrast, liberalisation has largely supported the activity of regional airlines, partly owing to easier market access and partly owing to the transfer of routes from larger carriers who need, for cost cutting reasons, to re-orient their structures towards longer distances or higher capacity routes.

Because much of the benefits of European integration ultimately hinge on increased competition and the existence of a level playing field, competition policy is a crucial element of the 1992 programme. In particular, the sector is characterised, in several countries, by a large amount of state-ownership so that a sound policy in terms of state subsidies becomes particularly important. In terms of competition, another crucial factor is inter-modal competition between air transport and high-speed-rail. The EU environmental policy has so far failed to recognise that air is not less environmental friendly than high-speed rail and that the subsidisation of the high-speed rail is therefore unfair for commercial aviation.

There remains important barriers to the completion of a fully integrated market. One of them is the necessary liberalisation of ground handling services, the cost of which can sometimes seriously distort competition. Another, considered by the in-

dustry as a chief priority, is the cost burden resulting from the non-harmonisation of air traffic control systems in Europe and, more generally, the existence of serious shortages in terms of airport capacity.

## ENVIRONMENT

The two most important environmental impacts of the air transport industry are noise and air pollution. Noise is particularly important. Estimates included in the Commission's Green Paper on The Impact of Transport on the Environment suggest that the percentage of the population exposed to aircraft noise above 55 db(A) varies from 35 % in the Netherlands to 1.7 % in Denmark, and above 65 db(A) from 1 % in Germany to 0.3 % in Denmark. Hence, the location of airports close to residential areas is a key factor in noise pollution. Estimates released by the AEA show that the modern jets generate about the same level of noise as a TGV, but for a comparatively minute distance (some 4 kilometres). However, the discussion about noise continues at full pace, and most services that land or take off at airports near residential areas have strict requirements about night flights and the levels of thrust that can be used. This has a detrimental impact on the airlines costs as it can take much longer for an aircraft to reach optimum cruising altitude and hence the fuel burn and the time taken for a particular stage length is higher.

Estimates for air pollution put carbon dioxide emissions second to road transport but the gap is considerable, with road accounting for almost 80 % and air taking almost 11 %. Other emissions such as nitrogen oxides are still under investigation, however, some figures from the UK indicate that air emissions of NOx account for only 1 %. Further research is being conducted on the measurement of NOx in the troposphere, where it is feared that the effect of the greenhouse gases is greater than at ground level.

An important caveat to understanding the relative pollution of air transport vis-à-vis other modes is that the advances made by modern technology are substantially reducing both air and noise pollution.

## REGULATIONS

The Commission of the European Communities has taken a gradual approach to deregulation in order to avoid the pain experienced by the US industry following the deregulation of the US market. In 1978, the US government deregulated

the domestic market by abandoning the geographical limits to route networks, fare regulation and refusing to enforce the hitherto powerful economic regulations. The result of deregulation in this market was a proliferation of new entrant carriers in the early 1980s. The lower unit costs arose from the surplus of experienced labour that had been made redundant by the established airlines. However, a large number of these new entrants were later either taken over by the larger airlines or went bankrupt and ceased operations, as well as some of the very large operators. The effect of this was to concentrate the US domestic and international air travel in a handful of 'mega' carriers with a number of substantially smaller 'niche' carriers. As a result of the deregulation in the US and in some other markets, deregulation is often accused of aiding or at the very least not stopping concentration. However, in the recent past, US skies have remained fiercely competitive, partly under the spur of low-cost entrant carriers, and fears of anti-competitive behaviours due to increased concentration now appear largely overdue.

Following the US, European support for liberalisation of air transport policy gathered momentum, with the United Kingdom being one of the leaders. In 1984, the UK signed a new air services agreement with the Netherlands, which was further modified in 1985 and in essence completely freed air services between the two countries. The agreement allowed free entry of new carriers, open route access by designated airlines to any point in either country, no control on capacity and a double disapproval fare regime. This agreement represented the first major break in the usual bilateral traditionally found in Europe. More agreements followed in Europe, some of which were very liberal in that they removed any controls on the points that could be served in each country by the other country's airlines. In theory this offered equal opportunities for either countries' airlines.

Typically, the bilateral agreements that were negotiated in Europe during the mid 1980s allowed first, third, and fourth freedom rights, but more importantly relaxed the limits on

capacity as well as fare regulation and propagated the double disapproval fare regime.

The Commission of the European Communities added weight to the existing agreements in a series of three packages, which enforced new agreements on members that had not negotiated liberal bilateral agreements, and, more importantly, allowed more extensive fifth freedom rights, as well as paving the way for cabotage later in this decade.

Although the first two packages were quite limited in scope, they nonetheless underscored the Commission's commitment to deregulating the air transport sector within the European Community.

The main achievement of the first two packages was to harmonise national legislation at the then most achievable level for competition as well as providing the foundations for the third package. The process has been quite gradual due to the negotiation required between the individual Member States and the need to keep in line with the progress towards the Single Market. The first and second packages were thus not viewed as deregulation since there remained a number of legislative constraints including continued capacity limitations and some fare regulation.

It is the third package that came into force on 1 January 1993 that really liberalised the air transport market in the European Community and that will influence most of the future organisation of the sector. This package essentially allowed any airline, existing or start-up, to operate anywhere in the Community with whatever capacity and fare level the airline chooses. There exist a small number of exceptions, such as very thin routes which can be protected, but these do not detract from the aggregate effect of liberalising air transport in the European Community. However, in order to obtain an 'air operator's certificate (AOC)' for start-ups, the airline has to provide the relevant authorities with a business plan that includes minimum capital requirements and the ability to operate for a minimum term. Cabotage is currently restricted to 50 % of capacity and is only allowed if the airline starts or finishes the flight in its home country but it will be completely unrestricted from April 1997.

So far, the reaction by the airlines to the third package has been relatively cautious. There has been no explosion of fare reductions or added capacity, however alliances, whether equity based or not, are increasing, both amongst the EU airlines and between EU airlines and non-EU airlines. This increasing concentration is based on both the EU airlines' desire to seek positive positioning within the EU and the need to act global. This somewhat mirrors the situation that was observed in the US in the 1980s, but with less equity involved.

Recent agreement has been reached by the EU transport ministers on a code of conduct for computer reservations systems

**Table 14: Air transport  
Air freedom rights**

First Freedom	To overfly one country en-route to another
Second Freedom	To make a technical stop in another country
Third Freedom	To carry passengers from the home country to another country
Fourth Freedom	To carry passengers to the home country from another country
Fifth Freedom	To carry passengers between two countries by an airline of a third country on a route with origin/destination in its home country
Sixth Freedom	To carry passengers between two countries by an airline of a third on two routes connecting in its home country
Seventh Freedom	To carry passengers between two countries by an airline of a third on a route outside and completely separate from its home country
Eight Freedom/Cabotage	To carry passengers within a country by an airline of another country on a route with origin/destination in its home country

(CRS) which in essence ensures that airlines that own a CRS are prevented from poaching passengers from other airlines that participate in the same system.

In January 1993, the European Council also reached an agreement on common rules for the allocation of slots at Community airports. The new code of conduct sets out transparent and non-discriminatory rules for the allocation of slots in order to avoid competition distortion due to an unequal access to slots.

Following the industry's structural difficulties, the European Commission set up a "Comité des Sages" to review the situation of the European airlines and to propose policy actions. The committee's final report was published in January 1994 and was followed by a communication of the European Commission in June 1994 which set up guidelines for a concerted action programme for civil aviation in Europe. In short, the communication recognises that the present difficulties of the industry stem from a combination of world overcapacity and European specific problems such as low productivity and high costs. The Commission regards efficiency improvements and cost-saving measures in the civil aviation system in Europe as political priority for the years to come and stresses that making the internal market fully effective and achieving significant enhancement in infrastructure are key elements for the improvement of the sector's competitiveness (COM(94) 218 final). In particular, air transport infrastructure, both in terms of air traffic management and in terms of airport capacity, falls within the scope of the provisions on Trans European Networks of the Maastricht Treaty and, as such, will benefit from European coordination and from European funds.

## OUTLOOK

With 1994 now promising to be one of the best years in terms of traffic growth in more than a decade, the outlook of the airline industry appears rather upbeat. The gradual recovery of European economies during the second half of 1994 will continue to fuel short and medium term growth in European air traffic. Table 15 illustrates the AEA forecast by country, with nearly all countries providing reasonable average growth rates for the period 1994-98. However, European airlines are still characterised by large differences in competitiveness and some carriers are better positioned to take advantage of future growth opportunities.

The deregulation of the skies will force continued consolidation within the industry in order for airlines to remain competitive with both their competitors within the EU and outside the EU. Hence the number of major EU operators is expected to decline in the future, whilst the number of smaller niche point to point airlines will increase.

One blight on future growth of air traffic in the EU is the limitations of infrastructure for air transport, in particular as to Air Traffic Control (ATC). Eurocontrol, Europe's largest air traffic control grouping, has re-iterated warnings that significant investment is required to harmonise and update Europe's air traffic control in order to avoid the crunch that is looming. At present, 23 countries of the European Civil Aviation Conference have 31 different air traffic control systems. These systems rely on 18 different types of computers and 30 incompatible programming languages. Though the situation somewhat improved in 1993, the vast majority of delayed flights in Europe are still attributable to airport and air traffic control system. Although improvements to ATC are being provided, there is still a long way to go in terms of investment capital and time before a harmonised system of ATC will be available that is comparable to the one currently in existence in the United States.

# Postal and express services

## NACE 79

The trend towards deregulation of the postal market in Europe has received a boost by the recent developments in Germany, which are likely to be echoed in other EU countries. The driving force behind deregulation is undoubtedly the globalisation of the communications market, which calls for European postal operators to be able to offer more market-oriented services.

Further policy initiatives put forward by the European Commission are likely to cause further structural changes in the services provided by both postal administrations and private operators.

### INDUSTRY PROFILE

#### Description of the sector

NACE 79 includes all units exclusively or primarily engaged in transmitting sounds, images, documents and packages for the benefit of the general public. Apart from postal and express services, this NACE heading includes telephone, telegraph, telephotography and telex services.

This monograph deals exclusively with postal and express services. In particular it concerns the activities of postal administrations of Member States and private operators. However, postal administrations are also involved in financial services like postal giro offices (NACE 812) and post office savings bank branches (NACE 813.1).

Postal and express services provide the mechanism whereby letters and packages are moved between two distinct groups of users. The service provides transmission for business to business, business to private and private to private.

The distinction between letter services and parcel services for both postal and express is determined by weight and contents (typically letters carry 'communication'; parcels carry 'goods', although letter services can carry small goods). Pricing of the services is determined by weight, geographic destination (where zonal price differences are typically

differentiated into domestic, EU, and substructures for the rest of the world) and required speed of delivery.

Letter services provided by postal administrations can be categorised in three main areas:

- Standard letter services for letters, post-cards, printed papers and small packets with or without priority delivery;
- Subsidiary letter services, which include registered letters, recorded letters, certificate of posting/advice of delivery, special delivery, express, direct bags ("M-bags"), post office boxes and post restante;
- Additional specialised letter services, such as postal electronic mail, "hand delivery", "city mail", periodics (magazines and newspapers) and direct mail.

Most postal administrations provide letter services under a monopoly (reserved services); except for Sweden and Finland. In general a concession is granted to the postal administrations, in which they have special and exclusive rights for offering these services. The provision of the service is then obligatory. Parcel and express services are offered in a more competitive environment (non-reserved services), where postal administrations usually dominate in some parcel sub-services (such as private-private), whilst private operators can dominate express services and business to business transmission.

In financial services, postal administrations offer the following:

- postal payments (money orders, postal orders and cheques, "valeurs déclarées");
- girobank operations (tele-payment, interior accounts/deposits/pay-out, foreign currency, mortgages and charge/credit cards);
- savings bank operations (home savings and common funds investment);
- other payments (pensions, welfare services, licences, taxation and public payments).

However, the services are not always offered directly by the postal administrations but sometimes as agents on behalf of separate banking companies.

#### Recent trends

The postal services sector is an important sector for the European Community, accounting for about 0.9 % of total GDP of the European Union and employing about 1.7 million staff.

**Table 1: Postal and express services**  
Postal administrations - Receipts as a share of gross domestic product

The sector is critical for most business and private interaction and trade, as it provides an important mechanism for communication, which although facing competition from other forms of communication such as telephone and fax, remains a major force.

Measured in terms of the number of items handled, the largest postal administration in the EU is France's La Poste (22.8 billion in 1992). The German Bundespost ranks second (17.0 billion) and the United Kingdom's Royal Mail third (16.3 billion). These top three provide more than half of item movements in Europe.

Over the last ten years the number of post offices open to the public and the numbers of employees have broadly been stable or slightly declining in most EU countries. The analysis of available data (presented in Table 3) is made impossible by the varying definition of post office and of post employees.

Competition from private operators has taken some of the aggregate market share (in value terms) as in the late 1980s private express services had strong growth with rates in the range of 30-40 % a year. However, estimates in volume terms for the intra-European express market are at around 30 million items per year, which is significantly smaller than the comparable total for the postal administrations (including extra-EU movements) of over 80 billion items.

The private operators have caused a shift in the market for postal services. National postal administrations have been faced with increasing competition in non-reserved services from the private international operators aggressively moving into the market, especially in the field of parcels and priority express services. This has hastened most postal administrations into improving their own priority and package services.

#### International comparison

Comparing postal administrations in the EU with those in the USA and Japan reveals that on average each EU citizen received 260 mail pieces in 1990. In the USA, the number of mail pieces received annually by citizens is much higher at around 650. This difference is due mainly to a much higher level of direct mailing activity. In Japan the average amounts to about 160 pieces.

Within the EU there are large differences in the average number of per capita mail items received. In countries such as the Netherlands this number is the highest with over 400 items per year. On the other hand, in Greece and Portugal the average is below 100 items annually. Figures for Japan reveal that in

Tokyo mail received per capita amounts to 388, whereas in some rural prefectures this is less than 60 pieces.

Comparisons of relative efficiency of the postal administrations often use the number of items handled per employee. These comparisons, although partially useful for broad brush comparisons, are fraught with problems as the number employed by an administration may include workers who are irrelevant to postal services, for instance in the girobank division, and the structure of mail services differs significantly within the EU itself and among the EU and the USA or Japan.

## MARKET FORCES

### Demand

Customers of postal services are either businesses or domestic households. According to industry sources, about 60 % of all mail originates from businesses and is destined to domestic households; around 30 % is "business to business", and the remaining 10 % of postal service traffic circulates among domestic households.

For parcel services the distribution is slightly different. Businesses and organisations send about 85 % of all parcel items, the bulk of which (70 %) is received by individuals. About two-thirds of parcels sent by individuals are destined for other individuals.

For postal administrations, the market is rather evenly spread over various end-users. The more important outlets are the publishing industry, which sends periodicals to its readers by mail and accounts for about one fifth of the shipments made, and direct marketing/advertising mail; for instance, non-addressed mail delivered to households in 1992 by Belgium's De Post/La Poste was 51 million items, which is more than 7 % of all items. Another important segment is mail ordering.

During the past few decades, mail order developed as a competitor of store retailing services. This allowed postal services to benefit from the growth in package movements created by mail order, as they have been able to meet with requirements such as customer communication, catalogue distribution, statement sending and goods distribution. More recently, private operators have taken part of this market too from public administrations.

Advertising by mail (direct mail) has also increased its importance for postal services over the years. An increasing share of marketing and sales budgets is spent on direct mailing activities. In this market segment too, postal administrations

are losing market share to private operators, particularly in urban areas.

Distribution of publications by mail remains important for postal administrations. They can offer cheap mailing services at preferential tariffs. However, private operators are competing with this low value mail services, as other requirements can be important (e.g. a guarantee to deliver the next day).

### Supply and competition

The past two decades have witnessed a considerable alteration of the competitive environment for postal administrations.

The widespread development of cable communications (i.e. fax, electronic mail) has reduced the postal share in the com-

munication market. Also the success of private operators on the parcel market has further reduced the postal administrations' dominance of the sector. In the near future, the expected rapid expansion of home shopping is perceived as yet another competitive challenge to postal services.

Nowadays, private operators are mainly active in the high value added express services from business to business. In the future, they could enter the thriving business-private segment, in order to profit from the booming trend of direct mail. Private operators might also be interested in unsophisticated, low-value added advertising which is distributed to households in large volumes.

If one analyses the market for mail, it is true that in the business-to-business segment (30 % of total traffic), the advent of electronic mail will reduce market opportunities for the post; on the other hand, the private-to-private segment (10 %) will remain largely dominated by physical mail.

More importantly, the business-to-private segment, which is the largest of all, offers good growth opportunities for postal administrations which are sufficiently equipped on the technology side, and which have an adequate commercial and marketing freedom.

The best opportunity for public postal operators is represented by the so-called "hybrid mail", i.e. letters which are electronically printed and addressed and delivered by hand. In this market segment, post offices can offer their services to businesses interested in direct mail campaigns, by providing

electronic printing and hand-delivery of letters. Other opportunities lie in the provision of on-line electronic mail and data exchange services, in competition with cable communication companies.

#### Production process

The production process of postal services can be divided in five stages: collection of mail, sorting for destinations, transportation, final sorting and delivery of mail. Mail delivery is the largest cost item, accounting on average for about two-thirds of operational costs. Next comes transport and sorting for destination with a combined share of about one quarter of total costs. The remaining is accounted for by mail collection and final sorting for delivery. These figures are aggregate approximations and vary widely between administrations.

Source: UPU, national postal administrations

A good network is of crucial importance for postal services. The complexity of the interactions between all the different points in a network demands a good logistics chain. For international mail the problem is even more complex, as domestic networks have to be matched. Essentially there are two network systems: the hub-and-spoke system, in which a region is serviced from a central "hub" via "spokes" with local centres; and the spider's web system, in which local centres interact directly with each other.

Productivity is very different between the postal administrations of the EU countries. On average, postal administrations have an estimated turnover per employee of about 22 000 ECU. On the other hand, private operators have a turnover per employee that is more than double the postal administrations. These differences mainly arise from the different value added provided and consequently are not totally comparable. Also, network quality, labour costs and productivity are among the factors that cause wide ranges in tariffs for what, apparently, are the same services. Private operators charges are substantially higher, since customers pay for a higher service quality.

An often used indicator for service quality in postal administrations is the percentage of domestic mail delivered the day after collection. In small countries like Denmark, Netherlands and Luxembourg this rate is in excess of 95 %. In Germany, a large country relative to the previous ones, the Deutsche Post AG manages 81 %. On the other hand, in Italy, another large country, it is 17 %. This poor service quality of the Italian postal authority can allow private operators to gain a larger market share. It is important to note that these estimates of delivery rates are not strictly comparable, and should only be used for broad comparisons.

## INDUSTRY STRUCTURE

### Companies

Table 6 profiles the legal status of the postal administrations of the Community in 1994. All public postal operators are controlled and owned by the various governments, with the notable exception of the Netherlands; where the government sold 33 % of its shares to the public in 1994. At the same

time, all postal administrations in the EU enjoy various degrees of financial autonomy.

Private operators can be classified into four categories: companies operating globally or intercontinental, pan-European companies that are essentially EU domestic, national operators and local operators. The globals include companies such as the big four 'integrators': DHL, Federal Express, GD Express Worldwide (GDEW), a joint venture between TNT and the postal administrations of France, Germany, the Netherlands, Sweden and Canada) and United Parcel Service (UPS). They offer services which go beyond postal services and integrate various forms of transport and distribution. Examples of the second category are Kühne & Nagel (D), Jet Services (F), TAT Express (F) and Securicor (UK). In the national and local levels a host of small companies offer express services that range from long distance indigenous city to city pairs, to city or conurbation area delivery by specialist motorcycle couriers.

The initial strong growth in the market for express services has attracted companies active in other fields of transportation and forwarding. For example airline companies like KLM, Lufthansa, British Airways and Air France support the services offered to the market by providing inexpensive, but otherwise redundant, cargo space in their aircraft to the freight forwarders and consolidators. Freight forwarders and railroads have started express services. Postal administrations have set up their own international express service (EMS) in order to take advantage of the higher value added market, and in some cases are involved with the private sector, for instance GDEW.

At the beginning of the 1990s, the large private operators have been faced with weakening growth and have experienced some setbacks due to the downward pressure on the high value added end of the market caused by recessionary constraints. Rationalisations and closure of some activities has occurred as well as a fall in aggregate employment in the private sector. However, in 1994, these courier companies have all been experiencing very high growth.

### Strategies

The trend towards deregulation of the postal market has gained momentum in the past few years. Examples provided by the Netherlands (30 % privatised), Finland and Sweden have shown that postal administrations are able to turn postal services into profitable operations.

In Germany, the government has recently decided to end the post office monopoly for deliveries of mass printed materials and catalogues of over 250 grams from 1 January 1995. The second step of the deregulation process in this area will reduce the weight limit for private transport companies to 100 grams from 1 January 1996.

The recent victory of the conservative coalition in the German general elections is likely to push further the deregulation process.

The most immediate impact of liberalisation measures will be the need for postal administrations to offer more market-oriented products in order to survive in a competitive market. In anticipation of such development, postal administrations have already become increasingly commercial.

For example, following the above-mentioned deregulation measures, the German post office has announced that, starting from 1 April 1995, it will cut prices for mass mailings to better face private competition.

In some countries, the profitability of financial services provided by postal administrations is high, sometimes well above 10 % of the turnover in that sector. This enables a partial and sometimes full compensation of losses on postal services, but at the same time begs the question of what is the level of cross-subsidisation in the administrations.

Together with a strong drive towards meeting customers' needs, postal administrations have also improved efficiency on the supply side. This has been achieved mainly by investments in automatic sorting of mail. Also the efficiency of operations in the network has been improved by a more cost-based attitude.

In an international perspective, postal authorities cooperate in various organisations, such as the Universal Postal Union (UPU) of the United Nations, the European Conference of Postal and Telecommunications Administrations (CEPT) and the Association of European Public Postal Operators (PostEurop).

PostEurop, which regroups postal operators from 38 countries in Europe, has been set up in 1993 as a forum for coordinating result-oriented developments within the European postal market: among its specific tasks, PostEurop aims at raising quality-of-service standards by monitoring market developments and facilitating the exchange of experience and expertise.

In the private sector market for parcel and express shipment services, the level of demand has placed a limit on the number of operators. Hence there has been a number of mergers and strategic alliances, which is likely to continue in the short to medium term. These have and will continue to involve integrators, carriers and forwarders, and also postal administrations.

A key example of the changing structure of the industry is TNT Australia, which sold most of its European network to GDEW. In GDEW the five key member administrations combine their EMS services with the international express network of old TNT network. This alliance is attractive for postal

administrations as they have reduced their exposure to the old bilateral agreements structure. The success of this strategy is confirmed by the news that also the post offices of Austria, Switzerland and Hungary are negotiating their entry into GDEW.

### Impact of the Single Market

The Single Market programme had a positive, though limited impact on public postal operators. The most relevant measures of the programme have undoubtedly been those contained in the EU competition policy. The progressive opening up of mail services and the increasing competition from telecommunications services have turned postal operators into more customer-oriented entities. Additionally, the progressive liberalisation of transport services could have a direct positive impact on postal services by reducing transport costs (the major input after labour). Many of the Green Paper's recommendations are seen as vital to improve public postal services throughout the EU. Some proposals (such as a possible liberalisation of direct mail and inward international items) are still under discussion. Public postal operators welcome the Single Market programme and the EU's initiative to review its implications for the postal sector. In particular, clarification of universal services and reservable area requirements should provide a solid base for improving services to customers.

The Single Market programme has been one of the major catalysts for the rapid expansion of the private express services sector. The most relevant measures for the sector are enshrined in the competition policy. The progressive dismantling of monopoly and the monitoring of state aids are of utmost importance for the continuation of growth in the sector. The achievement of the free movement of goods within the EU has also eased the activity of global couriers, who have adapted their strategy and logistics in order to operate within a single market. According to the EEO, there are some important obstacles to the completion of the Single Market which are yet to be removed: the industry asks, in line with the spirit of the Treaty of Rome, for the complete liberalisation of cross-border mail services, the abolition of cross-subsidies on grounds of unfair competition and the total liberalisation of transport services, notably in rail and air transport. Finally, according to industry sources, more harmonisation is needed concerning customs clearance procedures, which are still based on different criteria for the same items throughout the EU.

### REGULATIONS

In each country governments have legislation for postal administrations to provide universal postal services. Provision requirements differ from Member State to Member State.

In non-reserved services the market has tended to regulate itself. For reserved services however, a body has been responsible for regulating the monopoly market. Historically the regulator was also the operator, i.e. the postal authority. The recent trend has been for Member States to try to separate the regulatory authority from the operational function by establishing a body under the responsible ministry.

The removal of custom barriers within the EU has helped levelling the competitive playing field between postal administrations and private operators for intra-EU services, by significantly reducing the cost of customs clearance which were required to private operators. Previously, these costs were minimal for the postal administrations as they were directly borne by the service users.

In the continuing formation of the Internal Market, the European Commission is developing a common policy for postal services throughout the European Union. This requires substantial policy harmonisation in the various Member States.

The Commission presented a Green Paper in June 1992 on the development of the single market for postal services. This was followed in June 1993 with a communication from the Council to the European Parliament on Guidelines for the Development of Community Postal Services (COM(93) 247 final). This latest communication has taken into consideration the large (and generally positive) response generated by the Green Paper, and consequently seeks to provide a detailed approach to action by specifying the measures required. The communication discusses in some detail the following topics: the common definition of the universal service; the maintenance of reserved services; service quality standards; measures that may be required to promote harmonisation in the Community; separating the functions of regulation and operation; and some aspects of extra-EU postal interaction. In order to harmonise and liberalise the EU postal services, a provisional implementation process is proposed, which acknowledges that legislative action will be required at the Community level; but that strongly strives to avoid measures that will lead to a deterioration of the level of service provided in Member States.

More recently, the Council of Ministers asked the Commission to present legislative proposals to change the regulatory system of postal services. The Commission, in its paper entitled Proposal for Regulatory Framework for Postal Services in the EU, makes a strong case for liberalisation by affirming that justifications put forward by some postal administrations for restricting the operation of direct mail and cross-border mail are not proven.

### OUTLOOK

The outlook for postal services differs according to the type of service offered. For traditional letter services, growth is expected to continue but only at a marginal rate due to competition from advances in modern communication such as facsimile, electronic mail and EDI.

In parcels and express services, growth is expected to be substantially higher. The integration of the European market implies increased interaction (in terms of traffic and trade) between the Member States. This increased interaction will continue to put pressure on postal administrations to provide high quality services.

Another strong growth market will be with direct marketing & sales related mail. This will be a market with strong competition between postal administrations and private operators, as confirmed by the forthcoming developments on the German postal market.

Of crucial importance for today's postal services is the application of modern technologies. Private operators can generally boast a high-tech structure, while some postal administrations are in the need of a large investment effort into new technologies to raise their competitive profile.

Another important issue is the regulatory environment. A community policy for postal services will seek to reduce the present lack of harmonisation in legislation concerning reserved and non-reserved services, to introduce a more cost-oriented tariff system and to apply free market principles where possible.

# Sea ports and other sea transport facilities

## NACE 763

*Supporting services to sea transport are highly heterogeneous in nature, and range from loading and discharging ships to several other ancillary services such as operation and maintenance of docks.*

*Within the EU, port authorities can be either publicly owned or privately owned (or a combination). This distinction entails a different conception of the nature and functions of a port, which has given rise to a dispute about state funding of ports in some Member States.*

*Competition among ports is very strong. In recent years, most ports in Europe have been investing heavily in modern infrastructure, superstructure and facilities in order to keep ahead of competing ports.*

*The European Commission has recently made a series of proposals to integrate EU ports in the trans-European transport network. The proposed guidelines recognise the role of ports as essential interface between sea and land (about 90 % of the EU external trade operations are carried out by sea).*

### INDUSTRY PROFILE

#### Description of the sector

NACE 763 includes all supporting services to sea transport and coastal shipping, that is sea ports and other sea transport facilities. Examples of service types are tugs at sea, pilotage, lighthouse operations, buoys and other navigation facilities, stowing, stevedoring, loading and discharging of sea-going vessels, and operation and maintenance of sea harbours, piers and docks.

The supply of seaport facilities and services must be distinguished in the provision of infrastructure and superstructural facilities and handling services. Facilities are generally managed by a port authority, whereas handling services are mostly in the hands of private companies. The situation however, greatly differs from country to country.

Also, it is important to mention the distribution and industrial activities carried out in or near the port areas, although they

are not included in the statistics. These activities create employment and added value and are one of the reasons why competition between ports can be so intense.

#### Recent trends

In 1992 the 177 seaports in the EU which reported to the MERC World Ports Database, handled total traffic of about 2 236 million tonnes of cargo. The three top individual country volumes were handled in the United Kingdom, with some 444 million tonnes in 42 ports, the Netherlands with 369 million tonnes in 10 ports, and Italy with 319 million tonnes in 18 ports. These three countries account together for just above 50 % of total traffic volume in seaports in the EU.

Figures for the top 12 EU ports indicate that 1993 saw stagnating or negative growth in total traffic, thereby accentuating a downward trend which became apparent in 1992. Within the top 12 EU league, the three largest ports, Rotterdam, Antwerp and Marseilles all reported declining traffic volume: the fall was particularly important in Rotterdam (-4.4 %). However, there are early signs of a recovery during 1994 at least among some ports (e.g. Antwerp).

#### Passenger transport

In most ports in the European Union, passenger traffic is negligible or even non-existent. For some ports, however, it is the main activity. For example, the ports on both sides of the Channel depend heavily on ferry traffic between the United Kingdom and France. Even amidst several logistic difficulties, the opening of the Channel Tunnel in 1994 is perceived as a major competitive threat to the ferry operations on the Channel and as a consequence to the ports along the Channel.

Passenger traffic is also important between mainland United Kingdom and Ireland and Northern Ireland. A number of ports in the Mediterranean have significant passenger facilities for ferry links. Particularly important examples are in the south of Italy, where ferry connections exist with Greece and the countries in Northern Africa. Also, Greek ports generally have passenger facilities providing for domestic inter-island ferry links in the Aegean Sea.

Finally, mention should be made of the ports in Northern Germany and Denmark. From these ports, important ferry links exist with Sweden, Finland and Norway. The port of Copenhagen is currently completing the construction of a new passenger terminal enabling the handling of 10 vessels simultaneously. However, the proposed bridge between the south

of Sweden and just south of Copenhagen across the Öresund will have a major impact on traffic currently on ferries between southern Scandinavia and mainland Europe (potentially similar in effect to the Channel Tunnel).

### Container transport

Container traffic emerged from the need to unitise general cargo items into manageable units of equivalent size. For this purpose the twenty-foot container was developed which could be easily filled with general cargo for transportation and easily unloaded when reaching its destination. During its development, containers of different size emerged, but the standard unit of measurement has remained the twenty-foot container. Traffic flows are thus expressed in Twenty-foot Equivalent Units (TEUs).

Port authorities and container handling companies make heavy investments to create an attractive infrastructure where containers and container ships can be handled as fast and as reliably as possible. Modern container terminals operate with highly automated container location and tracing systems. An example is the Maasvlakte-terminal of ECT in Rotterdam, where modern straddle carriers can trace containers automat-

ically. Large gantry cranes also need to comply with the increasing ship size: the largest ships (of so called 'post panamax size') carry up to 4 500 TEUs.

In 1992, the latest year for which data are available, total container handling in the 20 largest ports throughout the world amounted to some 53.3 million TEU (see Table 6), which represents an increase of about 23 % against 1990.

The largest container ports at world level are currently Hong Kong and Singapore, handling almost 8 million and 7.6 million TEU respectively in 1992. These ports have become major hubs in the Southeast Asian region for container traffic flows: Hong Kong's growth reached 30 % in 1992, whilst Singapore managed a healthy growth of 19 %.

In the EU, Rotterdam is the largest container port, as well as being ranked third world-wide. In 1992, following growth in container movement of close to 10 %, it regained this place that it lost in 1991 to the Taiwanese port of Kaohsiung. Other major EU container ports (respectively Hamburg, Antwerp, Felixstowe and Bremen) all improved their performance in 1992. The general economic recession which hit Europe in

1993 has likely brought about a reduction of container traffic in all major EU ports.

### International comparison

In the 1960s and 1970s, European ports were among the larger ports in the world; in the 1980s ports in South East Asia and Japan emerged among the largest in the world's top 12 seaports. Japan's presence in the league is spectacular, with half of the top 12, with ports like Kobe, Chiba, Nagoya and Yokohama. The port of Singapore has second position with large volumes of general cargo (mainly in containers) and liquid bulk (mainly oil). There are presently no US ports among the world top 12.

The EU has three ports in the world's top ranking, which are Rotterdam, Antwerp and Marseilles. For more than 30 years, Rotterdam has been the largest port in the world. In 1993, total traffic handled in Rotterdam amounted to about 279 million tonnes, which is however just some 5 million tonnes ahead of second placed Singapore. Traffic handled through Rotterdam is dominated by liquid bulk (oil, oil products, chemicals, etc.) at 142 million tonnes, and dry bulk at 88 million tonnes, mainly consisting of iron ore and coal for the German steel industry.

Antwerp, the second largest European port, moved up to the eighth position in the world's top 12 in 1992, displacing Hong Kong. Antwerp handles a growing share of general cargo (45 million tonnes) and is also strong in the dry bulk segment (31 million tonnes). Antwerp is an important competitor for Rotterdam.

The third largest European port is Marseilles with some 90 million tonnes in 1992. Traffic through this port consists mainly of oil (about 50 million tonnes of cargo in 1992).

In 1992 the top three ports in the USA, according to MERC, were respectively Houston, Corpus Christi and Tampa. Their current capacity varies from about 87 million tonnes for Houston, to 72 million tonnes for Corpus Christi and 49 million tonnes for Tampa handled per year; this puts them into the medium-size bracket in comparison with European and Japanese ports. The most important types of goods handled are liquid bulk, which is essentially oil and oil products, and containers.

## MARKET FORCES

### Demand

Demand for seaport facilities and services comes primarily from transportation activities. Transport companies are in need of such facilities in order to move cargoes from origin to destination and from one transport mode to another. The demand for these companies (in effect the demand for transport services) comes from shippers wanting their goods to be transported and thus depends largely on the economic activity in the hinterland of the port.

### Supply and competition

The variety in the supply of seaport facilities and services is wide. It concerns not only the handling of cargo from one mode of transport to another, but also storage of goods, distribution facilities, customs clearance, towing and berthing of ships, food and fuel supply services, customs handling, ship-repair and other services.

Over the last ten years, there has been a tendency to broaden the variety of services available within the transportation services - which was traditionally limited to cargo handling and movement. Hence, transport companies have changed into service providers offering a complete logistic chain from door-to-door. In addition, increasing automation and electronic data interchange techniques have made transportation and handling processes substantially more efficient than what was available in the early 1980s. This has enabled transport companies to more closely match customer requirements, for instance, just-in-time delivery systems for industries.

## INDUSTRY STRUCTURE

### Port traffic

Most of the EU's largest ports can be characterised as importing ports as incoming traffic is much higher than outgoing. There are only a few ports where exports exceed imports, such as Calais and Rouen (F) and Tyne (UK). Similar situations exist in the USA and Japan. In the USA, only Duluth is effectively

an export harbour; in Japan, Tokyo can be characterised as such.

The breakdown by type of traffic in Table 4 shows which is the dominant traffic through the major EU's ports. In each Member State, one or a few ports specialise in liquid bulk traffic. These are essentially the locations for import of oil and oil products. Examples are Le Havre and Marseilles in France, Wilhelmshafen in Germany, Trieste in Italy, Sines in Portugal and Southampton in the United Kingdom. Similarly, specialisation exists for dry bulk traffic. Ports like Bremerhaven and Lubeck in Germany and Limerick in Ireland handle practically only dry bulk goods. Finally some ports can be characterised as general cargo ports, such as Zeebrugge, Calais, Dublin, Valencia and Felixstowe.

### Strategies

There is substantial competition among ports on the northern seaboard of Europe (the Hamburg to Le Havre range) to attract container traffic and become the one of the major hubs in Western Europe. Expansion by investment in facilities is seen by the ports as a major weapon in maintaining or improving their relative competitive positions.

The Port Authority of Rotterdam is particularly ambitious to maintain its pole status with large investment plans. These investments should enable the port to reach 400 million tonnes of traffic handled by 2010. The total investment budget amounts to some 11 billion Dutch guilders, of which 7 billion will come from the central government. In addition, private companies will have to invest another 20 to 25 billion Dutch guilders in superstructures and facilities.

Additional multi-modal access to the port will be crucial in the development of the port of Rotterdam, requiring investment in more infra-structure. Very important for Rotterdam will be the planned construction of the Betuwe-lijn, a freight-only railroad connecting the port with Germany, which is currently under discussion. Another issue is the opening of the Rhine-Main-Danube canal, enabling Rotterdam to extend its hinterland connections to the countries bordering the Danube and the Black Sea. Furthermore, the transformation of certain parts of the port area into specialised port locations have been rated

as a success: in particular the 'Distriparks' distribution centres, with nearly all of the allocated land being taken up.

In Belgium, significant investment in port expansion is planned. In Antwerp, the Left Bank development will cost about 37 billion Belgian francs. Further plans are in progress to construct a second container terminal, which will cost about 13 billion Belgian francs, of which the port authority has allocated 750 million Belgian francs in 1993. This second terminal is expected to manage 600 000 TEU a year following completion due in late 1996. Also, plans to renovate existing docks and locks are under way costing another 13 billion Belgian francs. The Port of Zeebrugge authority is investing in a new container terminal, which will provide three berths with an annual capacity of 600 000 TEU. The amount of the investment is put in excess of 10 billion Belgian francs.

In Germany, two operators of Hamburg, HHLA and Eurokai, have invested in improved infrastructure and equipment to boost capacity. Also, a new container complex is under discussion for the Altenwerder area of the port, which would expand the ports throughput to 4.2 million TEU per year by 2000. Bremerhaven is building two new container ship berths by extending the existing container terminal. Completion of this expansion will allow Bremerhaven to offer 12 berths for container vessels.

France's second largest port, Le Havre, is currently expanding by expanding the dock extension, which is due for completion in 1993.

Not only Europe's larger ports have investment plans. Smaller ports also want to improve their position by investing in infrastructure, superstructures and operation facilities.

In Italy, a new multipurpose container terminal recently became fully operational at the port of La Spezia. In Genoa, the new Voltri terminal handled its first containership in May 1994.

In Spain, the Port Authorities of Barcelona and Valencia have initiated major container terminal developments in view of attracting direct liner calls. Barcelona is one of the larger container ports in the Mediterranean, and is planning to construct a new container terminal with multi-modal links that will expand current capacity from 500 to 700 million TEU per year.

In Greece, the port of Piraeus also has ambitious plans: over a five year period the current central harbour facilities will evolve into a pure passenger and cruise terminal, and the cargo handling facilities will continue to be relocated to the 'west-side', where additional investment is in place to expand facilities. The port of Thessaloniki is planning to invest 30 billion Greek Drachmas by 1998 to expand port facilities and land area.

In the UK, the port of Southampton has announced in June 1994 that it will increase by 25 % the area of its container terminal.

### Impact of the Single Market

The impact of the Internal Market on sea ports has so far been relatively muted. The only noticeable effect is a trend towards an increase in the size of the largest ports as a consequence of the reorganisation of distribution and logistics in Europe. Integration means that the European market can now be supplied from a more limited number of distribution centres, a trend which benefits the largest ports because they offer the best potential in terms of logistics. In the long run, the Internal Market is likely to have a marked positive impact on the sector. European integration will translate into a more efficient European economy, faster GDP growth and therefore more trade. In general, the progressive emergence of a more efficient and cheaper transport industry (for all modes) will result in a more transport intensive economy. Sea ports will also benefit from the liberalisation of intra-EU shipping, from the environmental assets of this mode and from an increase in their own efficiency. The Internal Market will continue to have different implications depending on the ports considered. For instance, the progressive liberalisation of rail services will favour those ports which have a good connection to the rail network. Besides, an efficient competition between ports requires a careful monitoring of state subsidies which presently differ depending on the ports and countries considered.

### REGIONAL DISTRIBUTION

With Rotterdam, Antwerp, Hamburg and Le Havre, most of the EU's larger ports are to be found in the Le Havre-Hamburg range. These ports are the most important gateways to industrial and consumption areas on the European continent. This hinterland can be reached easily by way of a high standard infrastructure in terms of road, rail and inland waterways. The Rhine River is especially important for the port of Rotterdam. This connection and its good geographical location on the North Sea have combined to help Rotterdam evolve into the world's largest port.

The importance of German ports has been greatly enhanced by the opening of Eastern Europe. Transit traffic volumes from the Baltic Sea are increasing, as has trade with Russia (mainly through the port of St. Petersburg).

Ports in the United Kingdom and Ireland have their domestic markets as their hinterland, which has typically kept their ports smaller than similar ports on mainland Europe. Good connections (highways, railways) exist from UK ports to the major industrial areas. Inland waterways have declined significantly over the years, plans abound for the revival of these canals. An important activity of UK ports (especially in Scotland) relates to the offshore activities on the North Sea. A

port like Aberdeen, for example, is highly dependant on service provision to oil rigs in the North Sea and on oil handling coming from the North Sea oil wells.

In the Mediterranean, Marseilles and Genoa are important ports, especially for the import of oil and oil products. Their hinterlands can be found in the southern part of France (e.g. Lyon and surroundings) and the North Italian industrial areas (Milan and Turin), respectively. Other goods handling activities are very dispersed over the broad variety of small ports along the coasts of the Mediterranean, Adriatic and Aegean Seas.

---

## ENVIRONMENT

---

Increasingly, port authorities are taking a stance on environmental issues in their ports. The major issues that cause concern are accidental or illegal discharges of waste, leakage or spillage of fuels, spillage during bunkering, and pollution from in-port hull cleaning and re-coating operations. Port and ship operators will have to comply with environmental legislation that is becoming more stringent each year.

The basic text on marine safety, environmental protection and overall shipping standards is the Paris Memorandum on Port State Control. The agreement makes provisions for non-discriminatory (i.e. not targeting individual flags) inspections of ships visiting the ports of Europe. There has been a clear improvement of the environmental record of European port as a result of port state activity, testified by the fact that the number and amount of oil leakages in European waters has decreased in recent years.

Also shippers, in many cases, want their products transported in an environmentally responsible way in order to avoid negative publicity from environmental pollution and accidents that could be associated with these products. In some cases, the shippers require environmentally friendly transport facilities which exceed those obligatory by national legislation. This acts as a spur to port operators to make additional investments in environmentally sound handling facilities.

---

## REGULATIONS

---

Port authorities and companies can be either publicly owned or privately owned (or a combination).

In general, three types can be distinguished concerning the principle of exploiting port facilities:

- fully centralised ports, where exploitation is in the hands of the port authority. This authority is a state body. It does not exclude collaboration with private companies, but decisions on investments are mainly with this body. Examples are most Spanish ports, Italian ports, some ports in France and Denmark.
- decentralised ports, where the port authority is a municipal or collective body. Examples can be found in Belgium, the Netherlands, Germany and Portugal.
- fully private ports, where the port authority is a private company. Examples can be found in the United Kingdom, where Associated British Ports is the owner of 21 ports throughout the country, in Germany (e.g. Wilhelmshafen), Greece and Spain.

The different nature of ports in the European Union has sparked a row about port funding by national authorities. Private ports (mainly British ones) complain that state funding to fully or partially publicly-owned (mainly continental) ports actually consists in a subsidy, which distorts competition in the sector.

The issue is complex, as it involves a different conception of the nature and functions of a port. While the British view considers a port as an autonomous transport operator, the

tradition on the continent (particularly in North German ports) is to regard ports as a hub for economic growth at national and regional level.

The European Commission (DGVII) has recently launched an exercise to investigate the subject. The Commission's first step has been to send out a questionnaire to major port authorities to obtain a clearer picture of the system of financial flows of EU ports.

Another very difficult issue is related to this basic difference of nature among EU ports, namely port pricing. Various principles of port pricing are used and depend effectively on the extent of public funding defined in national port policies. On the one hand are policies based on pricing to recover all costs of operations together with depreciation and financing costs of infrastructure and superstructure. On the other hand are policies that port services are public services to be priced at marginal rates. Cost recovery is then made from subsidisation originating from public budgets.

The European Commission proposed in March 1994 a Council Decision on trans-European guidelines for transport networks. The proposed guidelines recognise the role of ports as an essential interface between sea and land (about 90 % of the EU external trade operations and around 35 % of the trade between Member States are carried out by sea) and the need to integrate them into the transport chain. The proposal lists the criteria to be used to identify projects of common interest for the entire Community. These criteria include helping the growth of trade, encouraging the development of short-sea shipping, improving accessibility and strengthening cohesion. EU funding will be available from the Cohesion and Regional funds.

Finally, another issue is cabotage. For the transport sector as a whole, cabotage will become important in the future. New regulations will allow domestic transport by operators from other Member States which may cause shifts in transport flows throughout the EU and, as a consequence, shifts goods handling through EU ports. If this occurs then clearly some ports will benefit whilst others will be harmed. Some of the smaller ports may lose cargoes to the larger hubs, but at the same time may remain competitive for the smaller niche cargoes, that are either required or manufactured for export in the localised hinterland of these ports.

---

## OUTLOOK

---

The outlook for cargo handling depends heavily on the prospects for world trade and world shipping. As the negative effects of the economic recession which hit Europe in 1993 are slowly fading away, we estimate that growth in European ports may reach about 4 % on average until the end of the decade.

The outlook for container handling in ports is more optimistic. It is expected that liner cargo growth will be about 5-6 % for imports and 2-3 % for exports over the next four years. Also, the penetration of containerisation for general cargo will continue to increase, hence, container handling growth rates are thus expected to somewhat higher.

Individual ports, however, might be able to achieve higher growth rates. This will depend on the increasing tendency to create large trunk lines between major hubs in various regions throughout the world. From these hubs, feeder lines will service container traffic demand in other ports in the region.

# Airports and other air transport facilities

## NACE 764

Airports are a key component to air transport industry and to national and regional development. However, congestion in the EU's airspace and at some of the major EU hubs is causing problems for the operating economics of both airports and airlines as well as having an increasing impact on the environment. To overcome this, the EU is developing an improved air traffic management system, whilst some airports are actively investing in infrastructure improvements and additions.

Competition between major European airports for transit traffic is heightening and this is allowing some of the national competing airports to gain share of traffic.

### INDUSTRY PROFILE

#### Description of the sector

This sector comprises supporting services to air transport (airports and airfields). It includes units exclusively or primarily engaged in the activities essential to air transport, without actually transporting passengers or goods. Hence, units exclusively or primarily engaged in the operation of civil airports and airfields (public and private), radio beacons, radar stations, and units that manage air routes and air traffic control are classified in this group. This monograph will focus on airports.

Airports are the focal point of all aspects of the aviation industry. They are where passengers and freight concentrate before departure and after arrival, they provide bases for the airlines, air services related organisations and the physical means of providing air services - the aeroplanes.

#### Recent trends

Following the recessionary pressures on the airline industry, the number of passengers handled at the major EU airports dropped by 3 % in 1991 before rebounding by 10 % in 1992. Cargo (including mail) weathered the recession more effectively in 1991, expanding by 1 %, but accelerated only marginally the year after (2.4 %). In 1993, growth in passenger and cargo again reported differing trends with a slowdown

for passengers (3.9 %) and a solid acceleration for cargo (6.8 %).

For passengers, the largest five airports in the EU are, in rank order, London Heathrow (48 million), Frankfurt (33 million), Paris Charles de Gaulle (26 million), Paris Orly (25 million), and Amsterdam Schiphol (21 million). In terms of cargo, Frankfurt stands as the unquestionable leader (1.14 million tonnes), followed by London Heathrow (0.758 million tonnes) and by Amsterdam (0.695 million tonnes).

In 1993 the individual growth in passengers handled at the major airports varied widely. Whilst 11 airports out of the 24 largest had reported double digit growth in 1992, that number dropped to two in 1993 (Amsterdam and Tenerife). The other airports have reported either medium to solid growth (e.g. London Heathrow, Frankfurt or Manchester), near stagnation (e.g. Paris Orly, London Gatwick, Rome), or even a decrease in passengers handled (e.g. Madrid and Barcelona). London Gatwick, the sixth largest airport in the EU, now remains the only large airport which has still not recovered its 1990 level of loadings.

Individual airport results are still more contrasted for freight. In 1993, six airports registered double digit growth while another six airports reported a decline in the amount of freight handle. The top four ranking in the EU for cargo growth were Luxembourg, London Stansted, London Heathrow and Amsterdam. Heathrow's growth was partially due to taking some of Gatwick's share of London freight.

#### International comparison

When comparing volumes of passengers and freight handled in the three dominant world regions, the USA has the largest share (about 60 % in passengers and about 50 % in freight). In this country aviation has developed into the major transportation mode for domestic connections. The bulk of passenger and freight flows through USA airports are movements within the country. For freight, developments have been particularly influenced by express freight services. The equivalent share of EU airports amounts to just over 23 % for passengers and just under 21 % for freight. A major portion of this is intra-EU or intra-European traffic.

The large South East Asian airports handle about 17 % of passengers and 29 % of freight. In Japan, traffic is dispersed among a number of regional airports due to capacity problems. In the future, some may become major hubs for both intra-regional and intercontinental traffic. Freight handling at Asian

(1) Airports with over 20 million passengers handled for USA and over 10 million for South East Asia  
 Covers airports participating in ACI Annual Traffic Collection  
 Source: ACI

airports is important for high value electronics shipped to the European and American markets.

Europe, the USA and South East Asia benefited from relatively similar growth rates in 1993, both for passengers and for cargo. Hence, the three regions' respective market shares changed little compared to the year before. The share of the EU increased slightly for passengers (from 23.1 % to 23.3 %) but decreased in the same proportions for freight (from 21.1 % to 20.8 %).

The world's largest airport city is New York. Its three airports handled more than 72 million passengers in 1993. However, a vast portion of this is domestic travel - some 73 %. Of the New York airports the largest is J. F. Kennedy which handles most of the international traffic. New York is also the most important freight centre in the world with close to 2 million tonnes. Second in city rankings is Chicago with two major airports Chicago Midway and O'Hare, which between them handled nearly 72 million passengers in 1993. O'Hare is the world's largest airport in total passenger numbers at 65 million, of which 90 % are domestic. However, ranking on international traffic only, London Heathrow is the world's largest with 40.8 million loadings.

In South East Asia the largest airport city is Tokyo, which handled 64 million passengers and 1.9 million tonnes of freight in 1993. Its major airport for international flights (19 million international passengers) and freight (1.4 million tonnes) is Narita.

## MARKET FORCES

### Demand

The strong growth in demand for passenger and freight air transport during the 1980s was due to the increasing globalisation of trade, the growing internationalisation of companies and demand for leisure. This has led to increasing demand for rapid and reliable air transport for business people and enabled leisure travellers to spend less time reaching both short and long distance holiday destinations. The growth in air freight has benefited from the growing requirement for express freight services, in particular documents, high value goods (of limited weight) like electronic products, and goods for which fast transport is important, for instance perishables such as flowers, and urgent deliveries such as parts required for mechanical repairs. The growth in the air industry has had a direct and proportional impact on the demand for airports.

The type of demand, whether business travel, leisure travel or freight, has tended to partially focus on some airports. Also, airlines, in particular the 'flag carriers', have tended to focus on particular airports. The 'flag carriers' have usually dominated the largest of their indigenous airports, with smaller hubs at the more important indigenous regional airports, due to the nature of the restrictions that used to be prevalent in the EU before liberalisation. The larger non-flag carrying airlines have also based their operations at the larger airports of their countries of origin and the smaller regionals are usually based at regional airports that have a sufficient catchment area to support profitable operations. In non-scheduled serv-

ices, a number of airports in Portugal, Spain and Greece are largely dependant on charter flight handling. In Northern Europe, some airports have also tended to specialise in charter flights (e.g. Manchester, Maastricht). In some cases, however, this specialisation has been due to reasons other than commercial policy. For example, until 1991, charter flights from London were deliberately assigned to Gatwick in order to alleviate capacity problems at Heathrow: these non-scheduled services made up 44 % of all traffic at Gatwick.

### Supply and competition

Airport capacity is determined by several factors, such as runway layout, number of runways and gates at the terminal and number of positions on the apron. Also, within the terminal, the check-in capacity depends on the access to the airport, the number of check-in counters, the capacity of the baggage handling system and the use of modern electronics. Further, juridical conditions are of relevance, such as restrictions on night flights, customs control capacity, etc.

One of the most significant current limitations on capacity, both for airlines and for airports is the present limitations of Europe's Air Traffic Control (ATC). At present, 23 countries of the European Civil Aviation Conference have 31 different

air traffic control systems. These systems rely on 18 different types of computers and 30 incompatible programming languages. According to the Association of European Airlines (AEA), the share of flight delays attributable to ATC in Europe decreased markedly in 1993 but ATC still represent the major source of delays. Although improvements to ATC are being provided, there is still a long way to go in terms of investment capital and time before a harmonised system of ATC will be available that is comparable to the one currently in existence in the United States. One fillip for international airlines, including those of the EU, is the development of satellite navigation system, which if approved by the 33 members of the International Civil Aviation Organisation (ICAO), will move much of the current ground-to-air based navigation and air traffic management to satellite-to-air. Estimates on the savings for airlines reaches as high as ECU 7.8 billion by providing more efficient routing and reducing delays caused by air traffic control.

A recent report from Airports Council International, European Region (ACI Europe) on the Economic Impact of European Airports stresses airports are substantial contributors to regional development and public revenues. The airports contribute to employment through three mechanisms: the first is

via direct employment in the airport by the airport itself and by the activities carried out by companies operating at an airport; the second is through an indirect impact of services related to the airport's business, for instance hotels and tour operators; and there is a third impact of induced employment which results from a multiplier effect from both the direct and indirect impacts. A case study on Copenhagen Airport showed that of total employment that could be attributed to the airport, 35 % was direct, 27 % was indirect but the balance of 38 % was due to induced employment.

### Production process

The services provided at airports form part of logistic chains. Passengers travel from one location to the other using air transport as one part, albeit major, of their total routing. Air transport involves adequate connections with other transport modes, lounges for waiting passengers, customs facilities for international flights. Further the passenger wants sufficient facilities such as bars, restaurants and shops in order to while away necessary waiting time.

Airlines also require services: they need weather forecasting services, fuel provision, flight catering services, and maintenance facilities. In particular, they need an adequate check-in procedure in which the passenger and its accompanying luggage is well administered and allocated to the correct flights. The Commission adopted an initiative concerning the organisation of groundhandling services at Community airports on 13 December 1994. This initiative will allow for a greater degree of access to the market.

The vulnerability of aircraft to terrorist devices has meant a substantial investment in equipment and personnel to supply adequate security monitoring of passengers and their luggage in the EU.

Local and national government has impacted the process through the provision of facilities such as law enforcement, customs control and aspects of air traffic control.

Similar requirements exist for freight forwarding at airports. Services also form part of logistic chains in particular for industries. These more and more require modern logistic concepts like Just-In-Time and Door-to-Door transportation. Such facilities are comparable to those for sea ports.

## INDUSTRY STRUCTURE

### Strategies

The major airports in the EU are competing with each other for passenger and freight traffic that is not destined for those particular airports, typically traffic that is using one of these airports as an intermediate staging post or hub. Estimates for London Heathrow indicate that about 30 % of passengers arriving from extra-EU flights are transferring to other flights, whether for intra-EU connections or even extra-EU connections. Hence airports such as Paris Charles de Gaulle or Amsterdam Schiphol can easily supply a similar routing. The major airports have been competing aggressively to take a larger share of the transfer market, and this competition has also been supported by the airlines that use these airports as their major hubs.

Though competition between major hubs is largely international (for instance between London Heathrow and Amsterdam Schiphol), there is a number of examples of competition between hubs in the same country (for instance between London Gatwick and London Heathrow). Besides, major (and minor) regional airports are not confining themselves to the role of feeder of major hubs but are also offering direct point to point services and are even, in a limited number of cases, aiming at developing into hubs. An example is Manchester Airport, which is considering to expand capacity by adding a second runway and supporting infrastructure to attract additional airlines, passengers and freight to capture the traffic generated in a large catchment area in the North of England. A significant portion of the potential traffic used to go (and some still does) via one of London's airports either by flight transfer, or by a combination of travel that would involve a train or car journey to a London airport, or via Manchester's regional competitors. The investment allows Manchester Airport to expand its market share at the expense of the other airports in northern Britain, as well as taking some share of the London airports, and attracting new induced traffic. The success of Manchester's strategy is shown by the numbers of passengers, which have more than doubled from 6 million in 1984 to 13.5 million in 1993. The growth in freight for the same period is even more phenomenal, from 29 000 tonnes in 1984 to 89 000 tonnes in 1993. Whereas Manchester Airport is essentially providing point to point services, it is also developing into a hub in its own right, with around 7 % of passengers hubbing compared to around 2 % six years ago.

Capacity problems, in terms of air traffic control and airport infrastructure, are a major issue in airport strategies. Apart from improvements in air traffic control, airports' improvement of capacity availability takes many forms, including additional runways, additional infrastructure and improved equipment. In addition, ground congestion resulting from too slow improvement of road and rail access is also a problem at a number of airports.

Capacity problems and safety provisions together with the need to keep ahead of competition have prompted airport authorities to invest in new facilities and service improvement.

The attraction of additional traffic has also been achieved by offering higher quality services to all users of the airport. Airports also try, in co-operation with regional authorities, to attract economic activity and to develop into full-fledged business centres. An example is Amsterdam-Schiphol. Together with regional and local bodies this airport drafted a strategic plan for the development of both the airport and the region into a main complimentary port similar in concept to the port of Rotterdam.

There are many investment initiatives by airports. The Airports Council International Europe reckons that its members will invest about 19 billion ECU in modernisation and expansion over 1993-97 alone. The Airport Authority of Copenhagen has drawn up a master plan for a substantial enlargement of facilities including a second terminal due for 1997 and co-operation in the Copenhagen Central to Kastrup rail link. The British Airports Authority is pressing for the development of a fifth terminal at Heathrow to be opened in 2002. In the meantime continental airports such as Paris Orly and Frankfurt have each opened a new terminal respectively in 1993 and 1994, thereby raising capacity by about 10-12 million passengers in each case. Amsterdam Schiphol is in the middle of a ambitious plan which will stretch its capacity to 40 million passengers by year 2015.

Moreover, in the context of the provisions of trans-European transport networks of the Treaty on European Union, the Commission identified the trans-European airport network and defined the guidelines for its development so as to ensure that airport capacity in the Community is able to meet the growth in demand for air transport, while taking account of environmental concerns as well as the objectives of economic and social cohesion (COM(94)106 final of 7 April 1994).

The guidelines are based on a global approach, which made it possible to identify the main functions of the network as well as the development priorities necessary to meet demand, while taking account of the need to ensure a high level of safety and environmental compatibility as well as limit the impact of infrastructure policy on the competitive position of airports.

The key functions of the network are to provide links between the Community and the rest of the world, links within the Community and access to the core of the network and/or links to remote areas.

In order to ensure that the trans-European airport network can fulfil its function of providing the necessary infrastructure capacity for air transport, development priorities for airports of common interest have been identified. These include the enhancement of existing capacity, development of new capacity, enhancement of environmental compatibility and enhancement and development of airport access.

This framework should provide the necessary guidance, so that the investments in airport capacity in the Community take place where they have the best possible impact on airport capacity.

### Impact of the Single Market

The airports environment has recently changed, due mainly to two factors: the free movement of persons and the airlines deregulation. These measures have led to an increased number of passengers and traffic, leading to an increase in the airports activities. However, some problems have arisen from this situation. Indeed, large investments are needed in order to distinguish EU passengers from non-EU passengers in the airports. In addition, the airlines deregulation has also increased the competition between airports, though at the same time the major airports compete for transit extra-EU traffic and so become hubbing centres, allowing them to gain share of traffic. To overcome the problems of congestion, which might result from the strong increase in the number of passengers and traffic, the EU has developed an improved air traffic management where airports are classified in three categories depending on their importance in international traffic. In the future, the sector in the EU has three priorities: the complete suppression of identity checks, the continuation of the duty and tax free allowances for passengers travelling

within the EU (which have been postponed until 1999) and an intensification of the relations with non-EU destinations.

### ENVIRONMENT

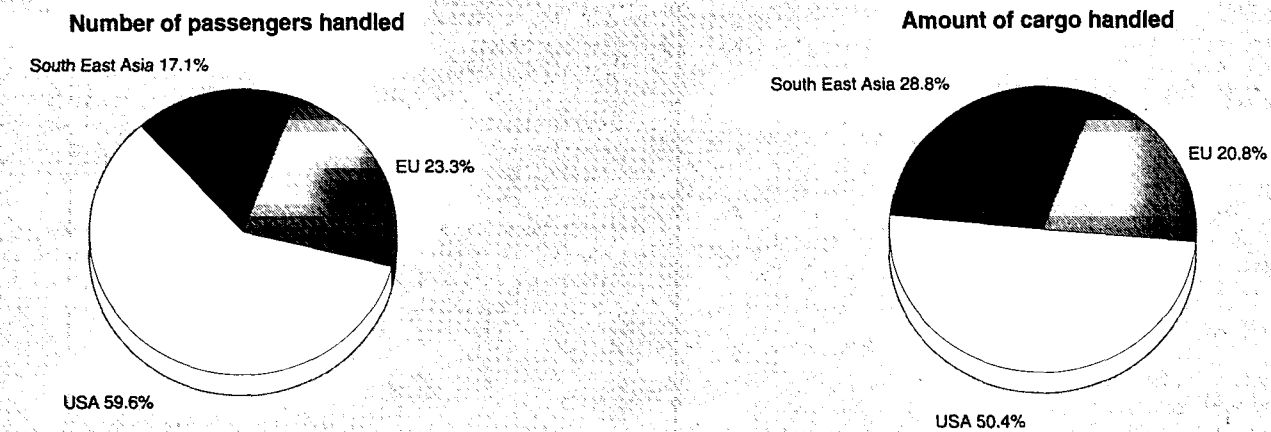

The conflict between air transport's major contribution to economic growth and its impact on the environment remains somewhat unresolved as policies (at both governmental and operator level) to minimise the environmental impact should also work hand in hand with growth in the sector.

The major negative environmental impacts of airports are air and ground pollution, substantial land use and noise. These impacts are both directly attributable to the airport itself and its users, and indirectly attributable to factors such as the external infrastructure required and other forms of transport used to and from the airport.

The major cause of air and ground pollution is the emissions from the engines of the aeroplanes and the land service transport. Advances in jet and turboprop technology has produced engines that are substantially more efficient than their earlier counterparts. However, congestion at the busy airports can lead to an excess fuel burn and hence emission that is 30-50 % higher than would be the case in the absence of congestion. The requirement by the end of the century that jet engines conform to Chapter III regulations will help reduce the amount of emissions (and noise), but the overriding issue that is likely to have a major positive impact in the short term is a reduction in congestion. The Chapter III regulations apply to:

- subsonic jet aeroplanes, with an application for certificate of airworthiness for the prototype accepted on or after 6 October 1977;
- propeller-driven aeroplanes over 5 700 kg, with an application for certificate of airworthiness for the prototype accepted on or after 1 January 1985 and before 17 November 1988; and

**Figure 1: Airports and other air transport facilities**

(1) Airports with over 10 million passengers in 1993.  
 Source: ACI

- propeller-driven aeroplanes over 9 000 kg. with an application for certificate of airworthiness for the prototype accepted on or after 17 November 1988.

Improvements in congestion can be achieved by improving the air traffic control system and expanding available infrastructure, but this will in turn for the major airports allow additional flights so that some of the gain will be used up.

Concerning noise pollution, estimates included in the Commission's Green Paper on The Impact of Transport on the Environment suggest that the percentage of the population exposed to aircraft noise above 55 db(A) varies from 35 % in the Netherlands to 1.7 % in Denmark, and above 65 db(A) from 1 % in Germany to 0.3 % in Denmark. Hence, the location of airports close to residential areas is a key factor in noise pollution. Estimates released by the AEA show that the modern jets generate about the same level of noise as a TGV, but for a comparatively minute distance (some 4 kilometres). However, the discussion about noise continues at full pace, and most services that land or take off at airports near residential areas have strict requirements about night flights and the levels of thrust that can be used. This has a detrimental impact on the airlines costs as it can take much longer for an aircraft to reach optimum cruising altitude and hence the fuel burn and the time taken for a particular stage length is higher, which in turn has negative implications for emissions.

Land use and noise tend to receive more public attention than air and ground pollution due to the direct and observable impact on people. Many applications to increase or change land-use go through a lengthy negotiation process at national and local governmental levels as well as public enquiries.

Both airport and airport services have become very aware of their responsibility to the environment. The service suppliers are taking increasing responsibility to minimise pollution in maintenance and repair facilities for aircraft, fuel provision services and catering services.

## REGULATIONS

Community legislation on the liberalisation of air transport makes a distinction between two categories of airports. Category 1 airports are the major hubs or capital airports such as London, Paris, Frankfurt, and Amsterdam. The second category are the regional airports and covers all airports which are not category 1 airports.

On the problem of air traffic control (ATC), the Ministers of Transport of the European Civil Aviation Conference (ECAC)

established the European Air Traffic Control Harmonisation and Integration Programme (EATCHIP) in 1990. In 1993, the Commission issued a directive (65/93/EEC) mandating the use of standards set by Eurocontrol throughout the Community. Eurocontrol is also responsible for implementing EATCHIP. These efforts will go a large way in improving the management of flows of aircraft in the EU (and Europe), as more cohesion and compatibility will be brought to the various national air traffic control networks. The gradual global movement towards a Single Air Traffic Management System and the future development of a Global Navigation Satellite System (GNSS), which, if approved, will move much of the current ground-to-air based navigation and air traffic management to satellite-to-air, will act as a fillip to Europe's air traffic control improvements. Both ATC and GNSS are part of the Trans-European Network as proposed by the Commission in 1994 (COM(94) 106). They are also explicitly mentioned in the Commission White Paper on "Growth, competitiveness and employment". The Commission has recently stressed its determination to provide funds for both initiatives (COM(94) 218). In addition to ATC, the development of a trans-European airport network will also provide for the allowance of European funds for the development of airport capacity.

In January 1993, the Council adopted the regulation on common rules for the allocation of slots at Community airports (95/93/EEC). This regulation forms the basis for allocating slots on neutral, transparent and non-discriminatory rules for Community carriers. It aims to allocate slots among existing carriers as fairly as possible, given severe congestion at some airports, and it also allows new entrants a fair opportunity to slots. It has a caveat on provisions for third country relations, in that if a third country does not allocate slots to Union carriers on a similar footing, then Union allocation of slots to carriers from the third country can be constrained or withdrawn. The regulation comes up for review in three years from adoption.

In July 1992, the Council adopted the regulation on licensing of air carriers (2407/92/EEC). This regulation per se has marginal impact on most airports, but it does have an impact on the small regional airports that cater for international flights. It is these airports that will host some of the new entrant airlines operating small niche point to point services, and the regulation requires that new entrants operating small aeroplanes (less than 20 seats or under 10 tonnes MTOW) maintain a net cash at hand balance of at least 80 000 ECU. The regulation is designed to ensure the financial fitness of air carriers in a commercial environment that has been shaken by company failures. However, niche start-up airlines initial outlay of start-

up capital is huge by most industry standards. This initial outlay includes plane purchase or lease, landing rights, purchasing access to computer reservation systems, hangerage and maintenance options, etc., and is estimated to be in excess of 350 000 ECU. The heavy initial investment coupled with the minimum requirements does not bode well for new entrants which, in turn, will severely reduce the small regional airports ability to attract additional business.

As to the use of airport infrastructure, the European Commission also plans to present, early 1995, a consultation paper on how best to ensure non-discriminatory, transparent and cost effective provision of airport services. Finally, the Commission adopted on 13 December 1994 a proposal for a Directive on the opening up of groundhandling markets.

---

## DUTY AND TAX FREE SALES

---

Duty and tax free (DTF) sales have become highly important for airports (and airlines) as a source of revenue, accounting for about 15-20 % of airports' income in Europe. Also, passengers want to benefit from low-priced products available in the DTF shops on the airports. The Commission originally envisaged abolishing DTF allowances for passengers travelling within the EU with the advent of the Single Market. Estimates on the impact of DTF abolition concluded that landing and passenger charges would have to rise by 13 to 25 % to compensate airports for lost income. In turn, airlines would pass these higher charges onto the traveller in higher fares, possibly causing a negative effect on traffic demand especially in the leisure market. The effect of DTF abolition would also be exacerbated by airline companies, especially charter airlines, losing revenues from on-board DTF-sales. This would cause another cost push on fares. Due to strong lobbying from many sections of the international transport industry, the abolition of DTF has been postponed within the EU until the 1st July 1999. In the meantime the DTF industry has developed a system of vendor control, in which the vendor checks compliance with DTF allowances. This system is necessary as customs control for travelling within the EU will disappear, but it has increased the allowance to travellers within the EU, for each intra-EU stage is counted as one for DTF purchase. Previously, a passenger travelling from the UK to Denmark, then to Italy and returning to the UK was only allowed to import one allowance into the UK, however the equivalent for this route is now three times as purchases are possible and legal at each stage for importation into the UK.

---

## OUTLOOK

---

The outlook for airports depends on the demand for air passenger and freight, which is expected to be fairly buoyant in the future. However, in the short term, some of the larger congested airports will not be able to take full advantage of potential growth as congestion will be the limiting factor. As the EU's air traffic control improves, part of this constraint will disappear temporarily. However, this will not be enough and expanding infrastructure remains necessary though adding capacity is a thorny problem at most of the largest airports close to dense populations. The medium sized airports will continue to expand, especially those which have positioned themselves as competitors to the major hubs. The small regional airports will see some growth, but the major limiting factor for these will be the size of the catchment area.

The industry is represented at the EU level by: Airports Council International / European Region (ACI Europe). Address: Rue du Luxembourg 16b, B-1040 Brussels; tel: (32 2) 513 1382; fax: (32 2) 513 2642.

## Overview

### NACE 81, 82, part of 83

The financial services industry currently finds itself in a decade of fundamental change. Intensifying competition, a new regulatory framework, the burgeoning role of technology and increasingly sophisticated, and mobile customers - in combination - are placing pressure on traditional credit institutions. As a result, these institutions are paying greater attention in areas of marketing and operations yielding more cost-efficient operations, product innovations, and market-oriented strategies. These industry-wide developments, in turn, have blurred the lines of demarcation that traditionally have distinguished providers of financial services

and administrative regulations allowed acquisitions, mergers and other alliances to occur, both within domestic markets and across national frontiers. Such a deregulatory environment within the EU has impelled the creation of a single market in financial services which, in turn, is expected to create opportunities for financial services companies to compete in previously inaccessible foreign markets.

Technological advances have also had significant impact on the way in which financial services are provided. By lowering the cost of entry, new technologies have enabled institutions to enter or compete in new markets. Examples include telephone or screen-based banking, the sharing of ATM networks, and prepaid microcircuit cards.

Additionally, the recent economic downturn, in general, has resulted in a weak demand for financial services and the introduction of international supervisory agreements, in particular, has forced banks to focus more closely on returns on capital. As a result, firms have scaled down or sold off activities which were not deemed to be 'core' business. For others, the sale of these businesses has offered opportunities to develop strategic focus.

These political, economic, and technological developments made it more difficult to provide discriminatory definitions for the individual financial market segments. For example, it has become harder to define what is meant by a "bank" as the barriers between different types of financial institutions break down and the basic business of banking is invaded by non-banking institutions. Moreover, the increasing interdependence of markets worldwide is further blurring the distinctions between bank credit and securities issues, domestic

## INDUSTRY PROFILE

### Description of the sector

The last decade has witnessed dramatic changes within the international banking and financial services industries. In this regard, changes in market structure have been particularly prominent. Indeed, deregulation and the abolition of protectionist market structures were worldwide trends in the 1980s, causing major structural changes within the European, American, and Japanese financial services industries. Important examples of these trends included moves to abolish exchange control regulations. Moreover, the removal of legal barriers

and international paper, cash instruments and derivatives, and between different categories of derivative products (futures, options and swaps).

Therefore, it is more appropriate to describe the financial services industry by function and by type of institution. The following functions can be identified:

- Payment services;
- Saving products;
- Fiduciary services;
- Lending to business (corporate);
- Lending to consumers (retail);
- Underwriting/issuance of equity;
- Underwriting/issuance of debt;
- Insurance and risk management products.

These functions are provided by an array of institutions, including insured deposit institutions, insurance companies, finance companies, securities firms, pension funds, mutual funds, diversified finance firms and specialist firms.

For the EU as a whole, the gross value added of financial services at market prices as a share of total value added was 5.0 % in 1992. This share has increased by 0.6 % since 1980. The deviation between most Member States is not large. Only in Luxembourg does the financial sector appear to be disproportionately important to the economy as Table 1 shows.

Four large EU countries account for 75 % of gross value added in financial services: Germany constituting the largest share, followed by Italy, France and the UK. These figures, however, do not provide information about the relative importance of each country on the different financial markets, since value added measures the contribution to the 'real' and not the 'financial' economy. In order to measure the 'financial' economy, figures on assets, premiums written, and stock turnover are more appropriate. Based on the latter figures, the UK appears to be the most important financial market within the EU. Over the past decade the British financial service sector showed an enormous growth in value added. However, because of the rationalisation which started in the UK, the employment in financial services has been decreasing in recent years.

## Recent trends

The 1993 monetary turmoil established that the European Monetary System (EMS) rules were politically motivated and underscored the need for changes in economic practices. Specifically, in an attempt to fight the wave of speculation hitting their respective currencies, the Member States of the EMS decided to protect their exchange reserves either through allowing their currency to float within broader bands vis-à-vis their reference rate (August 1993) or else by leaving the EMS altogether. Such was the case when, in July 1993, attacks against the Belgian and French francs as well as the Danish crown occurred. This untenable situation forced the authorities to widen the floating bands by 15 % on the 2nd of August (formerly established at 2.25 % and 6 % around reference rates). Only Germany and the Netherlands provided for an exception such that the bandwidth of 2.25 % between the Dutch guilder and the Deutsche Mark remained unchanged. Although the EMS was in a sense "rescued", it remains doubtful that the EU Member States are still willing to establish the Economic and Monetary Union (EMU) before the end of the century. It should be noted, however, that the majority of Member States have confirmed their intention to finalise the Monetary Union in 1999 at last, as stipulated in the Maastricht Treaty.

Free competition in the EU has been the explicit and chief aim of that portion of the single market legislative program governing the provision of financial services. However, credit institutions and investment firms providing services in other Member States still have to comply with some domestic regulations of their host markets.

On January 1, 1994, the European Economic Area Agreement (EEA) came into force, extending the single market to the five countries of the European Free Trade Association (EFTA), thereby creating the world's largest free trade area. EU financial services rules now also apply throughout the EEA, as do services regulations. The agreement will have far-reaching effects on business in Europe.

The availability of current and emerging technologies offer the opportunity to restructure relationships by "wiring" the customer into the suppliers' service channel. In a world where the convergence of telecommunications and computing technologies is already opening up global financial markets to new players, the suppliers of financial services have a duty to orient - or reorient - their business along technology lines. Technology is generating new, electronic delivery channels

that challenge conventional supplier-client relationships in all areas of financial services.

### International comparison

The leading financial centres are clearly New York, London and Tokyo. Although trade in financial products is to a large extent international, the international part of trade primarily originates from large (private as well as official) financial institutions or multinational firms. National regulations, conventions and culture still create distinct national markets. For instance, the consolidation of financial services in Europe - linking banking, insurance and other financial services - makes Europe the laboratory for new products and merged companies.

Japanese banks dominate the world market in terms of reserves. This is the result of a decade of exceptional growth during which Japanese banks pursued an aggressive policy of market share expansion, aiming for leading positions in terms of deposit size. However, such growth has been counterbalanced to a large extent by significant devaluation of the yen vis-à-vis the dollar, the European currencies and the ECU.

The comparatively poor performance of US banks, in this regard, is the result of restrictive regulation, which limits the field of activity of the banks both geographically and commercially. The US banking system is fragmented and poorly diversified.

Deregulation and the revolution in communication technology has enabled a substantial degree of internationalisation in the provision of financial services. The resulting integration of financial markets has extended the free choice of participants: issuers have gained a better access to foreign markets to raise capital, whilst investors have tended to internationalise their portfolios.

Compared to the USA and Japan, the European insurance market - except for the UK - is less developed in terms of premiums per capita. With premiums per capita of 996 ECU, the European market is lagging far behind the USA and Japan with corresponding per capita figures of 1 807 and 1 909 ECU respectively. Also, if gross premiums are taken as a percentage of GDP, it is seen that the insurance market in the USA and Japan with percentages of 10.13 % and 8.39 %, respectively, are more developed than the European market (6.53 %). In terms of 1992 market share, the USA had almost 40 % of the world insurance market while the EU and Japan accounted for 32.1 % and 20.3 %, respectively. With current high growth rates in the EU, however, the gap with the USA is closing.

The currency turmoil in 1992 (and in 1993) stimulated securities trading in so-called safe-haven currencies at the expense of high-yield sectors. It also triggered a dip in bank credit. Lower long term interest rates stimulated demand for capital through financing and refinancing in longer-term instruments to the detriment of short term paper. The greater risk associated with the variability of exchange rates and short term interest rates stimulated the use of derivative instruments as a means to hedge against these risks or to exploit opportunities to profit from these risks.

### MARKET FORCES

#### Demand

Demand for financial services is determined by demographic and savings trends, deregulation and liberalisation of capital markets, and changing patterns of consumption. In general, the population of Europe is ageing. Such implies that, in the future, a relatively smaller workforce will be available to generate the social security and pension benefits in pay-as-you-go systems. In anticipation of inadequate social security payments, many people are saving in order to ensure sufficient retirement funds. Through the late 1980s, personal savings rates had been declining in many countries, thereby constraining the financing of economic growth, and stimulating competition between banks, insurance companies, mutual funds and securities to attract savings. Since the late 1980s, however, the fraction of saving in disposable income has taken an upward trend in several countries. Should this trend continue, the supply of savings on the financial markets will increase, raising the question of which financial instruments will be in demand.

Households have changed their investment behaviour in the past decades. The high inflation during the 1970s made them fully aware of the phenomenon of monetary erosion. They have demanded higher yields on savings and have become actively involved in securing the best investment opportunities. This has stimulated the success of more sophisticated saving instruments, including insurance products with a 'financial component' and mutual funds.

Retail banking, including investment of savings, portfolio management, consumer credit and mortgages, payment services and a wide range of advisory services, constitutes one of the most important branches of the financial services sector. Because the retail banking sector has grown enormously since the 1960s, the market is saturated in many countries. This is seen in the significant decrease in certain Member States of

the number of banks branch-offices. Banks can often only gain new business by directly luring it away from their competitors.

In the area of financial services for the industrial sector, three main trends can be identified. The first is an increasing demand for very specialised services for the management of assets and liabilities. Financial management increasingly relies on computer assistance and uses a wider range of instruments, such as options and new fixed-term instruments. Additionally, the traditional role of banks has been challenged by large companies, who have set up their own systems of financial management. The second trend is a growing intervention by banks in the management of businesses. Banks are increasingly being asked to assist with financial restructuring and reorganisation, mergers and acquisitions, take-overs and leveraged management buy-outs. The third trend is the emergence of a capital market to finance small and medium-sized enterprises that have a solid track record but are unable to meet the criteria for an official market listing. These enterprises are served by risk capital companies, as well as by new segments of the official stock markets, such as secondary markets or over the counter markets.

Financial services linked to shares (especially the issue of shares, brokerage services, share transactions and portfolio management) have become one of the more important segments of financial markets since the beginning of the 1980s. Around 1982, during a period of high exposure to liquidity and country debt risks, financial institutions reoriented their activities towards stock-market based operations, especially the underwriting of international bond issues and the intermediation of international transactions.

Consumers are also becoming more conscious of the wide range of products and services which are offered in the insurance industry. As the number of product varieties increases, the need for independent advice is also growing. This trend is reflected in a growing importance of independent intermediaries.

The market for derivative instruments has grown exponentially. The function of derivatives is to hedge against risks. Consequently, the trading of these instruments involves a degree of speculation. At present, there is a debate between banks and supervisors (e.g. BIS, Bundesbank, Federal Reserve) about the risk of the derivatives markets. The Group of Thirty asserts that these markets provide an important service and are not excessively vulnerable. Supervisory organisations, however, emphasise the substantial undiversifiable market risks inherent in these instruments. These risks could materialise when the liquidity of the markets dries up.

## Supply and competition

The banking and financial services industries clearly have a financing need, and more specifically a desire for wholesale money. A secular shift in retail banking patterns seems to have occurred with savers now much more conscious of opportunities in other vehicles such as equity-linked investment through mutual funds. A significant proportion of the Euro-market's biggest borrowers are banks with strong retail bases such as Deutsche Bank, Abbey National and Crédit Lyonnais.

Since the mid-1980s deregulation has liberalised capital markets, thereby permitting the introduction of many new products, and has blurred the demarcation lines between different market players. In particular, deregulation involves:

- an end to brokers' monopolies within stock exchanges and other organised markets accompanied by free negotiation between brokers and clients, which led to a reduction in commissions;
- reorganisation of the market for treasury bonds, with the appearance of specialists whose role is to stimulate the market and assure its liquidity;
- development of secondary markets;
- computerisation, resulting in improvements in market liquidity and in the precision and speed of information;
- creation of markets in derivative products, notably the United Kingdom's LIFFE and France's MATIF, respectively the fifth and sixth largest derivative markets in the world.

The result has not only been a more intense competition, but also a wave of acquisitions, mergers and alliances. Competition in new products and, to a lesser extent, price intensified, competition in territory (through building and extending a network of banking outlets) was less severe from the beginning of the 1980s as new organisational features such as home banking and automated banking facilities diminished the need for extensive branch networks. Product competition became particularly intense in the investment of household savings, with the appearance of a greater number of market participants including traditional banks as well as insurance companies and investment funds.

One of the major trends in Europe has been financing with securities rather than with (bank) loans. Examples include credit notes negotiable on the market in national currency, bonds issued by business firms, negotiable gilts issued by national treasuries and deposit certificates issued by banks. In line with this trend, financial disintermediation has spread. Increasingly, firms bypass banks by going directly to the capital market (for an over-the-counter loan from for instance a life-insurance company, or the issue of bonds or commercial paper).

**Table 7: Financial services  
Chronology of principal financial innovations in Europe**

Year	Country	Reform undertaken
1978	France	SICAV
	Italia	Creation of secondary market
	Nederland	Creation of options market (EOE)
	United Kingdom	SICAV, deposit certificates
1979	France	Creation of joint investment funds
	United Kingdom	Removal of exchange controls
1980	United Kingdom	Creation of unlisted securities market (USM)
1982	Italia	Issuance of deposit certificates, creation of inter-bank market
	United Kingdom	Opening of futures (LIFFE) and options (LTOM) markets
1983	France	Creation of secondary market
	Italia	Lifting of credit controls
1984	France	Removal of framework credit restrictions
	Italia	Creation of variable capital investment funds
1985	United Kingdom	Interest-bearing current accounts
1986	BR Deutschland	Creation of secondary market
	France	Issue of negotiable credits notes (deposit certificates, treasury bills, negotiable treasury bonds), end to monopoly of brokers and the creation of stockbrokerage houses, reform of the publicly-quoted stock market, creation of futures market (MATIF)
1987	Nederland	Liberalization of capital market: bullet loans, floating rate notes, commercial paper and bank issues of certificates of deposit are allowed, introduction of green-based system for block-trading according to the market-making principle (AIM)
	United Kingdom	Big Bang stock market reforms: system of brokerage commissions and rules relaxed, end of enforced separation of brokers and jobbers, deregulation of stock exchange membership, creation of international SEAQ and reform state funds, issue of treasury bills in sterling
	BR Deutschland	Creation of secondary market
1988	France	Creation of share options market (MONEP), reform of the government securities market
	Italia	Plan to reform the stock market: computerization and complete integration of the different functions, centralization of all stock trading
	Nederland	Creation of futures market
	United Kingdom	Introduction of the Building Societies Act
1989	BR Deutschland	Creation of DAX stock index
	France	Opening of an options market in MATIF and a market for contracts on the CAC 40 index and on the OMF 50
	Italia	Reform of the publicly-quoted stock market
1990	Nederland	Creation of automated transactions information system (HOS)
	BR Deutschland	Introduction of stop-loss and stop-buy orders
1991	BR Deutschland	Creation of DTB futures and options market
	France, Italia	Last phase of the removal of exchange controls
	Nederland	Introduction of system for professional trade in government bonds (OOB), stamp duty abolished
1992	BR Deutschland	Introduction of electronic transactions system (IBIS), abolition of stock exchange transactions tax
	France	Foreign companies are allowed to issue corporate paper on the French market without prior Treasury approval
	United Kingdom	Launch of futures and options contracts on the FT-SE Eurotrack 100 index measuring developments in the main European stock markets
	Italia	A new type of multi-functional investment firms, incorporated as public limited companies becomes optional

Source: OECD

As banks made less money out of 'normal' on-balance business, they had to seek other income sources. Such sources were found in off-balance activities thereby bringing commercial banks and investment banks into direct competition.

The supply of insurance within Europe has traditionally been dominated by domestically owned insurance companies. Domination on a European scale used to be difficult as many insurances are comparatively standardised products, leaving little opportunity for product differentiation. In life insurance and pensions a greater possibility for differentiation exists, but regulation in some European countries has tended to inhibit

product innovation. Moreover, since there are no patent laws in insurance, new products could and still can be copied relatively quickly, especially as production systems are not complex.

Foreign direct investment (FDI) has responded to the developments in financial services markets. The level of FDI has increased substantially when comparing the 1987-89 period with the period of 1984-86. The share of insurance in intra-EU investment has increased considerably, but those of banking and real estate have lost a few percentage points. In banking and insurance, there is a redirection of direct investment flows

towards other EU countries and away from the rest of the world. Accordingly, the intra-EU share of total direct investment flows in banking and insurance has increased significantly. In real estate, virtually all foreign investment by the EU remains within the EU. The strong decline in the ratio between outward and inward extra-EU FDI-flows indicates that the EU has become an attractive location for direct investment, originating from non-EU countries. Measured by this ratio, both banking and insurance appear to be much more attractive for FDI than the industrial sector.

### Production process

Three developments keep the financial system vulnerable to excesses. Firstly, there has been a flight of investment away from traditional institutions with the enormous growth of mutual funds. A second development includes the increasing deregulation, securitisation, the greater use of new instruments and trading techniques, and the growing numbers of high-octane portfolio managers. The third development concerns the tremendous infrastructure of banks and non-banks in industrial countries which may result in a rapid expansion of credit mostly outside the control of central banks.

The decade of the 1980s was marked by the liberalisation of financial markets resulting in the removal of brokers' monopoly, the authorisation of new products and the removal of credit restrictions. This triggered the expansion of markets and the introduction of innovative new products. Moreover, the distinction between brokers, banks, exchanges and electronic markets has become less clear, and in several instances even obsolete. All compete to provide services to the suppliers and demanders of capital.

An indispensable factor behind the explosion in market activity and the proliferation of products permitted by deregulation has been the availability of enhanced information and communications technology. From a cost perspective, as a mass processing tool, computers permit significant increases in employee productivity. Productivity related to administrative functions is growing in the banking sector at a rate of 5 % to 7 % per annum. At the same time, computers' importance manifests through minimising manual intervention, using real time operations, keeping customer files updated to the minute, reducing delays and making deadlines more reliable. Finally, technology is necessary for the provision of new services such as remote banking.

Technology and competition have resulted in organisational changes within financial institutions. The most important changes concern the overall responsibility of employees for good performance and cost control; the improvement of working conditions; the increased direct contact between employees and customers; and better internal control.

New technologies and methods presuppose new staff skills. Financial establishments that hired large numbers of untrained staff during the expansion race in the 1960s and 1970s are now faced with major investments in training and writing off redundancies. Furthermore, the additional costs of investment in computerisation diminish the profits of banks and insurers. Set against a background of growing competition, the way institutions handle these changes will be critical for their future success.

---

## INDUSTRY STRUCTURE

### Companies

The fifteen major European banks, ranked by Tier One capital, include French, Swiss, UK, Dutch and German banks. Tier One capital includes common stock and declared reserves. In short, Tier One capital measures only the core of the banks' solvency. If banks are ranked according to their assets, German banks figure more prominently. There are over 10 000 banks in the EU.

In 1992 there were some 4 343 insurance companies operating in Western Europe against 4 246 companies in 1991. The number of independently controlled groups was less than 2 500 and is declining. When insurance companies are taken over, the acquiring companies often do not incorporate them into their own structure for marketing and/or tax reasons. As a result of the ongoing mergers and takeovers, it is possible that the total number of insurance companies is increasing, while the number of independently controlled groups is further declining. The average size of insurance companies is measured in terms of gross premiums divided by the number of undertakings. In 1992, within the EU, the average size was 80 million ECU against 66 million ECU in 1990.

### Strategies

The large financial services groups follow two main strategies. The first is diversification: offering a complete financial service package ("Allfinanz"). The second strategy is cross-border expansion or linkage (global player). Allfinanz (also named 'bancassurance', although there the emphasis lies on insurance products) offers benefits to banks and insurance companies, especially in the life insurance sector. The life insurance market offers banks attractive prospects for improving the return from their distribution network. The scope of the banks' networks is also an attractive feature for the insurer in that a larger volume of customers can be accessed at lower cost. The strategy of the global player is pursued through acquisitions, mergers and alliances.

Other financial intermediaries, such as securities brokers, must first determine if they want to be an international, regional or niche player. To be an international operator the successful strategy seems to be to invest in international networks of offices. Goldman Sachs, Credit Suisse First Boston and S.G. Warburg all have invested heavily and all are leading advisers.

A strategy of innovation can create competitive advantages for all players in the financial services sector, especially for the stock exchanges. International capital investments increasingly use new financial instruments, simply because they offer a better performance.

### Impact of the Single Market

The creation of the Single Market has prompted a major reorganisation of the sector in the late 1980s and early 1990s, including a number of mergers and acquisitions. EU regulation has been extended, or is being extended, to cover freedom of establishment for banks and other financial institutions, harmonisation of banking supervision, accounting and a number of other subjects relevant to the business of financial services. The obvious advantages of the creation of the Single Market (trade facilitation, removal of inefficiencies, fair competition, etc.) are considered very important. For some elements, however, the importance can only be transformed into advantages if national economic, fiscal and legal differences are effectively removed and if the EU measures are translated into national regulations. Harmonisation in implementation is considered a very important priority for the industry, especially in the field of taxation. Liberalisation in all markets, deregulation and a greater access to financial sources for SME's are all considered high priorities, as is the achievement of the Economic and Monetary Union (EMU).

---

## REGULATIONS

In all Member States, governments regulate the functioning of financial services activities for a variety of reasons including market failures. Regulatory instruments are usually divided into two broad categories: those that effect the structure of the industry, and those that impinge upon conduct of industry participants. The former govern the entry of new firms into the industry, while the latter control the behaviour of existing industry members. Banking and insurance have traditionally

been subject to a high degree of both structural and conduct regulations. In the financial services industry as a whole, the government role has been indirect even though some Member State governments used to be or still are major shareholders of financial institutions. Still, regulatory rules have been stringent, mostly (but not exclusively) for prudential reasons.

---

## OUTLOOK

---

The newly adopted EU directives will encourage competition and stimulate cost-efficient company operations. Therefore, attention is turning to improving operations in a cost-efficient way. Some cost savings will be reached in the distribution of financial services.

Market deregulation, increasing competition and new technology have made firms reassess their strategic objectives. For the rest of this decade, the following promising segments can be recognised as participants in the financial services industry:

- Traditional banking; interest-differential lending and deposit-taking for consumers, small business, agricultural firms, and the lower end of middle-market corporations;
- Financial intermediation and advisory services; underwriting debt - and in a lesser degree equity and securitisation - primarily to the upper end of the middle market and to larger corporations;
- Investment management; trust, mutual funds, broker/dealer activities, money-management;
- Insurance; as agent, underwriter, or both;
- Fee-based operational services; usually with a high-tech component area such as automated clearing houses (ACH)-processing, data-processing services, cash-management, letters of credit, and stock transfer;
- Trading; customer and proprietary trading for securities, foreign exchange;
- Merchant banking and equity investment; venture capital, equity "kickers", mezzanine financing, leveraged buy-outs (LBOs).

However, the landscape is unlikely to change radically in the longer run, despite the continued revolution in technology and the high cost of market-entry.

# Credit institutions

## NACE 81

European banking and financial markets currently find themselves in a decade of fundamental change. Intensified competition, a new regulatory framework, the increasing role of technology and more sophisticated and mobile customers all place pressure on traditional credit institutions.

### INDUSTRY PROFILE

#### Description of the sector

Banking involves an array of functions: management of deposits, loans, credit payment systems, and clearing mechanisms; providing services with capital transactions; performing various other services like the provision of guarantees and insurance. These functions are not performed by banks alone. For example, consumer and industrial credit are provided by finance companies (many of which have links with banks) and mortgage loans by life insurance companies. Banks' traditional status is being further eroded by a recent trend towards deregulation and disintermediation. In addition, the new EU-rules have created, at least in principle, the concept of a single passport for financial institutions offering services across the Member States. The new rules also effectively eliminate historical distinctions between different kinds of banks. All are now credit institutions.

In this regard, credit institutions can be classified along the following lines:

- Universal banks: multi-purpose banks which can offer the whole range of financial services. In most countries, there are universal commercial, savings, cooperative and public banks;

- Specialised banks: among them are the merchant banks, investment banks, mortgage banks, industrial banks, etc. which offer types of finance according to their scope (cf. industrial banks), or their financial techniques (cf. mortgage banks).

Mortgage credit plays a fundamental role in the EU economy, accounting for more than 80 % of all household debts. Outstanding mortgage debt accounts for 33 % of GDP in the EU as a whole. The mortgage debt to GDP ratio differs widely across Member States, from just 6 % in Greece and Italy to as much as 92 % in Denmark. Legal traditions are very important, and every country differs from the other in this respect. Notwithstanding the Second Banking Directive, the EU market for mortgage credit remains by and large the sum of the twelve national markets. National differences in the tax treatment of mortgage interest effectively obstruct the international expansion of banks engaged in mortgage credit. In general, financial markets have become internationalised. The same cannot be said for mortgage credit, however, where as yet no Single Market exists.

There are also institutions which offer some type of specialised credit, but are not credit institutions according to EU directives, and which are called "financial institutions" because they do not attract their funding from the public; such institutions are particularly active in consumer credit, industry credit, factoring, leasing and car financing.

Finance companies that specialise in providing credit to consumers and industry are also known as Finance Houses. Mostly, they are subsidiaries of larger credit institutions. New credit granted by Finance Houses in 1993 is distributed as consumer credit (46.2 %), car financing (40.0 %) and industrial credit (13.8 %). Industrial credit (to be distinguished from leasing) is common in Germany, France, the United Kingdom and Sweden. Transactions with private customers represent in general more than 50 % of the total volume. With the exception of own funds, the banks and the money markets represent the principle sources of funding in the majority of European

countries. Funding takes place in the short and medium term in most countries (with the exception of the UK, where demand for long term funds is widespread). The market is characterised by intense external competition in most countries, particularly from savings banks: in most cases, finance companies have reacted to this situation by becoming more specialised or by reducing their costs.

The UK has the largest banking sector, measured by total assets, followed by Germany and France. The German banking sector employs the most people. The number of banks in Germany is overestimated because all of the cooperative banks are counted as individual banks, whereas in other countries (e.g. France or the Netherlands) they are subsumed under the heading of their central or regional cooperative bank. Cooperative banks figure prominently in Austria, France, Germany, and the Netherlands, and savings banks in Italy, Portugal, Spain, Germany and Belgium. However, although the largest bank in Europe is a French cooperative bank, except in this country, Austria, Germany and Spain, most assets are held by straight commercial banks.

### Recent trends

Banks are confronting the strategic challenge of diminished loan income. This development has had its impact on valuation of bank stocks. Investors often distinguish between trading

income derived from serving a bank's customers, and that earned by risking the bank's own capital (so-called proprietary trading). The former is seen as inherently more stable, and therefore more valuable, than the latter. This perception benefits banks with many corporate customers. In spite of the generally poor economic situation in the EU during 1993, mortgage lending in fact performed strongly, boosted by lower interest rates. In particular, residential lending increased sharply in Denmark, Germany, the Netherlands and Belgium, while performance was less strong in Italy and Ireland. In the UK, mortgage lending stabilised after a difficult year in 1992. On the funding side, the level of mortgage bonds outstanding increased by 20 %, while there was also an increase of activity in issue of mortgage backed securities, notably with the issues in the Netherlands and in Spain.

Despite some differences in history and legal structures, savings and co-operative banks show some important common characteristics. The main characteristics are: firm roots in the regions and communities, no exclusion of any customer groups, and a business focus on small and medium-sized enterprises.

General trends among the Member States in housing and mortgage credit markets include an increased owner occupation and a diminished number of inhabitants per dwelling, a trend that has certainly influenced the development of mortgage

lending. The continued use of mortgage credit as a means of financing home ownership will represent a challenge which both national and European authorities will have to address over the next decade.

### International comparison

According to the results for 1993 Europe's banks appear to be on the road to recovery. While banks in France and Spain still manifest the impact of recession, elsewhere banks seemed to have emerged from the recession, with British banks leading

the way. An indication of the regaining strength of the European banks is their pre-tax profit against Tier One Capital-ratio of 13.7 %. This figure is starting to approach generally accepted standards. In the long run, a return of around 15 %-17 % is regarded as necessary to provide a proper dividend to shareholders and maintain necessary capital strength.

The Japanese banks still dominated the world market in terms of assets (size), with Japanese banks representing the first six places in the world's Top 1000. However, the profitability and capital strength of the Japanese banks is very weak, relative to their international competitors. With a pre-tax profit to Tier One Capital-ratio of 5.1 %, the Japanese banks are among the weaker banks within the Top 1000. Japanese banks have been slow to recover from problems with bad-debt. Standard & Poor's, a rating agency, reckons that it could take five to ten years before Japan's banks reconcile all of their bad debts. Because the earnings environment remains severe at home, Japanese banks are looking all the more to the USA market. Japanese banks operating in the USA have become more aggressive in lending, which shows signs of recovery from a long slump. The banks also are becoming more involved in securitisation (loans transformed into securities) and derivatives such as forwards, swaps and futures (forward-based contracts), and options, caps and floors (option-based contracts).

Banks in the USA have succeeded in restoring their health. Capital strength has been rebuilt, problem lending is being worked off, costs have been cut, margins and profits have recovered and prospects are opening for renewed expansion at home and abroad. For many USA banks, 1993 was a record year, with a pre-tax profit to Tier One Capital-ratio of 22.6 %.

financial revolution, brought about by technological improvements is by no means over. What is over, however, is the misguided notion of the 1980s that inspired almost unlimited financial investment in technology. In a cost cutting environment, credit institutions are more aggressively looking to get value for money. Considering that the financial sector dedicates between 12 and 16 % of its expenditure on computer systems, there is little wonder that credit institutions are seeking greater utilitarian function from the technology they buy. It is therefore the new utility that can be derived from the information technology (IT) expenditure which will fuel the continued growth.

Current trends in the implementation of computing are not new. They form a continuation of a general path marked by decentralisation, a shift to client server architecture (where

the applications and business data are held separately), open systems, and object-oriented programming.

These developments will enable credit institutions to have what they seek - a flexible information processing infrastructure that is more adaptable to change, which better reflects the organisational structure of the firm, which allows for quicker product development and greater customer orientation while keeping costs under control.

## INDUSTRY STRUCTURE

### Companies

The twenty major European banks, ranked by Tier One capital include six French, three UK, three Swiss, three German,

two Dutch, two Italian and one Spanish bank. The relevant Tier One capital definition (BIS strict definition) covers only the core of a bank's strength - the shareholders' equity available to cover actual or potential losses. This includes common stock and declared reserves plus the increasing number of perpetual, irredeemable and non-cumulative preference shares. However, this definition excludes hybrid forms of capital, items such as goodwill and revaluation reserves.

In terms of capital adequacy the Tier One capital to unweighted assets ratio for the Top 20 banks is 4.2 %. The ranking would change if banks were ranked according to this capital adequacy ratio in which case Italian and Spanish banks would advance at the expense of French and German banks. In terms of mortgage credit, national markets have become significantly more concentrated in recent years. Nine UK Building Societies, as well as three Danish mortgage banks, three Dutch and four French institutions feature among the 20 largest mortgage lenders.

The major retail banks in France are Crédit Agricole (biggest European bank), Crédit Lyonnais, BNP, Paribas, Société Générale and Groupe Caisse d'Épargne. The disaster at Crédit Lyonnais continues to colour the country's sector and the bank's 770 million ECU loss in 1993 does little to help the overall performance of the banks. Perhaps the ongoing privatisation process and restructuring of Crédit Lyonnais among other factors will help lift the laggard French profitability ratio of 5.6 %.

The German banking industry is dominated by such commercial banks as Deutsche Bank, Dresdner Bank and Commerzbank. These are all universal banks. Westdeutsche Landesbank Girozentrale, a savings bank, is another important player in the German banking market. German banks showed a modest improvement in returns, rising to 14.5 % following a flat performance the previous year. Market leader, Deutsche Bank, showed a strong 23.9 % return on Tier One capital. The German banks appear to prosper notwithstanding the recession within the German economy in 1993.

The UK banking market is dominated by HSBC Holdings, Barclays Bank, National Westminster Bank, Abbey National and Lloyds Bank. In terms of profitability, the UK aggregate return on Tier One capital has risen the most in the EU, nearly doubling to 20.9 % in 1993. The growth in operating profits in 1993 was driven particularly by trading activities.

The Italian banking market is more fragmented than the British and German markets. Only two Italian players, Cariplo savings bank and San Paolo Bank, are among the top twenty European banks. Other major players in Italy are Banca di Roma, BNL,

Istituto Mobiliare Italiano and Banca Commerciale Italiana. Despite convoluted Italian regulations, banks have been improving their returns. Moreover, banks dominate the Italian government's privatisation program. Six of the country's biggest banks are offered for sale. Thus far, Credito Italiano and Istituto Mobiliare Italiano are two formerly state-owned banks that have been privatised.

The most prominent non-EU Member State in banking is Switzerland. Union Bank, Crédit Suisse and the Swiss Bank dominate the Swiss banking market. The Swiss banks showed a sizeable improvement in profitability with average ratio rising to 14.6 % in 1993 from 10.5 % the previous year. Strong trading profits contributed to this improvement.

### Strategies

Banks today compete in the broad-based financial services industry, not just in banking. Bankers recognise that the industry's future revenue streams will be quite different from the past. Beside traditional banking, there are at least six promising segments for banks to play a role of importance in. Those segments are: financial intermediation and advisory

services, investment management, insurance, fee-based operational services, trading, and merchant banking and equity investment. Because traditional banking, alone, will not provide enough revenue to serve as a viable strategy. As such, a bank's most important strategic decision may reside in choosing which segment to pursue and which to avoid. In today's broad-based financial services industry, performing only as well as the competition is not sufficient. It is increasingly important to determine - and sharpen - the skills needed for success in the segment(s) selected.

In general, four strategic elements are critical to the health of banking's future:

- managing current opportunities and risks;
- dealing with the impact of mergers and acquisitions;
- adding value through superior-quality services and products;
- raising human and financial capital.

Because it is so much within the purview of a bank manager's influence, strategic planning is clearly among the most important factors determining banking success.

### Impact of the Single Market

EU regulation has been extended, or is being extended, to cover freedom of establishment for banks and other financial institutions, harmonisation of banking supervision, accounting and a number of other subjects relevant to the business of

financial services. In spite of these efforts the Single Market in financial services does not really exist by now, as Member States continue to enforce national privileged positions. However, the process of bringing the Single Market into effect continues, especially regarding the translation of the measures adopted at Community level into national legislation. Harmonisation in implementation is considered a very important priority for the industry, especially in the field of taxation. Horizontal policies which aim to minimise the administrative and financial burden and encourage investment in SMEs are supported by the industry because of the high potential of those companies for the economy in general and for the financial services sector in particular. The creation of the European Monetary Institute (EMI) at the beginning of 1994 is seen as a milestone for achieving an Economic and Monetary Union (EMU). The change to a single currency is considered a high priority by the industry.

### REGULATIONS

In recent years, the Basle Accord on capital adequacy has been seen as a positive attempt to help level the global playing field through the establishment of a common framework leading to convergence. However, more and more the traditional business of banking is conducted by non-banks, such as finance companies, insurance and securities firms that are entirely outside the Basle framework. Although the Basle Committee

of bank supervisors has agreed on common minimum capital requirements for banks, there remains a lack of agreement among international regulators about the right approach to setting capital requirements, both for banks and non-banks.

In general, three regulatory approaches can be distinguished. The first method, the "comprehensive" approach, is used in Japan and the USA. It requires a firm to set aside a proportion (USA 15 %) of the value of long plus short positions. The second method, the "building block" approach preferred by the EU and the Basle Committee, uses both the gross value of a firm's positions (as in the USA) and its net exposure (long positions less comparable short ones) in fixing capital requirements. For example, the EU rules, which will be in force from 1996, require a minimum capital requirement of 4 %, i.e., 2 % of the gross value of the position on each side to reflect divergence and execution risks plus 8 % for the overall net position in an equity market. The third method, the "portfolio" approach, which has been used since 1988 in the UK, ties the amount of capital to a simple calculation of the overall riskiness of a firm's securities portfolio. It looks at the net position only, and defines riskiness as the extent to which, on past form, the value of a portfolio is likely to fluctuate from week to week (the more it does, the riskier).

## OUTLOOK

Given the various credit markets' development of more standardised underwriting and loan portfolios, and the increasing preference among depositors for mutual funds, annuities, and other "off balance sheet" investment products, it is clear that past notions of the synergism or interdependencies of bank assets and liabilities is vanishing. In the past, banks used deposits to fund loans. Asset and liability management techniques were used to mitigate the differences in demand between two markets, as banks held the position of "intermediary" or "manufacturer". In the future, banks will play more the role of value-added distributor. Banks will be less involved in turning deposits into loans, and more involved in providing their customers value-added access to various capital markets.

Most traditional banks already have been deriving an increasing proportion of their earnings through fee income and trading-related services. As the banking market worldwide matures, credit institutions attempt to move to more sophisticated areas where higher margins and fees have been available. Surveys suggest that banks and capital markets players will increasingly derive revenue from low-volume, high margin products rather than high-volume, low-margin ones. On the other hand, discount brokers among German banks and savings banks show an opposite tendency.

Strategic planning is the most important determinant of banking success. As the banking industry matures further it will be extremely important to position for the future. Choosing which segments to pursue - and those to avoid - will be a bank's most important strategic task. In this regard, the future of banking will be shaped by decisions made by individual bank management, not by macro events or transient changes in policy.

# Insurance

## NACE 82

After several years of restructuring, a certain degree of rationalisation is taking place within the insurance industry. Induced by the recently adopted Directives and the resulting intensifying competition, attention is increasingly shifting towards marketing and operations with particular emphasis on more cost-efficient operations, more product innovations and market-oriented strategies. In this context, the distribution of insurance products is expected to play an increasingly important role from strategic (structuring of product supply), cost-efficient (reduction of intermediation costs) and/or market-oriented (customer-services) points of view. The high growth rates of premium income since 1985 are expected to continue in the short and medium terms.

### INDUSTRY PROFILE

#### Description of the sector

The NACE classification defines the insurance sector as embracing all units "exclusively or primarily engaged in insurance," i.e. converting individual risks into collective risks. Compulsory social security is not included.

Insurance is thus defined in terms of the economic functions of converting and mutualising risks. NACE 82 distinguishes three main groups of insurance: life insurance, non-life insurance and composite insurance. Life insurance risk relates to the decease of the insured person. It embraces conventional life insurance contracts, annuities, unit-linked insurances and private insured pension schemes. Non-life insurance risk is defined as everything not included in the previous category. It includes assets or liability insurance covering either individuals or organisations. According to the EU's insurance directives there are 18 main classes of non-life insurance risks, ranging from health insurance to physical assets property damage, through transportation to credit insurance. Composite insurance risk comprises life and non-life risks. Composite insurance undertakings, however, are not allowed in all Member States and Community rules have banned the creation of new ones.

**Figure 1: Insurance**

The NACE classification does not consider reinsurance as a separate activity as most of the general insurance companies also underwrite reinsurance business, called 'accepted reinsurance.' It is assigned to one of the three groups according to the type of risk reinsured. The reinsurance market supplies capital support to the direct insurers and a variety of technical services under specific reinsurance treaties or contracts. As such, the activity in reinsurance is an important indicator of insurance activity as a whole. Reinsurance activity can be evaluated by two indicators: the rate of accepted reinsurance and the retention rate. The reinsurance rate is calculated by dividing the premiums on reinsurance accepted by total gross premiums. The retention rate expresses the percentage of total gross premiums written that is retained by the insurers; the remainder represents premiums ceded.

The EU-market is dominated by Germany, the United Kingdom and France. In terms of gross premium income, these countries accounted for nearly 75 % of the total EU-market in 1993. At 103 billion ECU, Germany recorded the highest gross pre-

Source: CEA

mium income, thereby employing 256 000 people. The United Kingdom and France followed with total turnovers of 103 and 89 billion ECU, respectively.

The Southern-European insurance markets are still relatively small. The density of insurance (premiums per capita) in countries like Spain, Portugal, Italy and Greece is rather low compared to other Member States such as Germany, the Netherlands and the United Kingdom.

If labour productivity is considered for each Member State, some other differences can be observed. While labour productivity was highest in Italy and France, these figures for Greece and Portugal were considerably lower in the same year.

#### Recent trends

Over the period 1985 to 1992 the EU-average direct gross premiums per capita has increased at a rapid pace. With an

average annual growth rate of more than 10 %, premiums per capita almost doubled in 7 years time. If related to Gross Domestic Product (GDP), it appears that gross premiums have increased at a rate faster than GDP. Gross premiums written as a share of GDP increased from 4.86 % in 1985 to 6.53 % in 1992. Recent years still demonstrate high growth rates, which are even slightly higher than the average annual growth over the 1985-1992 period. From these developments, one can conclude that the European insurance market has still not reached a level of saturation.

#### International comparison

With premiums per capita of 996 ECU the European market is lagging far behind the USA and Japan with corresponding figures of 1,807 and 1,909 ECU, respectively. In terms of gross premiums as percentages of GDP, it is seen that the USA and Japan, with 10.13 % and 8.39 % of GDP, compare favourably to the European market (6.53 %). In terms of mar-

ket share, in 1992 the USA had almost 40 % of the world market whilst the EU and Japan accounted for 32.1 % and 20.3 %, respectively. With current high growth rates in the EU, however, the gap with the USA is closing.

### Foreign trade

An indication of the foreign influence on domestic insurance markets is provided by the number of branch offices of foreign insurers and the number of foreign-owned insurance companies. In 1990 within the EU, a total number of 1 103 foreign branch offices and foreign-owned insurance companies (both EU and non-EU based) accounted for 23 % of all insurance companies. Their market share was estimated at 13 %.

The ongoing trend towards internationalisation and the recently adopted directives will further stimulate intra-EU cross-

border trade. From Figure 1 it can be deduced that insurance companies have been concentrating on the EU-market in recent years. Non-EU insurance companies, especially Swiss insurers, have entered the single market thereby increasing extra-EU imports. EU-insurers have actively restructured their activities within the EU. At the same time, they have consolidated their extra-EU activities. As a result, since 1989 the extra-EU trade balances have been negative.

### MARKET FORCES

#### Demand

The ageing of Europe's population has played and is still playing a decisive role in the growth of premium volume in life insurance. The need for comprehensive insurance coverage

**Table 4: Insurance

increases with advancing years, especially when social security benefits relating to pensions and medical treatment appear progressively inadequate. In an effort to compensate for the erosion of state benefits, the public is turning increasingly towards life-insurance related products.

In addition, there is a growing tendency for earlier retirement. The legal or accepted retirement age in every European country is now between 60 and 65 years (except Denmark, with a retirement age of 67 years). The effective retirement age, however, is below the age prescribed. Additional insurance for the years of earlier retirement is stimulating demand.

Improvements in living standards emerge as an essential factor in the shifting patterns of non-life insurance consumption. The population insures not only itself but also its growing number of possessions. In this respect, it is worth noting that the demand for passenger cars in the EU increased from 3 million in 1960 to more than 12 million in 1989, amounting to a stock of 128 million passenger cars (excluding eastern Germany). There are also now 150 million homes. Non-life insurance is coming to be regarded as a commonplace product. Here, a distinction has to be made between mandatory insurance coverage on the one hand (car insurance, workplace accident insurance, and so on) and other categories of insurance (health, legal etc.) which are currently marketed. It is above all in the former category that price sensitivity plays a key role.

Additionally, consumers are becoming more conscious of the wide range of products and services which are offered in the insurance industry. As the number of product varieties increases, the need for independent advice is also growing. This trend is reflected in a growing importance of independent intermediaries.

### Supply and competition

The supply of insurance within Europe has traditionally been dominated by domestically owned insurance companies. Domination on a European scale used to be difficult as many insurances are comparatively standardised products, leaving little opportunity for product differentiation. In life insurance and pensions a greater potential for differentiation exists, but regulation in some European countries has tended to inhibit product innovation. Moreover, since there are no patent laws in insurance, new products could and still can be copied relatively quickly, especially as production systems are not complex.

However, since the mid-1980s, there have been signs of a greater willingness to change. In 1985 the EU passed the Single European Act, which laid the foundations for the integration of the EU financial and other markets. This has resulted in increasing competitive pressures from the impact of new information technologies and from the entry of banks and foreign insurance companies into local markets.

The recently adopted Directives will pave the way for further integration. Competition is expected to intensify. The deregulatory impact of the Directives, however, will not only lead to more competitive pricing but also to product innovations and market development. The competitive challenge for the 1994-1998 period will come from all providers of insurance services: insurance companies, banks, and the bancassurers.

### Production process

The recession in the early 1990s had an adverse impact on profitability which in turn has made management look more carefully at their costs, particularly staff costs, because of the labour-intensive nature of the business. This growing attention for cost-efficiency is further stimulated by the integration of the European insurance markets. The intensifying competition is resulting in a pressure on tariffs and a search for cost savings.

In addition, the increased concentration within the insurance markets caused by take-overs has led to some rationalisation in the insurance labour force. When insurance companies merge into larger enterprises, there is usually some reduction in staffing levels as job duplication is eliminated.

The cost saving strategies concentrate on internal processes, entailing the introduction and development of cost-efficient administrative procedures, and on distribution costs. As far as operational costs are concerned, marketing and distribution costs rank immediately after policy payments in terms of size. Not surprisingly, a lot of attention is given to less expensive modes of distribution. The various approaches open to distribution include:

- salaried employees (particularly in the life sector);
- tied company agents: an intermediary between a client and an insurance company, who is contractually bound to, but not employed directly by, a specific company; remunerated on a commission basis;
- independent brokers, which are mandated by the client and usually do not have any link to an individual insurer; remunerated on a commission basis;

**Table 6: Insurance**

- direct-writing by the companies themselves;
- banks, in which case there is a great variety to market insurance products (e.g. distributed under the bank's own name or that of the insurer, sold by insurance salesmen on recommendation by bank staff, sold partly by the bank staff and partly by the insurance salesmen);
- others, e.g. retail chain stores.

The preferred strategies vary from one country to another, depending on the regulatory environment, the companies' strategy, the influence of shareholders and the market structure. Brokers dominate the markets in Anglo-Saxon model (UK and the Netherlands), whereas agents are more common in the continental model (Germany and France).

From the point-of-view of cost efficiency there is also a trend towards direct-writing. Through direct writing the expensive costs of distribution are saved. However, distribution is becoming increasingly important for the achievement of other goals. Reflecting the growing need among consumers for independent advice, the importance of the independent brokers as distributors of insurance services will increase. Furthermore, the growing demand for more convenience has been met by a concentration of supply within the distribution channels. As a result, a wide range of products can be offered at one place (one-stop shopping), bancassurance being the best example of this development.

## Companies

In 1993 there were some 4 318 insurance companies operating in Western Europe against 4 343 companies in 1992. The number of independently controlled groups was less than 2 500 and is declining. When insurance companies are taken over, the acquiring companies often do not incorporate them into their own structure for marketing and/or tax reasons. As a result of the ongoing mergers and takeovers, it is possible that the total number of insurance companies is increasing, while the number of independently controlled groups is further declining. In 1992, within the EU, the average size of insurance companies, measured in terms of gross premiums divided by the number of undertakings, was 80 million ECU against 66 million ECU in 1990.

During 1993, all European insurance companies increased their market capitalisation through rate increases and favourable stock markets. At the end of 1993, the German Allianz Group retained its leading position with a market capitalisation of more than 27 billion ECU against 17.4 billion in 1992. Allianz was followed by Generali (I), Munchener Ruck (D) and Prudential (UK). Not included in the top ten is AXA (F). AXA - with a market capitalisation of 7.4 billion ECU - is marked as a 'diversified holding company' but is very active in the insurance market.

## Strategies

Since the passing of the Single European Act in 1985, most of the leading European insurers have increasingly derived premium income from European countries other than their own. A combined total of one-fifth of the premiums of Europe's biggest insurer, Allianz, now come from Italy, France and Britain. This is largely owed to its purchase, since 1986, of stakes in Riunione Adriatica di Sicurtà, Italy's second-largest private insurer, Britain's Cornhill and France's Via.

Privatised in May, 1994, Union des Assurances de Paris, France's biggest insurance company, is even more European. It earns more than half of its premiums abroad, mainly from its neighbouring countries. It has purchased Colonia, Germany's third-biggest insurer; a controlling stake in Belgium's Royale Belge; and 50 % of Sun Life, a British insurer. AXA, the France's second insurance company bought the big British insurer Equity & Law.

Underlying the strategies of many insurers is the belief that owning an established firm is the only worthwhile approach for market entry into other European markets. Insurers fear that the tax treatment of investment in different countries

(which is not covered by the new rules) will still favour certain kinds of products especially those which are already provided by local companies. Another potential barrier to entry is the caveat in the new European regulations that allows countries to restrict the sale of some policies in the "common good." This could encourage the protection of national firms by Member States.

The third generation of insurance directives, which came into force in July 1994, has been heralded by a fierce Euro-battle for control of Groupe Victoire, France's sixth-largest life-insurer. Britain's Commercial Union triumphed over Assicurazioni Generali, Italy's biggest insurer.

The newly adopted Directives also pave the way for non-EU insurance companies. The Swiss company Zürich insurance, for instance, plans a fierce assault on the German market through direct advertising and telephone sales. Following their success with tele-marketing in the Anglo-Saxon markets of the United Kingdom and the Netherlands, the company also hopes to attack the Italian market. Furthermore, the US company General Reassurance has acquired a majority stake in the Kolnischer Rückversicherung.

Through a series of take-overs and mergers between banks and insurance companies, the phenomenon of bancassurance has emerged in recent years. Bancassurance offers advantages not only in distribution of insurance products, but also on the product side itself as it provides low-cost access to a

large volume of customers. Through the emergence of bancassurance a clear distinction between insurance companies, banks and bancassurance companies can no longer be made. The need for such a distinction is also fading as the financial companies increasingly focus on products, markets and their combinations.

### Impact of the Single Market

The overall impact of the Internal Market programme on the insurance sector is considered to have been positive. Every company has adapted its strategy as result of increased European integration. Competition within the EU has increased and has become fiercer. Most companies think more internationally and everybody is more 'single market minded'. Internal barriers still exist with respect to contract law, taxation and exchange rates, however. The harmonisation of contract laws is considered to be a highly relevant issue. Fiscal problems are often an obstacle for the freedom to provide services. The still existing national currencies require the matching of national risks in national currencies, which is inefficient and costly. The removal of the remaining internal barriers concerning contract law and taxation should have priority, as should the creation of a single European currency.

### REGULATIONS

In July 1994, the third generation of insurance directives (92/49 for non-life insurance and 92/96 for life insurance services) came into force. These directives seek to provide a single structure for business conducted either on an establishment or on a cross-border basis. Such implies that personal-insur-

ance policies can be freely sold throughout the European Union. The most significant feature of these directives is the attempt to move the regulatory focus from host-country control to home-country control. The acceptance of the principle of a single licence represents an important breakthrough and should facilitate the European integration. These directives will be supported by the implementation of the Insurance Accounts Directive. More standardised accounting systems will give confidence to the regulatory authorities within the Member States to operate within the single licence principle.

The new directives will be important to insurance companies not just because they increase the potential for cross-border business but mainly because they will be accompanied by changes which more directly address competitive policy within Member States. The minimum price restrictions, for instance, are phased out and some national regulations are removed. The consequence is a major deregulatory effect on the market. Furthermore, there is greater freedom for investment policy, which will be important for product innovation in the areas of life insurance and pensions.

Still, a complete free Single Market has not yet been reached. With respect to life insurance contracts, national laws often only contain fiscal advantages for contracts with domestic insurers or branches of foreign insurers. These fiscal differences have to be reconciled if a free Single Market is to be established - as do differences in indirect taxation. In Germany for example a 12 % tax is levied on life insurance by the Government. This tax, however, only applies to domestic insurers and not to foreign insurers.

## OUTLOOK

The third generation EU directives will contribute to the creation of a single insurance market. The insurance companies have already anticipated the single market by taking over existing insurance companies. Mergers and acquisitions are expected to continue, though to a smaller extent than in the early 1990s.

The newly adopted directives will encourage competition and stimulate cost-efficient company operations. As such, attention is turning to improving operations in a cost-efficient manner. Some cost savings will be realised in the distribution of insurance services. In this respect, direct writing will increasingly be used by the insurers.

From a market strategic point of view, however, insurers are increasingly concentrating on their markets, product innovation, and the distribution of their products. The number of new products and new product varieties in some segments is expected to grow, causing the need for independent, custom-tailored advice. In other segments, demand for more convenience is increasing, thereby further stimulating the importance of one-stop shopping.

In the coming years, gross premium income is expected to increase at the same rapid pace as in recent years. This continuing growth is motivated by the economic recovery, the still relatively less developed European insurance market, and the market stimulance by the newly adopted directives. In addition, insurers will try to develop further the insurance markets in Southern Europe and the Eastern Europe.

# Financial intermediaries

## NACE 831

Since 1980, various changes in regulation have served to liberalise the provision of services and increase competition. In this regard, financial intermediaries have become increasingly more important during the last decade as the large growth in demand and supply of funds on the financial markets (mainly fuelled by privatisations, mergers & acquisitions and the dismantling of barriers to cross-border trade), as well as the spate of new financial instruments have had a profound effect on demand for their services. The liberation of capital markets since 1986 has led to the emergence of sizeable financial intermediary groups.

### INDUSTRY PROFILE

#### Description of the sector

Financial intermediaries play a supporting role in the world's capital markets. They assist in the investment of savings with particular emphasis on portfolio management. Their activities include brokerage, advice, research, dealing in securities, market-making, clearing and settlement and more general organising of the "marketplace". Stock exchanges, brokers, and large investment banks operate in this industry. Financial intermediaries perform functions that are both complementary to and competitive with banks and insurance companies. However, the overall distinction between financial intermediaries, banks and insurance companies is becoming more and more vague.

As such, it is more meaningful to describe the main financial market forms as follows instead of focusing on unclear differences among various providers of financial services.

- money markets (short term instruments: call money, on-sight deposits, checking accounts) and capital markets (long term: securities, loans, mortgage loans);
- primary markets (issues of securities);
- regulated secondary markets (like stock exchanges) and non-regulated secondary markets (like over-the-counter markets, in which dealing takes place off the record)

- spot markets (operations and payments are carried out immediately) and forward markets (traded currency securities will be remitted later, and will be paid at the agreed time upon remittance of those securities).

The activities of financial intermediaries serve investors in equity, debt and derivative markets. By providing their services, financial intermediaries make the market for short- and long-term securities and, to a lesser extent, loans. Today, a very large proportion of the investment banks activities consists of advice and assistance on (cross-border) mergers and acquisitions (M&A).

#### Recent trends

Globally, economic growth was unevenly distributed in 1993. Whereas the USA, Canada and the UK showed encouraging signs of economic recovery, most of the countries of continental Europe struggled with economic stagnation and recession. The countries of the Asia region, with the exception of Japan, enjoyed among the largest percentages increases in the world. The stock indexes, on the other hand, performed extremely well worldwide and, especially in Europe, irrespective of the countries economic performance. Stock market performance in 1993, measured by the market capitalisation of stock exchanges, recorded an increase of 28.1 % compared with 1992.

Since 1989, several drastic changes have affected the securities markets world-wide, among which includes structural modernisation, with the introduction of the improvement of automated systems, the internationalisation of their activities, the derivatives products and the emergence of stock markets in developing countries. These changes have been accompanied by a shift in market value and turnover distribution among world regions. Investors involved in Japanese stock markets have transferred their portfolio from Japan to the USA and Europe where they found greater profit opportunities, as well as emerging stock markets, like Latin America. Such investment activity can explain the regional redeployment in turnover value.

Mergers and acquisitions (M&A) activity in the USA has been high and the debt market has derived some benefits. Yet, the predominant source of capital for European takeover activity has been shareholders equity rather than debt. For example, Europe's biggest takeover of 1993-4, Akzo's (NL) 2.65 billion ECU acquisition of Nobel Industries, was entirely equity based. What will underpin the debt market in the me-

dium term is the market's ability to provide financing structures. The three main sources of demand for this type of financing will be M&A and restructuring, project finance and, more controversially, junk bond borrowers.

A development that is viewed with concern in the financial world is the continuously growing trading activity in over-the-counter derivatives. The area of over-the-counter trading in derivative products has the attention of regulators, supervisors and media because of the systemic risks it imparts to the financial system. The biggest problem in assessing the risk of derivatives markets in financial instruments and the potential exposure of international banks lies in measuring the actual size of the business in fast-changing markets. One difficulty in identifying the actual sums involved is that derivatives activity is divided between the organised exchanges and the over-the-counter (OTC) markets. Independent in the way it is measured, there is no doubt that the volume of derivatives business continues to rise.

#### International comparison

The New York Stock Exchange (NYSE) is the world's largest stock exchange. The year 1993 was the best year in the exchange's 201-year history. The NYSE reported unprecedented operating and financial results resulting from record-breaking levels of trading volumes. In 1993 its value of share trading (turnover) was 1.7 times larger than in London, and 1.9 times larger than in Tokyo. In terms of market value of shares of domestic companies (capitalisation) the NYSE is 50 % larger

than the Tokyo Stock Exchange and 2.5 times larger than the London Stock Exchange.

In Europe, Italian stocks were outperformers in terms of price-earnings (PE) ratio, more than doubling its 1992 figure to 58.6 % in 1993. In Europe all PE-ratio were up in comparison with the 1992 figures. The only exception was Stockholm where the PE-ratio fell from 60.0 % in 1992 to 31.0 % in 1993.

London is undoubtedly the most important European financial market in terms of turnover and capitalisation. However, from a global perspective in 1993, London lost its leading position in terms of average value of transaction to Mexico. In this regard, investors looked with interest at the Latin American markets. For example, the Mexican stock market saw a surge in its market value by 44.8 %. This good performance can mainly be attributed to international factors, such as the ratification of the North American Free Trade Agreement (NAFTA) Treaty, rather than domestic ones.

The position of Asian-Pacific region is declining in terms of share turnover value. The Tokyo Stock Exchange, which accounted for 60.1 % of the region trading value in 1989, now represents only 39.5 %. The rapid growth of other stock exchanges in the Dynamic Asian Economies (DAE), such as Hong Kong, Singapore, Malaysia, Taiwan and Thailand, has not compensated for the significant decline in the Tokyo Stock Exchange's market value since 1989. However, the highest price-earnings ratio among the major stock exchanges is still for Tokyo with 64.9 % in 1993.

### Foreign trade

A substantial expansion of international activities was driven by deregulation and the revolution in communication technology. The resulting integration has broadened the choices of market participants: issuers have looked to foreign markets to raise capital, while investors have tended to internationalise their portfolios.

Indicators of activities in the international capital markets showed a remarkable growth of Euro-note programs, Euro-commercial paper programmes and other committed facilities in 1993. The growth was spurred by falling interest rates in a number of major markets and the large funding requirements of governments and corporations.

### MARKET FORCES

#### Demand

The increase in equity market valuation in 1993 implied that companies preferred to raise equity finance rather than debt. It is unlikely that this will change in the near-term even if

stock markets weaken substantially. There may be potential for hybrid equity-linked debt products such as convertibles and warrants. Convertibles have proved popular among Asian issuers while the Japanese equity-warrant market has begun to stir once again.

Still, a principle driving force behind debt financing has been largely absent in Europe. Many European companies - under pressure of recession - have become increasingly concerned about their debt/equity ratios. This underscores a greater effort to float shares rather than to borrow. Beyond the questions of demand, the huge majority of companies cannot bring issues of the size and frequency sought by those investors for whom secondary-market liquidity is a cause of concern.

Emerging-market corporations and banks have begun to borrow in increasing numbers and volumes. Apart from the biggest names, these issuers are little known to international investors and are tapping flight capital. This kind of institution should dominate both the demand and supply sides of the market, further consolidating the linkages between the exchanges and the OTC vendors. That pattern will tend to force the pace of innovation because institutions are much more demanding customers than retail investors.

Another driving force emanates from mergers, acquisitions, privatisations and management buy-outs, which require services from financial intermediaries in various forms. The demand for services involving management of corporate assets and liabilities has increased, especially in situations involving financial and corporate restructuring. Furthermore, the need for advice and support for cross border alliances and take-overs has grown.

#### Supply and competition

Financial services can be divided into two groups according to their target markets: institutional versus private markets and international versus local markets. Institutional lenders and borrowers have different needs, and it is within these markets that international competition mainly takes place. Local markets will keep their role, however, largely because many private persons and companies prefer the indigenous financial market to the foreign markets for borrowing and investing. Most domestic shares will be bought by the inhabitants of the country and not by foreign investors.

With respect to institutional markets, stock exchanges compete with each other to hold or increase their share of trading. An exchange's competitiveness is based on its technology and procedures for trading, clearance and settlement. In Europe, the London Stock Exchange has attracted much trade of foreign

shares of non-United Kingdom companies. The other European exchanges have also been investing heavily to make markets more efficient, in order to boost liquidity on their local markets. Although the London Stock Exchange was forced to abandon its investment in the computerised settlements system, Taurus, in March 1993, London's SEAQ International remains an important trading centre for many leading German, French, Dutch and Swedish companies. Regulation is very important to the competition between exchanges, both as an instrument or as a constraint in making exchanges attractive. Stamp duty, capital gains taxes, brokers' fees, trading hours and the delivery-clearing systems all determine competitiveness. It is thought that this is one of the main reasons that a level regulatory playing field should be achieved as a matter of policy.

Proprietary Trading Systems (PTS) operated by large international brokers compete with the stock exchanges, and with each other, in order to gain the business of the institutional

investors. They attempt to attract customers primarily with the advantages of one-stop shopping--institutions can deal with just one large broker via PTS. Through the large broker, investors can benefit from superior services such as 24-hour trading in stocks. Brokers compete with exchanges, because they can offer a customer a deal outside the exchange and directly through the broker with another customer. Only brokers with a sufficiently large customer base can offer such a service.

Electronic markets also threaten the more traditional stock and foreign exchanges. They allow investors and intermediaries to deal anonymously on an electronic system. Participants enter bid and offer prices directly into the system and can either trade instantly against these prices, or negotiate on screen on order size. Instinet (owned by Reuters) is a leading example of such an electronic market. Instinet works like an exchange, but is registered and acts as a broker, with membership on several stock exchanges including London, Frankfurt and Paris. As many as 35 % of the deals in the foreign exchange market are conducted to brokers who bring together bank buyers and sellers. There are now three competing systems: Reuters 2000-2; Electronic Broking System (EBS), owned by a consortium of banks and the information group Quotron; and Minex, a Tokyo-based company which operates mostly on the Yen market. Also, bond trading will increasingly be screen-based. Electronic trading has already begun in the USA Treasury bond market and recently CS First Boston began trading on European government bond markets through its on-line trading system. Electronic markets blur the distinction between brokers and exchanges.

The reorganisation of stock markets has also played an important part in stimulating the supply of financial services and the competition between financial intermediaries. Its aim was improving efficiency while ensuring stability and investor protection. Key elements include: an end to brokers' monopoly and liberalisation of commissions; a reorganisation of the market for treasury bonds, with the consequent adoption of a secondary market in such stocks to reflect the needs of investors; the creation of secondary listings, allowing medium-sized businesses, unable to meet the conditions for full listing, to improve their access to capital; and the computerisation

of stock markets and market operations in all European exchanges boosting market liquidity through more rapidly available and accurate information.

## INDUSTRY STRUCTURE

### Companies

Competitors in this industry consist of different groups of which brokers are the most important. They can be divided into large, international brokers, small, national ones and niche players. The stock exchanges themselves are engaged in competition, each positioned either as an international player or as a domestic one. Private electronic markets are becoming progressively more significant and, in some instances, Instinet already plays a leading role. Finally, the (investment) banks are also active in this industry.

In the past decade, large groups of financial intermediaries have emerged, consisting of combinations of brokers and banks. Monitoring these groups is a difficult matter, as they engage in activities that fall under different supervisory authorities in most European countries.

Stock exchanges can be compared by their stock index performance and value of share trading. Merchant banks and securities firms can typically be compared by their engagement in take-over deals. This measure underscores the dominance of Lazard Houses (UK), Crédit Lyonnais (F, a bank), and S.G. Warburg (UK). The role of financial intermediaries in insurance products can be seen by way of distribution. The distribution of insurance products via insurance brokers and agents shows a different pattern in the different European countries. In this regard, it is possible to distinguish two extremes: market domination by brokers versus market domination by agents. One extreme is represented by the Netherlands and Belgium, with a brokers' market share of respectively 75 % and 60 %. At the opposite end of the scale, one finds the market dominated by agents, with Germany (75 %), Italy (71 %), Portugal (67 %) and Spain (60 %).

### Strategies

The collapse of communism and the worldwide rise of free market economics brought the spread of privatisation which has created new openings and new dangers. For a financial intermediary to be a global operator, a successful strategy seems to involve investment in international relationships. Global distribution power is essential in this regard. Another important factor is the financial condition or soundness of the company itself.

The top USA securities firms, with a wealth of experience in a highly competitive market at home, are rapidly building up their presence around the world. They are exploiting their home market experience on a global level. They make use of the fact that countries from Latin America through Europe - west and east - to south-east Asia are opening their doors for foreign advisers.

Indeed, the privatisation trend can warrant a local strategy, coupled with an global presence. Local knowledge is needed in order to bring state enterprises to the market successfully. Global presence is needed to manage the typically large size of privatised companies. However, the USA investment banks illustrate that global distribution power becomes the more important factor for success.

Stock exchanges will compete with each other on market-making or order-driven trading systems. Brokers and electronic markets are offering more linkages between exchanges as Amsterdam has done for wholesale investors.

SWIFT, acting in its capacity as secretariat to the maintenance agency of the only recognised international message standard for the securities industry (ISO 7775), proposed that a new framework be established. One of the major components is

the establishment of an internationally recognised authority in the securities business industry, the Securities Standards Advisory Board (SSAB). Its objective is to promote the use of industry-wide standards by ensuring the timely availability of such standards and their relevance in meeting industry needs. The SSAB shall determine the strategic direction and priorities for the development of industry-wide message standards in the area of securities.

## REGULATIONS

The objective of the Investment Services Directive (ISD) which was adopted on 10 May 1993, is to create one single market for securities firms. The ISD must be transposed into national law by 1 July 1995 and be effective from 31 December 1995. A securities firm will then need a licence only in a single Member State to operate in all Member States. Investment firms and banks will, however, have to respect conduct of business rules on a host-Member State basis. The directive provides that banks and securities firms may become stock exchange members in their own name in each Member State, subject to a transitional period for France, Italy and Belgium until the end of 1996, and for Greece, Spain and Portugal until the end of 1999.

Furthermore, under certain conditions a Member State is allowed to force market participants to handle securities transactions on the regulated market. The investor, however, can demand that the transaction will be executed outside the regulated markets. A Member State can then require the investor to ask permission for such a transaction. This rule represents a compromise between countries with highly regulated markets and countries with less regulated markets.

Together with the Capital Adequacy Directive (CAD) of 15 March 1993, the ISD regulates the EU securities market. The CAD stipulates minimum capital requirements, as well as a minimum starting capital. The ISD stipulates that securities firms and banks need to fulfil the CAD requirements.

The Fédération Internationale des Bourses de Valeurs (FIBV) and the Federation of European Stock Exchanges (FESE) state that a level regulatory playing field between electronic and floor based markets should be achieved. Electronic markets performing similar functions should be regulated in a similar manner whether or not operated by an exchange. However, regulation should be appropriate to the system and to the constituencies served rather than identical regulation.

The International Capital Markets Group (ICMG), which is a cooperative arrangement between the International Bar Association, Section on Business Law (IBA), International Federation of Accountants (IFAC) and the FIBV, is dealing with a number of important issues including international regulatory issues, disclosure to investors in the secondary markets, regulation of electronic markets and, harmonisation of securities regulation.

### Impact of the Single Market

The impact of the creation of the Single Market on financial intermediaries is considered to have been generally positive. Freedom to provide services, the right of establishment and the free movement of capital are of extreme importance to this sector. In European exchanges, generally one transaction in seven involves at least one foreign counterpart. The field of taxation has a tremendous impact on the location of trading and on trading volumes. Tax measures that contribute to higher costs divert transactions to non-EU exchanges. Free movement of goods is also of great importance to the financial intermediaries, notably in the area of technical harmonisation, mutual recognition of rules and prevention of new barriers. Advance on an increasingly fluid and integrated capital market is considered a priority by the European securities industry.

## OUTLOOK

The leading investment banks face a serious diminution of their own role in the hugely profitable new issue business. Already a core group of 25 super-investors - mainly split between the USA and the UK but with some in continental Europe, Australia and Asia - are coming to dominate the business. Lead managers will increasingly syndicate deals to the super-investor, not to other investment banks. A future step will be the super-investors to deal directly with the issuers as disintermediation will become a big topic for investment banks. Even if the super-investors fail to organise an underwriting cartel to take control of the primary business, they will still dictate the pricing of new offers.

The lack of transparency that seems to be an inevitable component of the OTC markets will propel business to the exchanges. Over-the-counter derivatives will become more tightly controlled in terms of how they are sold and accounted for. As derivatives dealers find more of their products replicated on the world's exchanges, their search will continue for OTC deals that preserve their profit margins.

The tendency among the smaller exchanges favours full automation. In the next century they will link with the hubs electronically, offering local derivatives to a wider customer base while major markets will provide their smaller counterparts with capacity to trade international products. As a result, the gap between emerging markets and the established ones will close at an increasing pace.

# Real estate

## NACE 833

The European real estate sector is going through a severe downturn, which has set in after a long period of strong growth in rental and capital values. The downturn started in London and spread over the continent. Now, German cities are also affected. The recession in the property market has partly been caused by the general economic slowdown and high real interest rates, and partly by rental and capital values that have over-appreciated. The withdrawal of Swedish and Japanese investors has only worsened the situation. Falling rentals and rising vacancy rates underscore the difficulties within the commercial property market. However, in the UK the first signs of recovery are apparent. The residential property market already had its turning-point in 1993.

### INDUSTRY PROFILE

#### Description of the sector

The various professions active within the property sector attest to the dual nature of the industry, implicit in its primary and secondary markets. Certain activities relate to primary demand and the completion of property development, whereas other activities relate to the functioning of the secondary market. Within the first category are builders, developers and consultants specialising in feasibility studies. Real estate agents operate in the secondary market, with their expertise in surveying and valuation of properties, and their role in sales transactions and estate management. In addition, the property market sector may also be divided along two alternative lines: residential property and commercial property, where the latter includes office property, retail property and industrial property.

#### Recent trends

All over Europe a spectacular expansion occurred during the past decade, peaking in the first quarter of 1991. Since then the property sector has slumped, because of economic recession, high real interest rates and unaffordable office rents.

Figure 1: Real estate  
Growth of office rents, 1993 (1)

(1) Prime rentals  
Source: ICIPA

With respect to the housing market (residential property), the overall level of transactions in the eight countries where such information is available for 1993 (B, DK, D, F, IRL, I, NL and UK) rose by 8 %, principally as a result of a 17 % increase in the German figures as well as a 38 % increase in Dutch figures annually. The number of building permits issued (excluding I and UK) rose by 5.4 %. Housing prices rose in most Member States in nominal terms, with the exception of the UK where they continued their downward trend, albeit at a slower rate than in the past. On the basis of 10 year census data, homes occupied by their owners increased in most EU Member States. There are no recent figures available for Germany.

The office sector suffered more than either retail or industrial property; values within the office sector fell by 23 %, according to the Jones Lang Wootton property index. In other than prime locations, office rentals declined between mid-1992

and mid-1993 by on average 14 %, hence less of a decline than that which prime rental values experienced. The industrial rental prices declined roughly in line with the decline of the prime office rents. Prime retail rentals experienced the sharpest drop. Interest rates on mortgage loans fell considerably throughout the EU during 1993, as national governments progressively eased the tight monetary policies, although rates again started to rise in 1994.

Still, Europe's property markets have continued to perform sluggishly in the first half of 1994 although there are clear signs of a turnaround in office property values, with rental levels generally stabilised for the first time since the early part of the decade. The index of prime office capital values rose by 2.5 % in the second quarter of 1994, although it still stands 2.7 % below last year's corresponding value.

While the overall trend is still mainly negative, there are large differences between cities and regions. Stockholm and South-European cities have been hit particularly hard in 1993. The Spanish cities were also hard hit; there, the combination of a sharp recession and overbuilding in the early 1990s has produced rental drops ranging from 33 % in Madrid and Barcelona to 12 % in Valencia. Germany seemed for a long time invulnerable to the downturn in the property markets elsewhere in Europe, but now rates for prime space in Munich, Frankfurt and Hamburg fell, respectively, 28.6 % and both 11.1 % in 1993. In Berlin, Düsseldorf and Leipzig rates remained stable.

Paris' property market saw a further downturn, with office rents falling in one year by 7.5 to even 20.7 % in La Défense. While there have been signs of stabilisation in Central Paris, increasing vacancy rates render the market still vulnerable to

further rental decline. Outside Paris the office rents are far more stable. Other EU cities also saw rental performance deteriorate as their economies continued to slow down. However, in the UK, the picture improved considerably. In London, rents fell only 7.1 % compared to 26.3 % in 1992.

Against a backdrop of a gradual economic upturn, decreasing vacancy rates and limited development activity, there is now the prospect of a return to rental growth in some areas in 1995; slightly ahead of the continent in its economic cycle, such growth will develop earlier in the UK.

#### International comparison

The commercial property markets in the USA are very large compared to other markets. 1993 marked a decisive turnaround for office property, with the national vacancy rate dropping nearly two full points to 17 %. However, the office market is quite far from equilibrium and cannot yet be termed a healthy sector. Retail property improved, although, on average, rents remained on a downward path, falling 1 %. The best performance came from the more buoyant economy in Atlanta, where shops rents rose 12 %. In 1993, industrial property in the USA continued weak; rents and prices are stagnant in the majority of markets.

In Japanese markets severe problems were felt in 1993. Office occupancy in Tokyo's prime areas slipped in 1993. Negligible until recently, the vacancy rate is now 5 % to 7 %. Rents have dropped by over 50 % in the prime area of Maranouchi; with a 23 % increase in supply, a tenant's market has emerged. The national drop in consumer spending hit rents in retail property, both the prime and secondary areas. However, rents

are likely to remain stagnant over the coming year. Industrial companies in Japan have had another difficult year. As a result, demand for industrial space has been weak. However, rents have only gone down marginally, as industrial land in the immediate Tokyo area remains in very short supply. In other areas, rents have slipped further. Japanese banks' non-performing real estate loans continue to burden the whole banking industry. The government has encouraged the establishment of an agency to hold and dispose of these debts. However, this route has remained ineffective while banks and owners prefer to hold assets with the long-term expectation that values will return.

#### Foreign trade

The increase in the proportion of international investment in the property market has slowed down in the economic recession. At the moment, the German and Dutch investors are in the front line of cross-border property investment in Europe; Middle Eastern and Far Eastern money is playing a supporting role; Italian and Spanish financial groups are taking their first steps. Meanwhile, USA and UK institutions will take longer to be coaxed into European real estate. Japanese and Swedish players, who dominated the cross-border market in the 1980s, are on the sidelines for the medium term.

A survey by Jones Lang Wootton (JLW) estimates that around ECU 65 billion of European real estate is held by cross-border investors. When one looks at the time period 1987-1993 a pattern emerges. Investors have concentrated on northern Europe. The UK, Germany and France account for nearly three-quarters of total deals. In addition, the Benelux countries have seen a high level of inward real estate investment relative to the size of their economies. Cross-border activity has been highly concentrated by nationality. Swedish, Dutch and British investors account for two-third (by number) of cross border holdings. Of the other Europeans, only the French and German have a significant number of property investments outside their own countries. Belgian and Southern European investors are virtually absent. Only 12 % (by number) of cross-border holdings are non-European, with the Japanese accounting for most inward investment from outside Europe. However, Japanese have tended to focus on prime locations, so in terms of value, they are likely to be of higher importance. However, there have been major changes in the origins of those buying European real estate. The Swedes and Japanese dominated the boom years of 1980-90, accounting for two-thirds of transactions. During 1992-1993 it was German investors who came to the fore, with most of their investments going into the UK. Middle and Far Eastern investors also increased their activity during this period, while Dutch and UK players have accounted for a fairly consistent level of demand over time.

## MARKET FORCES

### Demand

Property demand is, of course, largely determined by local factors. The most important among these are: economic growth, replacement demand, luxury demand (upgrading) and locational preferences. Economic growth creates a need for more space for offices, shops and factories. Replacement demand is the basis of demand for commercial property. Its volume is dependent on the average lifetime of real estate. Upgrading occurs in a favourable economic climate and when the existing stock of real estate is estimated to be of poor quality. Finally, other factors can increase the attractiveness of a particular location and create an additional demand for property.

Another important factor which influences demand is the availability of mortgage credit which is connected with the interest rate on mortgage loans, especially in case of residential property. For example, in 1993 the Netherlands enjoyed a relatively low interest rate of 6.7 % on new mortgage loans, while over the same period the number of housing transactions increased from 245 400 to 339 000, an increase of 38 %. With government budgets under increasing strain, mortgage credit has taken on a more important social dimension, in that it represents the principal means by which the population can obtain access to housing.

The rental market is less dependent on economic fluctuations. Unlike the sales market, it is not bound by investment logic; rental is not investment in, but rather, consumption of, real estate. Therefore, interest rates are less crucial in the rental market than in the property market.

Transfer duties are levied at the time of sale of a property. At present, France has the highest such taxes in the world with 18.2 %, compared to between 6 % and 12.5 % in most other European countries. The United Kingdom and Germany are the exception, with transfer duties of 1 % and 2 %, respectively.

The level of infrastructural provision and planning also influences demand. The three regions of Greater London, the Rhine-Ruhr and Ile-de-France comprise the principal focuses of wealth of the EU. When cities are ranked according to several factors of attractiveness, Paris and London stand out ahead of others. These cities have an outstanding infrastructure and benefit from a strong presence of multinational firms.

In the commercial property market, the shift in business demographics towards the services sector increases the demand for office properties to the detriment of industrial sites. In addition, the demand for offices is becoming more sophisti-

cated, with the development of large luxurious American-style complexes, such as the Quarter de la Défense in Paris. The domestic property market is still a sector that appears resistant to the kind of factors noted above. In this case, other factors are at work that are sometimes less pragmatic and more personal.

### Supply and competition

National and even urban markets still have distinct evolutions. However, because of the growing activities of internationally operating firms, developments in the different national or urban markets are coming more in line with each other. However, the UK market, with London at the forefront, still is trend-setting for the developments in office space.

Currently, there is an oversupply in the property market. The boom in Europe's property values during the 1980s stimulated construction, often funded by large amounts of bank debt. Economic slowdown and high real interest rates hit these markets hard. Many countries have seen office vacancy rates rise. Overcapacity in property has been even more pronounced to the extent that foreign investors, notably from Japan and Sweden, have pulled out: Japanese investors because of too low rates of return and Swedes because of home market problems. Indeed, the slump in the Swedish property market has even undermined the Swedish banking system. Sales agents were the first to be hit by the property recession. Seduced by seven years of market growth, they counted on the rapid and highly profitable turnover of property and borrowed, in some cases, up to 100 % from the banks. The recession brought major losses, aggravated by the withdrawal of the banks.

The evolution was different in central business districts and outlying areas. In central business districts, the recession initially only reduced shortages as rents remained stable, whereas outlying areas were hit more severely. As the recession continued, however, rents in the central business districts also dropped sharply.

The property investment market has gone through the same developments, but in a more pronounced way. Investors have preferred to postpone their activities while markets are gripped by uncertainty. The degree of speculation that has characterised the investment climate in the 1980s and the early 1990s caused a severance of the link between supply and demand, exacerbating the current recession.

### Production process

Office supply is fed simultaneously by the arrival on the market of new buildings (60 to 65 % of supply) and the recycling

of older ones. Few markets have a primary sector coexisting with a secondary sector to such a degree. This secondary market allows property to be used as an investment base, as it guarantees a measure of liquidity. (This role as an investment base is more pronounced in office property than in residential property. The latter has more of a community character, and is often the subject of regulation designed to preserve its social utility. This in turn holds down yields on capital investment.) This closed-circle structure accords particular importance to the role of intermediaries. They exist to help transactions (and ensure market liquidity), performing an essential role in affording investors continuity between primary and secondary sectors. Another consequence of this special configuration is that the various players in the marketplace can either simultaneously or successively adopt opposing roles: buyer and seller, provider and consumer.

Satisfying end-user demands presupposes activity by developers, investors, financial funders and consultants. Each is in competition with the next - both over the character of the product and the means by which it is acquired, i.e. purchase, rental, or leasing. Professional competence in this sector takes a number of forms:

- Local market knowledge; the ability to put a precise value on a site and its possibilities, and to define a product suited to the needs of the end-user. This factor can only be provided by local experts, and has acted as a brake on internationalisation of the sector as a whole.
- Manpower resource deployment: this activity is an integral feature of the sector. It should be pointed out that high levels of productivity are present: consultants achieve rates of ECU 150 million per employee in the larger firms within this sector, a productivity level comparable to that recorded in heavy industry. In terms of sales, volume exceeds ECU 350 billion at the level of 300 employees and above.
- Financial expertise: the professions in the property market are closely linked to the world of finance, which explains the presence of banks in the sector. Financing of the product, besides production and sale, presupposes relevant management expertise.

As in every service activity, communication capacity plays a major role. The profession is able to intervene rapidly, which is a key element for success. This is seen, for example, in the auction process, where investor reaction must be immediate. In such conditions, the larger institutions, with their hierarchical structure and their prudential constraints, are at a disadvantage in the race to obtain business.

## INDUSTRY STRUCTURE

### Companies

Within the EU, property professionals represent a workforce of around 120 000 authorised practitioners. Most agencies are small and operate at a local level. There are two categories within the property profession: developers who construct buildings on land that they already own with a view to their sale or rental, and intermediaries who make markets in the product and counsel those involved. Outside the property profession two other groups play an important role on the market: firms or persons who construct buildings for own use, and the government, often an important owner of land.

There are four types of developers:

- Independent developers who make up only a small part of the sector.
- Subsidiaries of banking or financial groups. Almost all have in-house development divisions, both as a channel for the distribution of credit and as a profitable activity in itself.
- Subsidiaries of public works and construction authorities. The larger ones tend to have development arms.
- Institutional developers. One such developer includes the association of about 15 insurers and bankers in the Société Française d'Investissements Immobiliers.

At the intermediary level, the approach to the market is characterised by an increasing professionalism at the level of estate agents, an increasing role for consultants and a progressively national/international structure. In this context, three types of intermediaries can be identified. The first type, the estate agent and administrator, is specialised in marketing and renting to end users, as opposed to developers targeting institutional investors. The second type is the consultant; as products become more sophisticated and the sector more international, this type will increase in number and importance. Such consultancies usually assume the form of small, independent practices. Their importance reflects the fact that decisions on development, investment and acquisition are wholly dependent on market conditions. The third type is the market-maker who buys to resell. These are the speculators who exploit market imbalances (notably when causing undervalued purchase prices) to their own advantage. In addition, however, they also act as a buffer, mitigating the impact of major differences between supply and demand. Their ability to play this role depends on their capacity to carry a property over a period.

### Strategies

One current striking characteristic is the emergence of widely divergent strategies on the part of developers. Until recently, developers tended to adopt similar strategies; they were typically small-scale and unambitious, finding it difficult to operate on an international level in such a conservative profession. The current trend, however, is towards integration of upstream and downstream activities: development-proper upstream and commercialisation downstream.

One can also identify a growing tendency to extend the range of products offered in an attempt to reduce dependence on the vagaries of a single market sector. An example of this resides in developers, originally specialised in housing, who reposition to profit from the boom in office property. Two major strategic groups of developers can thus be identified. Some have elected to diversify into complementary development activities such as administration, hotel chain management or even insurance, which do not share the cyclic nature of property development. Others have opted to remain specialised, but have also diversified their product portfolio and attempted to become more international in scope.

For several years now, intermediaries have tended towards the Anglo-Saxon model of consultancy. This strategic transformation, which is accompanied by an increased presence of banks in the marketplace, has facilitated globalisation of the property market. The main consultancy offices assume the role of go-between by opening up their domestic mar-

ketplace to foreign partners. This development also admits a larger volume of transactions, regardless of the size of the market. For instance, while the office markets in London and Paris are almost the same by volume, there may be (depending on the period in question) between ten and twenty times more transactions in London than in Paris.

The present recession in property has induced the inadequate financial resources of estate agents. Developing these resources has emerged as a priority objective, and agents are working more closely with the banks to allow the development of projects for which no immediate client has necessarily been identified.

Despite growing globalisation of the property market and the increasing sophistication of products - both of which aim towards responding increasingly to demand along the lines of the Anglo-Saxon model - consumers tend to remain more attached to traditional national models.

### Impact of the Single Market

In the market for commercial property there has been a (positive) impact of the creation of the Single Market. The market as a whole is easier to identify and easier to reach as the market participants have started to think and act more internationally. This has resulted in the formation of informal groups and the exchange of information. In the market for residential property there has been no impact at all. The mutual recognition of diplomas, the related differences in level of education and the differences in requirement for obtaining licenses are barriers which have to be removed with high priority. The existing directive on the mutual recognition of diplomas seems to be applied only in one or two countries. Another priority concerns the 'timesharing'-directive. In this respect, the policy concerning transborder operations still needs to be clarified.

---

## REGIONAL DISTRIBUTION

---

Most real estate activity is concentrated in northern Europe, in an area that is bounded by Paris, London and Frankfurt and includes the Brussels area, the 'Capitals Centre'. This region has more than 30 % of employment in the EU (excluding the new German Länder) and more than 35 % of gross value added in the EU. London and Paris house the largest volume of office space in Europe, with a total surface area of around 32 million m<sup>2</sup>. Other European capitals typically average around 5 to 6 million m<sup>2</sup>.

As manufacturing activity moves increasingly out of the cities, European urban development is to a considerable extent influenced by the existing infrastructure and knowledge related to market services. These historically "locked-in" advantages create a significant element of rigidity in the economic ranking of European cities. London for instance has retained its prime position for financial services because of first-mover advantages (gained mostly to the early liberalisation of markets), and because of the depth of the supporting financial and business services.

However, the opening up of markets, political and infrastructural changes provide all challenges to established patterns. The cities best positioned to prosper in the more competitive environment are those that have attracted unique international functions and that have a critical mass of activity and infrastructure sufficient to support the presence of specialised services needed locally by other activities.

---

## REGULATIONS

---

The regulatory provisions that affect the real estate profession vary widely from country to country within the EU. Generally speaking, regulatory provisions apply mainly to estate agents. Certain countries - Denmark, Spain, France and Italy - have erected major barriers to entry into the profession; elsewhere, professionals are subject to the provisions of common law.

The abolition of exchange controls in France, Spain and Italy has facilitated greater intra-EU competition. The second banking coordination directive ensures that the remaining obstacles to cross-border activity are eliminated.

With the exception of Greece, Portugal and Denmark, each EU jurisdiction has a professional charter. However, further harmonisation of regulations on an European level will be an ongoing process.

---

## OUTLOOK

---

The outlook for the real estate industry is one of modest growth, which means that in the medium term, the current downturn will be reversed into a moderate upturn. In the medium term, growth in the real estate sector will pick up, but will not achieve the high growth rates of the 1980s. This outlook is based mainly on the anticipation of a slow recovery of general economic conditions. Moreover, growth will differ strongly between cities. There will be marked differences between central business districts (CBD) and outlying areas; for the latter, development prospects appear less promising.

Furthermore, one of the promising investment areas will be retail property, worldwide. In the 1980s, most cross-border investors concentrated on offices, which have been badly hit during the 1990s cool-down. Retail property - especially shopping centres - has shown better defensive qualities and is expected to lead offices and industrial property out of recession.

There can be identified four major longer term trends which offer good performance prospects. First, out-of-town retailing and shopping centres will grow in importance in several countries. Second, Eastern Europe will continue to develop and markets which allow access to the east will benefit. Third, high quality central business district (CBD) offices and shops in prime locations should recover as economies resume growth. And fourth, the relevance of "lifestyle" employment will increasingly influence corporate location decisions and, as working populations decline, will boost areas which can attract employees.

**Overview**

*Business services experienced considerable growth and development throughout the eighties. The market has been powered by greater awareness of the benefits from increased externalisation of certain activities. The recent slump in economic activity has, however, slowed down growth in a number of business services and even resulted in loss of turnover in some subsectors. In general though, the business services sector appears to be less vulnerable to economic downturns than the services sector as a whole. Prospects for the sector are rosy. As customers progressively recover from the economic downturn, performances are likely to strengthen over the coming years.*

**INDUSTRY PROFILE**

**Description of the sector**

The business services sector comprises a number of heterogeneous activities engineered by specialised companies, aimed at assisting customers in order to increase efficiency, productivity and competitiveness. The sector, classified on the basis of the function performed on account of the client company, includes the following subsectors:

- management and administration services (legal services, accountancy services, management consultancy, etc.);
- production services (architecture, engineering, operational leasing, repair and maintenance, packaging, quality control, etc.);
- research-related services (market research);
- personnel-related services (vocational training, labour recruitment, supply of temporary labour, etc.);
- information and communications services (software and computer services, advanced telecommunications services, data banks, etc.);
- marketing services (advertising, direct marketing and public relations); and
- operational services (industrial cleaning, security services, linguistic services, etc.)

**Recent trends**

The business services sector employs over 7 million persons, which is well above 5 % of total EU employment. The Netherlands has the highest share of persons employed in business services; nearly 7.5 % of total employment.

The business services sector was amongst the fastest growing sectors of the economy throughout the eighties. The economic recession which hit the EU during 1991 to the beginning of 1994 translated, for most subsectors, only into slower growth of business services activity. This was an outstanding performance which illustrates the relative insensitivity of some of the business services sectors to economic downturns. Significant growth was the result of increasing externalisation of these types of activities, coupled with the introduction of important innovations in service management. But, the major factor that generated such growth was the strong demand for these services, sustained by the expansion of economic activity.

Moreover, unfavourable market conditions have led industrial or financial organisations to get rid of in-house services and non-core activities, such as economic services, legal or mar-

**Figure 1: Business services**

Source: Eurostat: International trade in services

keting services, and to use professional consultants instead. This occurred particularly in 1992 and 1993, when companies were in the throes of a financial turmoil. Interestingly, dismissal from industrial or financial companies led some people to either join existing business services firms or to establish their own company. This phenomenon has counted among the factors underlying the increasing externalisation of business services.

A case for concern is the considerable decrease of the trade surplus over the years: from 3.8 million ECU in 1980 to 0.4 million ECU in 1991. The emerging global market, the sector's dynamism and freedom of geographic location, facilitated by advanced information technologies, may well account for this phenomenon.

## MARKET FORCES

The business services sector has been relatively sheltered from the economic downturn. Despite the poor financial position of the sector's customers, the business services industry reported continued growth of employment, albeit at a slower pace. Outstanding performance can be explained by the need for customer companies to meet such challenges as new technologies, emerging or plummeting markets, or new regulatory environments. Determination to maximise competitiveness under changing and difficult business conditions has obliged firms to increasingly externalise functions requiring new or specialised skills that they either cannot afford or do not want to acquire for their own premises.

Furthermore, the economic downturn has led a significant number of industrial and financial organisations to try and find new forms of production organisation or production processes, in order to get out of the turmoil. This translates into increasing demand for business services aimed at supporting their client's activity.

## INDUSTRY STRUCTURE

The business services sector is characterised by considerable fragmentation and intense competition. The sector is composed of a large network of small companies, a size which gives them the flexibility, quality and specialisation necessary to perform their businesses. However, in activities where economies of scale are important, companies are usually larger. Overall, the sector counts a limited number of large, often multinational, firms. Consulting engineering, accountancy, market research, testing, inspection, quality control and some operational services are subsectors of the business services

industry where larger firms (i.e. companies with more than 50 employees) can be found.

## REGIONAL DISTRIBUTION

As far as marketing or research services are concerned, location of offices does not necessarily depend upon demand. Furthermore, the development of information technologies gives companies, active in these businesses, increased flexibility and freedom in the location of their offices. Consequently, these companies are often found in large urbanised areas; particularly around national capitals.

In contrast, for operational, production, labour-related, management and administration services, it is a real advantage (sometimes even mandatory) to have offices in the places where high demand is expected. For example, vocational training is typically an activity highly correlated with population distribution and economic activity. This service is, consequently, quite evenly spread over the EU; although, a bigger concentration is observed in urbanised and more industrialised areas.

The major European economies are the largest employers in the EU's business services sector. Germany and the United Kingdom lead with approximately 1.7 million persons employed, while France and Italy follow with approximately 1.4 and 0.9 million, respectively. The average share of part-time workers in business services amounts to nearly 15 % in the EU. The largest shares of part-timers are to be found in The Netherlands (24.7 %), Denmark (20.9 %), and Germany and the United Kingdom (both 18.5 %). The share of female workers in business services ranges from 36 % in

**Table 2: Business services**

Spain to 46.3 % in France, against an average of 43.5 % for all Member States.

Along with differences in the size of the workforce, there are considerable differences in market growth between Member States. Variations mainly reflect the diversity of industrial market organisations that can be observed in the different Member States. In this regard, the EU's southern countries have posted more rapid expansion in the second half of the eighties than the Big Four economies, in line with the process of integration of these economies in to the European Union.

## OUTLOOK

In the future, quality of service will constitute a key asset for companies to increase their market positioning.

For the time being, strategic alliances and mergers and acquisitions involving companies from different Member States are not very numerous. However, an acceleration of this concentration is foreseeable, thanks to the increased integration of the EU's business services practices, and the facilitation of the movement of services through the development of international communication and information networks.

As customers of the business services sector progressively recover from the economic downturn, performance in the sector over the coming years is likely to strengthen, leading to a further increase in employment.

Written by: Bakkenist Management Consultants

# Advertising and direct marketing

NACE 838

*Due to the recent recession in most EU countries, the total expenditure on advertising and direct marketing for 1993 was only marginally higher than in 1992. The turnover of advertising actually showed a decrease, although this was compensated for by a considerable increase in expenditure on direct marketing. Advertising agencies are expanding into direct marketing because it is regarded as a business sector with a greater potential for growth than general advertising. The value of direct marketing has been recognised for longer in the United States than in Europe. Hence, it has reached higher levels of sophistication there. On average, it is estimated that the US is ten years ahead in terms of direct marketing innovation. Thus, a high degree of technological development can be expected in this sector.*

*Due to the positive outlook for the European economies, the expenditure on advertising and direct marketing will increase. Consequently, the agencies will keep their turnover at a high level. Competition between agencies will become tougher and the investment in information technology (IT) will increase the costs of many agencies. Therefore, an increasing degree of specialisation is expected.*

## INDUSTRY PROFILE

### Description of the sector

Advertising and direct marketing is classified under section 838 of NACE, called advertising. The turnover of the sector was approximately 75.5 billion ECU in 1993, making it one of the most important service sectors in Europe. Also in 1993, advertising accounted for 61 % of turnover, direct marketing for 39 %. Both professions have one thing in common: an ability to deliver vital information effectively. The sector is engaged in communications services that promote ideas, goods and services.

### Advertising

Advertising is the main form of mass selling. It tries to communicate with a large number of customers simultaneously. Mass selling is less flexible than personal selling, but when

the target market is large and dispersed, mass selling may be less expensive. Advertising is any paid form of a non-personal presentation of ideas, goods or services by an identified marketer. It involves the use of such media as television, radio, cinema, newspapers, periodicals and outdoor posters and billboards. In 1993, newspapers and magazines took up approximately 56 % of the total advertising expenditure, with television accounting for 33.5 %, and radio/cinema and outdoor advertising making up the remaining 10.5 %.

Europe counted almost 160 television channels in 1993, of which six reached more than ten countries: Eurosport, MTV, TV5, CNN, Euronews and NBC. Compared to 1980 figures, the number of television channels had more than doubled. There are almost 7 000 commercial radio stations, 19 000 cinema screens and 2 000 000 outdoor billboards in Europe. France, Germany and Italy have the highest number of cinema screens and billboards. Along with Spain, Italy has one of the highest numbers of commercial radio stations as well.

Some major pan-European publications (with a circulation of more than 150 000 copies) are: the Financial Times, the International Herald Tribune, The European, The Economist, Newsweek, Time and National Geographic. In-flight magazines are considered an important pan-European medium also. The in-flight magazines with the highest circulation (more than 200 000 copies) are: Bordbuch (Lufthansa), Swissair Gazette (Swissair), Atlas (Air France), Motion (Olympic), High-life (British Airways), Ronda (Iberia) and the Holland Herald (KLM).

### Direct marketing

Direct marketing is a series of different marketing techniques which use a number of different media to allow direct contact between an organisation and an individual consumer or company, in order to achieve the maximum response. Most definitions of direct marketing encompass four areas: direct mail (mail order catalogues, addressed, un-addressed and bulk mail); direct response advertising in the printed press and broadcasting, including teleshopping systems and other mass media (cinema, outdoor and transport); marketing by telecommunications (telephone or fax); and interactive communications, e.g. videotext. One of the main perceived benefits of direct marketing is its accountability, but as it becomes more widely accepted and integrated into the mainstream activities of advertising and marketing, it has to compete on other grounds as well. For example, direct marketing is increasingly being asked to improve brand awareness. Direct marketing has always been a readily quantifiable form of pro-

motion. Be it direct mail or telemarketing, response rates can be measured and segmented by age group, socio-economic group, region, etc. But when combined with above-the-line advertising, direct marketing becomes an even more powerful tool. Direct mail accounted for approximately 52 % of the total expenditure on direct marketing in 1993, with direct response advertising for 32 % and telemarketing for 16 %.

### Recent trends

Due to the recent recession in most EU countries, the total expenditure on advertising and direct marketing for 1993 was only marginally higher than 1992 (i.e. less than 1 % higher). The total expenditure on advertising and direct marketing was around 75 billion ECU in both 1992 and 1993. In 1992, advertising accounted for approximately 64 % of the total expenditure, while in 1993 the share of advertising accounted only for 61 % of the total expenditure. The turnover of advertising also showed a decrease of almost 6.5 % (48.7 billion ECU in 1992 down to 45.5 billion ECU in 1993). Despite the recession, the turnover of direct marketing increased almost 12 % in 1993 over 1992 (26.7 billion ECU in 1992 to 30 billion ECU in 1993).

### Advertising

Advertising agencies define turnover or 'billings' in terms of the amount of money they spend with the media on their client's behalf. Normally, the gross earnings are fixed as 15 % of turnover. The mass media with the highest billings by advertising agencies are newspapers and television. Both media together account for more than two-thirds of the total adver-

tising expenditure. In 1993, the printed press accounted for approximately 56 % of the total advertising expenditure, television for 33.5 %, with radio/cinema and outdoor making up the remaining 10.5 %. The average expenditure on advertising in the EU is 131 ECU per capita. Spain, Denmark and Germany have the highest per capita expenditure, at more than 150 ECU.

Television is the only sector to expand its share of total advertising expenditure in all mass media since 1990. Over the last ten years, there has been a massive expansion of choice in television viewing in almost every country in Europe. This expansion was due to the development of communication satellites, and consisted mainly of new commercial stations, financed by advertising. When new channels are launched, viewing often increases, because the new channels frequently broadcast for longer hours. Therefore, competition tends to increase the total audience in underdeveloped markets, but it has very little effect on saturated markets. Further competition in countries such as the UK, France and Italy has led to the fragmentation of existing audiences, rather than an increase in them. Television is generally not competitive with other media for more than a very small proportion of its revenue, as each media serves a different purpose for the advertiser.

Roughly ten to fifteen per cent of the total workforce is self-employed. Usually they are photographers, illustrators, designers, copywriters and translators. Average wages are higher in advertising than in direct marketing because more specialised people work in advertising.

### Direct marketing

Direct marketing is a large industry, which contributes a significant amount to the total marketing expenditure. Where comparisons can be made with earlier years, the direct marketing business appears to be becoming increasingly important, even in spite of the recession.

Direct marketing is traditionally less expensive than mass media advertising because creative and production costs are lower. The importance of direct marketing also will increase as its customers have access to new electronic media such as E-mail, teletext, Minitel and other telecommunications systems.

About 52 % of the total expenditure is accounted for by traditional direct mail, and 32 % by direct advertising in mass media and specialist media which generate responses through the return of coupons or telephone orders. The average annual growth rate of direct mail since 1981 across Europe is calculated at 7 %. France, the UK, the Netherlands, Belgium, Spain and Denmark all have achieved growth rates in excess of the average. On the other hand, the largest market, Germany, has experienced a below-average growth. Telemarketing, by telephone or by electronic media, accounts for 16 % of the total expenditure but its proportion is growing.

The expenditure on direct marketing in the EU is 87 ECU per capita on average. Denmark, the Netherlands and Germany

have the highest expenditure per capita, above 135 ECU. Expenditure per capita on direct marketing in 1993 was 66 % that of advertising. In 1992 this was 56 %. It should be noted that direct response advertising in the mass media (broadcasting, press, etc.) is counted twice (i.e. calculated for both direct marketing and for general advertising). An increasing volume of direct marketing is included in the marketing sector, where direct marketing is replacing the more expensive form of promotion by salespeople.

### International comparison

Since 1981, the EU narrowed the gap between its advertising investment and that of the United States. In that year, EU advertising was only 50 % of US expenditure for advertising. In 1992, the EU was able to reach 85 % of US expenditure, but EU expenditure in 1993 dropped to 69 % of US expenditure in 1993. The largest medium in the US in 1993 was newspapers, with 40 % share of total expenditure. Television had been the most important medium in 1992.

Japan saw a four-fold increase from 1981 to 1991. After a little dip in 1992, expenditure on advertising increased to almost 17 % in 1993. Japan's most important mass medium is still television, which accounts for about 40 % of the total advertising expenditure.

In relation to GDP, Japan has a smaller advertising expenditure than the United States and Europe. However, in relation to the expenditure per capita, Japan's advertising expenditure is larger than Europe's.

Germany still held the first rank in total advertising expenditure for Europe in 1993, followed by France, the United Kingdom and Spain. Concerning the expenditure per capita, Spain is in first place. It is important to note that the importance of mass media varies enormously across Europe. Newspapers are by far the most important medium in Denmark and Ireland; while television dominates in Spain and Greece. The ranking of direct marketing expenditure per capita is led by the Netherlands and Denmark.

The value of direct marketing has been recognised for longer in the United States than in Europe and hence has reached higher levels of sophistication there. On average, it is estimated that the US is ten years ahead in terms of direct marketing innovation. Direct response television is extensively used in the US and has developed into the so-called infomercial. Infomercials are basically extended advertisements, commonly lasting as long as 30 minutes. They are one of the fastest growing television advertising sectors in the US.

## MARKET FORCES

### Demand

#### Advertising

The major products advertised are consumer products of both the food and non-food sectors. The most important are: alcoholic beverages, food and drink, baby care products, cosmetics, pharmaceuticals, tobacco products, sanitary products, toiletry goods, motor vehicles and car accessories, and financial services.

Very few large international companies run their own advertising department. Instead, most use advertising agencies. Multinational companies prefer working with advertising agencies with offices in all key markets. Advertising also plays an important role in promoting retail outlets. Although small and medium-sized companies often cannot afford organised advertising campaigns, the increase of local television and radio stations should induce more local advertising campaigns by these companies.

#### Direct marketing

Direct marketing helps promote customer loyalty and supports sales activities. Direct marketing is extremely popular for local companies, and allows local retailers, service providers and producers to contact consumers directly by means of addressed, un-addressed and bulk mail, free newspapers, local television, radio and cable systems, or by telephone marketing. Direct marketing is designed by either advertising agencies, specialised direct marketing agencies or is done in-house by the advertiser. Most telephone marketing is done in-house, although the use of telemarketing agencies is increasing, as a number of agencies now offer creative services to companies wishing to launch a telemarketing campaign. This occasionally extends to designing and printing support materials, but more often will include a liaison with an advertising agency and script writer. Telemarketing agencies are also offering inbound as well as outbound telephone systems (i.e. the taking of orders from direct response advertisements), which has increased their appeal.

According to a recent survey, 70 % of all printed press advertising now carries a direct response mechanism, and the proportion of direct response television commercials is increasing. So far, the main users of direct response television advertising have been services, charities and travel agencies, but the next area of growth is predicted to come from FMCG, toiletries and cosmetic companies.

**Table 8: Advertising and direct marketing  
Distribution of total advertising expenditure by media, 1993**

### Supply and competition

No regulatory barriers exist to starting an advertising or direct marketing agency in Europe. Newcomers face difficulties entering the market, however, since client loyalty is quite common in this business. Consequently, the market is dominated by large, well-established agencies. International companies mainly choose a single agency which has offices in various countries.

Unlike other mass media, television is still tightly regulated in almost every country, and the ways in which the governments do this affects the amount of advertising carried. As a result, television expenditure is still more closely linked to advertising exposure - defined as the advertising time allowed on each channel multiplied by its audience - than it is to GDP. The potential for pan-European direct marketing is increasingly recognised, at least for major brands. The majority of direct marketing agencies, however, have neither the personnel nor the networks necessary to exploit this potential. Therefore, it is likely that the major agencies will increase their share of direct marketing business if demand for a pan-European service becomes evident. Data protection, sales taxes (VAT), the quality of postal services and other national rules have retarded the use of the single market.

International competition between direct marketers is determined by differences in standards and costs (especially labour costs) between the various countries. However, direct mail can not exploit the benefits of low product costs for high volume printing, or lower postal tariffs offered by some countries due to strict rules on remail imposed by national postal monopolies. This has reduced the potential for freight and courier companies to enter the delivery market for direct mail.

This trend is expected to become more restrictive over the next five years.

### Production process

Direct marketing depends on databases, which are becoming increasingly sophisticated in their ability to target and to create a dialogue with the customer. Direct marketing agencies, including list brokers and telemarketers, can build and update client databases, offer database management services, cleaning, updating and re-formatting. It is expected that direct marketing will become a major source of financing for the information super-highways.

## INDUSTRY STRUCTURE

### Companies

The sector is dominated by large advertising companies, which include direct marketing services. Within Europe, 16 agencies have more than 1 500 employees. All of them are working on an international level.

Advertising agencies are effectively divided into two types:

- large, multinational agencies and agency groups;
- small to medium-sized agencies mainly operating in domestic markets.

Both groups are represented in the European Association of Advertising Agencies (EAAA). The aggregate membership represents about 1 800 agencies, which place about 80 % of all media advertising and a very high percentage of all marketing communications in Europe.

**Table 9: Advertising and direct marketing  
European advertising expenditure by medium**

(million ECU)	1980	1990	1991	1992	1993

18	TBWA	634.50
19	Testa International	623.40
20	Conquest Europe	311.70

Source: EAAA, Campaign

Since 1992 there has been a slight change in the ranking of the top five agencies. Young and Rubicam dropped from fourth to sixth place and BBDO (UK) rose to the fourth position, up from twelfth. The top 20 European agencies are still headed by Euro RSCG (F), followed by Publicis FCB (F) and McCann Erickson (UK).

### Strategies

Advertising agencies are increasingly expanding into direct marketing because it is regarded as a business sector with a higher potential for growth than advertising. This notwith-

standing, the spectacular growth which the direct marketing industry has experienced over the past ten years is now predicted to slow down. This is likely to force direct marketing agencies to expand their range of skills and services offered on the one hand, while increasing their degree of specialisation in serving a particular industry on the other. And, with respect to technological development, a high degree of innovation can be expected in the field of direct marketing (e.g. interactive media and automated response).

### REGULATIONS

Regulations have an important effect on advertising and direct marketing, and vary from country to country. As recently as five years ago, there were only four countries in Europe with any kind of competition in television airtime sales; and large parts of northern and eastern Europe had no TV advertising at all. By 1994, this situation had changed considerably. Advertising is now legal everywhere, yet a monopoly is still maintained by only four countries: Ireland, Finland, Austria and Switzerland.

At present, European directives exist on misleading advertising, pharmaceuticals, baby foods and tobacco advertising. There are also rules on various other product sectors, often related to labelling. Other notable EU regulations include credit, public procurement, copyright, broadcasting, product safety, product liability, etc. Meanwhile, directives concerning data protection and distance selling, environmental packaging waste, postal services and database protection will provide a major contribution towards harmonising the legislative environment in which direct marketing takes place.

The Commission is currently preparing a Green Paper on commercial communications (due in June 1995). This Green Paper seeks to examine the whole area of marketing communications in terms of their key role in the Internal Market. It will be the basis for a more co-ordinated Commission policy approach in this field. The Commission ran a survey asking operators to identify the key regulatory barriers that they faced when planning, designing and undertaking transborder campaigns. The result of this survey will form an integral part of the Green Paper.

**Table 11: Advertising and direct marketing

## Impact of the Single Market

The effects of the Single Market have been positive for the advertising industry. It has resulted in the development of new markets and consumer demand for information concerning products and services available in other Member States. However, the industry is experiencing certain difficulties due to a number of economic and regulatory issues, as well as barriers preventing free competition.

The further development of a single currency and harmonisation of the level and manner of taxation of advertising currently form the most important economic priorities. Within the existing regulatory framework, considerable differences exist between Member States regarding advertising for alcohol, tobacco and pharmaceuticals as well as advertising directed at children. Harmonisation is needed in this respect.

Forms of protectionism of national markets through stringent packaging and labelling standards and the overly dominant position of media companies in a number of Member States, most notably Italy, are considered to be the most important obstacles to free competition within the Union. The industry also experiences the cost of telecommunication, provided by amongst others, national monopolies, as being extremely high.

The Direct Marketing industry perceives the objectives of the Single Market as positive. However, the actual benefits have been negligible. This is proven by the fact that only 3% of the turnover in consumer goods is generated by cross border trade. Trade is hampered by the different forms of cross border payments being used (cash or electronic), difficulties related to exchange rates and the level of the bank charges involved in cross border payments.

The most important barrier to further expansion of the European Direct Marketing industry is formed by the national postal services which have generally employed protectionist measures to safeguard their national markets. Furthermore, different levels of indirect taxation (VAT) in Member States as well as a lack of clarity on VAT exemption inhibits cross border activity.

The outlook for the industry is nevertheless positive, amongst other reasons because of the impending break down of telecommunication monopolies throughout the Union as well as the technical developments in communication.

## OUTLOOK

Due to the positive outlook for the European economies, the expenditure on television advertising is expected to grow. This will have a marginal but positive effect on magazine advertising.

On the other hand, while many of the largest markets in Europe are already broadcasting almost 24 hours a day, many channels will be launched in the coming years which are unlikely to increase overall viewing in these markets. So, television audiences will increasingly become a fixed commodity. If the total audience is fixed, then individual television station audiences must fragment as the number of stations increases. The same trend will be applicable to radio stations.

There is no evidence that the multimedia interactive communication superhighway will have more than a marginal effect on television advertising. Nor is there currently a clear demand for personal scheduling of programmes, or ad-free channels. However, the interactive systems will have a profound effect on direct marketing.

Increased expenditure on advertising and direct marketing will enable agencies to keep their turnover at a high level. Competition will become tougher, and investment in information technology will increase the costs of many agencies, because of the degree of specialisation required.

# Public relations

## NACE 838

Today, a growing number of companies, organisations and public institutions are using public relations as a tool to develop communications towards public opinion or to pursue specific targets related to a company, its products and services.

### INDUSTRY PROFILE

#### Description of the sector

Public relations (PR) tools are used to establish and to develop appropriate relationship systems between an organisation, its products and services and the public opinion, according to the company's targets and with the objective of gaining, main-

taining and developing public confidence, acceptance and satisfaction.

Therefore, public relations are the result of a combination of different elements, such as human sciences applied to individuals; all this takes place in a context which uses communication channels, means and techniques that must involve the public's interest and expectations. The publics to which public relations refer may be identified as follows: journalists, consumers, employees, shareholders, public authorities and civil servants, the local community, suppliers, labour unions, competitors and so forth.

Handling systems of relationships with a wide range of publics implies specialisation tools to be applied in different areas, such as media relations, consumer relations, corporate and internal communications, product advertising, environmental issues, crisis management, house publications and audiovisuals, sponsorships, financial relations, public affairs, community relations, institutional advertising, business to business communications and so on.

### Recent trends

The European Confederation of Public Relations (CERP) carried out a study among the national PR associations of 19 European countries - the 12 members of the EU plus Austria, Cyprus, Finland, Norway, Slovenia, Sweden, Switzerland, i.e. all full members of CERP in 1993.

The objective of the study was to update the existing data on the PR profession with reference to the researches performed by CERP in 1991 and 1992.

The 1993 survey shows that the PR sector is overcoming the critical period linked to the economic recession, as a result of a general turnover increase, which in each country was above the inflation rate: the total turnover of consultancy fees reached 1.80 billion ECU versus 1.65 billion ECU in the previous year (which represents an increase of 9.1 % in nominal terms).

*(1) Excluding Luxembourg 1991**Source: CERP*

This situation is mostly due to two contributory factors:

- firstly, in the mix of enterprise communications, investments in advertising are decreasing in many European countries, in favour of other communication means, in particular public relations;
- the other reason is that during economic recessions, companies' communications mainly refer to very specific targets: also in this case, there is a stronger use of PR, due to its selective character.

In 1993 the number of PR agencies and PR firms in the twelve EU Member States was estimated at around 5 080, including 607 PR agencies and 4 473 PR firms, with a total occupation of 6 282 employed consultants, to which 13 670 freelance consultants must be added, reaching a grand total of 19 952 consultants working in the PR sector.

If we consider the annual turnover derived by consultancy fees in the twelve countries of the EU, the highest figures are to be found in the UK (190.4 million ECU), followed by Germany (144.1 million ECU), the Netherlands (59.5 million ECU), France (48.8 million ECU) and Italy (45.2 million ECU).

If we consider the number of consultants, the first place goes again to the UK, where 6 525 people work in the sector, followed by Germany (5 700), Italy (2 254), France (2 201) and the Netherlands (1 620).

## INDUSTRY STRUCTURE

### The current situation

The PR consultancy sector is made up by PR agencies, PR firms, freelance consultants.

A PR agency is usually a registered firm, a company created and managed by some consultants working together and providing full service in PR. On average, a PR agency is composed by a minimum of three to a maximum of ten PR consultants, assisted by executives and secretarial personnel.

A PR firm is a small unit, usually not registered as a company, created by one or two consultants working with a small sec-

retarial support and handling PR services in some specialised areas. Usually, a PR firm does not cover all publics and issues related to global corporate communications.

The freelance consultants mainly provide their professional service in two different ways: some of them operate on an annual contract basis for two to three clients, covering the largest part of the clients' communications needs. Others operate under contracts for specific short term PR projects related to single issues, publics and clients' needs.

### Impact of the Single Market

The impact of the Single Market on the Public Relations sector has been positive. Considering that the same products and services are made available in all Member States, the establishment of a system of relationships between companies and specific targets of people who buy these products and services are all important.

Harmonisation is still needed in a number of fields. Regarding training and education, Public Relations is taught at a number of schools across Europe, however, the programs differ between schools and countries. Secondly, the professional codes of conduct adopted by the National Associations are homogeneous, but due to the different legal situations, the application of these codes varies from country to country. Thirdly, concerning the fee system, only the principles are common, not the procedures and the related applications.

# Legal services

## NACE 835

The advent of the EU has focused attention on a number of large-scale changes which are reflected on a much smaller scale within the legal professions. These trends are characterised firstly by a process of harmonisation, or recognition and simplification of common elements; and secondly, by acknowledging the need to compete in a supra-jurisdictional marketplace. The process of simplification is taking place in both common law and civil law jurisdictions, and not only in the EU. Over the past few years, international legal practice has been growing rapidly. Within the EU, economic integration and growing trade have challenged the traditional jurisdictional restrictions that have characterised legal practice. Multinational partnerships are permitted within the EU and function to varying degrees within a number of Member States. These developments are likely to continue.

### INDUSTRY PROFILE

#### Description of the sector

In this context, the legal services sector covers all professional staff working in the liberal legal professions within the states of the EU. In general, the following professions fall within this definition:

- Advocates, barristers and solicitors (as defined in the EU Directive to facilitate lawyers' effective exercise of freedom to provide services (77/249));
- Public notaries;
- Patent lawyers;
- Legal consultants.

Lawyers undertaking legal work as employees of central or local government, the judiciary, prosecution services or commerce and industry, respectively, are not included.

Since figures relating to the number of firms, employees and turnover in some countries are derived from VAT and social security registers, a large proportion of the firms, as well as employees (e.g. self employed persons), and turnover are not registered. The figures are also difficult to compare because

of the emphasis on in-house lawyers in some jurisdictions, whom are included in some figures (e.g. in Italy and France), and not in others (e.g. Germany). For certain countries, more detailed information is available on some sectors in the legal services.

This monograph mainly covers registered lawyers (advocates etc.) and notaries. However, it is important to note that the boundaries between these professions differ between, and even within, countries. The services provided by the legal professions (i.e. by "lawyers") fall within the following general categories: negotiation on behalf of a client; the preparation of legal documents; legal advice; and representation of clients before Courts, Tribunals and administrative bodies. The principle function of a notary is to prepare deeds and legal documents (e.g. wills and documents for the transfer of real estate).

In total, there are almost 400 000 registered lawyers in the EU, and the number of notaries is estimated at between 30 000 and 40 000. The first figure may include lawyers that are registered but not currently practising as such. The Athens Bar Association estimates that between a quarter and a third of its members are not practising. In Spain, more than 22 000 of the registered advocates fall under the same category. Even if one takes into account the many registered lawyers in these countries that are not in practise, it is apparent that Spain and Greece have the highest number of registered lawyers per 10 000 inhabitants, followed by the UK, whereas France and the Netherlands have the lowest. Meanwhile, Spain and the Netherlands have the lowest number of practising notaries per 10 000 inhabitants, whereas Greece, France and Germany have the highest.

Such differences are in part explained by the differences in the legal systems of these countries. In Denmark, there are no notaries and their functions are carried out by the city courts. In Scotland, every solicitor may become a notary public and 95 % of the solicitors in Scotland do so. Many lawyers in Spain also perform notary functions, although not registered as notaries.

#### Recent trends

A key trend in the legal services is that, in the absence of a distinct limit to their size (numerus clausus), firms have been growing rapidly. It is estimated that between 1989 and 1993, the number of professionals providing legal services has increased on average by over 20 % across the EU, with the

largest individual increases in Luxembourg, Portugal, and Belgium.

The advent of the EU has drawn attention to a chain of large-scale trends reflected on a much smaller scale within the legal professions. These trends are characterised firstly by a process of harmonisation, or recognition and simplification of common elements; and secondly, by acknowledging of the need to compete in a supra-jurisdictional marketplace. These two characteristics dictate a third development: the establishment of international regulations to codify and structure behaviour in the new system.

The process of simplification in the legal professions is taking place in both common law and civil law jurisdictions, not only in Europe. The legal professions in the UK, Germany, France, Greece and Spain have undergone, and will continue to experience, substantial structural and legislative changes.

In Germany, reunification triggered the re-orientation process of the domestic legal services market to shift from a focus on small firms working within court-delimited areas of practice, to trans-local firms with as many as 80 partners, and offices in cities throughout Germany. A number of these new trans-local firms have subsequently set up offices in Brussels and then moved on to enter alliances and networks with other European law firms.

The considerable shifts in policy towards the public funding of legal aid in a number of countries constitute another, possibly important, factor with respect to the provision of legal services. Although many areas of law and legal practice are becoming more European in character, legal aid appears to remain something that primarily is defined by national policy. Given national parameters, no government (with the exception of France the expenditure of which prior to the 1992 reforms was one of the lowest in Europe) is expected to increase expenditure on legal aid. A situation, common to a number of countries, is that the state wishes to control the steady increase in legal aid expenditure, whereas law professionals have indicated that the provision of work that falls under legal aid is becoming increasingly unprofitable for them to carry out. In some jurisdictions, legal-aid work accounts for as much as 12 % of the estimated gross income in the legal services.

### International comparison

Reliable data on the patterns of development in the US and Japanese markets for legal services are also difficult to obtain, as individual states (including the District of Columbia) are considered to be separate jurisdictions, and there is little information available on Japanese lawyers in private practice. In 1986, there were 12 500 licensed lawyers in Japan of which approximately 9 000 were in active practise. This equals roughly one practising lawyer per 14 000 people. Meanwhile, the number of law graduates from Japanese universities is high, between 65 000 and 70 000 per year. Approximately 30 000 to 35 000 per year take the examination to continue their training to become advocates, judges or public prosecutors. However, in 1993 only 712 passed the examination, hence the low number of lawyers in private practice. Most of the large corporations in Japan have in-house legal departments staffed by non-licensed law graduates. A licensed lawyer is used only when a court appearance is necessary.

Japan appears to be opening up its borders for foreign lawyers. The results of the GATT negotiations will have positive effects in this respect. A law has been adopted by the Diet allowing lawyers with at least five years of experience to offer legal services in Japan, together with a Japanese lawyer. Services concerning domestic Japanese law are excluded. It will also be allowed to use the name of the company in the home country.

Long-term outlook is promising in Japan, although Japanese legal services have been hit hard by the problems in the real estate market. Japanese companies are expected to need more lawyers since the cost of handling legal affairs by themselves has proved to be too high.

In the USA, it is estimated that the number of lawyers has tripled over the last 20 years to approximately 800 000 in 1993. Around one third of all lawyers practise law outside the legal sector. There are some 925 000 employees working in the sector, an increase by 1.1 % compared to 1992. Gross income in professional legal services reached an estimated 93 billion US dollars in 1993.

Key trends in the legal services in the USA are: a business approach to providing legal services (the economic downturn in the US in 1990 and 1991, cost conscious clients, technology, litigation reforms and other factors, have reduced the demand for legal services, forcing firms to become more efficient and

competitive); alternative dispute resolution (ADR, a kind of arbitration with the purpose of avoiding interference with business operations, and preserving confidentiality); development of legal policy by client companies, in order to reduce legal expenses; and internationalisation (US law firms have increased their turnover more rapidly in international operations than in domestic ones, due to the expansion in the international marketplace. The new markets are Eastern Europe, the former Soviet Union and, increasingly, China and Taiwan. In 1991, gross income for the provision of legal services to foreign individuals or organisations was nearly 1.2 billion US dollars. The trade surplus in legal services reached 951 million US dollars.)

The top ten legal service providers in the USA recorded gross revenues of 3.2 billion US dollars in 1992. The largest law firms (by number of lawyers) are Baker & McKenzie (1 604 lawyers) and Jones Day (1 170 lawyers).

#### Foreign trade

Over the past few years, international legal practices have been growing rapidly. However, it is important to note that international legal practice, are only a small part of overall legal services. The key source of work for many international law firms (especially in the UK and the USA) has been in capital markets and tasks related to the large number of pri-

vatisations undertaken during the 1980s in the EU and Eastern Europe.

The Council of the Bars and the Law Societies of the European Community (CCBE) provides support to Eastern European bar associations and actively participates in co-operation programmes with the EU Commission and the Council of Europe. Moreover, delegations from the Czech and Slovak Republics, Hungary and Turkey have joined the CCBE as observers, so as to be provided with information by the CCBE (e.g. on establishing a new legal system, in organising their national bars and safeguarding their independence, and in establishing rules of deontology).

In Europe, economic integration and increasing trade has strongly challenged the traditional jurisdictional restrictions that formerly characterised legal practice.

Multinational partnerships are permitted within the EU and function to varying degrees in most Member States. It is expected that the number of multinational European firms, such as the Dutch-French-Belgian firm Stibbe Simont Monahan Duhot, will increase.

These practises function through numerous mechanisms: they deliver occasional services in another country; lawyers become fully integrated members of another jurisdiction's legal profession or establish themselves in another jurisdiction but re-

tain their home state qualification; and through association with other firms, groups, networks or through European Economic Interest Groupings (EEIGs). Lawyers in the Netherlands appear to have been the most active in developing international links recently.

One of the sources of international legal work are representations before the European Court of Justice. There is no clear tendency towards more representations since 1989 and the number of cases has remained more or less stable.

## MARKET FORCES

### Demand

As consistent statistics are not collected in all Member States, it is difficult to fully assess the effects of market forces on and within the legal professions throughout the EU.

### Supply and competition

Legal services are not only provided by registered lawyers and notaries. Accounting firms, trade unions, employers associations and banks also provide such services to their clients or members.

The CCBE has issued a statement that co-operation with other professions (notably accountants) is undesirable, as it believes that such partnerships would not be favourable for clients (who do not yet demand such partnerships). According to the CCBE, the quality of services would not be expected to improve, on the contrary, such partnerships would suppress the valuable "cross-control" of advisors. Moreover, insufficient lawyer independence vis-à-vis accountants, and the state of dependence in which the system of "integrated services" puts the client, would jeopardise the latter's interests. Partnerships with notaries are considered less dangerous in this respect.

Paradoxically, lawyers in Europe are trying to learn as much as they can from accounting firms: some law firms in Spain, for example, send junior lawyers to train with accountants to acquire skills perceived as necessary to a new breed of European lawyers.

However, co-operation with other legal professions is increasing in many Member States. In Belgium, the Belgian Order of Advocates announced a "joint declaration of rapprochement" between advocates and notaries, stating that it is advisable to allow lawyers and notaries to work together, provided that clients are informed of such collaboration.

In Germany, partnerships between attorneys performing advocacy work and patent attorneys, tax consultants/auditors, and notaries are allowed in regions in which attorneys are permitted to be notaries. The success of this arrangement is widely attributed to a common code of ethics which protects the interests of the clients.

The legal professions are not the only ones struggling to obtain a place in the European market for professional legal services. Arthur Andersen, one of the "big six" accounting firms, has established a legal arm in many countries of the EU, e.g. in France, Germany, the UK and Denmark, by associating itself with a newly-created law firm.

### Fees, income and prices

The extent to which fees for legal services are regulated varies between different countries. There appears to be a spectrum, with total control of pricing and billing for legal services on the one end (by the profession and/or the state) and complete non-regulation on the other. The one shared element appears to be a high level of control over legal fees for cases in which the State is the indirect client, i.e. for legal aid work.

However, it may be argued that civil law jurisdictions exercise greater control over fees for legal services, and most Member States have adopted and maintain more institutional mechanisms for regulating legal costs.

### Impact of the Single Market

The provision of legal services has a predominantly local character. The number of lawyers and law firms operating internationally is increasing marginally, although they only account for some 1-2% of the total market. The effects of the Single Market Programme have hardly been of influence in this respect.

In general, one can say that many European measures have an indirect influence on the way the (international) legal service sector is operating. The international orientation of lawyers has increased due to the increasing ease of the cross border movement of persons and cross border payments.

Two directives, and a third which is in the draft phase, have a direct influence on the sector. They deal with the mutual recognition of diploma's and the right of residence and operation. The importance of knowledge of European Law and of law of other countries is increasing and is being stimulated by the training and education programmes of the European Union. This will eventually result in further harmonisation of the EU legal services' market.

## INDUSTRY STRUCTURE

### Companies

All in all there are 34 different legal professions in the EU Member States, for historic reasons and different domestic social structures. The structure of the legal professions and the limits it imposes on how lawyers work; e.g. what legal work they can do or where they are entitled to practise also defines (at least in part) the type of legal service which lawyers provide.

In the British jurisdictions, the legal profession's formal specialisation and separation into solicitors and barristers may entail the use of more than one lawyer for a single legal issue.

Other countries have a geographically delimited or local jurisdictional system. One example is that of "localisation" in Germany which prevents individual lawyers from practising outside their court-delimited jurisdiction. Before trans-local firms were legalised, a "system of correspondence" had evolved whereby two or more lawyers worked on a shared case in their respective jurisdictions. Again, such division of legal functions, in this case based on geographical limits as opposed to speciality, may lead to the use of multiple sets of lawyers for a particular case.

There are numerous clauses controlling the number of notaries in operation in the Latin notary countries. Notaries occupy a unique position in most European jurisdictions, as they are both independent practitioners acting solely on behalf of the

**Table 6: Legal services**

client, as well as officials of the state from which the power to serve as a notary is derived.

Most EU law firms are small. In Belgium, Greece and Portugal, more than 90 % of all practises are individual ones. As for notaries, an office in which five notaries co-operate, would be considered large. The large law firm is a phenomenon particular to common law jurisdictions. Of the 40 largest law firms, there are 25 American firms, 10 British, 4 Australian and 1 Canadian. However, there is evidence that a direct challenge to the common law hegemony may be emerging in Europe where 5 of the 30 largest firms are Dutch.

In jurisdictions with relatively low population density and/or smaller economic centres, legal needs may be best met by smaller firms. For example, French notaries are among the most profitable in the legal professions in Europe, yet the number and size of their practices are relatively small. International association, co-operation and EEIGs give the smaller group of practitioners access to the international legal marketplace.

## REGULATIONS

### EU regulations

Two EU Directives define and regulate the activities of legal professionals within the EU. The Council Directive to facilitate the effective exercise by lawyers of freedom to provide services (77/249/EEC), also known as the EU Services Directive, requires each Member State to recognise lawyers from another Member State for the purpose of providing occasional services. It does not address the issue of the rights of establishment or the mutual recognition of diplomas. It does allow the foreign lawyer to practise under his home title, but submits him to the deontology of both his home state and the host state and requires him to be presented and assisted by a local lawyer for in-court services (only if requested by national lawyers or required under national rules). This Directive has been implemented by all the Member States.

Also important is the EU Directive 89/48 on the Mutual Recognition of Qualifications. This, so-called "Diplomas Directive", provides for the full integration of e.g. a lawyer into the legal profession of a host Member State, upon that state's recognition of the home state legal qualifications. Recognition can take one of two forms: the host state may require an aptitude test, or it may subject lawyers to an adaptation period before becoming fully qualified members of the host state

profession. As of January 1994, all Member States had implemented the Directive and, with the exception of Belgium, all had opted for an aptitude test, although the practical organisation of the tests has not yet taken place in all states. The content and the difficulty of the aptitude test, as well as the help provided by the local bodies to the applicants, varies from country to country. The CCBE is monitoring the implementation of the test in the different Member States and has issued an interim report.

The new EU Member States have been changing their laws in anticipation of accession to the EU. In Finland, the Act of Advocates has, from early 1993, allowed lawyers from other EFTA and EU Member States to be admitted to practice in Finland. The Finnish Bar Association plans to develop an aptitude test as a requirement for admission to the Finnish Bar.

At the beginning of 1995, the EU Commission issued a proposal for a Parliament and Council Directive to facilitate practice of the profession of lawyer on a permanent basis in a Member State other than that in which the qualification has been obtained. The Commission was inspired by an earlier draft forwarded by the CCBE, but substantially modified it. The proposal will go through the co-decision procedure of article 189B of the treaty of Rome.

The Commission Programme for the Internal Market promotes the dissemination of Community law amongst lawyers. A first initiative has been taken by DG XV, with which the CCBE collaborated in issuing a questionnaire with the objective of evaluating the knowledge of professionals in this respect.

One of the issues for the development of the Internal Market is effective legal protection for consumers, also when small amounts are involved, but especially for cross-border transactions. In the last respect, the CCBE has stressed the possibility of extending the existing schemes for legal aid to EU residents' "small claims" arising out of cross-border activities, and the need to use the existing European Conventions governing legal aid more intensively. It also highlighted some improvements that could be made to the Brussels and the Hague Conventions to achieve a virtual "free circulation of judgements", and has suggested the exploration of the extension of legal expenses insurance to cross-border cases.

### International regulations

To cope with the issues raised by the numerous changes, a number of supra-jurisdictional organisations have attempted

to lay down common ground rules to regulate the new scope of the professions. The CCBE has been at the forefront of organisations trying to address the issues and has issued an International Code of Conduct for European Community lawyers.

The code reconfirms certain fundamental principles (e.g. independence, confidentiality, pactum de quota litis), recommends approaches to dealing with fees, and makes recommendations on how to deal with lawyers belonging to more than one bar or law society (e.g. in matters of publicity, relation with the Courts and between lawyers).

These provisions have been adopted by most professional bodies in Europe; where the local bar has a regulatory function, the national bar has suggested the adoption or incorporation of similar rules. On a smaller scale, the International Bar Association has been working on an international code of conduct along the lines of the CCBE provisions.

In addition, the legal services were included in the Uruguay Round GATS negotiations. A working group on services will begin to negotiate the implementation of liberalisation measures on a sector basis, beginning with accountants. Legal services will be negotiated at a later stage.

## OUTLOOK

It is most likely that the overall trend of growth in the legal professions throughout Europe and the increasing internationalisation of services will continue.

If the trends of cross-border co-operation, simplification and the creation of pan-European organisations continue, the legal professions in each jurisdiction are likely to grow and cross-border legal activity is likely to increase. Co-operation (and mergers) between the providers of legal services within jurisdictions as well as between jurisdictions is likely to grow rapidly over the next few years, especially within the European market.

In addition to increasing co-operation, another likely result is that of more direct competition on both a national and international basis, as providers of legal services within and across jurisdictions attempt to promote themselves in an increasingly international business context.

Rising competition will force law firms to become more efficient. This will most likely result in a reduction in employment, increased use of computers, including databases and customised legal software.

The experiences from German reunification and from the USA have taught the legal services to regard legal advice as a vital export product. Already, lawyers from Europe and North America are battling to establish their system of law as the primary one to govern commercial contracts in the new markets opening up in Eastern Europe.

# Accountancy services

## NACE 836

"Accountancy services" is a generic term embracing a number of activities. There is no strict correspondence between accountancy services and the scope of practice of the accountancy profession. Within the EU, the existence of independent professional institutes is perhaps the only common feature to be found in this otherwise diverse sector. Despite efforts at the EU level to eliminate barriers to cross-border practice by professional accountants and accountancy firms, national differences in business and accounting practice still prevent a truly open border situation for this sector.

### INDUSTRY PROFILE

#### Description of the sector

Accounting services long have existed in Europe, but it was not until the mid-19th century that specialists started to organise themselves professionally. These developments took place in the UK, which has since kept its tradition of a self-regulated accountancy profession and services. As a result, the British and Irish markets for accountancy are the most developed in Europe today. Similar developments later took place through continental Europe, where the market has been structured according to local traditions, with a greater use of laws and regulations.

Financial information is at the heart of accountancy services. Accurate, relevant and timely financial information has been a key to businesses' success since the beginning of the market economy. Accountancy services have logically followed the development of the European economy, in terms of volume, variety, sophistication, etc. With the expansion of capital markets, financial information has reached the status of a public utility. Given the many possible methods of accounting for any one economic reality, public authorities have felt it necessary to intervene in order to protect the public interest. As a result, accountancy services and the accountancy profession are heavily regulated in all EU countries, which gives a specific character to the market.

The rules and regulations governing the profession and the services it provides have so far been developed from a national

perspective, in order to respond locally to national problems. It is no surprise that significant differences between the EU Member States have resulted from the process.

The range of services accountants offer is very wide, although again it can vary from country to country. It is, however, fair to say that the core activity of accountants remains centred on financial information and, hence, on accountancy services. These cover primarily accounting and auditing. Accounting involves the production of financial information, which includes the analysis of economic transactions, the selection of a relevant accounting method and some data processing or computing. Auditing consists of the expression of an objective opinion on a given set of financial information, according to a given set of standards, in order to improve the reliability of that information.

The competence developed by accountants to produce, process, analyse or audit financial information can be used for other purposes as well. Hence, the activities of accountants have been expanded far beyond accountancy services, within the realm of each unique national business culture. For example, as it is not possible to produce financial statements without having properly addressed the fiscal liabilities of the enterprise, accountants necessarily have developed an expertise in the tax area, which can be used outside the context of accounting. In the same way, accounting or auditing activities require a sound knowledge of the enterprise, its activities, structures, etc. On that basis, it is easy to develop management consultancy activities, and many accountants do so.

In addition to accounting and auditing, the range of services provided by accountants in most of the EU countries comprises:

- merger audits, which consist of the expression of an objective opinion on a merger in order to guarantee fair treatment of the shareholders of all merging companies;
- contribution audits, which consist of the expression of an objective opinion on the value attributed to non-cash assets (property, inventories, trade marks...) contributed by a shareholder to the capital of a company, in order to guarantee a fair treatment of the other shareholders of the company;
- insolvency services, which entail acting as liquidator, receiver or administrator. These may even involve advising clients on strategy before a critical stage is reached in its financial position;
- expert witnesses, which are accountants acting as experts in accounting matters before most types of courts;

(1) Number of persons employed  
Source: Eurostat; Mercure

- tax advice, which includes tax planning or tax compliance, with the former consisting of advice on the application of taxation law and the latter relating to the preparation and presentation of the various returns and declarations required by law, and assistance to clients in their dealings with the relevant authorities;
- investment services, which include advising clients on potential investments, performing financing studies, or even acting as trustee; and
- management consulting, which includes, inter alia, IT consulting, internal control and procedures review, organisational review, etc.

This large range of services is different for each EU country, according to local rules and regulations. In some countries, accountants may even be prevented by law from offering some of these services. In France, for example, accountants cannot offer insolvency services or tax advice - except in very limited circumstances - as these activities are restricted to other professions. In other EU countries though, accountants are the leading providers of such services. As a consequence, the NACE classification of services does not correspond to the division of the market between the various professions. Therefore, no reliable data are available on the turnover, profits, etc., of the accountancy profession.

### Foreign trade

More than 35 years after the signing of the Treaty of Rome, twelve national markets still exist for accountancy services and the accountancy profession in the EU. Many factors work towards keeping the existing barriers between national markets. These include:

- The dependence of the profession on law. Much of an accountant's work requires an extensive knowledge of law in several areas (accounting, tax, company law, social law, etc.). As most of these laws diverge considerably from one Member State to another, the investment necessary to bridge these differences in order to practice in another EU country remains substantial, although the professional know-how would be almost the same in a large number of cases.
- A number of services provided by accountants are supplied within a limited distance, because of the close relationship which should exist with the client. This is especially true for SME clients, which constitute the bulk of the market. Cross-border competition on these markets is very limited so far.
- The implementation of the general system of Mutual Recognition of Diplomas has not led to large movements of accountants across borders: only eight professionals in 1992 and fifteen in 1993 have benefited from the system. The system indeed is not designed to remove the existing barriers, but to help people establish themselves abroad despite

those barriers. All recent initiatives taken at the EU level have put a strong emphasis on maintaining the current legal status quo. This is why, despite the provisions of the EU Treaty, the cross-border provision of regulated accountancy services and the mutual recognition of professional firms is still not possible.

- International networks of firms of accountants have long developed their own solutions to the problem of barriers. They mainly rely on locally licensed professionals to supply their services and refer the work to their corresponding members in the relevant countries, as soon as any international service is needed.

For these reasons, it is very likely that intra-EU trade in accountancy services remains marginal. Unfortunately, no figures are available to confirm this.

## MARKET FORCES

### Demand

Although individuals may occasionally use the services of accountants, the bulk of the market comes from businesses, whatever their legal form (sole practitioner, partnership, corporate) or ownership (private, public, state, etc.). Therefore, professional accountants could be defined as professional advisors to the business world. The demand is potentially very wide and can be segmented according to many indicators. One is the size of a business, as the needs of sole-traders, SMEs and big companies are definitely not identical. Others could be the economic sector, the legal form of the business (e.g. corporations), quotation on a stock exchange, etc.

As is the case with many other markets, the scope of the demand varies with the size of the client, with big multinationals requiring very sophisticated and diversified services, and SMEs generally having more basic needs. However, it is fair to say that big companies can afford several consultants and have strong enough internal structures to get each service from the best specialist in the area. Conversely, SMEs appreciate that the same consultant, in whom they have "invested", can provide them with a large range of services, in order to limit both the money and time spent. Frequently, for example, the professional accountant is the sole external advisor to the management of small firms.

Legal requirements oblige many companies to have their annual financial statements audited. A properly approved auditor or firm of auditors must state whether the financial statements they have audited give a "true and fair view" of the results of the company's activities and its financial position, and whether accounts comply with the relevant legal provisions.

The purpose of the independent external audit is to lend credibility to financial information, thereby enhancing the effectiveness of economic decisions made on the basis of it. In

addition, many companies, and other entities not subject to the statutory audit requirements, voluntarily request contractual audits, in view of the benefits that accrue from this service. Finally, there is a growing demand for audit-related services, which involve the issuance of special-purpose reports and opinions on the application of certain defined procedures.

In the past, many small companies, self-employed people and small shops were unable to do any of their own accounting and bookkeeping and, therefore, depended on the services of accountants. However, because computer hardware and accountancy software programmes have become so affordable, nearly every business can make the investment required to have their own. Nonetheless, many businesses continue to use accountancy service firms in order to make better use of their own resources and to have access to a specialist's expertise.

Another source of demand can be the public authorities. Courts allocate insolvency work and require expert services; governments require audits and evaluations should they decide to privatise State-owned businesses. With the development of the so-called social economy, a market has recently emerged in the non-profit sector, as its requirements become closer to those of the rest of the economy.

### Supply and competition

In order to offer certain accountancy services, it is often a legal requirement that the provider holds a professional qualification and belongs to a recognised accountancy body. This is especially the case for statutory audits, which can only be performed by a properly qualified and approved professional. For the other activities of the accountancy profession, the requirements vary from country to country, some imposing

conditions similar to those of statutory audits. In any case, all the professional titles of the members of the main professional bodies in the EU are protected in their own countries, but not necessarily abroad.

The process of qualifying as a professional accountant is a lengthy one, requiring both theoretical knowledge and practical experience. It can last from six to seven years, or even up to ten or fifteen years in some countries. Many of those working in lower positions in accountancy firms are doing so to gain the practical experience necessary to qualify as a professional accountant. Most people working in the accountancy services sector are not professional accountants. They include support staff and technical staff as well as trainee accountants.

The accountancy profession is practised mostly through collective entities in almost all EU countries. Only Italy still prevents the use of such entities, and even there professional associations without legal personality are very popular in the sector.

Supply fragmentation almost equals that of demand. Most visible are the big international firms, which attract much public attention, the most famous being the so-called "Big 6," i.e. Arthur Andersen & Co, Coopers & Lybrand, Deloitte Ross Tomatsu, Ernst & Young, KPMG Peat Marwick and Price Waterhouse.

These firms mainly serve the big national and international companies in each EU country, as they do all around the world. One of their major features is the ability to provide the same services with the same quality wherever their client is located. These big firms dominate the market of big quoted companies, banks and insurance companies.

Source: FEE

However well-known these big firms may be, the bulk of the accountancy profession is made up of small and medium-sized firms, which are often better suited to serve the many SMEs of each Member State. Altogether, these smaller firms cover the same range of services, although each firm on its own may, obviously, supply a more limited range of services to its clients.

Unlike the 1980s, the beginning of the 1990s has not witnessed any more mega-mergers at the top end of the sector. Small and medium-sized firms in the EU are currently developing regional networks to gain national or even international exposure. That evolution follows the trend set by a number of enterprises that use the internal market to expand their activities abroad.

The general economic slowdown of the early 1990s affected the accountancy sector as all others. Pressure on fees has been strong, and the growth rate of the profession's turnover which long stood above 10 % in most EU countries, barely shadowed inflation. The recent recovery of the economy in most Member States benefits the accountancy profession as well.

### Production process

Information technology has already been integrated in accountancy services for a long time. However, some further developments can be expected in that respect in the near future. EDIFICAS is the latest initiative of the accountancy profession to tailor EDI (Electronic Data Interchange) to accounting and auditing needs. Although accountancy services are not technology driven, these developments, which should help accounting data circulate more rapidly and accurately, will impact the way the services will be supplied in a few years.

Given that professional standards have long existed in the sector, ISO 9000 has not yet had any real impact on the accountancy services. Developments are taking place, however, and the British profession recently took steps towards its implementation on a voluntary basis. It is too early to state, however, whether this will constitute a precedent for the other Member States.

### INDUSTRY STRUCTURE

The structure of the accountancy profession in the EU is very diversified, and one can find a different national model in almost each country. The existence of independent professional bodies or institutes is actually the only common feature. These bodies have either been established by the profession itself, as in the UK and the Netherlands, created by law, as in France and Belgium, or combine structures of both origin, as in Germany and Spain. Recently, governments have become more and more involved in the regulation of the profession, partly as a result of the implementation of EU directives.

The profession is generally structured with several tiers, corresponding to the segmentation of demand in terms of the level of the sophistication of the services given. The differences between the various tiers is a matter of, *inter alia*:

- level of education, measured in terms of university education, practical experience, etc.
- scope of practice, the less qualified members of the profession having, in principle, more limited rights to practice;
- ethics, the code of conduct of some bodies being looser or less stringent than others;
- international recognition, as some international professional bodies like FEE only have first-tier members, etc.

There are, however, some exceptions to the multiple-tier rule. In France, Greece and, to a lesser extent, Luxembourg, several professional bodies exist, although these all belong to the first tier. Consequently, in these countries it is not possible

**Table 4: Accountancy services  
Membership of FEE Member bodies, 1994**

Source: FEE

to get a less sophisticated level of service (from less qualified professionals) for the many activities reserved solely to accountants.

In addition to the ordinary functions of any professional body, the accountancy bodies are heavily involved at the national and international levels in the development of accounting standards and reporting standards, of auditing standards and other standards on professional activities and, finally, of ethical codes. They have an important role to play in overseeing the conduct of their members.

The structure of the profession has been rather stable over the years. Any evolution is hence rare and is thus quite significant, given its potential impact on the market (on the supply side at least). The implementation of the 8th and Mutual Recognition Directives (see Regulations section) has had a major influence on the structure of the profession in a number of countries, including Germany, Spain and Italy. Over the last year, two countries, France and Portugal, have seen evolutions in that respect. In France, the law implementing the Mutual Recognition Directive included some other provisions designed to modernise the regulation of the profession as well. The changes are, however, relatively minor and do not affect the substance of the regulations. In Portugal, the law implementing the Eighth Directive did not change dramatically the specifics of the regulation in that country.

In the EU, approximately 300 000 people are members of the professional organisations belonging to the Fédération des Experts Comptables Européens (FEE). About one-third of them work in the accountancy services sector. Most of the remaining 200 000 members of professional bodies represented in FEE are employed as accountants in industry, commerce, education and the public sector. Tables 4 and 5 show how these accountants are spread over the EU. Obviously, the size of the profession in one country does not mirror the size of its economy. This derives from the conception of the profession in countries like the UK, Ireland, the Netherlands, Italy, etc., where all those having the relevant educational profile are permitted to be members of professional bodies, be they in practice, in industry, retired, or whatever. On the other hand, countries like Belgium, France, Germany or Greece restrict the membership of the professional organisations to those in public practice. The membership of the institute is then associated with a given function, and not with a certain educational background.

### Impact of the Single Market

In practical terms, the Single Market as yet does not exist for Accountancy Services. The differences in rules and regulations governing the sector still differ significantly between the Member States, virtually ensuring that the national character is, at least for the moment, kept in place. Very little harmonisation has been reached and considerable effort will have to be invested to reach the Single Market status.

The larger firms operating in all the Member States do this as separate, national legal entities, since there is a complete prohibition on foreign direct investment in firms operating locally. This results in a considerable administrative burden for the international firms. It poses an even bigger problem for the firms classified within the category of small and medium sized enterprises. In order for this group to service their clients, whom may also increasingly operate abroad, significant investment is demanded to develop the international structure needed to service these clients.

The agenda towards achieving greater harmonisation and freedom of operation is considerable. A number of issues which need addressing are, amongst others, the easing of restrictions

on advertising in different Member States, greater freedom in the scope of practice, thereby being allowed to provide services closely related to accounting in the different Member States and measures related to taxation, for example to avoid double taxation of firms operating in more than one country.

Some concern exists as to developments in emerging markets, most notably in Eastern Europe, where individual countries are increasingly moving towards the European model of nationally inspired rules and regulations.

### REGIONAL DISTRIBUTION

As the provision of accountancy services usually requires a degree of geographical proximity to clients, the regional distribution of accountancy services throughout the EU closely mirrors the regional distribution of economic activity in general. However, special concentrations can be noted in the major financial and administrative centres. Another determining factor is the scope of practice permitted to the profession, with a relatively greater concentration of providers in those Member States with a broad-scope profession.

## ENVIRONMENT

There is a clear and definite growth in the importance given to environmental accounting and auditing. The number of companies disclosing environmental information in their annual reports is growing, although the information in most cases is limited to that of a qualitative nature, with no assessment of the financial impact. Companies in a number of countries are moving towards the production of "greener" financial statements; however, the development of an accounting and management reporting framework which specifically deals with environmental issues is some way off. The environmental audit requires knowledge and experience which go beyond that of a financial auditor. The financial auditor does have a role to play in this field, but only as part of a multi-disciplinary team of experts. The accountancy profession, with its considerable experience in carrying out financial audits and in reporting the results of such work, may provide the starting point for the creation of a new function comprising individuals from different professional backgrounds.

## REGULATIONS

Accounting and auditing services are highly regulated in the EU. Regulations are both numerous and complex and vary from one country to another, despite the attempts made at the Community level to bring them closer together. These regulations fall into two main categories: the regulation of the services themselves, including rules governing the manner in which the services should be provided; and the regulation of the accountancy profession and its members.

### Regulation of services

Many of the services provided by the accountancy profession have been regulated for a long time in most European countries, often in different ways. These services include: statutory audit, accounting, public sector audit, contribution audit, insolvency practice, etc. National regulations define the type of work to be carried out, when, under what conditions and by whom.

Statutory audit is the only service provided by the accountancy profession which is regulated in the same way in all EU countries. It is also the only service which has been subject to specific EU directives. As a result, all companies above certain minimum thresholds must now prepare and file financial statements audited by an independent expert. All the other services have, until now, kept their own national specificities. Certain services are regulated in some countries, but not in others; some are reserved to one profession in certain countries but are shared between several professions (or even forbidden to the accountancy profession) in others. Consequently, the range of services provided by the profession varies significantly within the EU, as does the degree of competition which exists in each of these markets between the accountancy profession and other professions.

### Regulation of the profession

In addition to the services it provides, the accountancy profession itself has been regulated for a long time in Europe. Because the economies of the Member States developed in different ways, the regulation of the profession differs from one country to another. The degree of self-regulation has decreased in recent years, mostly as a result of the implementation of EU directives.

In a majority of Member States, the profession has been created and organised by legal or public authorities. Even in those countries where the profession has been privately organised, it enjoys official recognition by the State, which entitles its members to carry out regulated activities. Regulation, be it public or private, applies to a number of areas, such as the definition of professional titles, protection of those titles, membership requirements, minimum levels of education and train-

ing, continuing education, ethical standards or codes of conduct, technical standards, additional licensing requirements for specialised areas of practice, rules for the establishment of professional firms, etc.

In the EU, only limited attempts have been made to harmonise these rules. This has resulted in the Eighth Company Law directive on "The Approval of Persons Responsible for Carrying Out Statutory Audits of Accounting Documents". The directive established minimum education and training requirements for statutory auditors, be they individuals or firms. However, Member States remained free to impose more demanding requirements, and many did.

Another directive applying to the accountancy profession is the First Mutual Recognition directive which, when implemented, allows professionals from any Member State to seek recognition of their qualifications so as to be able to carry out regulated activities in other EU countries without having to re-qualify. In the case of the accountancy profession, Member States can require applicants to pass an aptitude test on local laws and ethical requirements. Although such a regime previously existed in some countries such as Belgium, France, Ireland, Luxembourg and the United Kingdom, it is new for others. This new system should have come into force early in 1991, but its implementation has been delayed in a number of countries. However, it is already obvious that it will not generate significant flows of accountants across EU internal borders. Despite making it easier for professional accountants to establish themselves abroad, differences remain between national laws and regulations with which accountants must be familiar. These differences will continue to restrict the free movement of accountants within the EU.

## OUTLOOK

Growth of the accountancy services market is dependent on the general state of the economy, and the current recovery has benefited the accountancy profession as it has all others. However, the shape of the economy does not seem to be the main challenge accountants face at the moment, as it is very likely that their activities will sooner or later resume with double-digit growth.

The recent wave of financial scandals, and the litigation which followed, has had an effect on the whole profession. Some now question its credibility. Even if one can argue that accountants are easy scapegoats for business failures at a time of economic recession, the challenges ahead for the profession now include, in addition to the increased financial pressure resulting from the huge claims made against its biggest members, the evolution of laws and regulations that may limit its freedom to act, and the strengthening of its public standing. Considerable work on these issues has started already, both inside and outside the profession, and no doubt will lead to a satisfactory response.

The industry is represented at the EU level by: *Fédération des Experts Comptables Européens (FEE)*. Address: Rue de la Loi 83, B-1040 Brussels; tel: (32 2) 231 0555; fax: (32 2) 231 1112.

# Market research

## NACE 839.1

The EU accounts for 38 % of the world market for market research. Four of the world's largest ten market research companies have their headquarters in the EU. 50 % of all EU market research is bought by manufacturers, 12 % by the public sector and 15 % by the service sector; 67 % of research is for consumer products and services. The market research sector employs more than 29 000 permanent employees and over 86 600 interviewers, as well as freelance researchers and other self-employed consultants and sub-contractors.

### INDUSTRY PROFILE

#### Description of the sector

Marketing research is covered by NACE category 839.1 and is distinct from management consultancy. Market research analyses the markets for products and services. It provides a flow of information between consumers and suppliers on what people want and why they want it. It is used by decision makers to:

- identify and define opportunities, threats, competition and emerging trends;
- initiate, modify and evaluate marketing activity;
- improve understanding of marketing processes.

Marketing research enhances economic efficiency by enabling companies and other organisations to provide the goods and services that customers want, by investigating their needs, attitudes and behaviour. This helps companies to avoid wasting resources by developing unwanted products and services, or not communicating the benefits of their goods and services adequately enough. Marketing research designs a method of collecting the information required to address these issues;

manages and implements the data collection process; analyses the results and communicates the findings with recommendations for action. In recent years, marketing research has heightened manufacturer and governmental awareness of the increasing public concern about environmental and associated health issues.

The structure of the market research industry is remarkably similar among the Member States. Generally, the market can be divided into three areas:

- **Media market research:** This measures the readership of newspapers and magazines, audiences of television, radio, videos and films; and even viewers of outdoor billboards and posters. This can be done by asking sample households to keep diaries of their media habits, or by day-after interviews, but electronic devices such as "peoplemeters" - which record television viewing habits - are being increasingly employed. Pressures to monitor, justify and optimise expenditures on advertising, sponsorship and promotions have increased with the emergence of a global marketplace and ensuing fragmentation of audiences. More and more, advertisers need to know if they are reaching the right targets to ensure that their commercial communications maximise volume sales and profitability throughout the course of a brand's lifetime.
- **Warehouse and shop auditing:** Electronic scanner information can be gathered through bar code scanning technology to provide detailed sales data on a daily basis. From this information, analyses of consumption can be made. It can be used, for instance, to track the effects on sales of advertising, pricing strategies and special promotions.
- **Specialised market research:** This includes both quantitative and qualitative research to determine consumer behaviour and attitudes. Quantitative research comprises statistical sampling and analysis of the respondents' views obtained through interviews (face-to-face, telephone or mailed questionnaires). Qualitative research includes group discussions and in-depth interviews with individuals.

Research can also be categorised by its different characteristics, for instance, that which is continuous (e.g. audits and panels) and that which is ad hoc. Another distinction can be made between single-client studies and omnibus and other syndicated surveys wherein clients can buy space for specific questions they wish to ask.

#### Recent trends

The rapid growth in market research since the 1950s was interrupted by the economic recession triggered by the oil crises of the 1970s. The 1980s saw an annual real growth in excess of 10 % with very strong growth in Southern Europe, albeit from a low base. Growth has slowed since 1989 because of the recession. Nevertheless, the market research industry has outperformed the advertising business since then. In the EU, the industry grew by 6 % both in 1991 and 1992, and by 7 % in 1993.

#### International comparison

The ESOMAR study on the research industry showed a 7 % growth in the size of the market within the EU from 2 516 million ECU in 1992 to 2 684 million ECU in 1993 (see Table 1). This includes work conducted by research institutes but excludes in-house research by companies, advertising agencies, governmental and academic bodies and consultants. The EU accounted for 38 % (2 684 million ECU) of the total world market for market research in 1993. The USA accounted for 38 % (2 690 million ECU) and Japan for 9 % (603 million ECU).

The 1993 EU industry growth rate of 7 % compares to 21 % in both the USA and Japan when quoted in ECU. However, the major realignment of currencies over this period distorts the true picture. When calculating in local currencies and taking inflation into account, real growth rates were 5 % for the EU, 6 % for the USA and there was a shrinkage of 6 % for Japan.

**Table 3: Market research

As shown in Tables 1 and 2, in 1993 Germany had the largest share of market research turnover in the EU of 703 million ECU (26 %), ahead of France at 604 million ECU (23 %) and the UK at 599 million ECU (22 %). Italy was in fourth place with 261 million ECU (10 %), followed by Spain at 177 million ECU (7 %) and the Netherlands with 164 million ECU (6 %). Germany, France and the UK continue to account for over two-thirds of EU market research turnover.

After taking inflation into account, and calculating in local currencies, Spain and Luxembourg experienced strong real growth rates of 31 % and 29 %, respectively. Other relatively strong growth rates were in Portugal, with 14 %; Greece, with 13 %; and the UK with 11 %. Denmark had a 9 % increase in growth. Finally, growth was at 2 % in Germany, while Belgium, the Netherlands and Ireland all increased just 1 % in terms of their real growth. Meanwhile, turnover in France and Italy was static.

If market research turnover is compared with population, Gross Domestic Product and advertising expenditure (see Table 2), the significance of market research in 1993 in France, the Netherlands and the UK is apparent. At the same time, one notices that its use was more limited in Greece, Italy, Portugal and Spain.

### Foreign trade

As shown by Table 3, 81 % of the market research conducted in the EU was commissioned by domestic clients in 1993. The share of international research has grown steadily, rising from 10 % in 1990, to 14 % in 1991, 16 % in 1992 and 19 % in 1993. Foreign clients are particularly important for Belgium, Germany, Italy, Greece and the UK. Of the total European research expenditure in 1993, 6 % went to multi-country research where an institute in one country coordinates studies and subcontracts fieldwork abroad. UK institutes conducted about 33 % of such work, with French institutes handling 22 % and Italy 13 %.

## MARKET FORCES

### Demand

Manufacturers of consumer packaged goods are the main buyers and users of market research. In fact, 50 % of all research done in the EU is for manufacturers (see Table 4). A broader range of business and non-commercial organisations is now using market research to facilitate their decision-making. Taking 15 % of research spending, service industries are growing

clients, with hospitals, banks and airlines now amongst those who use market research to improve the quality of their services. The public sector is a significant client with 12 %, and research is becoming an important tool through which local and national governments receive feedback about public reaction to their policies. Additional clients are: wholesalers and retailers (7 %), other research organisations (6 %) and advertising agencies (5 %). Other clients (6 %) account for the rest. In the EU, approximately two-thirds of total expenditure stems from research for consumer products and services, while the non-consumer sector (including business-to-business and government research) constitutes the remaining one-third.

There have been major changes in the information needs and priorities of marketing companies. A key factor is the growing number of multinational companies and their branded properties. An increased demand for pan-European information is exacerbated by the proliferation of media. This underscores the need to remove barriers created by different national statistical definitions so that survey findings are more comparable between nations. Clients require research companies to have a wider geographic spread of resources while maintaining a strong local presence and perspective so that national insight is not lost in the global picture.

Another major influence is the growth of profitable and relatively undeveloped new markets in South East Asia. Furthermore, whilst markets in Central and Eastern Europe will grow relatively slowly in the short term, the potential demand is significant in the long term. The growth of demand depends on the productive investment rate as well as variables such as qualification standards, and is strongest in those countries where the labour force is highly qualified. Business opportunities for market research are increasingly visible as public institutions have begun conducting their own studies and a number of cooperation agreements between EU and Central and East European private companies have been made.

Brands are increasingly viewed as a company's key asset. A greater emphasis on building and maintaining strong brands will have a major influence on the types of market research that are in demand, as companies strive to understand brand elasticity and the measurement of brand relationships, positioning and brand equity, particularly in relation to the growing competition coming from own-brands.

Growing areas are research into customer satisfaction, branding and corporate image, as well as for the business-to-business, finance, retail, utility and legal sectors. Studies suggest

that expenditure on most types of market research is likely to increase over the next five years. This will be markedly so in the areas of usership and attitude studies, product testing, advertising and concept development and evaluation, as well as advertising campaign tracking, particularly with the growth of electronic and published media.

### Supply and competition

The trend of many major US corporations to disband or downsize their market research departments during the past few years has become evident in Europe as well. This has allowed research institutes to develop new, and often closer, relationships with clients, through which the client benefits from the switch from fixed to variable costs.

Changes in technology, growth in the information industry, diversification of life-styles and proliferation of media all have made marketing research that monitors changes in the market place that much more valuable. Technological developments have meant a greater detail in and frequency of reporting, which has inspired the opinion widely amongst many users that a sort of data overload exists. This, along with the diversification of sources of marketing data, has meant that it is increasingly necessary for researchers to help marketing management understand the implications of the data so that they can effectively apply it in their marketing strategy. In addition, they must provide added value to their clients by offering diagnostic, interpretative and predictive services and by gaining expertise in the client's business sector. It also implies that clients will demand an on-going strategic counselling relationship rather than one characterised only by a string of separate projects.

This trend is already evident, with a growing number of researchers acting as consultants to companies. ISO 9000 accreditation has been taken up by research institutes in certain countries, notably the Netherlands and the UK, as a means of guaranteeing to clients - who are not professional market researchers themselves - that procedures exist to confirm that quality standards are being upheld.

There is considerable cost and price variation between the EU countries, largely reflecting differences in salaries and social costs. For instance, freelance and part-time interviewers in France and other countries are eligible for benefits. The subsequent costs for employers include: income tax, social security contributions, holiday entitlements, redundancy pay and pension provisions. In other countries, they are employed on a very different basis. This will probably change with greater harmonisation of the benefits that freelance and temporary workers are entitled to in the EU. Other factors affecting pricing include: the degree of competition in the local market, the enhanced efficiency that comes with greater experience in certain types of research, the mix of research and data collection methods and the geographic dispersion of populations.

In an ESOMAR survey designed to discover how research prices vary from one country to another, research institutes were asked to state what price they would quote a client to carry out six different types of surveys. On average, France and Italy emerged as the most expensive countries, with Belgium, Greece and Portugal as the cheapest. In 1991 the rank order in terms of average research costs from the most to the least expensive was France, Italy, Germany, Ireland, UK, Denmark, Spain, The Netherlands, Belgium and Greece, with Portugal being the least expensive. Research prices in Germany and Denmark were relatively much lower than they were three years before. These are relative changes and they should not necessarily be taken to mean that research prices in Germany and Denmark had fallen in absolute terms.

Continuous research has always demanded a higher level of investment than ad hoc research. The advent of scanners, "peplemeters" and single-source data services has added further

**Table 7: Market research**

Source: ESOMAR Directory 1994

to the high technology and investment that characterise this sector. Data collected from these and other sources increasingly form part of database management information systems (decision support systems) - requiring a further substantial investment. Computer-aided interviewing, especially that which is done by telephone (CATI) has involved sizeable investments in facilities with as many as 20 to 100 telephone booths along with the accompanying telecommunication and computing equipment.

Over the past decade, more EU research companies in the ad hoc sector have begun to emulate US research firms in standardising and branding their research products. This too involves investment, although typically more in the time of research technologists and innovators. Significant investment in designing, testing and validating new research techniques, and the subsequent marketing of these techniques to customers, is only possible if the costs can be amortised by applying the same techniques across many countries over time.

These costs, and the protection afforded to research suppliers by time series data, have created entry barriers, which have led to a small number of very large players. Corporate prescriptions for research buyers identifying the preferred research suppliers or techniques world-wide, as well as a demand for increasingly sophisticated international co-ordination of research projects have all led to the concentration of ownership, and the formation of international research chains or networks of national agencies.

Parallel to this has been the emergence of more specialist research companies dedicated to CATI omnibus services, advertising tracking and research in particular business sectors, such as pharmaceuticals and automobiles. Larger research businesses also have been broken down into separate operating divisions or subsidiaries focusing on specific areas of information need or research techniques. Clients can now choose among a wide spread of suppliers ranging from large, full-service research companies to specialist research boutiques and consultants.

Market research always has been highly competitive and subject to intense price pressure. Recession exacerbates this tendency, with a number of research professionals leaving research institutes or client corporations to set up their own

**Table 8: Market research****Top 10 market research companies in the EU, 1993**

(2) The figures reported derive from the extrapolation of the ratio between EU: non-EU turnover for the company in 1992 based on the worldwide turnover figure for 1993.

Source: ESOMAR Annual Market Study, major research companies, J. Honomichl/Marketing News

consulting businesses. An estimated total of 29 000 people are employed on a permanent basis in the EU market research industry with a further 86 600 as freelance interviewers (see Table 5). In 1993, several countries saw a slight rise in the number of permanent employees, evidence that despite the effects of automation and downsizing for greater efficiency, the industry is coming out of recession.

External competition is emerging as management consultants, accounting firms and database marketing organisations also have begun offering marketing and management information. Changes in client requirements and intensifying external competition mean that new skills are required within the market research industry. In addition to having expertise in marketing research techniques, researchers increasingly are required to possess a broader range of marketing and management skills, and at the same time to specialise in a specific sector, in order to best serve their clients. Furthermore, interviewers are requiring more training, particularly those who use portable computers for interviewing instead of paper questionnaires.

### Production process

In 1993, 57 % of research was ad hoc and 43 % was continuous (27 % on panel research, 7 % on omnibus research and 9 % on other continuous research). About 81 % of ad hoc research expenditure in the EU is from quantitative research and 20 % qualitative.

Data collection methods in quantitative research include mail survey, telephone and face-to-face interviews. Despite the higher costs involved, face-to-face studies continue to account for the largest part of quantitative research expenditure in the EU: 27 % of total turnover compared to 13 % telephone and 4 % mail studies. Smaller countries with a highly developed infrastructure tend to make more use of telephone studies (e.g. 35 % of research in Luxembourg) compared to 3 % in Greece, 5 % in Portugal and 9 % in Spain. The proportion of telephone studies is rising because of cheaper costs, higher telephone penetration, faster delivery of data and the problems associated with conducting face-to-face interviews in some inner city areas.

Group discussions account for a larger part of qualitative research expenditure in the EU than do in-depth interviews.

## INDUSTRY STRUCTURE

### Companies

There are well over 1 500 market research companies and consultancies in the EU, including the headquarters of several of the world's largest. Four of the top ten market research companies in the world and two of the world's major research chains (networks of independent companies) have their headquarters in Europe (see Table 6). Although there are a number of major players in the EU, the industry is characterised by considerable fragmentation and intense competition nonetheless. Barriers to entry are low except in the high-tech/high investment areas. Many of the major research organisations are listed in the ESOMAR membership directory (see Table 7).

Historically, pre-tax margins have been modest (averaging around 5 to 6 % of turnover for ad hoc research companies) though they were slightly higher in recent years. Substantially higher margins are earned by companies with multi-client services and a contractual customer base.

### Strategies

Several companies have restructured to survive in the rapidly changing market. A number of mergers and acquisitions have taken place, often as part of the creation of global marketing service corporations. As a result, industry concentration has increased, and eight major research holding companies have been established, as shown in Tables 8 and 9. Two Dun & Bradstreet companies - A.C. Nielsen, the world's largest market research organisation and IMS International, the second largest - were restructured in 1993 to form D & B Marketing Information Services.

Developments in automation and technology, along with the growth of international research chains, have enabled buyers to go to one head office to commission a research project in many countries or several regions. A variation of this is the licensing of particular research techniques or brands in other countries. This is practised most commonly by US research firms which license their techniques in advertising pre-testing, simulated test market, brand position and customer satisfaction/service quality.

The other major structural change is horizontal specialisation. Increasingly, market research organisations in the EU have set up specialist divisions or operating subsidiaries that concentrate on key business sectors (e.g. media, health care, auto-

motive, finance) or research specialisation (e.g. qualitative, advertising, customer care). Also, growth in international research has led some research suppliers to set up multi-country syndicated services on a regional or global basis.

Vertical integration has always been a feature of the European market research industry. All but the smallest companies have combined a client service function with a data handling facility (data collection, preparation, processing and printing). However, it seems that some companies are starting to question the effectiveness of this arrangement, especially where personal interviewing fieldwork is concerned. For instance, the US market typically has been characterised by a separation between the ownership of research companies and fieldwork suppliers.

The client-research company relationship is likely to be affected by growing Total Quality Management (TQM) and Service Quality demands and their associated measurement needs. Many companies are adopting TQM and cultivating service quality. Research organisations should expect to do the same if they wish to continue offering a consistently high level of quality in their services.

### Impact of the Single Market

Market Research on a national level has traditionally been a well developed market. On the contrary, on the European level, the market was relatively immature. The inception of the Single Market has brought about a radical growth in multi-country market research resulting in a doubling of the volume during the last ten years. The growth has been particularly evident in the Mediterranean countries.

The opening and expansion of the market has resulted in increasing competition which is mainly based on price. It has also led to a higher mobility of labour, especially of personnel in higher positions. This in turn has led to a convergence of compensation levels, although different laws on social security and benefits in Member States lead to considerable differences in labour cost.

The priorities for the coming period are the following. Special attention should be paid to the installation of a common currency, or alternatively, a common currency parallel to the current national currencies. Furthermore, harmonisation of in-

direct tax levels is of importance. Regarding the legal framework, harmonisation of data protection and privacy measures needs addressing considering that a forthcoming directive is expected to facilitate the implementation of different rules in individual Member States.

### REGIONAL DISTRIBUTION

When a market reaches a certain level of maturity, an equilibrium is established, of which continuous research makes up about one-third of total expenditure. Other regular services (e.g. advertising tracking, quality of service monitoring) add a further semi-contractual sector, partly substituting for ad hoc studies and partly reflecting overall growth in the information market. Other geographic variations stem from broader economic and marketing influences. In smaller countries, less research on new product development is undertaken as the major R&D activities and corporate headquarters are located elsewhere. This leads to more research involving the concepts, products or communication approaches that have been developed and researched more thoroughly in the larger EU markets.

Market research tends to be used relatively less in countries where the emphasis is on industrial products. There have been different patterns between the post-war evolution of markets and that of marketing. Restrictions on television advertising (and hence, related research) in a number of countries also have contributed to this differential use of market research across Europe as have varying levels of retail trade concentration (broadly, more concentration in the North than in the South). These and other factors mean that compared with the national level of economic activity, the research market is particularly well developed in the UK, France and the Netherlands and somewhat less so in Italy, Greece, Portugal and Spain.

### REGULATIONS

Market research, like many other industries, depends upon self-regulation. The ICC/ESOMAR International Code of Marketing and Social Practice is applied by all ESOMAR members and the national marketing research associations in all EU Member States. This Code guarantees the respondent's ano-

**Table 9: Market research

Source: ESOMAR Annual Market Study, major research companies, J. Honomichl

nymity and specifies responsibilities towards respondents, the rights of respondents, relations with the general public, the mutual responsibilities of clients and researchers and reporting standards. The Code is particularly relevant in the light of the EU Directive on privacy of personal data. For the time being, such restrictions vary from one Member State to another. Many countries offer an exemption of some restrictions to marketing research, recognising that it deals with aggregated and anonymised data and not personalised data.

Another Directive which could influence telephone research, is the proposed Directive for the protection of personal data in the context of digital telecommunications networks, particularly the Integrated System Digital Network (ISDN) and digital mobile networks.

The proposed Directive on Temporary Employment is likely to affect most free-lance interviewers and ultimately drive up market research prices in some countries. At the moment, legislation on social security and other benefits varies widely among Member States.

Other restrictions which vary from country-to-country can affect the right to conduct and publish public opinion polls, particularly in the run-up to an election. Although political opinion polling constitutes only about 2 % of the entire market research industry and actual pre-election polling less than 0.3 %, it naturally attracts a lot of media and public attention.

---

## OUTLOOK

---

The adoption of TQM by many major corporations brings the need for a method to measure its success, both initially and over a period of time. This will involve behavioural measures of business control monitors in efficiency and quality, satisfaction studies amongst internal as well as external customers and the effectiveness of the communication between and studies amongst personnel. Furthermore, research companies increasingly will be working with central and local government institutions in areas including education, health and crime prevention.

Another trend is the enhancement of tracking services with a demand for more multi-country tracking on a comparative basis, with more emphasis on various types of brand equity measurement, and a wider scope for tracking studies. The latter will include business control monitors, advertising effectiveness, business efficiency and environmental and other issues of public concern.

Timeliness is becoming an increasingly important issue as clients need more immediate data to support a range of strategic decisions which go beyond marketing. Downsizing already has been seen in the USA and the UK and will be a continuing trend with many companies undergoing restructuring and process re-engineering in an attempt to cut costs and increase efficiency. This will feed client demand for marketing intelligence and added-value services from marketing research institutes, and not just market data.

A major change will be the move towards pan-European data collection where the region is treated as an entity. One-stop data collection through integrated European data handling companies will move the industry further down the road of international research co-ordination and steps in this direction have been taken already with computer-assisted telephone interviewing.

The outlook for market research is good. The market research industry will need to make certain that it is proactive rather than reactive, and researchers must ensure that they provide not only techniques and data, but timely advice and strategies for decision-makers as well.

Written by: ESOMAR

The industry is represented at the EU level by: The European Society for Opinion and Marketing Research (ESOMAR). Address: J.J. Vlottastraat 29, NL-1071 JP Amsterdam; tel: (31 20) 664.2141; fax: (31 20) 664 2992.

# Management consultancy

NACE 839.1

Management consultancy has shown an impressive growth for over a decade, both in terms of revenue and employment. Since 1992, however, growth has slowed down, forcing some firms to close entirely. The first signs of recovery have become evident only in 1994.

The industry as a whole is maturing and entering an era of further professionalisation and internationalisation. The business provides services to improve performance; therefore, management consultancies' function is to anticipate future growth for their clients.

## INDUSTRY PROFILE

### Description of the sector

Management consulting is an advisory service contracted for and provided to organisations by specially trained and qualified persons who assist the client organisation, in an objective and independent way, to identify management problems, analyse and recommend solutions to them, and help, when required, in the implementation of these solutions. Management consulting comprises advisory services in areas such as information technology (information strategy and architecture, systems development, project management); corporate strategy (planning, finance, communication); operations management (i.e. production management, research and development, total quality management, logistics); marketing and sales; human resources and organisation development; and finance and accounting. In fact, the services offered are very diverse, and

Figure 1: Management consultancy  
Number of management consultants per million inhabitants, 1993

Source: Alpha Publications, London

include, amongst others, environmental impact studies, economic studies and project management.

The clients of management consultancy firms are to be found in all sectors of society, e.g. manufacturing (of consumer goods, industrial products, etc.), private sector services (banking, transportation, communications, entertainment, etc.), public sector services (government, health care, education, etc.) and utilities.

Market penetration of management consultancy differs from country to country. Relative to population, the Netherlands, the United Kingdom and Sweden are the most "consultancy-intensive" Member States. In absolute terms the UK, Germany

and France are the largest users of management consultancy services (see Figure 1).

### Recent trends

The total EU market for management consultancy services in 1993 is estimated at 9 000 million ECU. This is based on a survey conducted by FEACO (Fédération Européenne des Associations de Conseils en Organisation), whose members account for a significant share of the different markets (see Table 1).

The average revenue growth in the industry amounted to approximately 16 % per annum in the past five years. After a slowdown in 1992 (3 %) and 1993 (5-7 %) (growth was even less in Spain and Italy), a return to double-digit growth in the EU is expected in 1995, and the EU market could equal the US market by the year 2000. The consultancy market in the US is now estimated at 13.7 million ECU (Source: Consultants News).

The turnover per consultant depends on the type of service rendered and varies from 50 000 ECU to 300 000 ECU per annum, with an average of 150 000 ECU per annum. Recent trends in the consultancy industry can be summarised as follows:

- growing client sophistication and demand for value-added service;
- reduction of staff and even a shake-up of consultancies in some Member States;
- increase in the number of mergers, acquisitions and joint ventures;
- proliferation of aggressive solo and small consultancy operations;
- blurring of lines between traditional consultancy services and relatively new services (i.e. further penetration of information technology in practically all strategic and functional areas); and
- overall increase of competition in the industry.

### MARKET FORCES

#### Demand

The demand for management consultancy services is closely linked with macroeconomic factors such as growth of Gross Domestic Product and government expenditure. Variances in the consulting market size are also caused by structural and cultural differences among European national economies. Part of the demand, however, is generated by the consultancy industry itself by introducing and disseminating new management concepts and methodologies, such as business process re-engineering (BPR), benchmarking, time-based competition, etc.

In most market segments, the demand for consultancy services is boosted by rapid changes in the macro-economic environment, technology and customer needs. At the same time, a strong increase in national and/or international competition obviously has an impact on demand as well. Clients are re-designing their strategies, which often entail cost reduction programmes and performance improvement in operations, organisation, information and communication, or even a drastic redesign of the business processes. Privatisation measures in

many Member States and, in particular, Central and Eastern Europe also create opportunities for the consulting industry.

Developing markets exist in Central and Eastern Europe. The number of consultancies in these regions, established by nationals as well as by international consultancy firms, is increasing rapidly. Typical consultancy services needed in these regions are: infrastructure studies, investment and market analyses, legal system assessment and management development programmes. Aid programmes initiated by the European Commission and individual Member States have induced many consultancies to take on assignments and even open up offices in the areas in question, although competition is stiff and fees are under pressure.

Another promising market for international consultancies is the Asia-Pacific region, especially in Hong Kong, Taiwan, Korea, China, Indonesia, Malaysia and Thailand.

A market breakdown by type of client shows that the manufacturing industry generates 40 % of the revenues of the management consultancy industry, followed by the private and public sector services with 25 % and 20 % respectively. Utilities and other segments account for 15 % of total revenues. These are approximate percentages (see Figure 2).

A breakdown by type of service reveals that information technology (IT) is the most important type of service. This consultancy service accounts for 44 % of the total demand (revenues). Human resources rank second with 20 %, followed by corporate strategy and operations management with 12 % and 11 % respectively. Financial and accounting make up 6 % and marketing and sales 4 %.

### Supply and competition

The consultancy business in the EU is predominantly a local business. As recorded by FEACO, cross-border activities account for a scarce 15 % of total revenues. There is, however, no clear consensus in the industry as to what exactly constitutes cross-border activity. Anyway, more and more clients, especially in manufacturing and in the private sector services, are pursuing a European or even a global growth strategy, and international projects are definitely on the rise. Some consultancies handle international projects by setting up ad hoc teams with members from two or more countries. Others form a team that is based in one office and handles a large share of all international projects.

**Figure 3: Management consultancy Market breakdown by type of service, 1993**

Source: FEACO

The management consultancy industry used to compete with the internal consulting departments of large organisations (amongst others). In the past few years, however, many of these internal consultancy departments have undergone a reduction in staff, were privatised or sold to independent consultancies. Nowadays, management consultancy increasingly faces direct or indirect competition from computer firms, software houses, contract research firms, advertising agencies, accounting firms, banks, temporary work services, interim management firms, outplacement firms, consulting engineering firms and university-based consultancies. Some of these parties enter the traditional consultancy market, as is the case with IT-firms. Others offer services which more or less overlap traditional management consultancy services, as is the case with interim management and contract servicing.

## INDUSTRY STRUCTURE

### Companies

The supply of management consultancy services in the EU is very fragmented. The twenty largest consultancies, with turnovers varying from 80 million ECU to 800 million ECU, account for about 50 to 55 % of the total European market. Their individual share in the European market ranges from 1 % to 10 %. The remainder comprises over 50 000 small consultancies and an unknown number of 'solos'. The latter category has increased considerably, because many experienced executives laid off during the recession have set up their own consultancy business.

There are four broad categories of consultancies within the industry: generalists, strategy consultants, IT-specialists and niche players. Generalists usually offer a wide range of services covering some or all functional areas. Within this category, two sub-groups can be distinguished. The first sub-group comprises large consultancies with over 500 consultants each, most of them with global operations. The 'Big Six' accountancy-based consultancy firms (Andersen Consulting, Coopers & Lybrand, Deloitte Touche Tohmatsu, Ernst & Young Consulting Group, KPMG Management Consulting and Price Waterhouse) can be included in this sub-group. The second sub-group comprises medium-sized generalists, mainly focusing on their national market, but increasingly crossing borders, predominantly through networks or consortia of independent consultancies in different Member States.

Strategy consultants mainly target the top management of large corporations and government with consulting services in the area of strategy, policy and issues. The larger ones are based in the US and operate in the EU and/or worldwide through branch offices.

IT-specialists are active in areas such as information strategy and architecture, systems development and integration, and project management. This supply segment is relatively new compared to traditional consultancy services, but it has an impressive growth record. It comprises a variety of large consultancy divisions of multinational computer, telecommunications and software firms and a great number of predominantly small to medium-sized independent IT-consultancies.

Finally, niche players are highly specialised consultancies. These focus on one or two functional areas (e.g. human resources) and/or market segments (e.g. health care) (see Table 2).

### Strategies

Strategies pursued by consultancies basically reflect developments in the market place such as internationalisation, concentration, professionalisation, rapid developments in telecommunications, growing client sophistication and, last but not least, increased competition in the consultancy industry itself. The industry as a whole, after being hit by the recent

recession and feeling the influx of many newcomers into the market, has become more strategy-conscious.

Associations of management consultancies in various Member States have embarked upon ISO-9001 certification programmes for their members. Programmes are also in place to professionalise management consulting and create demand for and recognition of the profession. Nearly 20 % of all consultancies in Europe has been certified; and over 75 % has a quality management programme in place. With regard to improving professional qualifications, the postgraduate university course for management consultants, launched by the Amsterdam Free University and the Dutch association of management consultancy firms ROA in 1993, is exemplary.

Depending on market position, ambition and objectives, individual consultancies are likely to pursue one (or a combination of) the following strategies: shifting the focus of service portfolios, with concentration on core consultancy services and/or on core market segments, blending cultures within the present operations (e.g. traditional consultancy with IT-consultancy); restructuring practice areas in order to serve new emerging markets; and extending service lines by opening branch offices abroad, through acquisitions, mergers, joint ventures or by building/strengthening international networks.

### Impact of the Single Market

The emergence of the Single Market and, in general, the globalization of business, has positively influenced the demand for and supply of management consulting services. Demand has shifted from a predominantly local orientation to a more European and/or global orientation. Assignments from large scale companies (establishing, concentrating, relocating facilities and re-engineering operations) and from the European Commission have boosted revenues and increased cross border activities of leading consulting firms. The total number of consultancy firms has increased by roughly 30% since 1992 and, at the same time, competition has become fiercer. The top 20 firms now account for some 50-55% of total revenues. The strategies pursued by consultancies to become a European or even global player are primarily based on the size of the companies and the resources at their disposal.

The 'Big Six', accountancy-related, consulting firms currently have local offices in practically all Member States. A number of large national independent consulting firms have also expanded to neighbouring States, but mainly through permanent networks or ad hoc consortia with local companies in order to compete for assignments on a European level. Others are in the process of setting up networks.

Management consulting firms operate in a market which is characterised by little or no external regulation. Self regulation is achieved through the legal and regulatory framework which is formed through a number of national and European associations. These associations endeavour to harmonise professional practices, codes of conduct and certification.

The European Union itself, the possible expansion of the Union and programmes in neighbouring, non-Union states currently form considerable demand for services, although competition is formidable and fees are under pressure.

---

## REGULATIONS

---

There are no regulations specifically affecting management consultancy or regulating the qualifications of persons engaged in the profession. Similarly, there is no requirement for consultants to be a member of any professional association. In fact, the EU market is currently open to all consultants aspiring to work internationally.

The legal/regulatory framework is one of selfregulation via a number of national industry associations, membership of which is voluntary. Harmonisation of professional practices, codes of conduct/ethics, and standards of certification applied by the different associations is being examined by the FEACO and the International Council of Management Consulting Institutes (ICMCI).

---

## OUTLOOK

---

With the economy recovering in most Member States, prospects for the management consultancy industry are promising. After a slowdown since mid-1990, the industry expects revenue growth to return to double-digit figures on the order of 10 % or more per annum in the next few years. These prospects, however, will depend largely on the further recovery of EU economies. All market segments are expected to contribute to growth. Information technology, human resources and operations management are the most promising service lines.

Opportunities in Central and East Europe do exist but they depend a great deal on aid programmes initiated by the European Commission and individual Member States.

Competition within the industry will increase as a consequence of client sophistication, the rapid proliferation of new management concepts and methodologies, IT-firms entering the traditional consultancy market and vice versa, large multinational consultancies striving for major multi-national market positions, and the proliferation of aggressive solo and small consulting operations.

# Architects

## NACE 837

*Like most members of the liberal professions, the architect is a provider of intellectual services who cannot be satisfied with an ambiguous position, who is sometimes an economic agent and sometimes a public servant. The architect must always seek a function more deeply rooted in the economic and cultural fabric of society.*

*An architect's role is that of an active mediator between supply and demand, the production and "consumption" of real estate and the legitimate interests of the market and those pertaining to the community's physical heritage and quality of life. To play this difficult role, the architect must be able to apply the "rules of the game," which safeguard his/her independence and integrity and which, along with his/her ability, make him/her credible in the eyes of the public.*

*The strategic position which the architect occupies upstream of the building process confers upon him/her the dual role of a privileged observer of economic movements as well as of a stimulator capable of guiding demand according to the varied needs of society, including the still ill-defined need for a better ecological approach.*

### INDUSTRY PROFILE

#### Description of the sector

The architectural profession is characterised by the great variety of services it offers to meet the requirements of the market while at the same time anticipating future demand. There are two primary types of intellectual services that the architect offers, which complement each other. The first is artistic in nature and requires the creativity, imagination and invention needed to design a structure. The second is economic in nature. It comprises elements of technical know-how, management skills and material factors necessary for the implementation of a project. This part of an architect's job is connected to the fields of real estate and construction.

However, architectural services must not be confused with the act of building itself, even though it is the edifice that represents the architect's creative concept in structural form. Lastly, the complexity of programmes, finance packages, design and construction techniques (as well as overlaps between project planning and project management) is such that the architect is increasingly a member of a team rather than an independent worker. This can make it very difficult to discern what his/her services are, especially when s/he is coordinating design work and contracting construction work.

In short, architecture is an art. The ability to design buildings enables the architect to adapt to a wide array of demands - be they minor or major, private or public - ranging from interior design to town planning layouts.

#### Recent trends

The size of an architect's business is just as varied as the demands made of him/her. Over the years, the very large number of small practices (i.e. employing only two or three persons) has decreased to the benefit of larger firms. There are many reasons for this shift.

First, a substantial increase in the number of new graduates each year, contrasted with the sharp decline of activity in the building industry during the recent recession has deterred architects from going into business on their own. The next factor is the growing dominance of the commercialisation of supply in the building sector, which encourages working as a salaried member of a staff. Finally, the scale and complexity of some

new building projects no longer require the services of small architectural firms.

One of the questions confronting large firms (with staffs of more than 50) is how best to adapt to sharp market fluctuations. Some have responded by offering a wider range of services and diversifying their expertise. Thus, in large firms, there has been a steady increase in the number of departments specialising in a host of peripheral activities such as programming, marketing and project management, building management, engineering, equipment and design, etc.

The recession was particularly felt in the architectural services sector of the United Kingdom, Spain and France. In fact, in only a very few countries (e.g. Germany and Luxembourg) was this sombre period for EU architects not as gloomy.

It is the medium-sized architectural firms which appear to be coping best with the adverse business situation. This is probably due to their flexibility and ability to deal satisfactorily with conversions, renovations, restorations, etc. Business is still relatively brisk for the smaller firms as well. One activity in which they specialise is that of giving expert advice on technical matters and real estate, either for legal purposes or at the request of private individuals.

#### International comparison

Statistics suggest that the industrialisation of the building sector in the US and Japan is much more advanced than it is in Europe. This is attributed in part to the highly sophisticated prefabrication of residential buildings which exists there. It is still generally accepted that a real demand for "products" of this type does not yet exist in Western Europe. However, if the economic slump were to persist, offering a well-prepared supply of such products could succeed in resolving the problem of dwindling resources and time available and increasing needs to some extent.

EU architects are no more open than producers or consumers to taking such a step, which would call into question the specific architectural features which characterise most of the Member States. Nevertheless, even if the single internal market were to remain insensitive to the search for effective ways of responding quickly to a housing demand that requires a minimum degree of comfort and also affordability (such needs are still immense: 1.5 million new dwellings in ten years are planned for Germany alone), designers and building firms would still be able to offer their services and products to many other regions of the world where housing needs are even more acute (e.g. Eastern Europe).

## MARKET FORCES

### Demand

One of the most pronounced tendencies in the demand circuit for construction is that the course of this demand is increasingly going directly "from the consumer to the producer," with "designers" being passed by. In other words, to start a project customers tend to consult less with an architect and instead turn to a general contractor who can provide them with all the services leading up to the construction of a building.

Therefore, the self-employed architect is increasingly induced to offer services which will make him/her better able to meet cost requirements and time schedules, whatever the size of the commission involved. The "project manager" aspect is taking precedence over the demand for unique, personalised designs. This trend of customer demand has forced the architect to equip himself with computerised means of tracking price fluctuations, planning the design work and even executing it.

This increased technological capacity has been supplemented by an extraordinary improvement in computer-aided design facilities. These techniques are becoming common in medium-sized firms and even more so in big ones. The high performance of such technology opens up prospects which were previously unimaginable.

However, methods still need to be perfected for transmitting data between the demand from clients and the architect's design and then between the latter and the demand for implementation. These integrated systems would not only lead to gains as regards performance and cost, but also would enable the reliability of such communication itself to be improved.

Such prospects shed a positive light on the architect's strategic position in the economic process of construction by preserving his/her creative role as designer and his/her active role as coordinator. This necessarily presupposes a sufficiently independent position to safeguard the architect's credibility in the eyes of those who seek his services.

### Supply and competition

One of the major markets for architectural services is public orders, although these are shrinking markedly in most countries as a result of the recession and the endemic shortages of public funds. A common method of gaining access to public orders is to participate in architectural competitions. It may be said that France is in a remarkable position in this respect (over 2 000 such competitions are held there each year). This is due to a legal obligation to hold competitions for the allocation of public architectural orders involving fees in excess of 900 000 FF, including taxes. French architects complain, however, that the return from these competitions is too low, because most of them do not offer sufficient compensation to unsuccessful competitors.

This tradition of architectural competitions differs from country to country in Europe. In Belgium, for instance, public competitions for the award of public contracts for architectural work are rare. There might be a decisive change in this situation in the very near future, as a result of the transposition of EU Directive 92/50/EEC on "Public Contracts for Services" into national law (see Regulations).

## INDUSTRY STRUCTURE

The following analysis is based on the results of far-reaching surveys for France, the United Kingdom and Belgium. Unfortunately, at the time of writing, figures were not available for the rest of the EU, and, therefore, no statistical analysis was done for the other countries.

### Companies

According to l'Observatoire de l'Economie de l'Architecture, the number of architects employed in France has more or less stabilised since 1991. In 1993, 26 280 architects worked in France (around 87 % of them are men), and more than one-third worked in the Paris region. Since 1983, over 70 % of all French architects were self-employed, although the level had dropped by 6.4 % by 1993 (to 71.9 %). Salaries also seem pretty steady in the sector, although between 1990 and 1992 the average annual income for all French architects actually increased slightly, rising from 25 869 to 26 347 ECU per architect (an increase of around 1 % per annum).

The number of architects in the UK is about that of France (24 000 and 26 280 respectively), although in proportion to the overall population it is a bit less. Of those, over 80 % were employed full-time; 76 % in the private sector and 24 % in the public sector. As in France, about one-third of the architects work in or around the capital city: 26 % of all British architects work in the greater London area. On the other hand, whereas salaries increased by 1 % in France between 1992 and 1993, they decreased by that amount between 1993 and 1994 in the UK. Regionally, incomes in the London area averaged 24 000 pounds in 1994, falling 9 % since 1993. Similarly, they fell 8 % in 1994 in the Midlands and East England, where they average 20 700 pounds. Conversely, in the south-west and Wales, salaries rose 7 % in 1994, to 23 000 pounds (Source: RIBA survey, April 1994).

Structurally, the majority of private practices are small firms employing one or two people (there are twice the number of such companies than those with six to ten employees). Only 8 % of all British private architectural firms have a staff of more than 50 people.

It is interesting to note that while the number of architects in Belgium is only about one-third that of the other two countries (8 685 including trainees), even without the trainees the percentage of architects relative to the entire population is somewhat higher. 73 % of them are self-employed (18 % are self-employed but in a partnership), and 57 % of all Belgian architectural firms are single-person operations. The average annual net income of self-employed architects in all of Belgium is 17 777 ECU. It is slightly higher in the Brussels area (21 000 ECU) (Source: 1992-93 survey by the Conseil National de l'Ordre).

### Impact of the Single Market

Directive 85/384/CEE, in effect in all Member States, gave architects the right to set up business and offer their services anywhere in the Union with a minimum of constraint. These rights are linked principally to the legal and regulatory contexts of each of the Member States. However, the widespread hope that there would be more active participation and exchange of architectural services was somewhat frustrated by the economic recession.

It must also be said that Europe and its Member States have introduced regrettably few instruments for the promotion of cross-border architectural exchange. In practice, the G.E.I.E. represents the only legal framework with satisfactory prevalence in cross-border architectural activities. This framework does not, however, entirely meet partners' needs for the integration of their activities.

Real cross-border movements for architects will rather be brought about by the implementation of specific directives, such as directive 92/50/CEE on the Public Service Market, whose translation into national legislation has so far proved to be a rather slow, but which should allow a more systematic development of procedures in architectural collaboration.

The Council of European Architects is working actively at all levels to promote the harmonisation of working methods

and to encourage policies of free movement in the exchange of goods and services within the European Union.

## ENVIRONMENT

Architects and their representatives have taken very bold stands on ecological issues. These statements recurred regularly between 1992 and 1994, particularly at the Rio Conference in June 1992, the Congress of the International Union of Architects in Chicago in June 1993 and the Münster Congress in September 1993. Furthermore, the Architects' Council of Europe (ACE) was co-opted to a European strategic seminar at the end of November 1994 by DG XI, in connection with the White Paper on "Growth, Competitiveness and Employment," which included a workshop on the urban environment.

Within the architectural services industry, the idea of environment is not solely a matter of nature (e.g. water, air, land, etc.). In addition, it comprises the constructed physical environment (i.e. urban spaces, architectural heritage, eco-architecture, etc.).

Architects are now making more stringent demands for credible information on the real ecological balances of materials, products and implementation techniques. But few scientific and technical research institutions give enough weight to this field in their programmes. As a result, designers remain ignorant of the consequences of their architectural choices.

The only reference field is that of energy savings: most architects have changed their design practices, and now use both passive energy techniques, insulating materials and air-renewal methods.

But ecological problems transcend national frontiers and therefore have to be tackled at all levels and on all scales. Harmonisation is thus a typical Community problem, one which represents a real challenge to all EU industries.

## REGULATIONS

The idea of free competition embodied in the Treaty of Rome puts some pressure on professional activities governed by rules which influence prices. In several EU countries, the architectural profession is regulated by the recognition of a degree in architecture and the registration of the holders of that degree.

EU Directive 85/384 EEC stipulates that, "... considering that architectural creation, the quality of the structures designed, their harmonious insertion in the surrounding environment, respect for natural and urban landscapes and for the collective and private heritage are a matter of public interest:... reciprocal recognition of diplomas, certificates and other evidence of formal qualifications must be based on qualitative and quantitative criteria which ensure that the holders of recognised diplomas, certificates and other evidence of formal qualifications shall be able to understand and translate the needs of individuals, social groups and communities with regard to spatial arrangement, the design, organisation and execution of building projects, the conservation and enhancement of the heritage in the form of buildings and protection of the natural equilibrium...."

In the UK an attempt to abolish the registration in 1993 failed. In Spain there has been some pressure to reduce the prerogatives of the professional boards, which were seen as being either too protectionist or too corporatist. Ireland has attempted to introduce registration that would extend the right to exercise the profession to insufficiently qualified persons. The debate remains open, however, as some countries, (e.g. Denmark) favour greater regulation of the profession. In France, recent legislation assigned more extensive and compulsory checks on the execution of public works. Thus, the situation varies greatly from country to country.

Be that as it may, the public importance of architecture is constantly recognised and was confirmed by this directive. There is little probability of the emergence of a consensus in favour of a drastic deregulation of the EU architectural profession in the near future, because most of the ethical rules by which it is guided are in line with the interests of the "consumers" as individuals or as a community.

Two directives evoked strong reactions from European architects. The first concerned the liability of providers of services. This horizontal directive has been withdrawn, but the European political authorities have instructed architects to coordinate, within the GAIPEC, the views of all the partners in the construction sector on the possible harmonisation of liability, guarantees and insurance. This step might lead to a new vertical directive or a sectoral recommendation. The second directive, approved by the European Parliament (EP) in 1992, concerns safety and health at mobile work sites. Directive 92/57/EEC has been transposed into national legislation partially in France and completely in the Netherlands. Everywhere else it has encountered strong opposition, and in Germany the Bundestag actually rejected it. In short, architects are opposed to this directive insofar as it implicates them in liabilities which were hitherto assigned to the builder alone.

Another important directive is Directive 92/50/EEC, which lays down rules for public contracts for services, including architectural services, involving fees in excess of 200 000 ECU. Although this directive does not make competitions compulsory, it does open the sector up to cross-border competition by harmonising basic Community rules for their announcement and transparency. It is to be hoped that the organisers will use the regulations which guarantee the credibility of demand. This directive will make a positive contribution to healthy competition between architectural firms and will encourage the development of an order culture, which is necessary not only for the harmonisation of procedures, but also for true openness in the quality of architectural demand. It could also curb the abuse of procedures for invitations to offer general "design and build" contracts, in which the work to be tendered also includes the architectural design. Several countries, including France and Germany, have taken steps in this direction after seeing the adverse effects of these procedures on both architectural quality and the cost of implementation.

Cooperation by architects with the Commission and the EP is steadily improving. The ACE has made proposals concerning the environment and the organisation of a European competition for executed urban architectural projects. In 1995 the ACE will publish the "White Paper on Architecture in Europe," which should make a useful contribution towards a better profile of the general or specialised professional architects within this wide field.

The industry is represented at the EU level by: Architects' Council of Europe (ACE). Address: Avenue Louise 207, Bte 10, B-1050 Brussels; tel: (32 2) 645 0905; fax: (32 2) 645 0964.

# Construction economists

## NACE 837

*The construction economist, traditionally known in various countries as the quantity or building surveyor, the metreur-verificateur, and the geometra, is a professionally qualified expert who assists the client/owner/building promoter in contractual, financial, managerial and economic matters, to optimise the value of a construction project over its lifetime.*

### INDUSTRY PROFILE

#### Description of the sector

Construction economics encompass:

- project development - new and rehabilitation;
- project and quality management;
- feasibility studies - including environmental issues;
- risk analyses related to construction;
- cost information and time scales;
- bills of quantity;
- advice on design and construction procurement;
- management of design and project documentation;
- tender procurement;
- planning of site and security measures on site;
- logistics to and on site;
- planning of building maintenance and operation;
- facilities management;
- valuation of property;
- services related to building pathology; and
- arbitration and related services.

In France, construction economists are educated as construction economists, while in Ireland and the United Kingdom, construction economists are educated as quantity surveyors and building surveyors. Traditionally, quantity surveyors deal with new construction, while building surveyors are specialised in facilities management, building pathology, and refurbishment. In Germany, construction economics are performed by architects or engineers. In Spain and Portugal construction economists are trained as technical architects: Aparejadores y Arquitectos tecnicos. In the Netherlands and Finland they are architects and engineers who have specialised in construction economics. Construction economists in Belgium are predominantly engineers and in Denmark they are architects, construction technologists and engineers who have specialised in construction economics and participated in a post graduate training programme.

As professional training and the role of the construction economist varies between Member States, two interlinked Pan European Associations have been founded: AEEBC and CEEC. The general objectives of AEEBC and CEEC are to:

- establish guidelines for the definition, contents, practice, and supervision of construction economics;
- coordinate working methods;
- facilitate the exchange of information and experience;
- promote basic and continuing education of construction economists; and

**Table 1: Construction economists**

- promote the use of qualified construction economists.

So far, CEEC has organised a system for the exchange of information and experience; especially on costs, time scales and tender actions.

The principle of cooperation and exchange of information is a common definition of construction economics. The next phase of Pan European cooperation will be the development of guidelines and tools for the execution and management of construction.

#### Recent trends

In 1994, close to 90 500 construction economists were registered in national, professional associations covered by AEEBC and CEEC in the EU, excluding Germany, where presently no figures are available. Apart from the United Kingdom though, there is no data available on turnover and value added. Turnover in the United Kingdom by quantity and building surveyors in 1994 was about 4.0 billion ECU.

Activity of construction economists mainly follows general economic developments, but performs slightly better than the construction sector in general. This is due to the EU industry focusing on re-engineering and value for money.

### MARKET FORCES

#### Supply and demand

Capacity of the EU construction industry exceeds demand for construction. This will be the case for years to come, except in eastern Europe. Demand here refers to effective demand reflected by the resources actually allocated to construction, not to the obvious need for improvement of older dwellings with poor sanitary installations, inadequate heating systems and in poor repair. Only a substantial increase in productivity, consumer orientation and a large-scale, determined EU effort to obtain a substantial reduction of CO<sub>2</sub> and CFC pollution within a short span of time might be able to redress the balance between supply and demand in the building industry. The resulting demand for the modernisation of existing buildings could lift construction demand to full capacity levels.

The number of construction economists in EU countries reflects the degree of competition and the stage of professionalism in the particular property market. Until now, the decision to start a construction project has been motivated, almost everywhere, by a direct need for production infrastructure, or for dwellings for growing city populations, and not by considerations on the internal interest rate of the project. The exception is the United Kingdom where professional developers of construction projects emerged, as early as the second half of the last century. Furthermore, until recently, a substantial part of income from investment in property originated from increases in value. Consequently, the incentive for im-

provement of productivity in construction has been small. However, over-capacity in the industry and high vacancy rates in existing buildings have depressed the value of real estate substantially. However, unoccupied space is not only a result of economic recession, but a consequence of increasing cost competition in many economic sectors. In addition, increases in productivity are often accompanied by a decline in the need for labour and space.

Response to increased competition in the construction sector has been an increase in productivity, achieved by an increasing specialisation of various construction activities. This creates a need for the services of the rapidly growing number of construction economists. Their function, in the construction process, is to optimise the contractual and financial interests of the client.

The need for construction economics is amplified by the EU Directive on Procurement of Services. Public procurement contracts with architects, consulting engineers or design teams exceeding 200 000 ECU can be awarded only after an open or limited tender. Criteria for awarding contracts are either lowest price or the economically most favourable bid. The EU directive on services only deals with public procurement but, in reality, the principle of tendering is expected to be applied to almost all procurement of services. For these reasons, there is a growing demand for the skills of construction economists even though demand for construction is declining. Their skills are needed by purchasers of construction services in planning the procurement of services, evaluating the bids, as well as, formulating competitive proposals.

### Production process

The nature of the services provided by construction economists evolves over time. The following elements are becoming increasingly important:

- optimising the financial interests of the client;
- assistance with bidding for construction services;
- quality management; and
- care for the environment.

Financial interests of the client are optimised by evaluating the expected payback of the project over 20-30 years (before the project is started), and by efficient management of the design and construction process. As future income from property will only be derived from the difference between income/rent obtained and the costs of running and maintenance, calculation of the payback must focus on life cycle costs, location, indoor climate, design and various 'green' issues, in that order.

The salient characteristic of tender and bidding for immaterial services is the difficulty of specifying the exact nature and quality of services wanted. The present classification of services in the construction industry, often drawn up as part of fee scales, is rather general and, consequently, not very suitable for tender or bidding. In response to these problems the CEEC has started to formulate a Code of Practice. The Code is a model for project management based on a functional data and process model independent of procurement methods and the roles of various professions and kinds of firms. Initially, it will merely serve as a structure for decision making. Gradually, however, it will prescribe general contractual conditions, definition of services, logistics etc.

Quality management, according to EN 29 001, is expected to be included in all contracts. The primary aim of quality management standards is not to improve basic services but to reduce: time spent on negotiation of contracts; time wasted on misunderstandings; inter-professional friction; and, judicial disputes. For the client, the main advantage will be the reduction of indirect costs. Safeguarding the interests of the consumer, in the case of design and construction defects, may be provided by an EU directive on liability.

A thorough and intelligent use of information technology and exchange of data offer possibilities for substantial cuts in production costs. Furthermore, as a service to the client, a database can be constructed with all data relevant to facilities management, structured in a functional way. When such a database is handed over to the operator of a completed building, costs for organising facilities management can be cut substantially.

---

## INDUSTRY STRUCTURE

---

### Companies

Construction economists are engaged as employees by governmental institutions, local authorities, architects, contractors, and in consulting companies owned by construction economists. The total number of construction economist companies operating on a business service basis is about 10 000 in the EU. In most Member States, the majority of construction economists are employed in private consulting companies. However, in some countries, notably the Netherlands and Spain, a substantial majority work as employees within contracting organisations. In all countries a smaller number of construction economists work for the public sector.

The total number of private companies within the EU varies from 10 in Belgium to 3 000 in Spain. The average number of qualified staff in such firms is less than 10, except in the United Kingdom, where the average is 20. However, there are a small number of firms, particularly in the United Kingdom, with a total world-wide staff in excess of 100, and, in some instances, in excess of 500. In Denmark, only 5 private companies work exclusively with construction economics. The others are predominantly architectural firms owned by or employing construction economists.

### Impact of the Single Market

Although the effects of the Single Market Programme are positive, the sector is very prone to new legislation on a European level as well as on the national level. National laws and legislation differ significantly between Member States, thereby constraining cross border activity. Competition on the one hand has increased due to, for instance, public procurement but on the other has been inhibited by protective measures installed by individual Member States.

A lack of standardisation exists within the sector. This is especially applicable to training- and qualification levels. Some Member States offer under- and post graduate courses in construction economics. Other Member States do not offer specialised courses. In these instances, the sector is formed by, for instance, architects and engineers who specialise in this field. This discrepancy inhibits the ease of working in different countries.

Although the outlook for the sector is very much dependent on the economic cycle, it can be described as positive. The increasing relevance of environmental measures and the social dimension, i.e. worker safety and productivity, lead to a higher demand for services. In addition, due to an increasing consciousness of life cycle costing and return on investment, the role of the Construction Economist is becoming increasingly important.

---

## ENVIRONMENT

---

About half of the CO<sub>2</sub> emissions in Western Europe results from the use of energy in buildings for heating, lighting and air conditioning. Air conditioning also accounts for about half of the CFC emissions. Consequently, major changes have to take place in the design of new buildings, as well as in existing buildings. Along with other environmental concerns, this presents an enormous challenge to building owners and a need for services rendered by construction economists in order to safeguard their financial interests.

---

## REGULATIONS

---

No formal regulations exist for construction economists, but professional education is based on the directive on Mutual Recognition of Diplomas.

---

## OUTLOOK

---

In general, the outlook for the construction industry is depressing. In contrast, due to increased competition among building owners, the directive on Procurement of Services, and the need for a variety of measures to protect the environment, the outlook for construction economists is quite good. The sector will experience growing demand for its services in construction, as well as civil and heavy engineering. In addition, the need for new construction and extensive rehabilitation in Eastern Europe and an absence of know-how concerning project management and other kinds of construction economics will increase demand for construction economists.

# Engineering consultancy services

## NACE 837

In 1993, engineering consultancy and related services affiliated with EFCA included 24 national associations from 17 European countries (12 EU and 5 EFTA countries) representing over 8 400 firms active in the field of engineering consultancy and employing about 200 000 people. EFCA represents 40 % of all engineering consultancy in Europe; wherein the total sector comprises 21 000 firms employing 500 000 staff. Due to the generally poor economic situation in recent years, the sectoral turnover decreased with the provision of services far outweighing the demand. The increase in private demand could not compensate for the feeble level of public demand. For 1994, another minor downswing was expected, but in the medium term, a slight upswing, caused by new market opportunities like environmental and facility management, could be forecasted.

### INDUSTRY PROFILE

#### Description of the sector

Engineering consultancy services are defined as the intellectual services which aim to optimise investment projects in industry, construction and infrastructure, at all stages of a project: from its conception through to its final execution. These services are provided either by engineering consultancy firms, consulting engineers, engineers employed by construction firms, design firms or public agencies which employ engineers and design consultants, or by individual engineers and consultants. All of these are armed with highly specialised technical knowledge and provide comprehensive multi-disciplinary neutral services, independent of any supply or manufacturing interest.

They seek to optimise investment projects by proposing the lowest cost, highest investment productivity engineering solutions, consistent with the particularities of the specific markets. The broad range of their services includes: pre-feasibility studies, preliminary designs, cost-benefit analyses, working drawings, efficiency investigations, building management/supervision of construction, technical management/advisory services, as well as overall management, planning, project supervision and logistics.

Engineering services include engineering design and construction. An engineering consultant can be responsible for only a part of a project (e.g. the construction itself) or for an entire project (i.e. through to the final inspection). The latter projects are known as turn-key projects. Engineering services apply to residential and non-residential buildings, civil engineering (e.g. transmission lines, power plants, transportation facilities, public work facilities, environment, telecommunication and industrial plants) and to other technical services (e.g. geology, hydrology, shipbuilding and marine engineering).

Consulting engineering services has close ties to other service sectors, such as architecture, quantity surveillance and land surveillance, as well as to all sectors of the building trade industry. For the housing, construction and civil engineering sector, consulting engineering services are of the utmost importance, since obviously no construction could be made without design, planning and project management. Though engineering consultancy services represent only about 8 % of the construction industry, their economic significance is far more important, because the sector causes a large turnover in the production of equipment and material. The total amount of private and public investments involving engineering consultancy within the EU are estimated at 670 billion ECU. The engineering consultancy requirements amount to 55 billion ECU.

Traditionally, a great portion of consulting engineering services has been provided in the UK, where they were offered for the first time in the 18th century by the British construction

industry. After the Second World War, Denmark, Germany, France and Italy became more important within the European market.

Engineering consultancy services are not separately accounted for and therefore are not reported in official statistics. They are, to a large extent, part of the building trade industries. Data are only available for the EFCA and its national member associations, representing 40 % of the sector in Europe.

### Recent trends

The period since the end of the Second World War shows different trends in the development of consulting engineering services. In the production sector, UK companies faced more and more competition with US companies. Since the mid-seventies, German, French and Japanese firms also have become of greater importance in the international market, and gradually the US and the UK have lost their leading positions in the sector.

On the demand side, international aid programmes were responsible for a growing export market in the sixties and early seventies. Foreign direct investment and large public expenditures for the development of infrastructure in the former Third World Countries launched this trend. The oil price shock in 1973 caused decreasing income especially in the Middle East, where aid money was spent on the improvement of the national infrastructures. At the beginning of the eighties a worldwide recession, accompanied by strong inflation and high interest rates, influenced the market. Consequently, planned projects were sometimes cancelled or diminished. During the second half of the eighties, utilisation of consulting engineering services started to rise. But the structure of demand had changed, with mainly East European countries spending money on the development of their infrastructures.

During the nineties the consulting engineering services within the EU have been mainly offered by British and German companies. Although they lost their leading positions, US firms also played an important role in the international market. Consumption is mostly coming from the Visegrad and former GUS states and from the states which were involved in the Gulf War.

Also significant for the nineties has been the diametrically opposed development of the number of firms on the one hand and the number of employees on the other. While the number of firms has increased gradually since 1990, the number of employees has, after a visible rise from 1990 to 1991, steadily decreased since 1991. In particular, the number of draftsmen, secretaries and accounting personnel was reduced. The average number of employees per firm in 1993 was again smaller than the year before. And, the average turnover per employee in 1993 was significantly lower than that in 1992, because the total EU turnover was reduced by around 12 %. So, after a slight yearly increase between 1990 and 1992, the turnover of the registered firms in the EU shows a loss of 2.5 % from 1992 to 1993.

### International comparison

The traditional pattern of the output of consulting engineering services is becoming more and more blurred. Although the market is still dominated by companies with headquarters in the United Kingdom and the USA, it is necessary for the large companies to have representations all over the world. This is especially the case for American and Japanese companies, as their countries are too far away from those countries with the most active body of customers.

During the first two-thirds of the eighties, a great part of the consumption had its origin in less-developed countries. Today, foreign trade is still of significant importance for the engineering consultancy service sectors, dominated by a flow from developed to less-developed countries. In this context it is interesting to notice that some EU countries mainly serve specific regions of the world. For example, Denmark's consultants often work in Africa. The majority of companies exporting their engineering consultancy services are registered with international organisations which play an important role in the awarding of contracts to consulting firms. The most well-known are the World Bank, The Asian, Inter-American and African Development Banks, the EU, and some organisations of the United Nations like the EBRD, FAO, WHO and UNDP.

Since 1987, domestic markets, especially in the EU countries, have become more important. Intra-EU trade is also increasing, as the internal market has brought about a tendency for companies to focus their business on to other EU countries. In general, there is a decrease of exports to less-developed countries which is compensated for by an increase of demand in the developed states. In the East Asian markets (ASEAN states and the little tigers) - the main markets for US and Japanese companies - demand for engineering consulting services is still high, as these economies continue to grow very quickly.

EU exports of consulting services in 1993 decreased from that of previous years. On the other hand, some national markets are still very export-oriented, namely Denmark, France, Italy and the United Kingdom. Italy is the only EU country to have raised its turnover from 1992 to 1993.

## MARKET FORCES

### Demand

Demand for engineering consultancy services is closely related to the general economic situation and activity level of individual countries. After a recession in all EU countries, most of the national economies are beginning to recover. Three main factors are important for the sector's growth: public and private investment, technological progress and the availability of finance. The average engineering consultancy services in the EU derive about 75 % of their annual turnover domestically (except Italy). In the export market, the most significant demand comes from international working organisations. Contracts are still being offered for consultancy in the Third World and less-developed countries. Additionally, some large European projects (e.g. the channel-tunnel) kept the intra-EC demand for engineering consultancy services high during the last decade.

### Supply and competition

Domestically-generated turnover from public demand decreased again between 1992 and 1993, as private demand dominated in almost all EU countries. The reason for this was the lack of funding for infrastructural investment in most EU countries. Housing construction replaced public investment as the market's driving force in most EU countries. But a new range of clients - the so-called developer-funders - is coming in, and some EU countries already are using private funds to finance public infrastructure work.

The recession seems to have made price the most frequently used criterion, creating concern among engineering consultants. The scope of work in a commission of engineering consultancy is often ill-defined and must itself be developed by the engineering consultant together with the client. When it is known that a commission is to be awarded at the lowest price, there is inevitable pressure on those submitting offers to calculate their proposals on the use of less experienced (and therefore less costly) staff. This tends to minimise the scope of the work offered, limiting it to no more than what the client specifies. Furthermore, an apparent savings in the initial stages rarely guarantees that the final project will be the best value for the money.

Most of the leading international agencies, however, select engineering consultants by using the combined criteria of quality and price. Meanwhile, the national associations try to set up systems which involve a greater amount of selection criteria. The main criteria for the placing of orders should be the firm's technical quality (including the quality of previous jobs fulfilled), price, workload capacity and competence for the particular job.

On public projects, private engineering consultancy firms are often in great competition with in-house engineering consultants. This is another competitive disadvantage for private consulting engineering companies, leading them to sometimes cut their profit margins in their bids simply to survive. The externalisation of in-house services could prove to be a decisive factor for the development of the EU engineering consultancy service sector.

Today, small enterprises, which cover only a part of the services required by the clients, face strong competition from large enterprises, which have their own planning offices and thus can offer the complete management and coordination of projects. This means that smaller firms or independents must specialise in fields where the larger enterprises do not operate, or cooperate more with larger enterprises, as has been the tendency in the past. The Single European Market should facilitate such cooperation.

In cases where foreign enterprises are commissioned with work abroad they will need local experts who know the ins and outs of the national markets and their regulations. 1993 already showed a tendency towards externalisation as well as a reduction of staff in favour of more freelance consultants who are hired by large companies. This means that large en-

terprises are working as main contractors, hiring some small specialised firms as sub-contractors for lower fees.

Price competition seems to exist primarily between smaller firms. And, whereas large firms receive the main profits, smaller firms are often facing bankruptcy. Labour cost advantages have had a minimal influence on the competition on the international market, however, with the exception of some firms from India and Brazil, which have succeeded because of their lower labour costs.

## INDUSTRY STRUCTURE

### Companies

There is a very high concentration of large companies in the sector, especially in Italy, the United Kingdom, Spain and the Netherlands. Going by the number of companies, Germany was in first place within the EU in 1993. But Germany's service structure is dominated by SME's, many of which are one-man firms. Other firms with a very small number of employees are located in Ireland. It is interesting to note that the greatest average size per enterprise within the EU is in Italy.

The largest engineering firms in the world (again, calculated according to number of employees) have their headquarters in Canada, the US and Finland. Of the Top 30 companies in the world in 1991, thirteen were from the US, with seven being British. There were two companies from Canada, the Netherlands and Sweden, and one from Finland, Germany, Japan and Egypt. Within the EU and EFTA countries the largest companies have their headquarters in The Netherlands, the United Kingdom, Finland and Sweden. Swedish and Finnish companies are of great importance to the European market.

### Strategies

For a few years now, even large companies have had to cut back their staff because of the recession, which is what has led to the proliferation of small enterprises. And, for cross-border projects or projects in countries where the contracting companies are not represented, large firms often cooperate with domestic, one-man firms specialising in design and construction, which have a thorough knowledge of the domestic market.

Three countries - Germany, France and the United Kingdom - held more than two-thirds of the turnover of all EU companies in 1993. Considering exports as a share of the total turnover,

**Table 3: Engineering consultancy services  
Development of employment (1)**

Total	167 570	167 600	170 780	173 220	176 030	177 910

(1) 1992 and 1993 are EFCA estimations; 1994 to 1997 are estimations of Volker Stabernak Consulting  
Source: EFCA

the United Kingdom is on top. Italy lost its second position in 1992 to Germany and France. Turnover per employee is the highest in France.

In the sixties, engineering design services were closely related to trade in engineering equipment. Due to the externalisation process, engineering design companies now operate more independently. However, engineering consultancy still brings about the export of material and equipment.

Mergers and acquisitions are undergone by companies which hope to gain market positions abroad. In the last few years, only a few of the larger companies merged. Since 1990, the list of the most important companies within the EU has not changed much. If companies expanded, it was mainly by acquisitions and not by organic growth, but the trend to create international alliances continues.

### Impact of the Single Market

The internal market for this sector is characterised by the relatively low level of cross border activity. Only some 3-4% of services are exported between Member States. In comparison, some 30% of services are exported to countries outside the Union. A reason for this is that the national markets are relatively saturated with consulting firms which makes penetration into these markets difficult.

There is still an inherent reluctance to open up domestic markets to foreign companies. Companies wishing to offer their services in a particular country need to adhere to numerous rules and regulations, for example, the requirement to be registered as a Engineering Consultant locally. This has resulted in numerous mergers, acquisitions and joint-ventures, as companies feel the need to be represented in the different Member States.

In general, the creation of the Single Market has had a positive effect. The size of the market has increased considerably and so has the level of competition. Competition is mainly based on price, which is causing some concern as to the quality of services rendered.

Issues which need addressing are the continuing payment of subsidies by certain Member States as well as the existence of 'in house' services. These are not open to public procurement but do, however, constitute some 45% of the total market.

### REGULATIONS

EU regulations have an important influence on engineering consultancy services, albeit one which varies from country to country. Some of the EU regulations influencing the sector are: The Directive on Services, the Directive on the Award of Public Service Contracts (Public Procurement) and the Directive on minimum safety and health requirements for construction sites.

The Directive on Services obliges all public contracting authorities in all EU countries to publish calls for tenders for public service contracts, the estimated value of which is not less than ECU 200 000. The aim is to open the services market for transborder services and thus increase competition. But the Directive is not yet adopted in all EU countries (e.g. France). Regulations for fees are not included in this Directive, even though the national regulations are still valid. Consultants working in foreign countries have yet to consider the national remuneration systems (e.g. the so called HOAI in Germany). Beyond that, some national associations developed a number of criteria which should be considered for the awarding of contracts in the national market.

The EU Directive 92/50 for Public Procurement relates to the coordination of the procedure for the award of public service contracts. Studies with fees exceeding 200 000 ECU fall within this Directive. They are to tender on the EU level. This Directive already has been incorporated into national law in Denmark, Luxembourg, The Netherlands and the United Kingdom.

The Directive about the minimum safety and health requirements is still being discussed in most EU countries. So far, it has been adopted in Luxembourg only, and is supported now by the ISO regulations 29000 - 29004 about quality management and quality assurance. The main subject of this Directive is a liability of 20 years for construction, which would result in an increase in costs. Discussions now involve the amount of the risks which should and/or could be covered by insurance.

### OUTLOOK

The improvement of the general economic situation in all EU countries which was expected in 1994 began in the second half of that year. Continuing small increases for most of the EU economies are forecasted for the years 1995 to 1997. But the most important clients for consulting engineering services, i.e. the public authorities and the states, are still in a bad financial situation, with ever increasing deficits. This situation is of great significance for the short- and medium-term perspectives of the engineering consultancy services sector. Presently, the demand for engineering consultancy services by public administration is at a standstill in some EU countries.

But the new tendency to finance infrastructure projects by private funds will cause new demand for consulting engineering services. The employment situation will be influenced accordingly, gradually increasing through 1997.

Other factors that will probably improve the situation of the engineering consultancy services in the near future include the harmonisation of environmental regulations, stricter environmental control and technological progress in Europe and the USA, and the reconstruction of the infrastructure in the former planned economies in Central and East Europe. Moreover, large projects planned in Asia (e.g. a huge dam at the Jangtse river in China), Africa and Latin America, and the construction and completion of a European transport network also should cause additional demand for engineering consultancy services.

Other new tasks can be found within the field of facility management as a cost saving instrument in the administration of buildings. An integrated and computer-based information system on buildings would supply the data for a more comprehensive controlling, which takes advantage of synergies, organises work more effectively and economises the operation of buildings.

As the above paragraphs imply, there is a substantial need for many of the engineering consulting services in Europe, which should have the effect of improving the market for them during the rest of this decade. Meanwhile, the Single Market is expected to encourage competition between domestic services and foreign services.

The industry is represented at the EU level by: European Federation of Engineering Consultancy Associations (EFCA). Address: Avenue de Cortenbergh 79, bte 7, B-1040 Brussels; tel: (32 2) 732 4990; fax: (322) 732 5126.

# Geodetic surveying

## NACE 837

Due to wide-spread market saturation, the industry will show no growth in the near future, even though the economy is showing an upturn in many Member States. The long-term prospects are promising, however. The number of people employed in the industry will remain stable, as qualitative demands rise. There are over 65 000 professionals working in the industry, of which more than one-half are in France and Germany. About half of these are working in the public sector. There is a trend towards larger companies offering a more diverse range of services, while small companies specialise.

### INDUSTRY PROFILE

#### Description of the sector

Geodetic surveyors measure the size, position and three-dimensional shape of the earth's surface and the objects upon or in it. The following areas of expertise fall within this broad description: cartography (national and international, small or large-scale maps, navigation charts, etc.), measured building surveys; tunnelling and mining surveys; measurement and location of underground structures and services; cadastral and boundary surveys; industrial and engineering surveys; preparation for construction; monitoring and deformation surveys; land and geographic information systems; ocean bed, coastal and river surveys; measurement of marine resources; and other surveying services.

In many Member States, urban and regional planning, land and building valuation, soil testing, land management, and management of development also come within the scope of the geodetic surveyor, although not necessarily as part of the traditional definition of his or her activities.

Measurement systems can be land, sea, air or space borne. Examples of these systems are remote sensing (land, air or space), Global Positioning Systems (space), hydrography (sea)

**Figure 1: Geodetic surveying**  
Number of geodetic professionals per million inhabitants, 1993

(1) Estimate

Source: CLGEE, Bakkenist Management Consultants

and tachymetry (land). Much of the geodetic surveyors' work, however, is in the management, analysis and structuring of the acquired data, in order to create maps, plans, etc. from this data.

#### Recent trends

In many Member States, the geodetic surveyor traditionally has been a public servant (e.g. the Netherlands, Germany, France). In others, access to the profession is legally protected (e.g. Belgium, Germany). Only in some Member States (e.g. the United Kingdom, Ireland) has the profession been open to competition. This has changed in some Member States (e.g. the Netherlands) in the last decade.

The number of people employed in the private and the public sector combined is given in Table 1. In total, over 65 000 persons are employed in the EU. If this figure is recalculated according to the number of inhabitants in each country, the level of penetration is highest in Denmark, Greece and the

Netherlands and lowest in Spain and the United Kingdom (see Figure 1).

The high level of penetration in Denmark and the Netherlands can be explained by the legal situation in these countries and the demand for high accuracy. In Greece, the penetration level is high because of the many other activities in which the geodetic surveyors are involved. Penetration in the United Kingdom and Ireland is low because of the numerous types of surveyors (not included in the figures) and the fact that the land registration system in these countries is essentially descriptive.

The sectors employing geodetic engineers vary among the European countries, as Table 2 clearly shows. Over 80 % are employed in the public sector in Italy and Sweden, while there are 66 % or more private employees in Spain and Switzerland. No major changes are expected which could significantly alter this in the near future.

In Belgium the figure is somewhat uncertain because no registration is available. The figure shows all geodetic engineers, whether they are currently involved in geodetic activities or not. Discussions are taking place in Belgium to make registration mandatory to work in the geodetic field.

The turnover in the private sector in each Member State is given in Table 3. About three-quarters of the estimated total turnover in the private sector is generated in just two countries: France and Germany. There is widespread market saturation within the EU. After the serious fall in turnover in 1992 and 1993, most countries expect the turnover will remain stable in 1994.

## MARKET FORCES

### Demand

Geodetic surveyors serve developers, builders, contractors, architects, planners, lawyers, engineers, geophysicists, oil companies and governmental bodies. This list is growing as more people start to benefit from the services and skills of the profession (e.g. in the earth sciences). Satellite positioning systems have opened new markets where conventional techniques would not have been considered previously because of cost. However, the apparent ease of operating such systems means that for low-precision work the geodesist often is involved more in the capacity of a consultant.

Market differences exist between Member States in the amount of work received from the private and public sectors. Belgium, Denmark, France, Greece and the United Kingdom have a larger proportion in the former and Italy, Luxembourg, Germany, the Netherlands, Portugal and Spain a larger part in the latter. In the long term, cadastral surveys and other public sector work will show a fall in demand balanced by an increase in engineering and industrial surveys and large-scale mapping. For the short term (1994/1995) an increase in the work derived from local and/or regional governments is expected in many countries.

### Supply and competition

Within each country, profit margins have been reduced considerably due to the economic downturn, which has an effect on government spending and the construction industry. Due to the effects of competition, these margins probably will not increase significantly. Cost-based operating for non-specialised work will, therefore, remain significant. In certain sectors of the industry, especially in the areas of land and geographic

 Source: CLGEE, Bakkenist Management Consultants, Amsterdam

information systems, computer software companies are competing for work.

Geodetic surveying is primarily a national business, and there is hardly any international competition. Generally, over 95 % of the turnover is generated in the home country. Only companies in Spain and, to a lesser extent, Luxembourg and Portugal, meet serious competition in their home market. The main disadvantages for outside competitors are the regulations necessitating membership in professional bodies and certain educational requirements.

The focus of some specialised areas, notably aerial photogrammetry and hydrography is almost by nature international. The largest photogrammetry companies have their headquarters in Germany, France, Belgium and the Netherlands, and the major hydrographic companies are located in the United Kingdom and the Netherlands.

The distribution of geodesists is highly related to population distribution. Also, the services provided are strongly tied to the land itself; hence, the industry polarises where land or real estate is being exchanged, monitored or developed.

## INDUSTRY STRUCTURE

### Companies

The number of private companies in each Member State is given in Table 4. In total the number of companies is around 6 000. Most companies are small (less than 10 persons employed). Belgium, Germany, Denmark, Greece and Ireland all have a high proportion of very small companies, and in Belgium self-employed status is the typical situation. The United Kingdom and the Netherlands have a more equitable spread of company size.

Most larger companies are either technically specialised, for example in aerial photogrammetry and remote sensing (Hansa Luftbild (D), Eurosens (B) and KLM Aerocarto (NL)), or are part of a bigger field such as civil engineering, offering geodetic surveying within their operation (Racal (UK), Oranjewoud (NL), Heidemij Advies (NL)). Some larger companies do offer a range of services purely within geodetic surveying (Engineering Survey (UK), Fugro-McClelland (UK/NL), Fjellanger Wideroe (N)).

Because many of the larger companies form a part of a company with activities in other fields, it is hard to rank the largest

companies operating in this sector with any certainty. However, the following companies are amongst the largest operating in the EU (in order of the estimated size by number of employees): Fugro-McClelland (UK), BRS Grontmij/Geogroep (NL), Oranjewoud (NL), Hansa Luftbild (D), Starkstrom Anlage Gesellschaft (D), BKS Surveys (UK), Geonex UK (UK), Egle Vermessungsbüro (D) and Eurosens (B). Elsewhere in Europe, large companies can be found in Norway, e.g. Fjellanger Wideroe and Blom.

### Strategies

The most general strategies, especially for the larger companies, lean towards diversification of services offered and collaboration with associated professionals, particularly in the field of information technology and aerial photogrammetry. Some smaller companies tend to specialise themselves, offering niche marketing solutions to specific problems (e.g. monument measuring).

Most companies try to keep abreast of the latest technological developments, since many professional customers use these technologies themselves. The result is that the educational level of the people employed is increasing (e.g. in the Netherlands and the United Kingdom).

Other trends include efforts to achieve quality accreditation, and a change in personnel structure. In general, one can see a reduction in staff among the larger companies aiming to operate more efficiently.

### Impact of the Single Market

Geodetic surveying (with the exception of aerial photogrammetry and hydrography) is closely connected to the 'field' and dependent on national legislation. It is estimated that some 95% of the business is local, meaning that measures on the European level have had little influence on the industry.

This will, however, change during the next five to ten years. The Comité de Liaison des Géomètres-Experts Européens is currently preparing a European Profile (i.e. a definition) of the profession to be published in the course of this year. Furthermore, European quality standards for measurements are being discussed and expected within two years. Should these initiatives find support within the Commission and acceptance by the Member Countries, they will most likely have an effect on how companies will operate in future and also on their price structure.

The most important remaining internal barrier is formed by the regulation concerning the description of land and the organisational and regulatory aspects concerning the measurement of property (kadastral). Regulations differ between Member States and therefore make cross border activities problematic. Measures are being taken in some countries to accept foreign geodetic surveyors (recognition of diplomas).

---

## REGULATIONS

---

The most important regulations are those concerning cadastre. Most countries recognise boundaries based on survey measurements. These measurements are carried out by a specialist organisation (e.g. l'Administration du Cadastre et de la Topographie in Luxembourg), by public servants (cadastral surveyors in most countries) or by (licensed) geodetic surveyors (e.g. Öffentlich Besteller Vermessungs Ingenieur (ÖbVI) in Germany and Austria). In the last case, this work often forms a substantial part of a geodesist's activities. Ireland and the United Kingdom have an essentially descriptive system of land registration. The geodesist's involvement in cadastral work in these two countries is, therefore, minor.

The differences in cadastral law between countries (and also between regions within one country, e.g. Germany) mean that this sector of the market sees little competition across borders. EU regulations concerning recognition of qualifications for migrant workers - especially the one on mutual recognition of diplomas at a higher level (BAC +3) - and the responsibility for services, are being addressed by the Comité de Liaison des Géomètres-Experts Européens (CLGEE). A detailed report of education for geodetic surveyors within the EU was published in 1988. A second update to this report is being prepared. The CLGEE is striving to harmonise qualification standards and mutual recognition of diplomas. Some cross-border activities have already resulted from these initiatives. EU directives concerning public service contracts have had no significant effect to date.

In Denmark, Germany, France and Italy, the profession is afforded legal protection. In the Netherlands, Ireland and the United Kingdom, however, no such legislation exists. The remaining EU countries have situations which fall somewhere between the two.

---

## OUTLOOK

---

The outlook in the short and medium term is strongly linked to the economic situation in the countries of the EU. It largely depends on the activities of the construction industry, public utilities, off-shore industry and cadastre. Since the construction industry in most countries shows an increasing level of activity, the turnover of the geodetic surveyors in this sector generally will remain stable and/or increase to some extent. The off-shore activities in the North Sea and the Continental Shelf are limited, thus effecting the hydrographic activities in a negative way. This is partially offset by the increase in activities in the Far East.

In most Member States, government or semi-government bodies are facing budget constraints and/or are reorganising to become more efficient. This too will have an effect on the activities of geodetic surveyors. In some countries (notably Denmark and the Netherlands) government bodies become competitors for the geodetic engineering companies in the private sector. In the Netherlands, a public-private partnership has come into existence for the production of the great-scale basic map.

In Germany, the near future looks brighter, especially for the ÖbVI's. All five new Länder (former East Germany) have accepted the ÖbVI's. The market in these five Länder is growing with the regulation of land property.

The long-term outlook for geodetic surveyors is good and will rest largely on their ability to adapt to change. Many of the traditional skills in data acquisition are becoming less relevant with the advance of automated systems. However, the processing, structuring and manipulation of these data within land and geographic information systems (GIS) for resource management, planning, route guidance systems and other projects is increasingly important.

Collaboration with information technologists will be essential to provide such services. Currently, the European Normalisation Commission is developing a European format for the transfer of GIS information. This would enable GIS information to be internationally exchangeable.

In many countries (Denmark, France, the Netherlands, the United Kingdom), there is a tendency towards fewer and larger companies offering more diversified service. There is also a place for small companies which offer simple, low-tech services with low overhead, or which invest in and can offer state-of-the-art products. It is estimated that the number of people employed in the industry will remain stable or decrease only slightly.

Industrial metrology is an area where the surveyor's measurement skills are competing with long-established methods. It is anticipated that some surveyors will choose to specialise and increase their market share here.

# Landscaping

*The landscaping, gardening and sports ground construction industry is finding increased demand with the growing urban population and a concern with a green environment. The sector is dominated by a large number of small to medium sized firms who operate labour intensively. Thanks to the expected economic recovery, landscaping companies anticipate increased activity for the future in renovation and maintenance of existing parks and gardens along with more complete biological and ecological environmental projects.*

## INDUSTRY PROFILE

### Description of the sector

This sector includes the installation, renovation and maintenance of gardens, landscaping and sports ground construction in private and public gardens, parks and leisure centres. Specific activities like tree maintenance or transplantation, landscaping of public works, installations for noise prevention, creation and construction of ways and places within parks also fall within this sector.

Traditional landscaping work such as construction, laying out and maintaining gardens and parks is the core sector. However, as a consequence of the recent economic recession, landscaping companies have seen the construction of new gardens, parks and sports grounds facilities decline. In response, firms have been seeking out new fields of work such as: gardens in the backyard, on the roof or facade and even indoor gardens. Thanks to the increased concentration of urban population, municipal and state projects have been areas of growing interest, for example: landscaping in traffic-restricted zones, natural landscaping of roads and highways, city redevelopment, new private and public parks, play-grounds, and leisure centres. Renovation of pre-existing sites and ongoing maintenance is also a significant field of work for landscape contractors.

The importance of less traditional activities such as biological engineering and natural landscaping is growing. The former is landscaping which uses living plants and inanimate materials like wood, stone, and geotextiles; natural landscaping is the creation of "almost" natural spaces or ecological niches not typically intended for public use.

### Recent trends

In 1993, the annual survey on the landscaping sector has been taken among national associations members of ELCA, the European Landscape Contractors Association. However, the survey does not cover all EU Member States.

Data indicate that in 1993, employment in member companies of national associations in gardening, landscaping and sports ground construction for nine Member States totalled about 192 000 individuals. Overall employment figures have greatly increased from the previous survey in 1991 because of two main reasons: first, the addition of Spain, with its 5 000 firms and 50 000 employees; second, the large increase of employment in Germany (80 100 persons), which is the result of the inclusion of figures for the Eastern Länder and of young people employed under training schemes (about 5 % of total workforce).

Germany has clearly the largest turnover per enterprise, with France and the United Kingdom following far behind. The vast majority of garden, landscape and sports ground construction companies is composed of small and medium sized firms.

### Foreign trade

As the vast majority of companies are SMEs, they mainly depend on small regional markets. Intra-EU projects take place when the landscaping firms are located close to national borders, or decide to join efforts for a specific contract, or if the firm is highly specialised and is able to fill special requirements such as transplantation of larger trees, roof planting, etc.

## MARKET FORCES

### Demand

Demand for landscaping services is strictly linked to the business cycles in the construction sector, both in building and civil engineering projects. On the other hand, developments in the construction sector itself are influenced by changes in the economy as a whole. Thus, the recent general economic recession which swept Europe has weakened demand for landscaping services.

On the other hand, recent years have seen stronger demand for a healthy environment for the public, fuelled by increasing pollution in modern society. As a result, the requirements for the construction of gardens, landscapes and sports grounds have not only increased, but are also undergoing a big change.

The available data, presented in Table 2, show that the demand for landscaping services is divided between private clients and public or semi-public clients. This division is not consistent throughout all Member States, for example, only 30 % of Denmark's demand comes from private clients, while private clients account for 80 % of demand in Belgium. In Italy and the United Kingdom, public demand represents the highest portion of sales (respectively 60 % and 48 %).

Landscaping often deals with various projects of re-cultivation and re-naturalisation. In general, these projects are a result of a legal condition. An example would be the re-naturalisation of gravel pits or quarries, greening of mounds or slag heaps, re-cultivation of industry fallows or areas under recent construction, and the restoration of damp areas.

### Supply and competition

Public authorities are among the sector's best clients, while at the same time they are the fiercest competitor for landscape contractors in the EU. Government initiatives such as employment programs, social rehabilitation, and agricultural programs compete with private landscaping firms in most European countries. State-financed employment and social programs employ untrained persons to maintain parks and

(2) Figures from 1991

Source: ELCA

public places. These programs are widespread in Europe, and particularly in Denmark, Germany and the Netherlands.

Competition is growing from farmers as government agricultural programs are reducing the amount of cultivated acreage by paying farmers to leave their fields untilled. Another objective is to maintain and beautify the land. Although farmers are not landscaping the countryside or building parks, some of the activity of maintaining uncultivated ground competes with landscaping companies.

### Production process

Landscaping is a typically labour intensive activity. The average salary per employee per hour varies between approximately 6 and 11 ECU with an average estimated work week of 39 hours. Within the EU, traditional construction machines i.e. wheel loader, excavator and tracked vehicle make up, on average, 45 % of equipment used. Transport vehicles are the

second largest capital expense followed by machinery and equipment for speciality use e.g., compressors for building paths and squares.

The use of special machines varies among the individual Member States. By way of example, winter equipment represents a large share of apparatus used in North European countries, while its importance falls considerably in the Mediterranean area.

Professional qualifications are treated differently by public authorities throughout Europe. In the Netherlands, Austria and Norway, a professional certification is required in order to manage a landscaping company, whereas, in other countries no certification is necessary to open a landscaping company although professional certificates do exist and membership in national associations require an adequate qualification.

## INDUSTRY STRUCTURE

### Companies

The landscaping industry is very fragmented. Available data indicates that 90 % of garden, landscaping and sports ground construction companies operate with less than 50 employees. In fact, in Belgium, Spain, France and the Netherlands, the majority of firms have five or less employees. The largest garden, landscape and sports ground companies with more than 50 staff are to be found in Germany, France, the United Kingdom. Firms frequently collaborate across national boundaries to expand capacity and expertise in larger projects.

### Impact of the Single Market

The overall impact of the Single Market programme on the EU landscaping sector has been small but positive. A few firms now compete on foreign markets, but landscaping essentially remains a business centred on local markets.

There is one remaining obstacle to be abated to fully achieve Single European Market for landscaping services. The access to public procurement markets indeed remains difficult, as bidding rules are often too complicated for small firms. Most of difficulties on foreign markets originate from the need to offer customer-tailored services: in this case, different languages and cultures often prove to be an insurmountable obstacle to internationalisation. Hence, the sector welcomes the initiatives and programs sponsored by the Commission to increase language awareness and to promote exchanges of experience and workers among firms.

#### ENVIRONMENT

The push for environmental quality in and around urban centres continues to benefit the industry. As land gets more expensive, gardens and green spaces become smaller. This encourages creative and intensive use of gardens. Reurbanisation projects such as Parc André Citroën in Paris are another example of the urban need for green space.

#### REGULATIONS

An important area for currently developing EU regulation is the standardisation of quality and safety norms. Lawn quality and maintenance for sports grounds alone is subject to several different norms depending on the use and need for safety of the different facilities. Another important area is the contract bidding process. Public works projects now must be offered for tender on the EU level, instead of a national or local level as before. Other areas of public policy like social legislation, industrial law and the safety and security directives for workplace and machines have an impact on the industry.

#### OUTLOOK

As mentioned above, landscaping is a sector linked to general economic development, above all the construction of houses, business facilities and public projects.

Landscapers in Europe are confident for their future, thanks to the general economic recovery whose effects are becoming more and more evident. Demand for re-cultivation and re-naturalisation, leisure centres, natural parks and maintenance work is set to start growing again. Biological/ecological and other more comprehensive environmental works will also grow in many Member States.

Landscape contractors in several EU countries anticipate in the near future a reduction of work carried out for public authorities, as a consequence of tightening state budgets. Hence, the importance of private clients will increase further.

# Linguistic services

NACE 839.3, 935

The sector includes translation services, interpreting services and language education. The number of professionals working in these three branches is growing steadily, although a large part of these services, e.g. translation, is provided by people other than professionals. Competition is keen in the most common languages, but there are good job possibilities for those who specialise in East European and Asian languages. The trend towards more international cooperation in politics and economics will spawn increasing demand for linguistic services in the near future. Specialised knowledge and technical progress are also becoming increasingly necessary for translators, interpreters and language teachers.

## INDUSTRY PROFILE

### Description of the sector

Translation and interpretation services as well as language teaching belong to the linguistic services sector. Translators and interpreters are included in NACE 839.3. Language teachers are under NACE 935, included in private tutorial. Close relations exist between linguistic services and other sectors covered by the Panorama, mainly those operating at the international level (especially the printing and publishing industry).

Translation covers an extremely diversified market. Today, translation is required in a wide variety of human endeavours, ranging from commercial and industrial affairs to scientific research, legislation, communication and literature. The translator's job is to translate texts from one language to another, one of which is normally his native language. There are two basic types of translators: the literary translator, who translates literary texts, and the so-called techno-scientific translator, who is responsible for all the other forms of translation. For the technical translator, it is necessary to be up-to-date on innovative specialised terminology, as new developments in technology lead to new technical terms. To create new words, a technical background is often required as a supplement to fluency in the languages involved. Literary translation encompasses fiction and non-fiction, including plays, essays and poetry. It often demands subjective involvement with the original author.

Interpreting covers a wide range of subjects. Interpreters translate directly from one language into another, using various

methods. Most important is simultaneous interpretation, used mainly during international conferences with the help of modern communication technologies. Similar to this form of interpretation is whispered interpretation. This means that the interpreter translates what has been said and whispers it into the client's ear. This form of interpretation is normally used if somebody is making a speech which must be translated for a single person. A third form is consecutive interpreting. In this case, the speaker stops talking after a few sentences, allowing the interpreter to translate. Then the speaker continues, and the interpreter translates again after a few more sentences. This continues until the end of the conversation, which is usually only between two people. A fascinating form of interpretation is the signing interpretation. Generally, interpreters do not have the texts being translated in advance. Only simultaneous and consecutive interpreters sometimes get to see the text before the speech is given.

In addition to the above-mentioned services, translators and interpreters are qualified to perform other jobs. Of these, the lexicographer, terminologist, publisher's reader and computer linguist are the most well-known. Additional qualifications are necessary for each of these professions.

Language instruction involves teaching language courses offered by public institutions, private enterprises or individual teachers. Besides the normal public school language education, language teaching is given as advanced vocational training in private language schools or public high schools, or provided in-house by large companies. Professional teachers in these areas work either as independents or for the public sector. Only a few are employed by private enterprises, such as publishing houses or television and broadcasting corporations.

The economic weight of linguistic services is difficult to measure because the services are usually included in the turnover of large enterprises and institutions and are not separately reported. Actually, their weight is more qualitative in nature. Linguistic services are the basis for international relations for large and small companies alike and cannot be avoided in enterprises that work with new technologies and technical equipment.

In general, linguistic services are concentrated in regions with high demand, i.e. areas with large population and extensive foreign contacts. In 1993, most of the EU's linguistic services were produced in Germany, the United Kingdom and the Netherlands. Germany and Spain had the highest number of literary translations during the 1980s.

### Recent trends

The importance of linguistic services is linked to the growing internationalisation of political and economic relations.

Source: National professional associations, F.I.T.

Throughout the period of economic recovery following the end of World War II, translation helped significantly to promote peaceful relations and understanding between nations, and international economic relations steadily expanded during the following decade thereafter. Relations between individual European nations, and their relationships with other countries became closer and more constant. In particular, Germany regained its economic importance and moved towards once again playing a meaningful role on European and overseas markets.

At the same time, exports became more and more important for national economies, particularly in the manufacturing sector. New affiliations were created between industrialised nations, and the foundation of international organisations like the European Community for Iron and Steel in 1951 sparked cross-border joint ventures and cooperation.

With the shift away from manufacturing and towards a service-oriented society, international contacts increased again, entailing more consumption of linguistic services. Especially, translations into or from English and French were in demand. The meaningful role that East Asian markets have played during the past decade, combined with the recent opening of Central Europe and the former Soviet Union, has opened up new market opportunities for the sector. There is a growing demand for translations into East Asian and East European languages.

The number of translators and interpreters registered in the national professional associations within the EU totalled approximately 15 000 in 1993. A significantly higher yearly increase from 1991 to 1992 was due to the new membership of the 'Institute of Linguists'. However, all other reporting countries showed only small increases from 1992 to 1993. A large part of linguistic services is still produced by women. Most professionals work as free-lance translators and interpreters, e.g. almost 100 % in France, about 90 % in the United Kingdom and about 85 % in Belgium. Larger groups of employed translators and interpreters are found only in Germany with around 50 % and in Italy with around 40 % of all registered association members. In many countries, the national professional associations estimate that their registered members cover only about 30 % of all persons working as translators or interpreters. The situation is different in Scandinavia, where 50-85 % of translators and interpreters are organised in associations. Especially short and easy translations (e.g. business correspondences) are done by part-time, non-registered translators or by persons with dual native languages, who have other jobs.

The situation is different for language teachers. A large proportion of them work as employees of private language schools or large companies which train their staff in-house.

### International comparison

Translation and interpretation are more important within the EU than in Japan or the US, because the countries which work together in the EU have eleven different official languages. Since English and French are the working languages of the EU, English- and French-speaking countries have no problem keeping informed about EU policy and regulations. At the same time, a majority of Europeans learn English at school, and English is a dominant language all over the world. Even many Japanese people are able to read English. But Japan has close trade relations with the EU and as even cultural relations are now becoming closer, so that the need for literary and technical translation between a European language and Japanese is rising substantially.

Foreign trade is not important for linguistic services, because texts to be translated are usually translated at the place where they are needed. For example, a company working in London will get a text translated into English by a translator based in the United Kingdom.

## MARKET FORCES

### Demand

In general, the demand for linguistic services has grown proportionate to the increasing interdependence of countries in business and government, and the ensuing proliferation of international organisations like the EU, OECD, United Nations agencies and others. However, decreasing budgets for translation, particularly in such international organisations, result in a curtailed demand for linguistic services. The expansion of the EU since 1 January 1995, on the other hand, will cause new demand, as in-house staff for the Nordic languages will be needed.

At the moment more than 50 % of the demand for translation comes from the commercial and industrial sectors; about 20 % comprises scientific translation and less than 30 % is made up of legislative and other translation, including press, audio-visual and literary translations. Demand for literary translation was decreasing or stagnant for a long time, but has been increasing in a few EU Member States during the past years.

(1) Including former East Germany  
Source: UNESCO Yearbooks

The demand for translation into and out of German has been the main source of the growing demand for linguistic services in Western Europe since 1990. Within the EU itself, the most important languages to be translated are English and French. As to the languages into which translations are made, there is almost a statistical balance among all EU languages.

Small enterprises are broadening their international connections and need more and more linguistic support. The demand from large companies is also increasing. The most important industrial sectors that require translations are the mechanical engineering and the metal, computer, chemical, plastic, cosmetic and car industries. For work in non-western languages, even large companies tend to hire free-lance translators.

Technological progress has been increasing in recent years. The computer is a prerequisite for every translator. Obtaining the hardware and software now used for translation involves high financial expenditures for the translator who seeks to maximise his or her potential for employment, as well-equipped translators have a better chance of receiving work. A new area of demand is for translation that involves desktop-publishing and/or machine-assisted translations.

Most of the registered translators and interpreters in the EU either work as free-lance, or are employed by private enterprises and translation offices or by the public administration. Interpretation is mainly needed for international conferences and is used both in the public sector and by private enterprises. In this context, privately organised meetings are gaining importance. Normally, conferences are not regularly scheduled and take place in various venues. This requires a great deal of flexibility on the part of the interpreters and is the reason why most institutions and enterprises do not have an in-house staff of interpreters. Hence, most interpreters are independent. Non-independent interpreters primarily work for international organisations such as the EU, the United Nations and the OECD.

The demand for language teaching services differs from that for translation and interpreting services. Large business enterprises and national and international institutions need language teachers for the vocational training of their staff. Usually, they have their own teachers for in-house tutoring. Smaller companies tend to use private language schools. The demand for independent language teachers comes from private individuals who need to learn a foreign language rather quickly. An interesting new market for language teachers has sprung up in recent years as the combination of travel and language courses has become an important part of the market. In this context, language instruction is mostly given by private schools.

In general, the demand for linguistic services is not dependent on the general economic development of a country. However, it is interesting to note that enterprises tend to reduce their in-house staff if their economic situation is bad. The upshot is that there are more possibilities for independent translators and interpreters to obtain free-lance work.

### Supply and competition

To meet the various needs of the private and public sectors, translators, interpreters and language teachers can either be free-lance or salaried. Traditionally, free-lance translators are members of a professional association. They work from their own premises and deal with the client either directly or through the intermediary of translation agencies. These agencies sometimes have no in-house translators, and subcontract free-lancers. The input costs of free-lance translators are reasonable, their most important overhead being an office and a PC. Technical translators are normally paid per word, line, page or hour. If they work directly for the client, they earn more money than working through an agency. Literary translators are either paid per line, per number of pages, in a lump sum, or they receive a fixed percentage of the royalties.

In recent years, government agencies and international organisations have increasingly awarded translation contracts to free-lance translators, because they have so much work that requires detailed knowledge and specialised skills. For free-lance translators as well as for staff translators, a combination of translating and commercial skills is an advantage in securing jobs and contracts. Many free-lance translators work part-time.

Nevertheless, in most of the EU countries many translators are registered as unemployed, and the number is increasing. For example, almost 1 800 translators were registered as unemployed in Germany in 1993. In 1993 the number of unemployed translators increased in almost all EU countries for the first time since 1988.

Although the unemployment rate among translators is quite high, competition between free-lance translators with specialised knowledge is not, except in the case of the high-salaried positions offered by international organisations. Large volumes of translation which require multilingual knowledge are usually done by translation enterprises employing translators with a variety of native languages. Free-lances sometimes tend to specialise in more exotic languages, and handle smaller projects. Compared with in-house translation, free-lance translators are cheaper in most EU countries, giving them a slight advantage. The strongest competition between single independent translators and interpreters is mainly concentrated close to national borders between countries in which the official languages are the same, e.g. Belgium's border with France and the Netherlands.

Normally there are enough free-lance interpreters within the EU. Though interpretation of English, French and German is required more than other languages, the competition is keener, because most of the interpreters will have at least one of the three languages as their mother tongue. Thus, specialisation in certain sectors (especially in the technical field) and the knowledge of exotic languages, will enable the free-lance to avoid competition, although there is always competition with the in-house interpreting staff of bodies like the EU and the OECD.

Language teaching services are offered by individual professors, private schools of all sizes and free-lance teachers. Other competitors are enterprises which offer telephone tutorials or training programmes such as books, videos, records, tapes and compact discs. The latter are cheaper and offer more flexibility than scheduled courses.

---

## INDUSTRY STRUCTURE

---

### Companies

The company structure is characterised by three types of firms: "one-person" firms, large private companies, or public employers. Free-lance interpreters, translators and language teachers comprise the first type. They offer their services directly to public or private clients or obtain work through an agency. Employed professionals are mainly employed by large companies or public bodies that have their own in-house translation, interpreting and language teaching services.

The European Commission is the most important public employer of translators and interpreters. Other private translation, interpreting and language teaching enterprises are often large. They sometimes have more than one-hundred full-time translators or interpreters and award contracts to independent free-lance professionals, if their in-house services are overloaded. The largest European companies in the translation sector are located in the United Kingdom. These are: Interlingua T.T.I. Ltd., Randall-Woolcott Services Ltd. and the Longman Group UK Ltd. The German company Brähler International Congress Service dominates the EU interpreting market. Brähler also provides all the technical equipment and experienced techni-

cians necessary for interpreting services. In the language teaching sector, Linguarama Ltd. (London) and Elsevier Languages from the Netherlands are the largest European enterprises. However, two other language schools are important within the EU: Berlitz, headquartered in Princeton, New Jersey (in the US) and E.F. with their headquarters in Lund, Sweden. Berlitz used to belong to the Maxwell trust. After the collapse of this trust, more than two-thirds of its shares were taken over by the Japanese publisher Fukutake Publishing Co. But they are still operating as Berlitz, and run around 300 schools all over the world.

SME's do not play an important role in the linguistic services market. For them it is too difficult to compete with large enterprises and free-lance workers because their fixed costs are relatively high and their degree of specialisation is too low.

### Strategies

Stronger competition will be the greatest challenge to free-lances and the enterprises working in this business, as shorter deadlines, more need for translations into East European languages and technical languages, as well as for translations using specific software and translations done by persons without certification, e.g. with dual mother tongues, penetrate the market. There is a trend among smaller firms to offer comprehensive services from translation to the printout of a manual. Also, a new branch is emerging, the so-called 'post-editor' who is needed as machine translations based on different systems such as Systran (used by the EU Commission), CAT and LOGOS are gaining ground. The post-editor's duty is to proof and structure machine-translated texts.

Overall, the technical ability of translators must increase, as computer-assisted translation becomes more popular. While the use of translation machines makes the work of the translators faster and more efficient, the construction of such a modern infrastructure is expensive. Only large institutions and enterprises are able to implement such translation-assisting tools. But computer-assisted translation is only acceptable when less emphasis is placed on quality. There is a chance for free-lance translators to excel by continuing to provide top-quality work in those subjects which require a fundamental knowledge of software and computers. As more specialists are required, firms with modern equipment offer free-lance translators contracts for certain periods and projects. In such cases, the contracted translators work with the machines of the clients, on their premises.

### Impact of the Single Market

The inception of the Single Market has provided new opportunities to this sector. The demand for all services has increased due to the presence and enlargement of international organisations like the United Nations and the European Commission. In addition, demand is created by increasing cross border business but also by the media, for example television and radio as well as the courts.

The structure of the sector is changing as individuals and companies form alliances and networks within the Union in order to strengthen their respective competitive positions. However, in terms of regulation, very little has changed. The sector can be described as generally unregulated but is moving increasingly towards a model of self-regulation. An example of self-regulation is the initiative employed to achieve quality assurance through the requirement of minimum qualifications and diplomas.

An important barrier which needs addressing is the ease with which cross border payments can be made. Considering that this is a very mobile sector with members of this sector working in many different countries, the level of bank charges related to cross border payments is considerable.

---

## REGIONAL DISTRIBUTION

---

Professionals working in the linguistic service sector are concentrated in the regions where large enterprises or international organisations are located. Inside the EU, the OECD and the Commission have the largest staffs of translators and interpreters. This means that a large part of all employed translators and interpreters work in Paris, Brussels, Luxembourg and Strasbourg. Since the EU and the OECD cannot translate everything in-house, a lot of free-lance translators and interpreters have their premises close to these institutions. The traditional structure of regional distribution will be supplemented by the need for translators, interpreters and language teachers in the countries which entered the EU in 1995, and in those where new EU offices will be installed.

Concerning private industry, translators and interpreters are concentrated in areas where international, export-oriented companies are located. This is the case in most capitals of the EU Member States and fast-growing regions of international importance.

---

## REGULATIONS

---

The titles of 'translator', 'interpreter' and 'language teacher' are regulated by the "International Standard of Classification for Professions" fixed by the International Labour Office in Geneva. According to this classification, translation, interpretation and language teaching the professions all require a university degree. But the titles are not legally fixed and protected in all EU countries. Worldwide, the legal status of these professions varies. Only in Denmark, Finland, Norway and Canada are rules for translators and interpreters stipulated by the state. There, translators and interpreters are authorised by the state if they comply with certain conditions, one of them being that they must have passed a special exam.

The role of translators and interpreters on international markets is only manifested in two documents:

- The relevant provisions and recommendations regarding translators and translations set forth in the Final Act of the Conference on Security and Cooperation in Europe (CSCE), passed in Helsinki in 1975;
- The UNESCO recommendation on the protection and improvement of the legal and social status of translations and translators, adopted in Nairobi in 1976.

Both of these documents recognise translating and interpreting as professions which play an important role in the interest of international understanding, the promotion of culture and the furtherance of science, technology and economic progress. However, they do not include any regulations for the professions, nor do they propose any educational requirements.

In addition to these documents UNESCO has installed two agencies that operate worldwide, the World Intellectual Property Organisation (WIPO) and the Committee for International Copyright Funds (COFIDA). WIPO aims at achieving copyrights in Third World countries. COFIDA is installed for the financial support of multilingual regions and countries to overcome their linguistic barriers.

For the EU countries, a draft of the Directive for liability on services is currently being discussed between the Commission and the professional associations. This draft was refused by the federations, because they do not agree with its content. In most EU countries, there is either absolutely no or only unsatisfactory regulations concerning translators' and interpreters' legal status. Often, they are not even offered copyright on their translations. Only a few EU countries have laws regulating admission to these professions. Otherwise, there is no professional job profile, no professional training is required, and there are no examinations or qualification criteria to protect the title "translator" and "interpreter", codify their

rights and duties, or provide for regulations regarding their practise. This opens the market to anyone who speaks foreign languages, allowing them to offer his or her services as a translator, interpreter or language teacher.

In most EU countries, civil law is decisive in such matters as negligence, libel and performance of contract. Some countries, such as Germany, have actually enacted legislative measures to regulate interpreting and translation in legal and administrative proceedings. But in general the public has no guarantee that every person offering and discharging services or performing as independent interpreter and/or translator in fact possesses the requisite ability. Only the interpreters and translators registered in national professional associations of some countries must have a university degree. It is becoming increasingly common for EU countries to offer academic degrees in translation which result in a legally protected title.

The EU Directive on the acknowledgement of academic education is the only regulation which applies to the professions of interpretation and translation. However, this has not yet been adopted as national law in all EU countries.

---

## OUTLOOK

---

The demand for the so-called "traditional languages" is almost satisfied within the EU. But the opening of Eastern Europe, the expansion of the EU in 1995 and closer world economic relations offer new possibilities for the profession.

By the year 2000, the number of translated pages is expected to triple within Europe. This fact will not triple the number of professionals because many translations will be done by machine, but an increase of 50 % in the number of registered members of professional associations, especially of translators, seems to be realistic up through 1997. Not only should the quantity increase, but the quality of the translation and interpretation needs to improve, too. In the future a good knowledge of Scandinavian, East European languages and other exotic languages will be necessary. More professionalism, specialisation and comprehensive services will be required by clients. The use of artificial intelligence will also be necessary, as machine translation will increase. Thus, free-lance translators and interpreters will face stronger competition from translation companies which are well-equipped with computers and various in-house specialists. But the market is large enough for free-lance translators and interpreters who are able to speak at least one exotic language and have special knowledge in certain branches.

# Publishing services

## NACE 839

*The publishing services sector is growing very rapidly, as technological advances and sharply falling prices bring high quality publishing within the reach of an ever widening customer base. This base ranges from small concerns such as hobby clubs to major international commercial enterprises. The sector overlaps other service sectors including computer consultancy, below the line advertising consultancy, and secretarial support services. The estimated turnover of the "publishing for profit" segment of the publishing services industry (i.e. excluding in-house operations) was roughly 5 billion ECU in 1993, employing about 50 000 people.*

### INDUSTRY PROFILE

#### Description of the sector

Publishing services are services which help people prepare documents for publication in print or, increasingly, in electronic form. This help can take various forms from consultancy to the actual preparation of documents ready for publishing. Companies and individuals providing publishing services include Desktop Publishing (DTP) consultants, DTP shops, pre-press companies and printing companies. These "publishing for profit" companies face increasing competition from in-house DTP departments which are believed to be taking a growing share of the market. Because of its diversity, no reliable statistics are available on the publishing services industry.

#### Recent trends

In recent years, the publishing services industry has been revolutionised by the introduction of computerised methods, and in particular by the growth of DTP. DTP equipment has replaced phototypesetting equipment in many printing companies. DTP shops have been established throughout Europe. It is thought that there are now up to 10 000 such shops in the EU, employing around 30 000 people. Finally many companies in all fields and of all sizes have found it worthwhile to establish their own in-house DTP facilities. A few years ago, working drawings and slides were the input for the graphic reproduction process, now in the Netherlands, for example, it is estimated that 60 % of the input of printers and pre-press shops is in the form of floppy disks.

Most DTP software is of American origin, notably PageMaker, of which 2.5 million copies have been sold worldwide, and Ventura. As a result, it was first available in English, which gave the UK a lead in the use of DTP in Europe. Nowadays, the major programmes are available in all European and many other languages, and the UK's lead in this field has been much reduced. However, English language versions of the software tend to be about 10 % cheaper.

#### International comparison

It is difficult to estimate the size of non-EU markets for publishing services owing to a lack of statistics. The USA has a sophisticated publishing service market and most of the major suppliers of DTP hardware and software are American. The EU lags behind the USA in desktop publishing and design services. Japan, despite being a developer of very hi-tech equipment such as scanners, is trailing a long way behind the EU in the development of DTP companies.

#### Foreign trade

There is very little trade in publishing services. The service companies involved sometimes have production carried out

in a country with lower costs, such as Singapore or Thailand, especially for regular large production volume publications. Extra EU imports and exports are very small. Taking data for the whole printing sector, these are less than 2 % of the internal market turnover. Cross border business within the EU is also minor, amounting to less than 5 % of the turnover of the sector.

### MARKET FORCES

#### Demand

Most printing businesses have now computerised their production processes. More efficient computerised systems at ever lower prices have helped them make the decision to convert. There is a polarisation in the demand for final finish of documents. For some customers, printing on a laser printer (300 dots per inch) gives an acceptable quality. Often this demand comes from persons and companies not using this type of promotion or communication tool before.

Those professional customers converting from the older technology often require the best possible finish and have 2 540 dots per inch bromide films made before printing. Professionals also enhance pictures in documents, often to give them a crisper look, using specialised desktop publishing program extensions.

Customers often require the flexibility of the electronic publishing system which allows documents made at the pre-printing stage in several formats so that they can choose the one they think is best. The latest computers such as the Power Macintosh allow very fast use of graphics packages and consequently the ability to produce a large number of alternatives. The text for a document, nearly always generated by word processor, is transferred to DTP software to enhance the way it looks. Style sheets, automatically set, present information in a given style. Very few key strokes are necessary to change style sheets. In fine tuning a document font types and character sizes can change to achieve the most suitable result.

The introduction of "in-house" DTP facilities in many companies reduces the potential demand for outside publishing services, especially if the company thinks it can handle the whole job itself, perhaps with the help of a colour photocopier. However, really high standard work still usually requires, sooner or later, the help of a professional pre-press or printing company. Moreover lack of graphic knowledge can cause trouble and extra cost at the next production stage.

#### Supply and competition

The traditional pre-press and printing companies are in competition with DTP shops and in-house DTP departments. Printing is a highly skilled profession, and in most countries the industry is a well organised, high wage industry often with strong trade unions. In competition with the new DTP shops, traditional companies must compensate their higher labour costs with higher productivity resulting from their skilled workforces and more sophisticated equipment. Nevertheless employment in the printing industry is declining.

There are no major pan-European DTP service companies. Most companies in this market sector only serve a limited locality in their own country. The level of investment required does not create a significant barrier to entry and economies of scale are limited.

Companies offering a full professional service are fewer than those offering processing and production at 300 DPI. Increasingly the latter subcontract pre-printing to printing companies, if they have to produce a high quality document.

Prices of publishing services offered by both pre-press and printing companies, and DTP shops have been falling, partly due to increased competition in the present economic climate, and partly because of falling hardware and software prices.

## Production process

Most of the companies in the sector are new. Many only started business in the mid-1980s. Leading DTP software companies such as Aldus and Adobe were also founded at this time. Some business service companies with longer histories have altered business plans to get into the flourishing DTP services market. Many computer consultants have become more involved in DTP than in other activities.

Other professionals attracted to DTP include those that were previously involved in translating, printing, typing, word-processing, copy-writing, and proof-reading. Publishing production professionals, photo composers, page layout specialists and photo engravers, have had to move with the times by making investments in electronic printing. Most have now converted from manual to computerised page layouts. These include PC picture publishing, PC art, computer aided design (CAD), and DTP.

Most DTP companies are very small enterprises. Their main work is to layout documents from manuscript or electronic text using professional DTP packages, and subcontract the production. Many use only four main tools: an Apple Macintosh, IBM compatible or other PC, a scanner, computer software including DTP programmes, and a laser printer.

Some have made investments in higher or additional cost pre-printing equipment. This includes film making and bromide, and Cromalin proofing equipment. Often DTP involves incorporating pictures, graphs and tables into a document, and this sometimes needs special scanning or filming equipment and software to create files in tagged image film format (TIFF).

PageMaker has offered colour picture DTP software for several years. This has meant that Apple Macintosh has been the computer system chosen by many printing companies for DTP. In 1991, Xerox's subsidiary, Ventura, now owned by Corel, launched some very professional colour printing products for its IBM compatible PC customer base.

Specialised computer programmes are available for making multi-coloured pictures. These programmes allow PC users to make colour separations and retouch images. Examples are Ventura Separator, Ventura Photo Touch and Ventura ColorPro.

Prices of scanners have fallen dramatically. It is now possible to buy a 600 DPI scanner for as little as 1 250 ECU compared to over 5 000 ECU a few years ago. However, very sophisticated scanners can cost up to 100 000 ECU. Suppliers to the printing industry such as Scitex, Hell, Crosfield and Dainippon, are now supplying scanners for DTP.

Although scanning photographs or drawing has been the main method of making electronics pictures, programs now exist to make picture films from video films. "Multimedia" computer programmes provide pictures by the latter method. An editor can also buy picture files. Many electronic picture libraries and software companies sell electronic pictures. Ventura has recently published a series of CD-ROM's at a very modest price containing photographs classified by theme and which are free of copyright. Documents containing line drawings, data tables and graphs must merge files or parts of files from other PC programmes.

Professional printing companies generally produce the final documents because they have the equipment for high resolution film or bromide production and large print-run capacity. Higher resolution desktop laser printers have recently become available. These will enable DTP shops to compete more effectively with printing companies.

Photocopy machine technology has developed to the extent that the newest generation of professional photocopiers integrate printing and binding of documents. This process involves a computer terminal linked to the photocopy machine.

There are many DTP programmes. They range from programmes designed to make single page layouts to those for long documents. Printing professionals often use PageMaker which costs about 1 000 ECU.

Companies not requiring so much sophistication or text adjustment can use other programmes such as Microsoft Publisher, which cost as little as 60 ECU, and which are very user friendly for novices. Most programmes are available for use in the DOS, Windows and Macintosh operating systems. Some are also available on UNIX and OS/2.

IBM compatible computers have become the standard for the PC computer industry and users are changing from the DOS operating system to Windows, but Apple Macintosh is still the major computer system for DTP and is protecting its position with the launch of the Power Macintosh.

PC art and picture publishing packages to create layouts are newer products for desktop publishers to work with. Some of them have existed for several years. PC art computer programmes such as Illustrator, FreeHand and Corel-DRAW, several in fifth generation versions, are relatively inexpensive (about 800 ECU per single user software). These programmes help operators, lacking flair for drawing, to produce very professional drawings.

The DTP market is growing organically as trade associations, clubs and various companies begin producing magazines, newsletters and other printed material for their members. A particularly important area is the financial sector with the rapid production of overnight reports for investors.

## Impact of the Single Market

Publishing has a domestic character, partly the result of the lingual and cultural bond to a particular geographical area. Only the large multi-national corporations operate across Europe, although this applies mainly to the holding companies, not the subsidiaries. The impact of the Single Market has been positive, starting with the recognition of culture in the Treaty of Maastricht (Article 128). Harmonisation in a number of fields is slowly being reached.

Two important issues currently have priority. Firstly, harmonisation is needed concerning copyright. There are currently two concepts in place, an Anglo-Saxon - and a Continental version. The former essentially benefits the producer, the latter the author. In certain instances this results in problems. A modest degree of harmonisation has been reached, at least in principle. The ultimate goal is to develop a European copyright law.

Secondly, the emergence of multi-media has resulted in the formulation of a number of priorities, amongst others, copyright law to protect publishers against piracy, training of personnel and users and the need for further liberalisation of telecommunications services to facilitate further development.

---

## REGULATIONS

---

There are no EU regulations governing this sector. National regulations which concern the computer and printing industries apply to publishing services. Companies involved in DTP must observe copyright and trademark laws.

---

## OUTLOOK

---

As the cost of DTP hardware and software continues to fall more and more, "non-professionals" will be able to afford the equipment necessary to prepare their own documents for publication, and to ever higher standards. Professionals such as DTP shops and pre-press houses will find their market increasingly restricted to, on the one hand, clients who do not have in-house DTP facilities, and on the other hand, to

the final preparation of high resolution documents, already in electronic form, for printing.

As costs fall, the overall volume of work undertaken both in-house and by independent professionals, will increase. More newsletters and publicity material will be produced and catalogues will be updated more frequently. Output will be increasingly in electronic form such as CD ROM or on-line, rather than ink on page.

The input for documents will also be increasingly electronic deriving from electronic databases and computer networks both private and public such as Internet.

There will be increased demand for ancillary services such as electronic picture libraries, although the cost of these is likely to fall.

It is generally expected that the pre-press market, which is rather sensitive to the economic climate (advertising and promotion are major clients), will grow by at least 10 % a year in the medium term.

# Temporary work services

## NACE 839.3

Over the past four decades, temporary work services have progressively changed into a sophisticated, professional service industry providing instruments for labour management. The industry has become not only the main tool for helping businesses fill temporary shortages in their workforce, but also - since temporary workers often find permanent employment through their temporary assignment - an important branch of personnel recruitment advisors. Temporary work businesses (TWBs) are now widely accepted in most countries. After a period of recession, which ended in most EU countries in 1993, TWBs showed double-digit growth figures in many of them for the year 1994.

### INDUSTRY PROFILE

#### Description of the sector

Temporary work businesses hire temporary workers and put them at the disposal of a third party. Key to this triangular relationship is the fact that workers receive their salary from the temporary work business but their work orders from the third party. Client firms call upon the services of temporary work businesses when they have temporary shortages of labour. The hourly cost of temporary labour may at times be higher than that of permanent workers, but since temporary labour is usually resorted to for short, well-defined periods or for specific tasks, the cost is borne only for effectively supplied hours of labour. The alternatives, overtime or a permanent reserve of extra manpower, would be more expensive. Temporary work businesses bear the costs of recruitment, selection, payroll, statutory social security insurance, etc.

For temporary workers, temporary work businesses satisfy particular individual needs and preferences. However, a growing number of jobless workers also resort to temporary work

businesses with the hope of finding permanent positions at a later stage. It is estimated that on average well over one-third of temporary workers find permanent jobs as a result of temporary contracts. The actual proportion varies widely between different EU countries.

The ageing of the European workforce and the increase of the female constituent also have an effect on the temporary work services sector. These developments have been associated with a greater desire for more flexible and temporary working arrangements.

#### Recent trends

The importance of temporary work can be shown by the number of people who are active in the sector each working day. In Table 1 it can be seen that France, Germany, the Netherlands and the United Kingdom are the largest employers of temporary workers in the EU. In the EU as a whole, it is estimated that well over one million people a day worked through temporary work businesses in 1993. In the United States, a country with a comparable workforce, this figure was lower for many years. But the past few years have shown a quickly increasing market penetration (also because of new services), so that employment per day is now higher than in the EU. For a correct comparison, however, it should be noted that the temporary work services sector is non-existent in Italy and Greece, and still not very developed in Portugal, Luxembourg and Ireland.

Most of the turnover in this sector is generated in Belgium, France, Germany, the Netherlands and the United Kingdom, as can be seen in Table 2. Overall, the sector showed double-digit growth in the years prior to 1991, in countries where temping was already more or less established, as well as in countries where it was still developing. The onset of the current recessionary period in many countries, however, resulted in a zero or even negative growth in 1991 to 1993. During this period, the sector was gaining importance only in Spain and Portugal, where temporary work businesses were legalised only recently. The market potential is, therefore, still large.

Most Member States indicate that 1994 brought clear signs of recovery. In the United Kingdom, this recovery had started in 1993, as Table 2 shows.

**Table 1: Temporary work services**

### International comparison

Total turnover in the EU was approximately 18 billion ECU in 1992, down from almost 20 billion ECU in 1990. Turnover in the USA, in comparison, was approximately 17 billion ECU in 1990 and is now estimated at 23 billion ECU. Market expectations in the USA are still positive. The turnover of the sector in Japan has decreased, and was estimated at over 8 billion ECU in 1993. In the new Member States, the sector is still not very developed, though it must be noted that the figures given are incomplete due to a lack of statistics from Sweden.

Currently, the world market is estimated at well over 50 billion ECU. All estimates are based on statements made by national federations, since no regular statistical surveys are taken in this sector, neither in the EU countries nor in other countries.

### Foreign trade

Basically, temporary work businesses operate on a local scale, whether they are a small, independent, one-office company or a larger (multi)national temporary work business enterprise. 'All business is local' is a saying which applies directly to this sector, with the possible exception of highly specialised businesses. Furthermore, it is difficult to send temporary workers across borders due to contradictory national legal regulations, thus limiting cross border activity. Temporary work businesses wishing to operate in foreign countries generally

do so by starting a local branch or by buying into a local company.

### MARKET FORCES

#### Demand

In the past, the enormous growth in demand for temporary work services clearly stemmed from the growing need for more flexible labour contracts. The favourable economic climate, however, also helped boost growth. As has been shown recently, the stagnation of economic growth or recession have caused zero to negative growth in most EU countries. Markets which are heavily effected by these trends are, for example, France, the Netherlands and the United Kingdom. In general, it is expected that growth for the industry will remain in line with general economic activity in the future, with the exception of countries where significant changes in regulations have taken place.

The fields in which temporary workers fulfil their assignments tend to differ between countries. In France and Germany, for example, the majority of temporary workers are blue-collar workers. In the United Kingdom, Denmark and Spain temporary workers are primarily active in the administrative or commercial fields, as is more or less the case in the United States and Japan. In some countries this is due to restrictive regulations. The differences are further illustrated by Table 3.

**Table 3: Temporary work services

Source: CIETT, Bakkenist Management Consultants

The length of the contract varies from client to client, depending on the function which the temporary worker will fulfil. If the temp is called in to replace someone who is ill or on holiday, contracts are usually fairly short: from one day to several weeks. However, if a temp is needed because of an unfilled vacancy, or because the client is not certain whether the development of his business will allow him to hire an extra worker permanently, contracts can be extended to months or even a year or more. Contract duration is usually limited by national regulations, and the maximum period varies per country. Client companies often treat temping contracts as if they were trial contracts. Increasingly, they tend to offer a permanent contract to workers who have worked for them through a temporary work business.

### Supply and competition

The number of establishments can serve as a basis for market coverage calculations and concentration figures. The third column in Table 4 shows quite clearly that the sector is the most concentrated in Belgium and the Netherlands. Market coverage in terms of active population per establishment is highest in the Netherlands and the United Kingdom (last column). In these countries, there is one office for every 5 000 potential temps. Differences in market coverage are large, as can be illustrated by comparing this last figure to that of Spain: there, the number of persons one branch office serves is many times higher. These differences will diminish with the further development of the sector. Naturally, the market coverage figures also give an indication of the degree of competition in the different EU markets. In general, it can be said that competition is fierce in well-developed and/or stagnating markets (such as the United Kingdom) and moderate in less developed and/or growing markets (such as Spain). The workforce served per office in Japan and the United States indicate temporary work markets which are fairly developed.

The degree of differentiation in supply varies from country to country, depending on market demand and regulations, but is less within any particular country. An exception is a specialisation in client markets, medical staff only, for example, which does appear regularly. Prices and other terms offered are more or less the same, competition takes place through elements such as response time to a client request, distance

between client office and temporary work business, past performance of temps hired and other client services offered.

## INDUSTRY STRUCTURE

### Companies

Following is a list of some of the largest temporary work businesses operating in the EU, with their home countries noted in parentheses. In alphabetical order, they are: Adia (USA/CH), Blue Arrow (UK), BIS (F), ECCO (F), Manpower (USA), Randstad Groep (NL), and Vedor (NL). Their estimated total market share in the EU is 35 %. In the United States, the four largest companies are estimated to hold 30 % of the market. Temporary work businesses of EU origin account for over 80 % of the EU market (above percentages based on 1989 data). Many temporary work businesses operate within the same market under more than one name. Some have the same management, others operate more or less independently. Franchising is known to be practised by, for example, Manpower and Adia. The market leader differs per country; regularly, the leading position is held by a business with its home base in that country. Examples are the Randstad Groep in the Netherlands and Belgium and ECCO in France.

A notable phenomenon is the existence of cost-based government temporary work businesses in Belgium (T Interim) and the Netherlands (START), which have gained a considerable share of the market. At the same time, their operation has proven to be beneficial to the acceptance of organised temporary work in these countries, and thus to the market size.

### Strategies

In the past, temporary work businesses - particularly the larger enterprises - have diversified into less related services such as security, contract cleaning and maintenance, language services, computer software services, business information and financial services. The present trend is focused more on efficiency and upgrading, while expansion is strongly geared to services related to personnel management and internationalisation. In their efforts to improve the efficiency of their operations and the quality of their services, temporary work businesses are investing heavily in computer systems and net-

works. The second trend (upgrading) is illustrated by the fact that some temporary work businesses are shifting towards temporary workers with higher educational qualifications and more experience.

The major temporary work businesses have extended their businesses internationally. Internationalisation takes place not only in EU countries - by acquisition or not - but also outside the Community, notably in the USA and the Far East (including Japan).

The TWBs have expanded into personnel management services for small and medium-sized enterprises, including: recruitment (including head-hunting), outplacement, pool-management and personnel training. This is triggered by the fact that the distinction between permanent and temporary employment is becoming less pronounced: as was mentioned above, a temporary contract often results in a permanent contract for the employee.

In the USA, there is also a clear trend towards providing personnel for entire non-core functions (outsourcing). In view of this trend the American association has even changed its name to the National Association of Temporary and Staffing Services.

In those countries with a liberal regulatory regime a shortage of qualified temporary personnel has proven to be an obstacle to growth. This shows the importance of education and training now provided by an increasing number of temporary work businesses. Typing, word-processing and low-level technical courses are forms of training that typically figure in their programme. Specific training tailored to the job or the individual is also common.

The issue of quality accreditation also has made its entrance into this sector. The countries in which the sector is well developed recently started efforts in this direction (e.g. Belgium, France, the Netherlands and the UK). This is a result of a more competitive market situation, combined with general trend in business towards a higher level of client service. Companies try to offer readily available and flexible services, while still complying to the high quality standards demanded.

### Impact of the Single Market

The Temporary Work services sector has a definite local/domestic character. Although cross border activity is increasing slightly, this is not substantial. Most of the European Union directives and measures have had little or no impact on the sector.

However, two important issues are currently being addressed which may have a profound impact the Temporary Work industry. At this point in time it is forbidden to provide temporary work services in Greece and Italy. Several multi-national tem-

porary work organisations have, in combination, started a lawsuit to confront the law prohibiting temporary work in Italy. This issue has now been brought before the European Court. A ruling is expected in the coming months. The second issue is a draft proposal which may affect the posting of temporary staff in other Member States and addresses, amongst other issues, pay and working time. It is, however, not clear if temporary work services will be included in this draft.

Some concern exists regarding the unfair competitive advantage the public sector has in some Member States. For example, in some instances, public sector companies have access to information not available to private companies, have extra (government subsidised) funding or certain tax advantages.

### REGIONAL DISTRIBUTION

Basically, temporary work business is local business. Most companies operate through a network of local offices, located in the near vicinity of either potential clients or potential temps. This differs for each country.

### REGULATIONS

Organised temporary work is widely practised in the majority of the Member States. There are, however, considerable differences in regulation between EU countries. Two countries, Greece and Italy, prohibit the operation of temporary work businesses. In these countries, illegal practices are known to exist. In Italy, the social partners are becoming increasingly aware of the benefits of temporary work and the negative effects of the illegal practices. The former Prime Minister had announced the intention to publish a new draft law in 1994, but due to the political situation this law has not been placed on the political agenda yet. Several Italian multinational TWBs joined to start a lawsuit to test the law prohibiting TWBs. The question already has been brought before the European Court.

A number of restrictions and requirements are common among the regulations in the other Member States, the most important being:

- requirements for the contract between the user and the temporary work business;
- registration and/or licensing of temporary work businesses;
- limitations to the conditions under which temporary work is allowed;
- limitations to the duration of contracts (varying from 3 to 24 months, or no restriction);
- requirements for wage levels and social security conditions.

For many countries within the EU one could say that 1994 was a year of change in regulations concerning TWBs. In general, a trend towards more liberalisation is visible. In Finland and Sweden, the regulations were liberalised almost completely in the beginning of 1994. Also, since mid-1994 temporary work has been allowed in Spain. In Germany, the maximum duration of an assignment has increased from 6 to 9 months and private placement is allowed since mid-1994. Double-placement has been required in this country, with the exception of long-term unemployment provided by the Employment Exchange. The trend in Germany is expected to go towards unlimited labour contracts with TWBs, as is common in most European countries.

In the United Kingdom, the government's initiative to delicense the recruitment industry became effective in January 1995. There is a reasonable chance that the law requiring manpower supply licenses in the Netherlands will be abolished in 1995. Together with a possible acceptance of temporary work in the building and construction industry, this could

open new possibilities for TWBs in this country. In Portugal the law will possibly be changed in 1995, allowing for a more flexible use of temporary services. Outside the EU, in Japan, the TWB regulations are scheduled to be reviewed in 1995, for the second time in the last ten years.

An indicative summary by the national branch federations of the degree of regulation is shown in Table 5. The statements 'liberal' and 'restricted' are relative, and should be taken as a means of comparing the EU countries to one another. The United States considers its regulatory regime liberal, while Japan characterises its regulation as restricted.

The Commission has put forward four proposals which are pertinent to the TWB sector. One, dealing with health and safety, was adopted. The remaining three (two on the so-called "atypical work" and one on the posting of workers) are expected to be adopted during 1995.

One of the most significant changes in the past year, although only concerning regulations indirectly, is the discussion that took place in the last International Labour Office (ILO) meeting. For the first time, the ILO acknowledged the role of private placement institutions like TWBs. Any changes of the ILO convention 1996, however, are not to be expected before 1997. If this convention is changed, countries like Italy and Greece will have to adapt their regulations to these changes, thus allowing for private placement.

---

## OUTLOOK

---

The expectations for growth vary from country to country. As anticipated in the 1994 edition, growth figures are improving in many countries of the EU, notably in Belgium, Denmark, France, Germany, the Netherlands and the United Kingdom. In these countries the growth figures for 1994 were likely to be expressed in double digits. In Portugal, however, growth should have been zero or negative in 1994. The national federations of temporary work in all countries expect continued growth for 1995.

In general, it is clear that the industry is dependent on the growth of the economy. Economic recession and full employment both tend to reduce turnover. The sector seems to thrive best in a climate of moderate or brisk economic activity.

In those countries where temporary work businesses are well developed, competition is strong. In the countries where the sector is less developed or as yet illegal, measures leading to a more liberal regulatory regime could still provide large growth impulses for the sector.

Written by: Bakkenist Management Consultants

The industry is represented at the EU level by: International Confederation of Temporary Work Businesses (CIETT). Address: 12-14 Denman Street, London W1V 7RN, United Kingdom; tel: (44 71) 439 3929; fax: (44 71) 734 2380.

# Industrial cleaning services

## NACE 923

In 1993, the industrial cleaning services sector reached a turnover of 21 028 million ECU (a 7.6 % increase over 1992), while the number of employees, totalling 1 961 030, had increased by 10 %, showing it to be one of the more important subsectors in Europe. The sector is subject to much restructuring, giving the big companies (over 1 000 employees) increasing economic power. Nevertheless, small companies (less than 20 employees) account for almost two-thirds of the total number of companies in the sector.

In the next few years, continued improvement in the areas of employee training and certification, as well as quality management, will be essential to its success as an expanding industry.

### INDUSTRY PROFILE

#### Description of the sector

The cleaning services provided by specialised cleaning contractors that will be considered in this chapter are : office cleaning, industrial cleaning (factories, nuclear power stations...), window cleaning, cleaning of hospitals and public transport, and small building maintenance. Other activities which may be carried out by cleaning companies but that are not covered here are : security services, waste management services, laundry and dry cleaning. In some Member States, chimney sweeping, facade cleaning, maintenance of areas around buildings and general sanitation are also part of industrial cleaning services.

The total turnover for the EU's industrial cleaning sector reached 21 028 million ECU in 1993 (see Table 1). The industrial cleaning sector remains one of the most economically important subsectors in the EU. Although the cleaning industry no longer records two-digit growth rates, as it did at the beginning of the decade, it still shows a sustained growth rate that reached 7.6 % in 1993.

While some countries did relatively well, with growth rates ranging from 2.3 % (for France and Germany) to 5 % (for Spain and the Netherlands), still others showed stronger growth

rates (10 % for Belgium and Denmark, and 20 % for Portugal). Turnover in the UK grew sharply in 1993, rising close to 20 % over 1992. Italy reached a 15.2 % increase in 1993 over 1991 (data for 1992 was not available).

The increase in the turnover mainly stems from an increase in the market penetration rate (see Table 2). Market penetration, extremely important for business services, measures the share of the total potential market to the market contracted out to cleaning companies. The market penetration rate is calculated on estimates of the sales of cleaning products and materials, among other things. At the end of 1993, the market penetration rate in Europe was estimated at 53 %, which is a 2 % increase over 1992. The UK, Portugal and the Netherlands, whose market penetration rates grew significantly in 1993, were responsible for this 2 % increase. The remaining countries were stable. The low market penetration rate in Denmark (30 %) accounts for its relatively low turnover compared to other countries with a similar level of development.

It should also be noted that the market penetration rate in the public sector is generally 10 % higher than the total penetration rate, ranging from 40 % in Denmark to 95 % in Portugal (see Recent Trends). In spite of the increase in the market penetration rate, which was over 50 % for most of the countries (see Table 2), the potential for business remains significant, and there is no sign of market saturation.

#### Recent trends

It is estimated that the public authorities contracted out the equivalent of 8 billion ECU worth of industrial cleaning services in 1993. In the cleaning sector, the rate of public market penetration (estimated at 70 %) is systematically higher than that of the private sector. The public procurement's share of the market is increasing in the EU, jumping from one-third in 1991 to an estimated 40 % in 1993. Cleaning services contracts of more than 200 000 ECU (falling within the scope of the directive 92/50/EEC on public services contracts - see section on regulation) make up an increasing part of the total public contracts. For example, they make up 35 % of the public contracts in Spain and the Netherlands, and 25 % of the contracts in the UK.

Office cleaning is traditionally more important, in terms of turnover, than other market segments. In 1993, it accounted for more than 52 % of the turnover. Office cleaning is the market segment in which in-house cleaning is estimated to be the most widespread, indicating a strong growth potential for cleaning services. The second most important market segment is industrial cleaning, which has a 13 % share of the

market and includes the cleaning of factories, nuclear power stations and agri-food industries. Coming in third is windows cleaning with 10 %, followed by hospitals and transportation vehicles with 5 % and 4 % of the total market, respectively.

Hospital cleaning must be separated from the other market segments inasmuch as its requirements are very specific. It comprises, on the one hand, the cleaning of common spaces and the cleaning of rooms, with job features quite similar to

those of hotel cleaning (day-time work, full-time job with longer daily work hours) and, on the other hand, the disinfection of operating rooms or laboratories. The latter requires specific skills and training. Rooms and public spaces are often cleaned by in-house staff.

## MARKET FORCES

### Demand

Broadly speaking, the cleaning services market is one wherein demand pull is significant, due to a series of internal and external factors (e.g. economic downturn, fierce competition among services contractors, budgetary constraints on the client's side). Two current trends seem to have had a major impact on the cleaning market: the demand for quality and a broader range of services. It is, however, still difficult to either quantify or measure their impact on the industry.

### Supply and competition

There is no denying that cleaning service customers are demanding in terms of quality. But what is quality? And, how can it be measured objectively? Quality is not necessarily cleanliness, but instead comprises three intertwined components: technical quality; integral quality (which aims to improve quality and productivity) and quality control (which ensures that cleaning services meet the client's needs). Cleaning companies have sought an objective quality measuring system that will help them avoid conflicts with their clients over the pricing of their services. The difficulty lies in finding

a quality measuring system which is as objective as possible. Some countries have tackled this problem, achieving some significant results.

The Netherlands developed a relatively sophisticated system called VSR which is used by 250 companies on the Dutch market. It consists of a very precise list of criteria (i.e. a range of errors agreed to by the company and the customer) according to which the cleaning jobs are assessed. The assessment is carried out on a probability random sample. The level of quality is periodically controlled. Under the VSR system, a dividing line between "good quality" and "poor quality" can be drawn. The Germans, on the other hand, worked out a system called "Güteschutzgemeinschaft" that covers the entire market. In France, the CTIP (the International Technical Centre for Cleanliness) devised a system for quantifying cleanliness that is implemented by major granting authorities, covering 10 % of the French market.

At the same time, there is, on both the client side and the company side, a growing interest in certification, whereby cleaning companies are certified according to ISO norms. A substantial number of companies are in the process of earning their certification, which they will use for marketing purposes and to create a quality-oriented corporate culture.

The client's demand for high-quality services often clashes with their tendency to choose the lowest-priced tenderer. The companies have made their clients aware of the problem. The national professional organisations also have contributed to

the professionalisation of the cleaning sector by setting-up national quality labels and codes of conduct.

A wide range of support services other than cleaning has been incorporated into the services offered by some companies in order to meet client demand while simplifying the process of subcontracting by limiting the number of contractors. These services include: security services, catering, building maintenance, green spaces and rubbish collection. Such diversification at first was a trend primarily found on the British, and, to a lesser extent, the Dutch markets, but now has extended to Belgium, France and Germany. It is difficult to forecast how much further it could go, given that the demand for support services seems to be limited to a few large clients.

## INDUSTRY STRUCTURE

### Companies

In 1993, the number of cleaning companies operating in the European Union was 41 093, up 3.4 % over 1992. The number of companies increased in every country except the United Kingdom, where the recession hit the small cleaning companies (which either went bankrupt or were incorporated into larger ones), resulting in a 3 % decrease overall. Luxembourg and Portugal did remarkably well, with a 20 % and 15 %-increase between 1992 and 1993, respectively. The number of companies in the remaining countries was stable or increased only slightly (see Table 3).

The structure of the sector is characterised by the predominance of small companies (of less than 20 workers) which accounted for almost two-thirds of the total number. But it is worth mentioning that the number of bigger companies (with over 500 workers) rose significantly, because of take-overs and mergers (see Table 4).

### Strategies

The cleaning sector is very vital; many companies are created every year. These new companies are often quite small and run by managers with little or no previous experience. As a result, a large part of them have collapsed within the first two years of their existence. This phenomenon damages the sector's image and the market itself.

Since it is awkward to restrict entry into the cleaning sector (respect of free enterprise), the national professional organisations have taken steps for its professionalisation by launching internal quality labels (Marque professionnelle FEP in France, Cleaning Quality Label in Belgium, OSB+ certificate in the Netherlands), and by setting up a professional charter (code of conduct).

Source: FENI

The trend towards a greater concentration of the market and mergers was evident in all EU countries. As the recession hit the cleaning sector, some small companies collapsed or were taken over by bigger companies. The big companies are growing in importance not only in terms of turnover but also in terms of employment. In France, for example, close to 50 % of the workforce are employed by companies of more than 500 employees, which account for less than 1 % of the total number of companies.

#### Impact of the Single Market

This industry is characterised by the large number of small- and medium sized enterprises and the local and domestic nature of their business. Only the four largest European companies operate in all Member States, while the larger national companies operate in a small number of countries other than their home countries. This means that the Single Market Programme and its effects are only experienced by the larger companies. Generally, however, it is felt that the measures in the Single Market Programme have had a positive effect, although these are hard to quantify.

Within the framework of the Single Market, the industry is giving priority to three issues. Firstly, on an operational level, special attention is being paid to quality standards and control (ISO-series) to guarantee uniformity of standards and procedures. Secondly, access to financing is of importance as the industry consists of a large number of small and medium sized companies. Thirdly, the enlargement of the market through public procurement remains extremely relevant. Considering that some 60% of the market is represented by public contracts, the liberalisation of public procurement is essential.

**Table 8: Industrial cleaning services  
Labour costs, 1993**

Portugal	1.76	2.19
United Kingdom	(2) 4.48	5.15

(1) Minimum guaranteed wage for an unskilled worker

(2) Minimum average wage

Source: FENI

In this industry, some 80% of the costs are represented by wages and social benefits. Due to the considerable differences in wage and benefit levels between Member States, some concern exists as to the competitive position of companies in certain countries. However, this concern may be irrelevant due to the local nature of the market and the restricted mobility of labour.

#### REGIONAL DISTRIBUTION

Cleaning contractors obviously must be located close to their clients, i.e. in industrial and urban areas. As a result, there is a high level of fragmentation in the sector. Those companies (especially the bigger ones) which develop activities in several regions usually operate via a network of local agencies.

In fact, most of the big groups are established in several countries, both EU and non-EU. The internationalisation of the groups is difficult to measure, however, since these large groups often enter new markets by taking over domestic companies. Cross-border provision of services is rare and is limited to either neighbouring regions or specific contracts.

#### EMPLOYMENT

The cleaning industry is one of the EU's largest employers, with 1 961 030 workers in 1993. Employment rose by close to 10 % between 1992 and 1993 (see Table 5). The inclusion of East German workers accounts for the sharp rise in employment in Germany. Women persistently have dominated the cleaning sector and accounted for 73 % of the total workforce in 1993. Blue-collar workers made up 90 % of the work-

Source: FENI

force in 1993 while the technical and executive staffs accounted equally for the remaining 10 %. Non-EU migrant workers' share of the total workforce is constantly increasing in most EU countries, but especially in Belgium, where 48 % of the workforce is made up of migrant workers. The numbers for Germany, Portugal and the Netherlands are 30 %, 24 % and 15 %, respectively.

The prevalence of part-time work in the cleaning sector is one of its most significant features. More than 75 % of the total workforce are part-time workers. At the same time, the average working time, though slightly on the rise between 1992 and 1993, remains quite low with an average of four hours per day (see Table 7). Cleaning services are provided mostly before or after normal working hours (20 % are performed during the daytime). As a consequence, full-time work is quite uncommon. The working day is usually split into two non-consecutive periods (one in the morning and one in the evening). (see working time organisation in the section on regulations).

The minimum hourly wage for an unskilled worker in the cleaning industry (see Table 8) is generally comparable from Member State to Member State, averaging between five and seven ECU. However, the percentage of social contributions paid by the employer differs greatly from one country to another, pointing to discrepancies among the national social protection systems and varying labour cost structures (see Table 8). For instance, the Danish social contribution system between employers and workers varies greatly from that of other EU countries, and the gross wages of Danish workers are the highest of any EU country, with 10.70 ECU per hour. Meanwhile, there is no legal minimum hourly wage in the UK, and therefore the figure given below is an estimated average of minimum wages paid by the British cleaning companies.

The prevalence of part-time workers and the importance of fixed-term employment relationships makes it difficult for cleaning companies to implement far-reaching training policies, thereby hindering the professionalisation of the sector. In an effort to ameliorate the situation, the sector as a whole - companies, national professional associations and the European federation - is engaged in the promotion of training within the cleaning industry. The European federation (together with its social partner EURO-FIET) is involved in the European Commission-sponsored FORCE training programme, out of which a series of specific recommendations for the promotion of training and the professionalisation of the cleaning sector have been drawn.

## REGULATIONS

The cleaning industry is highly labour-intensive. Labour costs represent between 75 % and 85 % of the companies' turnover.

The cleaning industry is therefore highly sensitive to European legislation in the social field.

A directive on "working time organisation" was adopted in November 1993 but the cleaning sector could get a derogation with regard to weekly and daily rest periods (article 17 of the directive). The EFCI and EURO-FIET signed a recommendation on working time in December 1993 within the frame of the social dialogue.

The directive on "information and consultation of workers in Community-scale undertakings" is the first of its kind to be adopted within the frame of the Social Protocol (i.e. with the exception of the UK). The directive was adopted in June 1994 and will have a significant impact on top European cleaning companies.

Another major issue for the cleaning sector is the revision of the directive on "safeguarding of employees' rights in the event of a transfer of undertakings. In most EU countries, the cleaning contractors are obliged to keep all or some of the workers at a given site permanently, in the event of a change in the owner and/or contractor. The revision of the directive could lead to compulsory transfer in the case of service markets contracting-out (Schmidt Case). As seen above, atypical work relationships prevail in this sector. A draft directive was released, which aims to provide equal treatment for part-time workers and workers with fixed-term employment relationships. A number of other regulations also affect the cleaning sector, albeit to a lesser extent. These relate to issues concerning equal opportunities for women, health and safety at work.

The first series of professional regulations deals with freedom of establishment and access to cleaning activities. Access to cleaning activities is unrestricted, except in Germany and Luxembourg. A law is currently being drafted in the Netherlands on this matter.

Still another issue is the "directive on the award of services public contracts" (contracts of over 200 000 ECU). This directive does not require certification as such. But in the event that the granting authorities do require certificates, these shall refer to the quality insurance systems based on EN 29000 European standards and certified by independent bodies in conformity with EN 45000 European standards. But some problems may arise involving the harmonisation of accreditation procedures, certification of quality insurance systems and the mutual recognition of certificates among countries. In addition, the cost of certification procedures may hamper smaller companies. One solution comes from Belgium where the smaller companies can produce the "Cleaning Quality Label" when tendering for a services public market.

---

## OUTLOOK

---

The importance of the cleaning industry in terms of economic growth and stabilisation will expand, insofar as this labour-intensive industry will be instrumental in fighting unemployment. However, the professionalisation policy must be kept at the top of the agenda, in order to make the most of the opportunities that will arise. Issues such as training, quality, consultation and participation in national and European organisations, will be indispensable to the success of this sector.

Written by: FENI

The industry is represented at the EU level by: European Federation of Cleaning Industries (FENI). Address: rue Lesbroussart 76, B-1050 Brussels; tel: (32 2) 644 3464; fax: (32 2) 644 2022.

# Security services

## NACE 839.3

*Private security, including the installation of electronic security systems, alarm monitoring centres, transportation of valuables and manned guarding services, had an estimated turnover of approximately 26 billion ECU in 1994. About three-quarters of the security activities in the EU related to manned guarding services is subcontracted to 6 000 private security companies employing 297 548 people, with the remaining quarter handled by corporate security divisions, which employ an additional 96 172 security guards. The turnover by the private security companies is estimated at approximately 7.5 billion ECU, and the total number of security guards at 393 719. Figures and statistics may vary when compared to previous reports, since there has been a considerable improvement in market statistics that are reported by the national branch organisations in the EU countries, which are members of the European Confederation of Private Security Services (CoESS).*

*One notices drastic changes in statistics and figures in some countries, often caused by political or economic reorganisation. Take, for instance, the situation in the former East Germany, where an additional 400 private security companies were founded - mainly very small or even 'one-head operations' - following the German reunification in 1989. The reason for the change in the statistics related to the number of private security companies in the United Kingdom is the fact that in 1994 the small companies have been reported as well, accounting for an additional 1 000 companies operating there.*

*Many Member States are working hard to improve the quality of the security services provided. Many companies already have been certified in accordance with ISO standard 9000. Quality improvement in the education and training of employees has in some Member States resulted in forms of co-operation with the regular police in the field of preventive supervision, leading to private public partnership between the regular police and the private security sector in some cases.*

---

### INDUSTRY PROFILE

#### Description of the sector

The term 'security' covers a variety of specific jobs within the sector. This monograph is based primarily on data concerning the 'manned guarding' sector, but also provides information on the transportation of valuables and other services.

Reliable statistics about the total (financial) volume of private security services could be obtained from only a few European countries. It is possible to get an idea of the state of the total private security market (including the installation of electronic security systems, alarm monitoring centres, manned guarding, etc.) by looking at the situation in the Netherlands, where accurate information is available. Based on such estimate, in the 12 EU countries (with 340 million inhabitants), we can estimate the total volume in private security to be approximately 26 billion ECU.

It is interesting to note the build-up of interest groups in Europe. Organisations of manufacturers, suppliers, users of security products and services as well as third parties, such as insurance companies, all may be considered as caretakers of the security sector in the EU, and are usually founded by existing national agencies.

The Confederation of Private Security Services (CoESS) for the manned guarding sector is also supported by the mem-

bership of the Federation of European Transport of Valuables (ESTA). In 1994, nearly all EU Member States were already members or had applied for membership through their national branch organisation.

The Association of European Manufacturers of Fire and Intruder Alarm Systems (Euroalarm) also plays an active role on the European level. In addition, Eurosafe, the European Committee of Safe Manufacturers' Associations aims at improved research and standardisation in the production of safes throughout Europe.

The European members of the American Society for Industrial Security (ASIS) founded ASIS-Europe. ASIS members are mostly individuals who are involved in private security as corporate security managers and can be considered as the 'users' of the security service industry.

The participation of organisations involved in accreditation, such as the European Organisation for Testing and Certification (EOTC) also has been noteworthy. Likewise, EFSAC (European Fire and Safety Advisory Council) plays a vital role in establishing certification requirements. A member of EFSAC is the European Association for National Insurance Companies (CEA), which develops, amongst other things, guidelines for security components and security installations.

Altogether, some 28 European organisations are involved in private security, playing a role in the accreditation, certification and standardisation of insurance companies as well as manufacturers, suppliers and users of security services.

---

### MARKET FORCES

#### Demand

At the beginning of the nineteenth century, all of Europe saw the advent of night security services, which at that time were usually small-scale, locally-active and established in industrial areas. Not until after World War II did a substantial growth occur due to a number of factors: the prosperity brought by industrialisation, increased crime; weakened social supervision (e.g. by family, church etc.) and increased awareness of the necessity to protect one's own belongings (e.g. entrepreneurs) instead of considering it more as the responsibility of the authorities or the police. Preventive security activities were carried out by security staff employed by the company itself as well as by the contracted private security organisation.

Following the path of the industrial cleaning, maintenance and catering services, security activities became subcontracted more and more frequently. Besides subcontracting, we find the birth of externalisation, i.e. corporate security guards are transferred to a security organisation specially selected for the employer's specific needs, as set out in legal terms.

Preventive security has also become a profession, of which the duties have grown more complex. Whereas in the past they were mostly concerned with porter services, mobile surveillance and the like, present-day security guards perform critical tasks within the framework of the overall management of extensive projects that involve a wide range of crucial security functions.

In large industrial plants and exhibitions, security guards are in charge not only of access control but also fire prevention and sometimes fire fighting; they help perform traffic control and parking supervision on the grounds or beyond, and provide first aid. For all these purposes, they man control rooms from where the security of the production process is monitored as thoroughly as possible.

Another reason for the growth is the diversification of the security services sector. The uniforms (often an element of identification), recognition, mobility and up-to-date communication equipment represent an infrastructure that allows private security organisations to explore new fields of activity

**Table 1: Security services

such as operating bridges and locks in water-abundant areas, management of nature reserves or preventive supervision in the recreational sector (campsites, beaches). Other activities include environmental screening in cooperation with companies or public authorities.

In many countries, there is some form of cooperation between the security services sector and public authorities. A common example is the security check of passengers in many international airports, where private security guards screen passengers under the supervision of the regular police force to ensure safe air travel. Less familiar forms of cooperation are the overseeing of detainees, traffic control, parking supervision in city centres and intendance of public transport particularly in large cities, where drug abuse in particular has caused the proliferation of crime. Security guards are also used to protect military interests and prevent criminal acts in prisons.

### Supply and competition

In many EU countries, much is being done to improve the quality of the service offered by security companies. Quality is increasingly becoming measurable in terms of: company management; i.e. organisation, procedures, etc.; staff performance, through education/training; and, finally, conditions of delivery.

In the countries where the relevant legislation exists, it often serves to promote this aspect of quality. Indeed, competition among security firms is first of all a matter of quality and much less a question of rates. In those countries where competition has focused on the costs of the service, there is little (if any) room leftover for financial investments in quality improvements. Although no unequivocal standard has been established as yet, it seems likely that the international quality standard for services (ISO 9000) will be applied as a certificate of quality assurance. Several security firms have been certified according to this standard and no doubt more companies will follow.

Mention also should be made of the enormous growth in the number of so-called one-head operations in the countries that

used to be a part of the Soviet Union (such as Hungary, Czechoslovakia, Romania, Poland etc.). Many ex-policemen, ex-military officers, etc. have founded their own private security companies on a very small, local basis, mostly without any laws or regulations pertaining to privacy, the use of protective fire arms, or criminal record checks of owners, staff or executives. These new operations could compete with similar companies which have blossomed in the former East Germany.

## INDUSTRY STRUCTURE

### Manned guarding services

The private security industry in Europe is very much alive and well. With an estimate of 26 billion ECU as total turnover, it shows its importance for industry in the EU.

The manned guarding sector fulfils a vital role in the security service business. CoESS members produce a turnover of approximately 7.5 billion ECU, with some 370 000 guards employed by over 6 000 companies, indicating that each company has an average of about 60 employees.

Many of these companies, however, are operating in small local areas, and are 'one-head operations'. But, in most countries, 80 % of the national turnover is achieved by 20 % of these larger, private security companies, which often operate on an international scale. The larger companies employ an average of 300 guards, while the remaining 5 000 companies have an average size of only 10-15 employees per company.

The security transportation sector in Europe shows an additional 50 000 employees, responsible for 1.8 billion ECU and manning 9 000 armoured cars throughout Europe.

### Transportation of valuables

The security transportation sector in Europe represents 1.8 billion ECU turnover, with 48 000 persons employed in 452 companies, manning 9 000 armoured vehicles.

As a sub-sector of the private security industry, security transportation operates in some countries of the European Union under very strict national regulations. In addition to the regulations for guarding, transportation of valuables is submitted to prescriptions regarding the vehicles, weapons and the employees' personal protection.

The work involved in armoured transportation includes diverse activities such as: coin processing, cash and note processing, cheque encoding and ATM servicing. The banks represent the biggest segment of customers for the transport of valuables, making the industry (and prices) very dependent on the evolution of the banking sector.

There is a fundamental difference between classic security guard services - where the organisation is only liable for carrying out an assigned commission dependably and professionally - and a security transport business, which has a far greater responsibility. The owner actually and physically hands over his valuables to the security transport firm, which is then in possession and complete charge thereof and thus, as a carrier, assumes full liability for compensation in case of loss or damage.

Transport contracts guarantee point-to-point delivery of the transported goods. This makes the transporter fully liable towards his clients for the perfect execution of the move under

Source: ESTA

all circumstances. Special insurance is taken by the transporters to cover all risks.

Consequently, with the shipment of valuables, business relationships are based on a high level of mutual trust, between principal and transport organisation on the one hand, but equally between the transporter and its insurance company on the other hand. Insurance companies covering transport risks exercise great influence over security transport companies.

The insurers are able to make strict conditions covering every aspect of transit or storage including the specifications of security vans, armoured cars, and all technical equipment involved, the most important factor being the quality and trustworthiness of the personnel employed to deal with valuable transports.

The quality of the services are directly dependant on the degree of training received by the personnel. Legislation in some EU countries specifies minimum educational standards.

High technology to protect crew members from attacks is progressively being introduced. The self-destruction of the transported valuables is used as a complementary security device in normal transports.

### Impact of the Single Market

In this sector, a distinction must be made between (manned) guarding services and the transportation of valuables.

In the segment of guarding services, the opinion exists that the Single Market Programme has on the whole had a positive effect. However, these effects are hard to quantify, mainly because of the fact that this segment still operates in a local environment with restricted cross border or transnational activity. Companies that are active in numerous Member States do this through local representations. These local representations, acquired through mergers or acquisitions, operate according to local laws and legislation, thereby making the ease of cross border operations a less important issue.

The most important priorities being faced by this sector are the harmonisation of legislation applicable to the industry in the different Member States, harmonisation of the social dimension regarding working time, night and day work and worker safety as well as the setting of training and quality standards.

The Single Market has not materialised in the transportation of valuables segment. Contrary to the envisaged goals, new

legislation was developed by a number of Member States, thereby further hampering the cross border functioning of this segment. The perception exists that Member States feel the need to protect their national identity and integrity. To achieve this, they create new legislation not compatible with the existing and that of neighbouring States. This is applicable to for instance direct and indirect taxation, cross border payments and the technical requirements stipulated by different Member States in order to be allowed to carry out an assignment. This has resulted in the opinion that the ease of operating to countries outside the Union is greater than operating within the Union itself.

### REGULATIONS

There are considerable dissimilarities between the laws and regulations related to security services across Member States. These laws and regulations are, of course, subject to change. The information supplied below was valid in late 1990 and early 1991. Since then, three EU countries have adopted new statutes: Spain (1992), Portugal (1993) and the Netherlands (1994). New legislation is under preparation in Italy.

Most European countries have some form of laws or regulations pertaining to security services. One noticeable exception is the United Kingdom where no government rules exist whatsoever. Germany too is atypical, particularly considering the size of the sector there. This country does have some incorporated legislation but no specific legislation.

A number of duties are included in the security officer's job description. In some countries the array of duties is quite wide. In Sweden the tasks include the production of identity cards and assistance in fire-fighting. In Germany a considerable amount of activities are connected with the maintenance of public order. In Spain part of the duty is to pursue and arrest lawbreakers.

All European countries (excluding the United Kingdom) have mandatory licence and practical requirements which are generally the same. Although such harmonisation exists, a number of countries enforce special requirements, including:

- compulsory third-party liability insurance (Belgium, France, Portugal, Spain and Switzerland);
- restrictions for those who have previously been employed professionally in the police force or have been in the military (Belgium and France), or, conversely, the requirement to

have accomplished one's military service to be allowed to work as a security guard (Spain); and

- the inability to enter the security services sector after filing for bankruptcy (France).

The requirements and the duration of the various types of schooling for security officers in Europe are quite diverse. In Germany, there is no unified set of educational guidelines, whereas in the Netherlands, the schooling is organised quite thoroughly.

Laws and regulations with regard to equipment (uniform, weapons, identification and even guard dogs) are on the whole similar in all countries. Wearing a uniform is compulsory in all but four countries. The uniform shall not resemble the police uniform.

Carrying arms is permitted in all Member States except Denmark, the United Kingdom, the Netherlands and Norway. Laws and regulations regarding arms sometimes are contained in the fire arms legislation of the country in question. In other countries, a separate article is included in the security legislation.

In most countries employees in the private security services sector are obliged to carry an identity paper; Austria is an exception. In Spain, although it is not really a proof of identity, security guards are required to wear a badge, which is easily recognisable.

As for government supervision, Belgium, the Netherlands, Portugal and Spain stipulate annual reporting to the Ministry in charge. In Sweden and Norway supervision is in the hands of the police.

The amount of possible sanctions varies widely. In the Netherlands there is only the possibility of withdrawing the licence. Belgium, Denmark, France, Norway, Portugal, Spain and Switzerland have, in addition to that sanction, the possibility of imposing fines and/or imprisonment.

Other noticeable clauses include:

- security firms are not to concern themselves with or intervene in political or labour conflicts (Belgium and France);
- a certain amount of force may be used in a case where a person offers resistance against arrest (Finland and Sweden);
- the wages of a security guard must not be lower than the starting salary of a police officer (Greece);
- approval from the Prime Minister is required if someone wishes to exercise other activities simultaneously with security activities (Austria); and
- each private security organisation is assigned an exclusive number, which must be noted on any document and in any publication the firm produces (Spain).

## OUTLOOK

Europe proves to be an interesting market for the private security business. Several facts lead to the expectation that growth of the sector (estimated at between 5 and 8 %) will be seen in the coming years. The first factor, which is providing hope for much of EU industry, is the generally better economic conditions being experienced by most of the Member States as at the end of 1994.

In addition, development in sub-contracting will lead to further growth of individual security (guard) companies on a national and an international scale. Also, growing statistics in (large-scale) crime will continue to make it necessary for investment in crime prevention by both the public and private sectors.

# Car rental

## NACE 844

The market for long-term car rentals is still relatively new in Europe, while the market for short-term leasing is dominated by a few large companies. Both markets are stimulated by the enormous growth of mobility. Nevertheless, the sector has some problems to deal with, car theft being the most important one. Car theft has become a real burden for car rental companies as insurance companies do not accept the risk of car theft with respect to short-term leases. On the market for long-term leases car theft has resulted in high insurance premiums. For these reasons, the industry is taking considerable initiatives for prevention. In 1994 and 1995 both markets will be stimulated by the onset of general economic recovery. In the long run, growth is expected to continue.

### INDUSTRY PROFILE

#### Description of the sector

Car rental is the most important subsection of NACE 84 in terms of turnover. The branch deals with the commercial rental of motor vehicles (passenger cars, vans and trucks). Car rental with a driver is not included, as it belongs to the taxi business classified in NACE 722.

A distinction can be made between short-term rental (a few days) and long-term rental (contract hire and leasing). The latter is basically used for business purposes. The former is used for both business and tourism purposes, but is mostly used for the temporary replacement of vehicles which have been involved in an accident.

In 1991, total turnover in France, Germany and the Netherlands totalled 8 621 million ECU. Compared to the GDP of these countries, on average the car rental branch accounted for 0.3 % of GDP.

The largest short-term car rental markets can be found in France, Germany and the United Kingdom. In 1993 France and the United Kingdom accounted for 25 % and 23 % of the EU total of short-term passenger car rentals, respectively. The German stake was 19 % of the EU total.

Germany is by far the largest market for long-term car rentals. In 1993 the German fleet amounted to nearly 2.4 million passenger cars and 230 000 light vans. The United Kingdom ranks second, with 1 million passenger cars and 70 000 light vans.

#### Recent trends

Over the 1985-1993 period, the EU market for short-term car rental has grown considerably. For ten Member States (Germany and Denmark excluded) the fleet of passenger cars and light vans increased by an average annual rate of 5.1 % and 3.9 % respectively. Except for the United Kingdom, growth was evenly distributed over the years. Growth rates, however, differ drastically per country. While the fleet of passenger cars almost tripled in Belgium and nearly doubled in France, Greece and the Netherlands, growth rates were much smoother in Italy, the United Kingdom and Spain over the same period.

The economic recession in recent years has resulted in a levelling-off of aggregate growth rates with respect to the fleet of passenger cars and light vans. From the country-specific data it appears that the car rental branches in the United Kingdom and Germany have been hit the hardest by the recession, resulting in a decrease in the number of rental cars in those two countries.

The average rental period for a passenger car stabilised at 4-5 days in 1993. For light vans and commercial vehicles the average period was 2-3 days.

The utilisation rate is the percentage of time the vehicles are actually earning money. In 1993 this rate varied from 57 % to 70 %, which is stable compared to the 1991 rate. The 1993 utilisation rates for light vans and commercial vehicles or trucks utilisation, however, were down from the 1991 figures. For light vans, the average utilisation decreased from 59 % to 51 %. For trucks, the same figure dropped from 65 % in 1991 to 56 % in 1993.

If compared to the market for short-term rentals, the growth rates of the number of vehicles for long-term car rentals were higher over the 1985-1993 period. For six EU countries (Belgium, France, Italy, the Netherlands, Portugal and the United Kingdom) an average annual growth rate of 9.6 % was recorded with respect to the number of cars.

In the United Kingdom, the economic recession in recent years has resulted in a dramatic decrease of total number of

vehicles for long-term rentals (-22 %). The other Member States were not seriously affected by the recession with respect to this market.

---

## MARKET FORCES

---

### Demand

The growth of the European car rental market is affected by three factors: general economic growth, airline traffic growth and consumer attitudes.

Between 20 to 30 % of short-term car rentals is distributed at airports. The supply of car rental services is a reflection of the demand for flexible and efficient transportation for business travellers. The fly-drive concept - either booked in advance or privately arranged - also increases the tourist's flexibility and reduces his or her dependence on public transport.

The ongoing European integration, the extension of the number of EU Memberships and the intensifying trade with Eastern Europe will increase international business traffic. This increasing mobility will have a positive effect on the market for short-term car rental. Growing demand can be expected from tourists, as they become more and more independent and adventurous, a tendency which benefits the car rental industry.

In long-term car rental, a growing need exists for advantageous financing and tax systems. Companies tend to sell their fleets and lease them back in order to benefit from such systems. Also, the trend towards concentration on their core business stimulates companies to outsource all activities concerning their car fleets.

### Supply and competition

A fierce competition exists, especially between the big, international car rental companies. These companies court the business sector as well as the leisure sector with a most flexible pricing policy, based on partial-cost thinking. At the same time, the performance standards (car plus service) have been expanded and improved substantially. Induced by the increasing competition and the high growth rates in the swelling pan-European market, much attention also is given to cost reductions and economies of scale in the operating systems. As a consequence, the modern computerised reservation systems (e.g. Avis' worldwide Wizard network) have become an essential competitive edge. Beside the price and service aspects of competition, a comprehensive presence at major locations such as airports, and in primary and secondary cities, is also an important advantage for these companies.

The partial-cost oriented pricing policy of the big car rental companies is possible because of the effects of rationalisation and declining costs resulting from the size of the companies. Perhaps an even more important factor is the sector's strong financial and/or contractual relationship with the automobile industry.

Companies involved in short-term rental compete for customers by offering a wide range of services. Express desks, self-service returns and reward schemes for frequent clients (e.g. Avis' Club, Hertz's Gold Club and Eurodollar's First Choice Card) appeal to the business clients. For the leisure traveller, rental companies have organised all sorts of arrangements together with airline companies and tour operators. An example of a very successful new product is the fly-drive arrangement, the success of which has led to the rail-drive and rail-sail-drive arrangements that are now available.

A new development in the industry is the rental of electric cars. These cars help to reduce air pollution and promote cleaner and quieter roads. In Rochelle (F), 90 electric vehicles are running already. They can be recharged at public car parks, shopping centres and rail and bus terminals. Measures have

been taken to encourage their use, including reserved car parking.

In response to the growing need for advantageous financial agreements, competition on the market for long-term car rentals is also intensifying. This increased competition forces leasing companies to focus on driving down costs and improving customer service. Furthermore, bank-owned lessors face competition from manufacturer-owned lessors.

---

## INDUSTRY STRUCTURE

---

### Companies

Commercial short-term car rental is provided by companies either exclusively or in combination with other business activities. The majority of the big companies are in this business exclusively, sometimes in combination with car leasing. The small and medium-sized companies, however, combine car rental with other business activities, in affiliation with gasoline stations, motor vehicle dealerships and auto repair shops/garages. For the most part, car rental is not the major activity in such companies.

The five big car rental companies in Europe are Avis, Budget, Eurodollar, Europcar and Hertz. Together, these five multinationals represent over 50 % of the market in Western Europe. The remaining share of the car rental market is accounted for by a great number of small, medium-sized and larger firms of local, regional and nation-wide importance, which frequently enter into horizontal cooperation arrangements in order to improve their efficiency.

Hertz, the largest car rental company worldwide, is owned by Park Ridge Corporation, in which Ford Motor Company holds a majority equity share. After Hertz, Avis is the second biggest car rental firm worldwide. Avis Europe, in which the Belgian Lease International and (to a lesser degree) General Motors and the American parent company Avis Inc. hold shares, is the market leader in Europe, ahead of Europcar.

Budget is the third largest car rental company worldwide, with a fleet of 250 000 vehicles and 3 600 outlets in 140 countries. It operates its own network (in Belgium and in France), as well as a franchise network. Despite difficult market conditions, its own network grew at a rate of 15 % in 1991.

Europcar was created in 1989 by a merger of InterRent, a 100 % Volkswagen subsidiary (which until then was the market leader in Germany) and Europcar, the leading car rental firm in France and the United Kingdom, a subsidiary of the Belgian-French travel firm Compagnie Internationale des Wagons-Lits et du Tourisme. Reorganisation, rationalisation and network adjustment took place in 1990 and 1991. With counters in about 260 airports in 79 countries, Europcar holds about one-third of the world market. Europcar is trying to establish a global presence through cooperation with Eurodollar.

Eurodollar International is the European franchise of the American group Dollar Rent A Car Inc. Dollar in turn belongs to Chrysler Corporation, which also owns Thrifty Rent A Car. Eurodollar owns and franchises outlets in 20 European countries. It has 700 locations in Europe and offers more than 70 000 vehicles (worldwide this figure is 125 000 in 1 800 locations).

Both bank-owned and manufacturer-owned lessors are operating in the long-term rental market. In most cases the lessors offer a range of leasing products, though car leasing is still the most important lease product

### Strategies

Some differences can be observed between the distribution strategies of big car rental companies. Avis and Hertz rely primarily on their extensive station networks at airports. Avis

Source: ECATRA

also has a comprehensive presence at train stations throughout Europe. Hertz has a strong foothold in British train stations. Europcar's presence at the major European airports is rather poor. Rather, it has a significant presence in the primary and secondary cities of Europe.

In order to take advantage of these networks exclusive contracts or partnerships have been signed or started with the transport companies, travel agencies and hotel chains. Avis, for instance, has exclusive contracts with the French, Belgian and Luxembourg railroads. In addition, there are cooperation agreements with most of the big travel agencies, many airlines (e.g. Lufthansa) and hotel chains. Hertz has numerous fly-drive agreements with airlines, e.g. its "Business-drive" programme in partnership with British Airways. Hertz also has an exclusive agreement with British Rail, and other cooperation agreements exist with the national railroads of the Netherlands.

In addition, the provided products and services are interrelated with the existing networks and cooperation agreements. For instance, in combination with British Rail, Hertz introduced its "Intercity-drive" programme. In 1991, a number of products were introduced for the leisure traveller, such as the "Holiday-saver" programme in Europe. Europcar is especially active in special products in the non-airport segment of the market. One specialty of Budget is the provision of luxury cars. Of all car rental firms, Budget maintains the largest Mercedes fleet and is, in fact, the biggest customer of Mercedes in the world.

A clear pricing policy and constant high level of service are becoming increasingly important. This trend favours the big car rental companies which have evenly high performance standards, large station networks and extensive integrated operating systems. With their extended networks, more econo-

mies of scale and even better financial and/or contractual interrelationships can be attained.

The numerous small and medium-sized car rental firms focus on the non-airport and often local segments of the market. These include the rental of substitutes for accident-damaged cars (turnover share approximately 50 %), the rental for business purposes (around 30 %), the rental to tourists (about 15 %) and the rental for other private purposes (roughly 5 %).

In geographical terms, much growth can be expected from the economic development of Eastern Europe. Europcar, for instance, is extraordinarily active in East European markets; it entered the Soviet market in 1989, and the East German market in 1990. In addition, it has licensees in Czechoslovakia, Hungary, Yugoslavia and Bulgaria.

### Impact of the Single Market

Car Rental is an extremely competitive market. The five largest European companies have a market share of more than fifty percent, the rest being made up of small and medium sized enterprises. Competition is primarily based on price, the level of service and the flexibility the client demands and experiences.

Car Rental is increasingly becoming a cross border activity. This calls for measures to harmonise legislation in the different Member States. Due to for instance the considerable differences in (indirect) tax levels, the consumer is being confronted to large price differences, decreasing the transparency of pricing within the sector. In terms of service, the client, be it the business traveller or the tourist, increasingly demands standardisation in the different Member States. Therefore, companies are addressing the obstacles which currently inhibit this standardisation.

The industry identifies further liberalisation of financial services and the ease of cross border payments as having priority. In addition, due to the large proportion of small and medium sized enterprises in the sector, minimisation of the financial and administrative burden is of importance.

---

### ENVIRONMENT

On the whole, car rental activity has a negative impact on the environment. Negative considerations include car pollution and the economic costs of car accidents. Positive environmental considerations include the substitution effects resulting from rail-drive arrangements instead of using a car or aeroplane.

With respect to car pollution some favourable developments can be noted, such as the increasing use of smaller sized cars and relatively new cars in rental fleets, particularly in the Western European countries. Further, car rental fleets get regular maintenance and inspection, which contributes to energy efficiency and the minimisation of harmful exhaust gas emissions. However, in Southern EU countries car rental firms frequently have older, poorly maintained cars in their fleets.

---

### REGULATIONS

One of the most important problems in the car rental industry is vehicle theft and conversion. In 1993 ECATRA's short-term rental members absorbed a loss of 11 550 vehicles, representing a value of 160 million ECU - nearly 2 % of their total fleet. This far exceeds the pre-tax profits of business in the industry. Similarly, for long-term leasing, insurance companies have had to pay out colossal sums, which has caused premiums to soar. Insurance companies rarely accept the risk of insuring short-term rentals against car theft. Theft by juveniles accounts for the majority of vehicle crime. Enormous losses are involved and the problem has been aggravated by the abolition of custom control at national borders.

The industry is taking considerable initiatives for prevention. These include the development of a data bank on a pan-European basis, which will provide an immediate signal if someone involved in previous rental frauds tries to hire a vehicle. Other suggestions have included the removal of any rental markings on vehicles; a contractual ban on travel to non-EU and non-EFTA countries; more dialogue and cooperation between concerned bodies; a call for improvement of car security systems by car manufacturers, a microchip security system on rental cars and car security cards.

The envisaged harmonisation of VAT and excise duties is important for the industry as well. Currently, large variations exist in the EU countries causing rental companies to charge different prices, which has a direct affect on the consumer by causing less clarity in the market on the whole. It also creates bothersome inflexibilities in international car renting.

---

### OUTLOOK

The markets for short- and long-term car rentals are both expected to grow in the coming years. Growth will stem primarily from the increasing mobility induced in part by the economic recovery, but also by an autonomic non-cyclical component. Growing business travel in the wake of the completion of the EU internal market, economic recovery in the EU and Eastern Europe, as well as continued expansion of Europe-wide tourism will stimulate the car rental market positively in the future.

Car rental has become a true alternative to the use of a self-owned automobile or truck. For short-term car rental there is an increasing tendency to use rail or aeroplane services in combination with a rental car for both business and tourism. Long-term car rental benefits from the increasing need for flexible financing of car and truck fleets.

In view of the above, growth in the car rental industry is envisaged to be relatively strong. In 1994-95 a recovery from poor 1993 figures can be expected. Growth rates are expected to reach 3 % on average. For 1995-97 a real expansion of close to 5 % is expected.

The industry is represented at the EU level by: European Car and Truck Rental Association (ECATRA). Address: Grafenberger Allee 363, D-40235 Düsseldorf; tel: (49 211) 685 373; fax: (49 211) 660 571.

# Leasing

## NACE 84

The market for equipment leasing is still relatively new in Europe, although its level of development is not the same in all European countries. In general, however, the leasing market has yet to fully mature, despite its already existent popularity in the European service sector. In some EU countries, some legal obstacles hindering the sector's growth remain, while in others competition is intense and new parties have entered the leasing market. Despite its relatively immature stage of development, the leasing market does have a cyclical character. The market for equipment leasing has suffered from the economic recession in recent years. In 1994 some signs of economic recovery can be noted which will further encourage leasing activity. This positive development is expected to continue in the future.

### INDUSTRY PROFILE

#### Description of the sector

NACE 84 covers renting, leasing and hiring of movables, of which leasing is the most important. The leasing of real estate is excluded. Consequently, figures only refer to the leasing of movables, or the so-called equipment leasing. More specifically, the following types of equipment leasing will be

dealt with: leasing of agricultural machinery and equipment (without permanent staff; part of NACE 841); leasing of construction machinery and equipment (without permanent staff; part of NACE 842); leasing of bookkeeping and office machines, electronic data processing equipment and cash registers (without permanent staff; part of NACE 843); leasing of cars (part of NACE 844); leasing of other means of transport without a driver (part of NACE 845); and leasing of other movables (part of NACE 847).

Leasing is defined differently by the Member States. Comparisons across Member States therefore have to be interpreted cautiously. Broadly speaking, leasing refers to the transfer of a good from the lessor (the owner) to the lessee, who can make use of the good upon the making of regular payments. While leasing concerns an operation of a medium- or long-term nature, renting refers primarily to the transfer of a good in the short term (hours, days, etc.) between two persons on payment of a fee.

Principally, two major categories of leasing contracts are distinguished: the financial lease and the operational lease. Financial leases are contracts with full pay out (full amortisation). These are, in principle, irrevocable, and do not provide for maintenance and service (the legal ownership stays with the lessor, but the economic ownership shifts to the lessee). Furthermore, in several Member States the financial lease includes an option for the lessee to buy at the expiration date.

An operational lease is a contract with non-full pay out (partial amortisation): the lessee only uses the capital equipment for a portion of its normal service life, and there are normally

one or more additional users. The leasing rates and payments are calculated at a fraction of the purchase value. Furthermore, an operational lease can, in principle, be cancelled. This form of leasing ordinarily calls for the lessor to maintain and service the leased equipment, and the costs of this maintenance are either built into the lease payments or contracted for separately: the legal and economic ownership stay with the lessor.

The industry's total turnover in 1993 reached 62 billion ECU (more than 1 % of GDP in all EU-countries). The European leasing activities are mainly concentrated in Germany and the United Kingdom. Both countries accounted for 60 % of total EU turnover in 1993.

#### Recent trends

The US was the first country to set up and develop leasing operations. In the early years of leasing, US-manufacturers of capital goods dominated the leasing market: They used leasing operations mainly as a marketing instrument in order to stimulate the sales of their core products.

The European market for leasing has always been dominated by bank-owned lessors. In the market for leasing these companies showed huge growth figures in the 1970s and the 1980s.

In recent years the economic recession in the EU has led to a decrease in investment, thus hampering growth rates. In some Member States, the recession and increasing competition between leasing companies have resulted in a shake-up of companies. In 1993 the UK already showed some signs of

recovery and during 1994 the economic developments in the other Member States have become more favourable for further sectoral growth.

#### International comparison

The leasing market in the US is relatively well-developed, with a leasing ratio (share of leasing in total investments) above 30 %. Japan has lagged behind, but is now making up for it with high growth rates.

Within Europe, the EU leasing market is far more developed than that of Eastern Europe. The countries which have shown the most rapid recovery from the post-communist inactivity - Poland, the Czech Republic and Hungary - are leading the development of western-style leasing in Eastern Europe.

In 1993 US lessors recorded high growth rates, especially in their domestic markets. Their European leasing activities, on the other hand, suffered from the unfavourable economic conditions. In contrast with Europe and Japan, the largest US lessors are manufacturer-owned (GE Capital, AT&T Capital Corporation and IBM Credit Corporation).

#### MARKET FORCES

##### Demand

The European leasing market has gradually undergone significant changes in terms of suppliers, customers and products. Before 1990 leasing operations concentrated on office equip-

Source: Leaseurope

ment. Nowadays, all kinds of goods can be leased, ranging from machines and industrial equipment to road transport vehicles, ships and even aircraft.

The decreasing role of office equipment is reflected in a lower share in total turnover of leasing machinery. In 1993 only 15.1 % of total turnover could be attributed to office equipment against 17.1 % in 1992. Although turnover stabilised in 1993, 'Motorcars' (including car leasing) remained the largest category, and it could increase its share in relative terms even further. 'Ships, aircraft, railway and rolling stock' was the only category that could record some substantial growth in absolute terms.

It appears that the service sector is still the largest customer of leasing products, although its share decreased in 1993 (from 48.4 % to 46.6 %). Further, it seems that leasing to private persons (mainly car leasing) has increased in both absolute and relative terms. To an increasing extent private households are attracted by the favourable leasing conditions offered by the car manufacturers resulting from poor car sales.

There are, however, signs of recovery. In the UK business volumes are increasing. Demand for leasing in the public sector is growing throughout the EU as is the demand for operational leases.

### Supply and competition

Originally, leasing companies were mainly manufacturer-owned and tried to stimulate their sales by offering additional

services for customers. A second family of leasing companies was formed by financial institutions which, because of their financial expertise, were able to overtake the manufacturers in several Member States. The European market continues to be dominated by bank-owned lessors. But there is some indication that this will change, as manufacturer-owned lessors again are increasing their market shares.

The recession has led to a serious shake-up of the European leasing industry. In recent years the number of leasing companies in Germany has halved from about 1 400 to 700. Throughout Europe there is intense competition for good quality credits with a consequent decline in margins.

## INDUSTRY STRUCTURE

### Companies

The European leasing market is still dominated by German, French and UK bank-owned leasing companies. Société Générale, which suffered from a drop of more than 15 % in turnover, stood down from first place, changing position with Lombard. Ford Credit Europe started operations in 1993, thereby indicating the threat posed by the manufacturer-owned companies.

### Strategies

The intensifying competition forces leasing companies to focus on driving down costs, improving customer service and identifying profitable niches by developing new leasing facilities

and/or specialising in certain selected markets. Bank-owned lessors are responding to the threat of manufacturer-owned lessors by offering leases alongside mainstream bank products, to take advantage of the parent bank's retail network; as well as by setting up specialised subsidiaries.

### Impact of the Single Market

The leasing industry is very sensitive to changes in the economic cycle. The recent recession has had a considerable negative effect on revenues. Therefore it is difficult to determine exactly what the financial and economic effects of the Single Market Programme have been.

Leasing has a very prominent financial and legal aspect. A very important role is envisaged for the Single Market Programme in harmonising rules and regulations concerning finance and (company) law which differ significantly between Member States. As yet, the uniformity desired by this sector on these issues has not been reached.

The leasing market has a predominantly domestic character. In order to stimulate cross border business, issues such as the freedom of movement of capital need to be addressed. In addition, harmonisation of accounting rules and taxation are required in order to create a true and fair competitive environment for leasing companies operating in different Member States.

### REGIONAL DISTRIBUTION

Leasing activities are mainly concentrated in industrial areas. Differences between the penetration of leasing products cannot be explained by cross-border regional patterns but are more a consequence of differences in the regulatory environment between Member States. A wide variety of civil law, fiscal and accounting rules exists in the EU. In some countries, such as Germany and the UK, this environment has stimulated leasing activity, whereas in other countries regulations have hampered market growth.

### ENVIRONMENT

The Green Paper on remedying environmental damage fails to answer the question of whether or not the responsibility for any damage of leased equipment can be addressed to lessors. Although the wording of this Paper can be interpreted in several ways, it does not require any position to be taken. The instances in which the lessor's liability could be invoked are, in reality, very limited.

Generally speaking, lessors of equipment have even less reason to be implicated in the costs of remedying environmental damage than do banking organisations, because lessors are merely concerned with the leasing of individual items of equipment

**Figure 1: Leasing  
Equipment leased by type of asset in the EU**

Source: Leaseurope

**Figure 2: Leasing**  
**Equipment leased by type of customer in the EU**

Source: Leaseurope

and rarely obtain the detailed information about the day-to-day business of its customers which is available to banks. Further, it is for that reason that lessors are rarely able to influence lessees about the manner in which operations may be carried out.

There are, however, some indirect consequences for the leasing industry if environmental measures are taken. The introduction of a carbon tax will influence mobility, which could affect the leasing market negatively. Such a tax, however, will only be implemented in the long run and the direction and magnitude of its impact is not quite clear.

Other measures aiming to discourage car traffic and/or stimulate other traffic modes might affect the leasing market. Although such measures on a national level have not been very successful yet, in the long run some successes will be realised.

## REGULATIONS

Since its establishment in 1991, the Accounting Advisory Forum discussed the accounting for leasing contracts. With respect to accounting rules, major differences between Member States exist. Accounting operates according to two methods: the economic approach and the legal approach.

The economic approach neglects the legal content of a contract and interprets the economic content ('substance over form'). This interpretation is decisive for the capitalisation of the leased good: the economic owner is allowed to capitalise and depreciate the leased good. This means that with financial leasing, the lessee (economic but not legal owner) can enter the leased good in his balance sheet, while with operational leasing the lessor (economic and legal owner) is allowed to capitalise and depreciate the leased good. This approach is also called the Anglo-Saxon method, and is advocated in Europe by the UK, Ireland, the Netherlands and Belgium.

The legal approach gives the right to the legal owner to enter the leased good in his balance sheet. Consequently, no distinction with respect to accounting rules is made between financial and operational leasing, since in either case the lessor is the legal owner. This approach is used in most countries of continental Europe, notably France and Germany.

In October 1993, the Forum discussed the accounting for lease contracts for the last time. According to the Forum the capitalisation of leased assets and recognition of income should be guided by existing national accounting methods. However, a "benchmark" is recommended for disclosure of the notes

of annual accounts. Although no distinction is made between the capitalisation of leased assets and income recognition, a distinction between the financial and operating leases is drawn for disclosure purposes.

On the first of January 1994, a new directive came into force for the monitoring and control of large exposures (a risk which exceeds 10 % of own funds) of credit institutions. It states that a credit institution may not incur an exposure to a client or group of connected clients of a value exceeding 25 % of its own funds. The total amount of large exposures may not exceed 80 % of its own funds. Exemptions for risks taken have been made by credit institutions on their parent company, on other subsidiaries of the parent company and on their own subsidiaries, as long as these companies are subject to supervision on a collective basis.

## OUTLOOK

The economic recession seems to have come to an end in most Member States. Economic recovery will positively affect leasing operations as investments will increase. The first signs of recovery in the leasing market are already reflected in the UK growth figures. An increase of leasing operations for other EU countries in Western Europe is expected for 1994. In the Mediterranean EU countries, a full recovery is not expected until 1995.

Further growth is expected as economic development and the accompanying increase in investments will continue in 1994-1997. All types of assets are expected to show a growth with respect to leasing operations. Investments in office machinery and computer equipment are expected to grow because of the increasing penetration of these goods and the intensifying importance of services in most Member States. The decline of hardware prices, however, will offset this positive evolution somewhat.

Investments in machinery and construction equipment, which show a relatively high cyclical character, are expected to increase because of the favourable economic climate. Furthermore, the growth and change of the former East Germany will result in a significant increase of leasing activities in Germany. Also, the evolution of East European countries like Hungary and Czechoslovakia can offer new opportunities for EU leasing companies.

Car leasing is still the largest segment in the leasing market and is expected to retain and even strengthen its leading po-

sition in the 1994-1997 period. This sector is not expected to become negatively affected by environmental measures against car traffic, as no serious measures on a European level will come into force during this period. For the moment, car leasing is only hindered by the fact that, in some Member States, leasing to private households is not allowed.

Written by: Netherlands Economic Institute  
The industry is represented at the EU level by: European Federation of Equipment Leasing Company Associations (LEASEUROPE). Address: Avenue de Tervueren 267, Bte 9, B-1150 Brussels; tel: (32 2) 771 2108; fax: (32 2) 770 7596.

# Franchising

*Franchising is a means of adaptation to local conditions without losing the benefits of global concerns, ideas and scales. Within the EU, franchising has become the most dynamic business development strategy. France is by far Europe's leading franchise country and second after the USA at the world level. The outlook is bright as franchising has an important role to play in the promotion of EU trade and has the tools for that purpose.*

## INDUSTRY PROFILE

### Description of the sector

Franchising is a strategy of business development that has remarkable success all around the world. Nevertheless, there exists a specific European form of franchising because the European culture has given this strategy a specific colour, a clear concern for balance and transparency.

Franchising is a means of achieving adaptation to local conditions without losing the benefits of global concerns, ideas and scales. Therefore, Italian or Belgian franchising is quite different from German or French franchising. The basic definition of franchising, contained in the Code of Ethics, is accepted by all members of the European Franchise Federation and by the European Commission.

Franchising is a system of marketing goods and/or services and/or technology, which is based upon a close and ongoing collaboration between legally and financially separate and independent undertakings, the Franchisor and its Individual Franchisees, whereby the Franchisor grants its Individual Franchisees the right, and imposes the obligation, to conduct a business in accordance with the Franchisor's concept.

The right entitles and compels the Individual Franchisee, in exchange for a direct or indirect financial compensation, to use the Franchisor's trade name, and/or trade mark and/or service mark, know-how, business and technical methods, procedural system, and other industrial and/or intellectual property rights, supported by continuing provision of commercial and technical assistance, within the framework and for the term of a written franchise agreement, concluded between the parties for this purpose.

### Guiding principles of franchising

The Franchisor is the initiator of a franchise network, composed of itself and its Individual Franchisees, of which the Franchisor is the long term guardian.

Obligations of the Franchisor. The Franchisor shall:

- have operated a business concept with success, for a reasonable time and in at least one pilot unit before starting its franchise network;
- be the owner, or have legal rights to the use, of its network's trade name, trade mark or other distinguishing identification; and
- provide the Individual Franchisee with initial training and continuing commercial and/or technical assistance during the entire life of the agreement.

Obligations of the Individual Franchisee. The Individual Franchisee shall:

- devote its best efforts to the growth of the franchise business and to the maintenance of the common identity and reputation of the franchise network;
- supply the Franchisor with verifiable operating data to facilitate the determination of performance and the financial statements necessary for effective management guidance, and allow the Franchisor, and/or its agents, to have access to the Individual Franchisee's premises and records at the Franchisor's request and at reasonable times; and
- not disclose to third parties the know-how provided by the Franchisor, neither during nor after termination of the agreement.

Recruitment, advertising and disclosure. Advertising for the recruitment of Individual Franchisees shall be free of ambiguity and misleading statements.

### A specific organisation

In 1972, the European Franchise Federation (EFF) was created, as an international non-profit association assembling all national Franchise Associations or Federations established in Europe. Members of national associations are Franchisors settled in the country. The aims of the EFF are:

- promotion of franchising in Europe;
- protecting the franchise industry by promoting the European Code of Ethics;
- influencing and encouraging the development of franchising in Europe;

**Table 1: Franchising**  
**Main indicators, 1993**

	Number of franchisors	Number of franchisees	Turnover (billion ECU)	Persons employed by franchisees

Source: EFF, national franchise associations and federations

- representing the interests of the franchise industry in international organisations, such as the European Parliament;
- promotion and representation of the European franchise industry and its members world-wide; and
- exchange of information and documentation between national associations or federations in Europe and the World.

Today, the EFF has 12 members. To reinforce its statistical basis, the EFF is creating the first European Franchise Data Bank. However, the following statistics are still under the responsibility of each national association and should, therefore, be interpreted more as estimations.

## MARKET FORCES

### Demand

The last 20 years have seen quite an evolution in the channels of distribution. Stronger competition resulted in increased specialisation and the emergence of new ideas, with franchising being one of them. Within the EU, it has become the most dynamic business development strategy. More than 3 000 franchisors and 250 000 franchisees achieved an annual turnover of over 75 billion ECU in 1993.

In Europe, franchising was first adopted in retail sectors, where, with some exceptions, the traditional forms of cooperation were not much used. It was also adopted in completely new business sectors, like do-it-yourself shops, fast food restaurants and car rentals. Although North American franchisors found their way to Europe, many national franchise networks were developed. Despite growing internationalisation, most national markets are still held by national networks.

### France

France is by far the leading country in Europe in franchising and comes second in the world after the USA. In 1993, there were 500 franchisors and 30 000 franchisees realising a turnover of 31 billion ECU. This represents 12 % of French retail turnover.

Franchising first appeared in the north of the country, where the major wool manufacturer Pingouin led the way in 1929. It then spread to the confection sector, giving a strong impetus to the growth of product franchising, which today represents 70 % of all franchising in France. Within product franchising, personal equipment represents 30 % of the market, the food industry 20 % and home equipment 20 %. The remaining 30 % consists of service franchising, which at present is achieving an annual growth rate of 20 % in areas such as fast foods, hotels, instant printing, car maintenance, etc.

Big trade marks such as Chanel, Yves Saint Laurent, Pierre Cardin are part of the French culture. The French franchising system gives much more importance to the trade mark than to know-how. The trade mark is considered the symbol of the franchise network identity.

Franchising in France is moving towards increasingly innovative and performance-oriented forms in services for the individual consumer or business. In these areas, a new trend is appearing. Franchisors are considering franchisees more like partners with an increased freedom in their actions, as long as the network's image is preserved.

Of the franchising networks present in France, 95 % are French. The remaining 5 % are mostly American fast food chains. Success in French franchising is best measured in terms of employment. In 1993, it is estimated that 10 000 jobs were created or saved by franchisors and franchisees.

### United Kingdom

The United Kingdom has 396 franchisors and 24 900 franchisees which realised a turnover of 6.4 billion ECU in 1993. In recent years, growth in turnover has been 25 %; mostly

due to expansion in services and specialised retail businesses. Characteristics of the United Kingdom are:

- the absence of confection franchises. In 1989, the UK had 7 confection franchises, while France had 150;
- the great influence of American franchises. For the US, the UK has been a natural gateway to Europe. Most US franchisors started their European strategies with an English subsidiary. Consequently, almost 30 % of the franchise networks in the UK are American. The UK is the leading country for Master Franchise.

### Germany

With 420 franchisors and 18 000 franchisees, German franchising realised a turnover of 10 billion ECU in 1993. Germany has become an important franchising country in Europe. However, because of its co-operatively structured retail industry with strong "Buying Groups", franchising did not really take off until 5 years ago. It has mostly developed in food distribution (with large groups like Spar or Eisman), in pottery and household equipment, followed by personal equipment and services. Service franchising in Germany is largely made up of fast-food chains.

Growth in German franchising will receive extra stimulus from the development of eastern Länder and countries. In 1993, distribution of franchisees in the western and eastern Länder were 81.2 % and 18.8 %, respectively.

### The Netherlands

With 340 franchisors, 12 120 franchisees and a turnover of 6.8 billion ECU, franchising represents 12 % of retail turnover in the Netherlands. Except in the fast food sector, developed generally in Europe by American franchisors, most franchisors are Dutch (soft drinks bottlers and petrol not included).

### Belgium

Belgium counts 2 495 franchisees sponsored by 135 franchisors with a turnover of 3.3 billion ECU. Here, franchising has revealed itself as a successful strategy for 15 years, and expands according to the French model. Product franchising is preponderant, while service franchising is only recently developing. Currently, 50 % of the franchise networks in Belgium are Belgian, with the GB Group being the largest franchisor.

### Italy

Italy has 361 franchisors and 17 500 franchisees achieving a turnover of 7.5 billion ECU. Italy experienced a sudden expansion in 1987 which lasted two years, with an important development in personal equipment. Franchising seems perfectly adapted to the needs of the country, which has experienced a severe recession and a rapidly spreading culture of individual entrepreneurship at the same time.

Still, however, franchise turnover is very low compared with total retail turnover, representing only roughly 1.2 %. Very few foreign franchisors, mostly American and French, have settled in Italy.

### Spain

Franchising is a rather new distribution channel in Spain. Taking off only in 1988, it expanded very quickly. Until 1991, the annual growth rate was almost 70 %. Today, Spain has 250 franchisors and 20 000 franchisees, realising an annual turnover of 2.3 billion ECU.

Expansion is mostly due to foreign franchisors. In 1991, only 58 % of franchisors were Spanish. However, the trend is now changing. An important number of national networks have been established, resulting in the Spanish Franchise Association being founded in October 1993.

Traditional economic areas are personal equipment, confection and food distribution. Service franchising is still not developed, but needs are obvious in sectors like car services, hotels, restaurants, as well as in specialised retail business.

### Portugal

In the past four or five years, Portugal has experienced the same evolution as Spain. Today, 70 franchisors and 800 franchisees are operating.

### Eastern Europe

In Eastern Europe franchising may be a way to import managerial know-how and an efficient retail structure. Countries like Hungary have grabbed this opportunity and today have a successful franchising sector.

### Impact of the Single Market

The most positive effect of the Single Market Programme is the freedom it brought about concerning the movement of persons, goods and capital, factors which are essential for this industry. A high degree of harmonisation exists regarding the legal aspects governing this sector. This was established before the inception of the Single Market, most notably by the Block Exemption of 1989. The regulatory framework remains very limited, making the Franchise industry an example of self-regulation. Self-regulation is based on and enhanced by a European Code of Ethics.

However, considerable barriers still exist on the product level. Member States impose different rules and requirements on products, making certain products acceptable in some Member States but unacceptable in others. The same is true for environmental measures which may vary considerably from one country to the next. It is clear that these two aspects need further harmonisation.

The need for a single currency and easy access to financing by small- and medium sized enterprises are considered to be the most important current priorities within the Franchising industry.

---

## REGULATIONS

---

While franchising occurs in many forms in the various EU Member States, its regulatory framework is very homogeneous, mainly ruled by two texts: the Block Exemption and the European Code of Ethics.

### The Block Exemption

Before 1986 no specific national laws existed and jurisprudence was poor, with the notable exception of France. In this context, a French company, Pronuptia, provoked the first judgement of the Court of Justice of the European Communities favourable to franchising. Article 85(1) of the Treaty of Rome, establishing the European Economic Community, prohibits cartels between suppliers of commodities. However, the Pronuptia ruling took into account, for the first time, both the interests of the consumer and of a new economic being: the network in which franchisor and franchisee together fight their competitors, and whose identity and image need real protection. It was the first step towards a global exemption for franchising from Article 85(1). This was in recognition of the fact that consumers benefit from the combined purchasing power and higher service level that franchisees are able to offer in comparison with independent, individual entrepreneurs, and that franchising does not in itself harm competition.

After four other individual exemptions, Yves Rocher, Computerlands, Charles Jourdan, and Service Master, the block exemption for franchising was passed in 1989. The EU regulation covers product and service franchising (Art 1) only if the interest of the final consumer is taken into account (Art 4). Franchising was at last recognised as a distinct form of

business, establishing a common legal basis for the development of franchising in EU Member States.

### The European Code of Ethics

Since the beginning of franchising in Europe, there has been a real concern for ethics and self-regulation. The first Code of Ethics created by the French Franchise Federation in 1971, followed by a European Code in 1972 permitted a smooth development of franchising, becoming a reference for all partners of franchising: franchisors, franchisees, lawyers and consultants, administrations, and governments. It is also increasingly used by courts throughout Europe as a benchmark of franchising standards.

Since 1992, a new European Code, drafted in close consultation between the European Franchise Federation and the Directorate-General XXIII of the European Commission (which has responsibility, inter alia, for Trade and Distribution), has been promoted in all countries where the EFF has members. The absence of specific laws in EU Member States is proof, if any is needed, of the power of a self-regulating effort, a code of ethical conduct and fair behaviour in an economical environment.

### The Franchise agreement (extracts of the Code of Ethics)

The Franchise Agreement shall comply with national law, European Community law and the European Code of Ethics and any national extensions thereto. Essential minimum terms of the agreement shall include the following:

- the rights granted to the Franchisor;
- the rights granted to the Individual Franchisee;
- the goods and/or services to be provided to the Individual Franchisee;
- the obligations of the Franchisor;
- the obligations of the Individual Franchisee;
- the terms of payment by the Individual Franchisee;
- the duration of the agreement which should be long enough to allow Individual Franchisees to amortise their initial investments specific to the franchise;
- the basis for any renewal of the agreement;
- the terms upon which the Individual Franchisee may sell or transfer the franchised business and the Franchisor's possible pre-emption rights in this respect;
- provisions relevant to the use by the Individual Franchisee of the Franchisor's distinctive signs, trade name, trade mark, service mark, store sign, logo or other distinguishing identification;
- the Franchisor's right to adapt the franchise system to new or changed methods;
- provisions for termination of the agreement; and
- provisions for surrendering promptly, upon termination of the franchise agreement, any tangible and intangible property belonging to the Franchisor or other owner thereof.

---

## OUTLOOK

---

Franchising has, more than ever, a role to play in the modernisation of commerce, not only because the existence of the network allows a rapid diffusion of technological discoveries (e.g. the computerised cash register that can treat and analyse sales data), but also because franchise is a means of making alliances for the benefit of the franchisor, the franchisee and the consumer.

Franchising is adapting to a new environment and may be showing the way to a new and better model of European

distribution. It should then be a means of standardisation. Franchising is a strategy that makes it possible to keep the advantage of scale economies, while respecting the identity of all the partners. Thanks to its centralised and flexible structure, and to the clear common interest which preserves the network's image, franchising makes it possible to redistribute decisions at the right level.

Now more than ever, franchising has an important role to play in the promotion of trade within the EU. Indeed, it has all the relevant tools for that purpose. It is certainly a way to grab the opportunities of a changing market. The present evolution promises a radiant future.

# Fairs and exhibitions

*Stemming from a long European tradition, Fairs and Exhibitions (F&E) make up one of the most important business service sectors in the EU. At the end of the 1980s, the sector generated around 17 000 million ECU of annual spending, thanks to the work of close to 500 000 employees. Eighties growth petered out more or less at the end of 1991 due to the economic recession, and exhibitions are still suffering to some extent. Despite current uncertainty about future development in the business, signs of recovery do exist, varying across exhibition sectors and countries.*

## INDUSTRY PROFILE

### Description of the sector

Fairs and exhibitions are trade activities linked to specific, extraordinary places and times in which suppliers and buyers gather together in a coordinated, organised fashion, seeking to exchange goods, services and information. Exhibition centres and organisers centralise the activity. They attract exhibitors and visitors interested in enhancing their sales opportunities, image, contacts and market knowledge. Objectives differ depending on the type of event. General fairs and professional exhibitions are the two main types of F&E, although the latter type is the more significant.

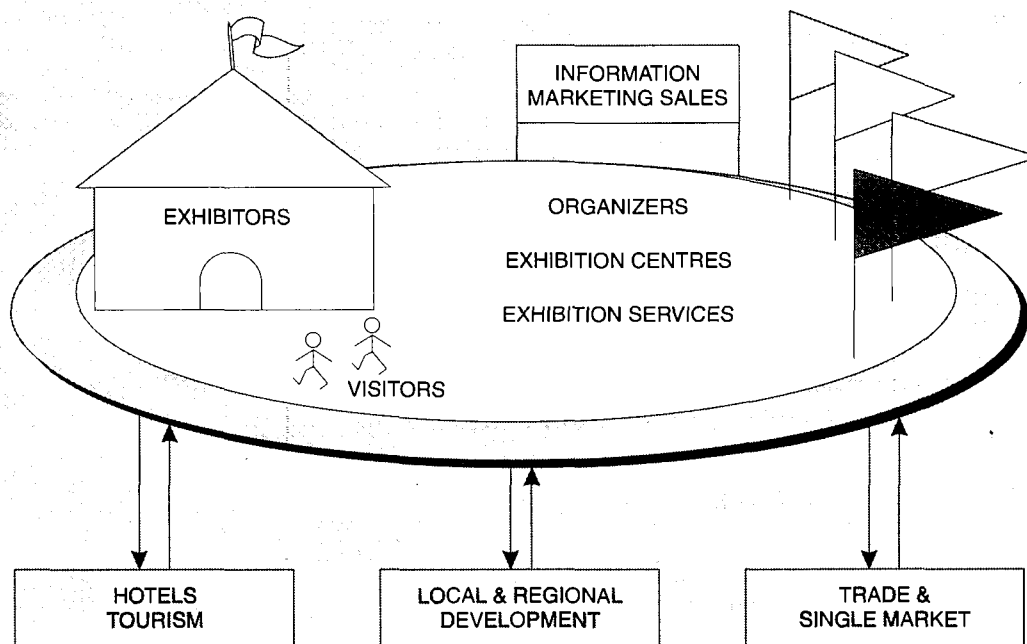

As is shown in Figure 1, supply of F&E is made up of organisers, exhibition centres and exhibition services, while demand is comprised of exhibitors and visitors. The affected local environment includes tourism supply (mainly accommodations, transportation and restaurants), the affected economic sectors (i.e. the local industries that are promoted as

a direct consequence of F&E activity), the public sector (mainly local authorities and governments) and public and private investments (e.g. when improvements are made to exhibition centres and their surroundings).

Since economic statistics are not available, some estimates have been made to measure the sector's overall economic importance. Thus, Table 1 shows available estimates from visitor and exhibitor spending, taking into account the number of major fairs in Europe. The F&E sector covers 3 500 to 4 000 fairs throughout the European Union, not counting local fairs held in small cities and villages. Depending on the criteria used, 100 to 300 exhibitions may be considered as being international in nature. Located in more than 300 cities, F&E generate around 17 000 ECU in direct visitor and exhibitor spending. Exhibition spin-off effects create close to 500 000 full-time equivalent jobs, 70 000 of which are in the exhibition sector itself. Profits from sales, plus contracts, contacts, and other benefits resulting from exhibitions obviously cannot be estimated.

To make a country-by-country comparison of the exhibition industry, Table 2 shows the results of the Feria data base (Eurostat), which gathers data from reports of national professional associations. Although some statistical problems (e.g. coverage and methodological problems) persist, the overall results are significant. Germany is the exhibition industry's leading country, with the highest figures in the number of exhibitors, net rented area and foreign visitors. France could be considered as the second most important exhibition country, as it features the major European exhibition city, Paris. Exhibition activity is also significant in the United Kingdom, Italy, Spain and the Benelux countries. Compared to these, other EU countries have but a minor standing. The relative importance of the major European exhibition countries is shown in Figures 2 and 3. Considering the EU as a whole, each year the sector moves some 450 000 exhibitors all over

**Figure 1: Fairs and exhibitions**

Europe, renting 20 million square metres of net area. Between 1988 and 1991, the number of fair visitors totalled 63 million.

### Recent trends

Since late 1991, the economic recession has affected the exhibition industry. As in other service sectors, the effects of the 1970's petrol industry crisis were negligible for the industry, whereas the effects of the recent crisis are still evident. As enterprises have tightened their marketing budgets, their exhibition budgets have been cut. Therefore, exhibitors scale down the area they rent and try to limit their spending at fairs. Visitors reduce their spending as well, but in some exhibitions the flow of visitors is increasing. In 1993 and 1994, the situation has varied widely by sector, country and individual exhibition. In some exhibitions, enterprises which formerly had decided not to attend now have returned; in others, they remain absent. Some enterprises trust in exhibitions' counter-cyclical effects and consider exhibitions as an important weapon for fighting against the recession. While some

countries still labour under the effects of a tough recession (France, Italy and Spain), the United Kingdom is displaying an impressively rapid recovery.

### International comparison

Although the major world exhibitions usually take place in Europe, the exhibition industry is also very important in the US and Japan. Although they do not share the same historical tradition, their exhibition sector has grown greatly in recent decades. In the US, exhibition activities began in the mid-1980's, creating a strong operation on the US economy. Some estimates given by the IAEM (International Association for Exposition Management) indicate that each year there are approximately 6 000 to 8 000 major exhibitions held, and that 85 million people, including international visitors, attend exhibitions in the US. The forecast for 1995 is that 90 million persons will attend. Lately, investments in the US, Japan and the south-eastern countries have become increasingly important. Atlanta, Los Angeles, Chicago, Las Vegas, Tokyo, Osaka,

Makuhari, Hong Kong and Singapore are some of the cities whose international positions are advancing. As a result, the international differences between Europe and the US and the Asian cities are becoming less significant than they were before.

### Foreign trade

The broad, Europe-wide F&E market involves a hefty volume of intra- and extra-EU trade. Unfortunately, the lack of statistics makes it difficult to find data on foreign trade. However, it is possible to estimate some trade figures by looking at the following variables: direct spending, percentage of foreign exhibitors and visitors and percentages belonging to the EU. Assuming the percentages of foreign exhibitors and visitors to be 20 % and 3 % on the average, and that exhibitor spending is around half of total spending, 12 % of total spending in a single country may be estimated to be made by foreign countries. In overall terms, that is more than 2 000 million ECU. It is mostly intra-EU trade, since more than half of foreign exhibitors and visitors come from EU countries. The rest may be divided into two parts: spending in country of origin (20-25 %) and spending in Europe. Thus, extra-EU exports may be estimated at 500 to 800 million ECU. EU spending in other countries cannot be estimated. The distribution of exports derived from spending can be seen in Figure 4.

## MARKET FORCES

### Demand

Most economic sectors use fairs as a tool for self-development. However, there are three kinds of sectors more liable to generate exhibitions. They are: sectors with vaguely-defined demand, technological changes and incomplete distribution networks; sectors with a high degree of innovation, such as the fashion textile and clothing sector; and sectors with a certain degree of imperfect or asymmetric information due to their scattered supply or demand or to widely differing processes or qualities. On the other hand, strongly concentrated manufacturing industries and some highly non-material service industries are less involved in exhibitions.

The relative importance of specialised exhibition sectors is shown in Table 3. Excluding general fairs because of their poor data coverage and increasingly clear differences with specialised exhibitions, the more important sectors are textiles and clothing, lifestyle, sports and other industries. Characteristics vary according to the indicators. For example, sectors open to the public (e.g. general fairs), make up a large portion of fairs, cities, exhibitions and visitors. However, they are less important in terms of foreign participation. Professional exhibition sectors, however, cover a wide range of fairs and cities, and some of them feature high percentages of foreign participation.

There are several reasons that would motivate a business to participate in exhibitions. The major functions of exhibitions may be summarised as shown in Figure 5. According to the European survey carried out by the Paris-Nord Villepinte exhibition centre, most enterprises decide to participate in order to develop a commercial policy (35.6 %) and to promote their own image (26.3 %). Other incentives are less definitive: to expand internationally (12.3 %); to study the competition (10.6 %); to make direct relations (8.1 %) and to launch new products (7.2 %). However, although some reasons are more important than others, the decision to participate in exhibitions usually involves an evaluation of a set of factors and depends on the company's size. Although a considerable part of the exhibition world is linked to major enterprises, small and medium-sized enterprises are participating more than before, becoming an emerging market.

### Supply and competition

There are three categories of exhibition suppliers: 1) organisers, exhibition centres and professional organisations; 2) exhibition service firms such as stand constructors, consultancies, business services, restaurants, etc.; 3) the city where the exhibition is being held, which itself offers reception services such as hotels, infrastructure, transportation, local government policies, etc. Each category has its distinct problems and outlooks.

The major competition is concentrated around international fairs. Organisers, exhibition centres and local administrations try to attract exhibitions from the most powerful, narrowest segments of the market. In many economic sectors, no more than two to six international fairs can be held successfully during a single year. The leaders in this market are the German cities, with competition between Frankfurt, Köln, Hannover, Munich and Düsseldorf. In France, international exhibitions compete with one another for venues in Paris. In the UK, Birmingham and London compete for the British share of the international market. In Italy, Milan is the major city, though other cities, such as Bologna, host some important fairs. In Spain, Madrid and Barcelona hold the major exhibitions, followed by Valencia and Seville. In the Benelux countries, the main cities are Brussels, Amsterdam, Utrecht and Luxembourg. Other EU cities hosting international fairs are: Copenhagen, Helsingør, Lisbon, Braga, Athens, Thessaloniki and Dublin. Obviously, the more local the exhibitions are, the less competition they face. Scores of cities host hundreds of small and medium-sized exhibitions which play an important role in regional economic development.

Among the factors increasing competition in 1993 and 1994, two are noteworthy: the increasing demand for information, quality and prices, and the growing internationalisation of markets. Other competitive factors, such as the arrival of new mobile organisers or State intervention, hold much less relative importance than these other two, and depend on the country and sector. Prices have not changed significantly, although the situation is heterogeneous. Some countries are cheaper than the rest in terms of the cost of renting space (Germany and the UK, for instance). In other countries, prices can vary fourfold, depending on the individual exhibition. In any case, the real price of participating in exhibitions includes the costs of additional spending, living, transportation and, more im-

portantly, the opportunity costs, i.e. the costs a firm will pay if it does not attend.

### Production process

Due to the vigorous competition and the unique features of F&E, innovative processes are highly important to the sector. New technologies are being used to provide technical facilities for stands and transportation. In addition, new spaces are being used to house complementary activities such as conferences, demonstrations, special meetings, etc. Finally, exhibition services are improving in quality and quantity. The first and last factors took the lead in 1993 and 1994.

A relative rise in staff specialisation through training courses could also be considered. However, training and professionalisation still have a long way to go before they offer real opportunities to industry participants. Organisers, as well as visitors and exhibitors, co-produce exhibitions, regardless of the type of education and specialised skills their deputies have. General and specific skills in the economic sector involved in the exhibition are much more important than specific exhibition skills. A major source of specialisation comes from the out-sourcing and externalisation of some (both routine and advanced) services, allowing for tighter concentration on the more important exhibition functions.

## INDUSTRY STRUCTURE

### Companies

Due to the large number of local exhibitions organised in Europe and the lack of statistics, the number of companies operating in the F&E market is difficult to estimate. At least 1 200 organisers exist in Europe. While most small cities organise only one or two major fairs, major cities can organise between 10 and 150 events. Some estimates put the overall turnover of organisers at some 4 000 million ECU. There are two main types of organisers: those which are exhibition centres as well as organisers, and those which operate independently of exhibition centres. The first type is more prevalent

in Germany, the Netherlands and Denmark. The separation of functions predominates in the UK, France and the United States. When organisation and exhibition centres are one in the same company, they usually are state-run, semi-public, or public institutions. When organisers are independent, they are usually professional associations or private non-state companies.

Some of these private companies are specialists in organising exhibitions only, and of those operating in Europe most are British. Such is the case of Blenheim Group PLC, Reed Exhibition Companies, Andry Montgomery Network, MacBrooks Exhibition Limited and EMAP International Exhibitions Ltd. Three of those producing important percentages of their turnovers in foreign countries are the Blenheim Group (80 % in France, Italy, Spain, Sweden, Denmark, the United States, Japan and Singapore), the Reed group, (65 % in France, Belgium, the Netherlands and Switzerland) and the Montgomery network (85 % in US, Germany, Saudi Arabia, Bangkok, Malaysia, Thailand, Singapore, Hong Kong, Indonesia, Australia, Africa and China).

Most of the rest of the major organisers are also exhibition centres. That is the case for all of the leading German centres, especially Messe Frankfurt, Leipziger Messe, Köln Messe, Messe München International, Düsseldorf Messe; and Messe Basel in Switzerland, the Ente Autonomo Fiera di Milano in Italy, and IFEMA and Fira di Barcelona in Spain. In some cases, the linked-to-exhibition-centre organisers have started to organise exhibitions far from their home city, in foreign countries, becoming a sort of hybrid of linked and unlinked organisers. These are represented by Messe Frankfurt, with exhibitions in the United States, Japan and Hong Kong.

The leaders in the exhibition centre segment are well represented by the European Major Exhibition Centre Association (EMECA). Most of the major European exhibition centres are members: Barcelona, Basel, Birmingham, Brussels, Frankfurt, Leipzig, London, Lyon, Madrid, Milan, Paris-Villepinte, Paris and Utrecht. Altogether, these centres represented 3.6 million square m gross built area, 272 thousand exhibitors

**Table 4: Trade fairs**

 Source: EMECA

and close to 25 million visitors in 1993 (see Table 4), and they held almost 800 exhibitions in all. These data show how concentrated the sector is in the major exhibition divisions. The Major Exhibition Centres, members of EMECA, represent roughly 20 % of the global market in terms of the number of fairs, but considering the number of exhibitors assessed for European countries (for both large public and professional exhibitions, source Eurostat), they should represent up to 50 %. A great number of exhibitions held in EMECA Members' facilities are trade exhibitions and are very internationally-oriented: 66 % of their exhibitors attend international exhibitions while 34 % attend national and regional ones.

### Strategies

During the economic recession, dynamics of the F&E business have remained vigorous. Competition has not stopped. Most international exhibitions operate in narrow markets, where only a few cities can possibly come out on top. The major international exhibitions are held in Germany. In many sectors,

the remaining countries look to secure second- or third-place positions.

Three strategies can be discerned which result from the current dynamics:

- **Investments:** The economic recession might be expected to mean a reduction in investments. However, the dynamic context of the sector has averted reductions, and there has been a surge in investments. Cities and local governments are investing in exhibition centres; organisers and exhibition centres are investing in new services. The case of Frankfurt Messe is illustrative of this, as it has put money into organising exhibitions in the US and Asia.
- **Innovation:** The changing factors are forcing organisers and exhibition centres to outline more careful strategies, with an aim to reducing costs and improving the quality of the exhibition services. Customer service has become

**Figure 3: Fairs and exhibitions**

Source: Paris-Nord Villepinte Tenth Anniversary

a priority, and service professionalisation is therefore on the upswing.

- Specialisation: Organisers look for more professional, better-specialised exhibitions, so, for example, the separation between open public days and professional days remains important. Major cities and exhibition centres, however, look for a diversification of sectors and exhibitions in an attempt to get the most out of the potential exhibition days that an exhibition centre can hold. On the other hand, some medium and small cities are highly specialised in one or two sectors, which are sometimes very international. This is the case of Bordeaux (Vinexpo), Cannes (Midem), and Oslo (Nor'Shipping'), Nürnberg (Toys), among others.

### Impact of the Single Market

All the measures targeted in the Single Market Programme are of importance to this sector. However, the international and mobile character of this sector has in effect had the consequence that measures designed to enhance the freedom within the European Community were taken long in advance of the inception of the Single Market. Examples are the free movement of persons, goods and capital and certain measures concerning direct and indirect taxation.

Any effect that the inception of the Single Market Programme may have had in terms of turnover, number of visitors, etc., was probably offset by the most recent recession, making an exact quantification of the effects nearly impossible.

- The remaining internal barriers are particularly those linked to language differences and differences in culture. In considering external barriers, one has to appreciate that this sector already operated in a global environment. Therefore, the inception of the Single Market has not significantly improved the internal movement of goods and services as compared to business with non-European Union countries.

### REGIONAL DISTRIBUTION

F&E play a key role in regional development. Exhibition activities generate regional spending and business in both the short and long term. In the short run, exhibitions mean spending from visitors and exhibitors. This professional tourism involves accommodation, transport, communications, business services, leisure services, etc. Such spending is always positive for host regions and cities, regardless of the exhibition's success. But the success of an exhibition also involves additional

short-term economic benefits when new contracts, distribution networks and business are achieved.

In the long term, exhibitions can be a key factor in developing some sites, since political support runs parallel to the exhibition centres' growth and infrastructure needs. From the business point of view, exhibition sectors obtain some long-term benefits since a certain rationalisation and reorientation of production and consumption is spurred on by exhibitions.

There is a certain relationship between regional economic welfare and exhibition development. However, factors other than regional economic income explain an exhibition's success. Exhibitions are located in cities that feature one or more of these factors: tradition, population, income, infrastructure, conditions appropriate for tourism, public investment and support policies, international city standing, exhibition centre size and regional industrial composition. The top exhibition cities are led by Paris, followed by the German cities of Frankfurt, Hannover, Cologne, Düsseldorf and Munich, as well as Milan, Birmingham and London. Bologna, Barcelona, Madrid, Amsterdam, Berlin, Valencia, Utrecht and Essen are also important. Ranking and classifications vary widely, according to the criteria on which they are based.

### ENVIRONMENT

F&E can also be used to test and promote environmental policies. New exhibition centres are rather like pilot cities, in which new methods of organisation are tested. These are the main areas in which F&E tend to contribute to a better environment: a) spatial distribution (helping to clear congested areas); b) classification of constructions (low-rise buildings, modern lines, safe structure); c) transport organisation (intensive electric transportation, close to airports); d) waste treatment (new processes for ecological waste treatment); e) green areas and reforestation. Once an exhibition centre organises its own urban development, it begins generating positive external economies. Technological hubs, enterprise investments and infrastructure can arise, improving economic growth rates and local living conditions.

During recent years, agents have focused on waste treatment processes. German cities in particular are studying new possibilities to procure an effective ecological system for recycling and eliminating waste material generated at fairs and exhibitions.

### REGULATIONS

The State has a considerable influence on the sector. Local, regional and national administrations have certain tools for regulating, controlling and promoting F&E activities. The use of these tools varies from country-to-country (e.g. differences between Germany and France) and city-to-city (e.g. differences between Birmingham and London). Some governments are more interventionist than others. In general, there are two levels of possible participation, one legal and the other economic.

- Regulation issues: Regulation of general activity and the granting of rights (specific laws); granting of licenses and permits for developing activities; restrictions on product imports (soon to end, due to the Single Market); criteria of recognition (e.g. nationality).
- Economic issues: Support for exhibition centres (investments in infrastructures, exhibition centre improvements); economic aid for supply (subventions for organisation, subventions for invitations and participation, special fiscal handling); economic aid to demand (export policy instruments, subventions for an enterprise's participation).

Recent trends imply that legal issues and regulations are losing their importance, while the role of economic issues is aug-

## NACE 839.2

The EU software and computing services market reached a market volume of 63 billion ECU in 1994, representing the second largest market in the world. Between 1992 and 1994 the market grew by 4.4 % per year, and an annual growth of 5.6 % is anticipated for 1994 to 1996. The software products segment generally shows higher growth rates than does the services segment. The still very fragmented market structure is going through a globalisation and concentration process. New multimedia applications and the emergence of a pan-European information infrastructure have created a huge growth potential for the market.

### INDUSTRY PROFILE

#### Description of the sector

The software and computing services sector comprises different kinds of software and services activities which usually are split into the following categories:

- systems software and utilities to operate hardware, ensure program integrity, etc.;
- application software, i.e. programs which provide packaged solutions for specific applications;
- professional services, which comprise customised or contractual software development or services;
- processing services, classified as bureau-type services for problem-solving and transaction processing based on the time charged or transactions processed;
- network services, that is, chargeable services for management, processing and messaging; and

Many of these activities are interrelated with the IT hardware sector. Strong relations also exist between the telecommunications hardware and services sector and the electronic information services sector.

With 63 billion ECU in 1994 the software and computing services market represents 56 % of the total IT and 26 % if telecoms hardware and services are included. Outside the sector, one sees that the EU software and computing services market is three times the size of the market for electrical household equipment.

#### Recent trends

Whereas the software and computing services market in the 1980s showed double-digit growth rates, the market in the 1990s is following a more moderate growth pattern. In 1994, the market grew by 5.3 % to 63 billion ECU and is expected to show growth rates of above 5 % in 1995 and 1996. Thus, software and computing services will remain one of the major forces driving the whole IT market (see Table 1 and Figure 1). The software products market, with 22.5 billion ECU in 1994, represented 36 % of the total market volume and realised a growth of 6.4 %. In 1995 and 1996 a growth of 7.5 % and 8.0 % is anticipated for this segment. This above-average growth of software products is mainly due to the ongoing shift from large range hardware systems to smaller computer systems.

Within the software products market, system software reached a market volume of 10.5 billion ECU in 1994 and realised a growth of 5.0 % against the previous year. With growth

**Figure 1: Software and computing services EU market for software and services**

(1) Expressed in constant exchange rates of 1993.  
Source: EITO

rates of 5.8 % in 1995 and 6.3 % in 1996 predicted, growth will remain stable.

The application software market is further profiting from the ongoing hardware downsizing and standardisation of solutions on the one side, and the spread of PCs with packaged software solutions into the small office / home office (SOHO) and private consumer markets on the other. Between 1992 and 1994 the application software market grew yearly by 6.9 %, reaching a market volume of 12 billion ECU. For 1995 and 1996 growth rates of 8.9 % and 9.4 % are envisaged. Due to an ongoing price decline in this market segment, these growth rates do not take into account the increasing penetration of application solutions in the market.

With 40.9 billion ECU, computing services represent 64 % of the software and services market. And, with an average growth rate of 3.6 % between 1992 and 1994, the development is far more moderate than in the software products domain. This will continue into 1995 and 1996, when growth rates of 4.2 % and 4.7 % are anticipated (see Figure 2).

Market share and growth differ significantly within the service segments. Professional services, with 20.1 billion ECU or 49 %, represented the largest services segment in 1994. Between 1992 and 1994 this segment grew by 6.0 % per year and growth should remain at this level in 1995 and 1996. The driving forces of this segment are IT consulting and outsourcing, whereas individual software processing is affected by the transition to standardised application solutions.

Due to the ever-increasing trend towards client-server applications, distributed computing network services realise the highest growth rates in the services sector. Network services grew yearly by 11.7 % between 1992 and 1994, and growth rates of 14.0 % and 15.5 % for 1995 and 1996 respectively will keep software and services the fastest growing segment.

#### International comparison

Western Europe represents the second largest world market for software and services (see Table 2). Of the world market volume of 223 billion ECU in 1994, the US held 44 %, western

(1) Expressed in constant exchange rates of 1993.  
Source: EITO

Europe 33 % and Japan 15 %. With 119 billion ECU projected for 1996, the US will reach a world market share of 45 %, whereas western Europe - with 82 billion ECU or 31 % - will lose some of its share (see Figure 3). Japan's share is expected to stabilise at 14 %.

This shift in market share is due to the fact that between 1994 and 1996 the US market (22 %) will grow twice as fast as the West European market (12 %) and the Japanese market (9 %). The world market in total will grow by 18 % during this period. As an emerging market, Eastern Europe will realise a market growth of 27 % between 1994 and 1996, though the market volume will stay very low, with only 1.8 billion ECU.

Structural differences also exist between the major world market regions. While in western Europe software products made up 35 % of the total software and computing services market, this share was 31 % in the US and only 19 % in Japan in 1994. The share of software products will increase in all three regions through 1996. The highest increase in software products will be gained by Japan with a share of 24 % in 1996. This can be explained by Japan's later shift from proprietary to open solutions.

## MARKET FORCES

### Demand

As the data processing budgets of European users are currently stabilising, they tend to choose the most cost-effective solutions regarding their software supply. Together with the shift from mainframe-based to client-server and open solutions, packaged software solutions clearly benefit from this development. Additionally, due to the ongoing price decline in the software products market, more and more users benchmark their internal software and service departments against independent providers. In a 1993 users' survey taken in the four major European countries (F, UK, D and I) for example, 44 % of users expected an increase in their packaged software investment, whereas only 9 % expected a decrease. Keeping in mind the price decline of packaged software, this implies a substantial shift away from individual software and towards software products.

Furthermore, professional users are undergoing a substantial business re-engineering process in the direction of inter-operability and communication of different business functions and are even linking suppliers with customers. This has implications on the need for software solutions as regards portability. This trend on the user side also favours standardised, packaged software product solutions. Another fast growing

user segment is private households which, due to their special needs and price-sensitivity, push the development of the software products market even further.

Regarding user attitudes on services, no distinct picture of the future development can be drawn. On the one hand, a relative decline of user demand in traditional hardware support services is brought about by the shift from mainframe-based to computer-based solutions. On the other hand, the increasing complexity of the IT systems (distributed computing, local and wide-area networks) generates an important demand in the IT management support and training on the user side. As a result, outsourcing of the whole or partial management of the information system has become a specific issue for IT users, though in Europe it is still very limited as regards market value. The above-mentioned 1993 survey on IT user trends also showed that 75 % of the users interviewed did not anticipate any need for data centre outsourcing services.

Demand by end market shows a different pattern. Table 3 shows that European IT expenditures in 1993, not including the branch for packaged software, generally grew on a two-digit level and with an average rate of 12 %. For the different vertical markets, the increase was at least twice as high as for the expenditures in outside services, which showed an average increase of 6 %.

The private home use of IT is a new potential area of strong demand. Compared to the traditional professional industrial and services market, it is likely to outrun the traditional customer base for software and computing services. Already, nearly 50 % of the PCs sold are purchased by private cus-

tomers, so the packaged software products which are easy to use in the home will be the first to tap into this market.

Additionally, new applications for home use (e.g. home banking and shopping, interactive television, etc.) are just starting to penetrate the market. Thus, new demand is emerging for the computing services as facilitators and providers of the necessary tools for these applications. However, this new demand will not arise directly from the homes but rather from the professional vendors of these new applications and services.

### Supply and competition

Within the software and computing services market there exist different types of vendors, each with a specialised product focus. The market is shared by hardware vendors, independent software vendors and independent services vendors. The latter focuses largely on special services like facilities management, processing services, IT consulting and training.

Within the software products segment, hardware vendors accounted for 41 % and independent software vendors for 59 % of the 1994 market (see Table 4). In addition to their traditionally strong position in the systems software market, hardware vendors - due to the trend of bundling hard- and software to a complete IT solution - play a key role in packaged software as well. As PC solutions have an increasing share of the hardware market and, as independent software vendors have a dominant position in this market segment, the market share of hardware vendors in the software products market will decline from 43 % in 1992 to 40 % in 1995.

**Table 3: Software and computing services**  
**European information technology expenditure growth by end market, 1992/1993**

(%)	Total expenditure	Outside services	Packaged software
Banking	3.8	4.5	10.0

Source: EITO

Key players in the software products market are US-based vendors, especially for systems and horizontal software. The major focus of European-based software product vendors is on vertical software solutions. In the global software market environment, Japanese vendors have not been (and are not expected to be) active. Due to the relatively high labour costs of software development, several European and US-based software product vendors have started to have their software products developed by companies in Eastern Europe and India, where cheaper labour is available.

Computing services is the domain of independent software and services vendors (see Table 5). In the professional services market in 1993, independent software vendors had a market share of 78 % against 22 % for systems vendors. This is due to the fact that in the services sector it is essential to be close to the customer; and social, cultural, administrative and regulatory issues have to be taken into account. Therefore, the majority of services vendors focus on regional and country markets. In the professional services segment in 1993, independent European software vendors held a market share of 63 % compared to 15 % for US-based independent software vendors.

Nonetheless, the competition on the traditional market for independent computing services vendors is increasing. Hardware vendors are improving their services on the facilities management and systems integration side and are able to provide services not only all over Europe, but, in fact, to customers worldwide. In addition, due to new applications and services in the realm of multimedia and information superhighways, new competitors (like telecoms carriers and media vendors) have arisen in the services environment. This development also favours globally-oriented vendors, which profit from their critical size. As a consequence, the smaller, local software and services vendors increasingly will lose market shares.

### Production process

Software technologies and product features play a key role in the user acceptance of IT solutions, as well as in the competitiveness and effectiveness of software vendors. Two recent trends are described below.

- Systems software: the increased use of open standards like X/OPEN and UNIX and the enduring lead of PC operating systems in connection with graphical user interfaces. The market tends to promote object-oriented solutions and a move towards relational and distributed database management systems.
- Applications software: As IT has become a nearly universal tool within the professional environment and is just penetrating private households, the requirements have changed substantially in this segment as well. Applications software now has to provide tools and serve the professional users' needs for interactive communication, information, coordination and cooperation via local or wide-area networks, so that groupware concepts and management information systems and work flow automation become more common.

**Table 5: Software and computing services  
Professional services - Market share by vendor type**

(%)	1993	1996
Systems vendors	22	25
US-based independent software vendors	15	17
European-based independent software vendors	63	58

Source: EITO

For all these new solutions, it is essential that the user has the same object-orientated command structure so that s/he can easily change between different applications. Due to these developments, application software vendors are directed to provide cross-platform applications. Furthermore, by emerging object-oriented programming, vendors expect encapsulation and reuse of software in order to shorten development time and to increase their ability to respond more quickly and flexibly to market needs.

## INDUSTRY STRUCTURE

### Companies

It is estimated that more than 16 000 software and services companies with over 300 000 employees exist in western Europe. The vast majority of these companies have less than 20 employees, and several of those are companies with no more than five employees. Only a few large software and services vendors are in the market. Most of these larger companies are located in the UK, France and, to a lesser extent, in Germany. This group of vendors mainly has pan-European activities, whereas most of the smaller and medium-sized vendors are often regionally focused.

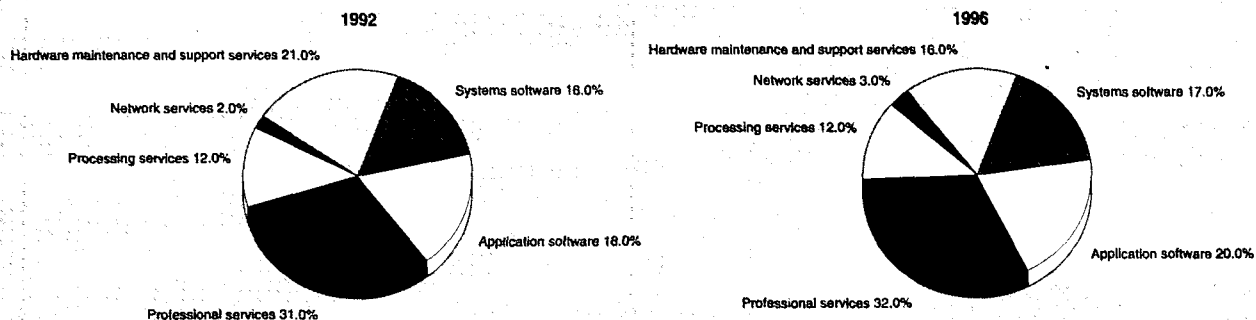

The software and services market is experiencing an increased concentration of market share though. The top seventy vendors in western Europe represented 63 % of the packaged software market and over 70 % of the professional services market in 1993. Table 6 shows the development of market shares of the top ten vendors in the larger EU country markets between 1991 and 1993. Whereas concentration in the software market for France, Germany and the UK has reached about 20 % market share of the top ten vendors, in Italy the market is still more fragmented with 14 %. In the services market of Italy and the UK, the top ten vendors hold a market share of more than 30 %. At the same time, the top ten vendors in France and Germany obtained a market share of only about 20 %.

### Strategies

As customer requirements have changed substantially recently, the future success and market position of software and service

**Figure 2: Software and computing services  
EU software and services market by segment**

Source: ETO

vendors will depend on which strategy is followed to fulfil these new requirements. For systems manufacturers, the key issues are technology ownership, international infrastructure and the ability to provide global integrated solutions.

The success of independent software vendors will depend on competitive prerequisites like having a global market and strategic scope, as well as a global infrastructure and international presence to service customers while covering a large number of vertical markets. In addition, it is decisive for services vendors to have the capacity and ability to address business process re-engineering needs and to leverage on the experience and scale economies from larger contracts. These new customer requirements lead to the need for large-sized vendor structures.

Whereas this trend favours systems manufacturers and US-based independent software and services vendors which already operate on a global infrastructure, European vendors have just begun to adjust their portfolio according to these requirements. Consequently, several major mergers and acquisitions, joint ventures and alliances have taken place in the last few years. The main strategies behind this concentration trend are: synergies, scale-economies and cost-cuts in R&D; completion of the product portfolio; and broadening of the customer and country base.

For systems vendors and suppliers of software and services alike, the major focus in regard to M&A is the completion of their product portfolio to strengthen their position in the field of systems integration. Independent services vendors primarily try to strengthen their pan-European presence. For independent European software vendors, all three major strategies lead to a variety of mergers, acquisitions and joint ventures.

A new form of acquisitions and alliances has emerged. It is the strategic repositioning against the background of multimedia applications and the building up of the information superhighways. In this context, traditional software and services vendors are joining forces with telecoms, media and consumer electronics vendors.

#### Impact of the Single Market

The software and computing services industry is largely composed of SME's operating at a local level. Even multinational groups are composed of independently operating national subsidiaries. The major exception is the packaged software sector which is dominated by US producers. The industry has therefore been relatively little affected at least directly by Single Market measures on the free movement of goods and people and the provision of services. Nevertheless, the Single Market has encouraged companies to expand internationally in order

**Table 6: Software and computing services

to take advantage of public procurement or to follow clients who themselves have been encouraged to expand internationally. In this way big companies are becoming bigger and competition is becoming stronger, especially for small companies.

#### REGIONAL DISTRIBUTION

Table 7 shows that the EU software and services market follows the general economic weight of the individual EU countries. France, Germany, Italy and the UK alone represented 84 % of the total market in 1994 (see Figure 4). These are also the countries where the majority of software and services vendors are located and the larger vendors are based. With no more than 0.5 % each, Greece, Ireland and Portugal have the lowest share on the EU software and services market.

Counter to 1992 and 1994, no shift in the country share will occur until 1996. The smaller country markets could realise the highest growth rates between 1994 and 1996. For instance, while France and Germany will grow by 5.7 % and 6.2 % annually in this period, Greece and Ireland can achieve an annual growth of 21.1 % and 9.4 %, respectively.

Within the EFTA countries, Sweden and Switzerland have the largest markets for software and services, comprising 60 % of the total 1994 EFTA market. Between 1994 and 1996 EFTA countries will realise an average annual growth of 6 %, which is similar to the EU growth. The EFTA countries together represent 13 % of the combined EU and EFTA software and services market in 1994.

## REGULATIONS

---

In order to promote the competitiveness of European industry and the efficiency of public services, the European Commission launched a new Telematics Applications Programme for the period of 1994 to 1998 which is based on several of the EU initiatives from the last five years. The program's emphasis is on new multimedia telematics, the importance of user requirements and finding affordable solutions. The program foresees the following sectors:

- telematics for administrations: tools and support services for trans-European applications;
- telematics for transport: network management, operation, control and services for travelling, freight and fleet operations;
- telematics for research: remote collaboration, teleworking and information services;
- telematics for education and training: innovative tools and applications;
- telematics for libraries: applications and services for interconnected services and access to networked information resources;
- telematics for urban and rural areas: teleworking and tele-services;
- telematics for health care: telemedicine and new services;
- telematics for the disabled and elderly: information and communication systems;
- exploratory actions;
- telematics engineering: process re-engineering and application engineering;
- language engineering; and
- information engineering: electronic publishing, information dissemination and retrieval.

---

## OUTLOOK

---

Regarding the future development of the European software and services market, three major trends can be observed. They are: the globalisation and concentration on the supply side, the penetration of new markets and, finally, growing inter-connectivity.

Local European country markets increasingly will open up to outside competition, thus enforcing local software and services vendors to globalise in the same way. In order to stay competitive, they will need to build up scale economies and a trans-European infrastructure. This development will lead to an increasing concentration within the European market as the globalisation process encourages mergers, joint ventures and alliances between the small and medium-sized independent software and services vendors.

As the traditional professional market segments mature, IT vendors are focusing their activities on the small and home office market, as well as on the private home market, where a huge potential for growth exists. Packaged software vendors will be the main beneficiaries of this development and, as far as horizontal solutions are concerned, the large international software vendors will maintain their dominant position. In the vertical solutions environment, independent European vendors will have a potentially stronger position, as they are nearer to the customer and can benefit from their better knowledge of the specific requirements of SMEs.

The globalisation process on the customers side and the spread of distributed computing and client-server-architectures against the background of business process re-engineering will further increase the market for software and services solutions, which serve the need for a free flow of information and interactive communication of data, voice and video via local and wide-area networks. The emerging private home market and the building up of a pan-European information infrastructure represents a huge potential for new applications and services addressed to new groups of customers.

Written by: Eurobit

The industry is represented at the EU level by: European Computing Services Association (ECSA). Address: Avenue de Cortenbergh 79-81, B-1040 Brussels; tel: (32 2) 736 6003; fax (32 2) 736 6004.

# Electronic information services

## NACE 839.2

Total revenues of professional electronic information services and products are rapidly increasing: they reached 4 212 million ECU in 1992, that is 21.4 % more than the previous year. More than 86 % of the revenues came from on-line services, while just 2.3 % came from professional audiotex services and 11.2 % from off-line information products.

The most consulted on-line information services are, by far, financial and business data bases: altogether they account for 87 % of the total turnover of the on-line information market, while scientific and technological databases, government, news and other databases account for 13 % of the EU market. Most of the segments operate internationally, like the financial and scientific information services. In these markets global suppliers are the most important players. In spite of the increasing dominance of the USA competitors, Europe has several world ranking information and publishing corporations that can compete globally. In some other important segments of the market, like in the company profiles one, national suppliers are the most important players because they have a deep knowledge of their domestic market.

Banking, financial and other services companies are the most important users of professional services. However, thanks to the development of audiotex and CD-ROM, the mass market is also growing in importance. Audiotex proves to be a very fast growing medium. The diffusion of videotex services, on the contrary, is very slow, with the notable exception of Teletel services in France. The substantial growth of optical media such as CD-ROM is particularly noteworthy and announces the birth of the new consumer information market in the EU.

### INDUSTRY PROFILE

#### Description of the sector

The sector includes on-line and off-line electronic information services, such as on-line databases, real time or not real time electronic information and CD-ROM databases. The major companies in the sector come from different categories of business: they can be publishers, information brokers, computer vendors or software producers.

Professional electronic information is related to various fields, like financial data, market research, business information, international and national laws and regulations, news, science and technology, or patents. In fact, the field of information that can be provided electronically is unlimited and growing continuously.

In the 1970s, when on-line services started developing in Europe, they were highly linked to the science and technology field and the majority of databases were on scientific subjects and came from public organisations. Afterwards, electronic information services increasingly became a specific business area through the growth in popularity of the financial and economic databases.

Videotex technology was introduced in the early 1980s by telecom carriers that wanted to offer easy access to information (data, text, graphics) via telephone lines. Videotex is billed to customers through a central billing system (or kiosk). Audiotex services (information and entertainment services offered via telephone by private and public companies and also billed through a kiosk system) were launched by EU telephone carriers in the late 1980s and early 1990s.

Figure 1: Electronic information services  
Worldwide online service sales forecast

Source: Simba/Communications Trends

Internet, the computer "network of networks" that supplies on-line services to over 30 million users worldwide and 7 million users in Europe in 1994, offers growing opportunities for the electronic information services industry. This network, in effect, gives access to a huge community of users, and offers possibilities to target specific user groups. The number of Internet users increases by one million each month. Recently initiatives have been announced in order to create commercial "areas" on the Internet network, like CommerceNet. In the EU the Internet commercial services are offered by EUNet, which announced to have 10 000 customer organisations in Europe in 1993; additionally, there are many Point of Presence suppliers (e.g. Demon, Inet, PTT Nederland, etc.) who may use EUNet facilities but who market their services separately.

CD-ROM and other off-line optical media were introduced into the professional market in the 1980s, but made large inroads in the consumers market in the 1990s. The CD-ROM information industry is composed of publishers and computer companies. CD-ROM titles comprise subjects like: general interest and leisure, arts, humanities, education and training, computers and computer programmes, advertising, design, marketing, business, languages, law and science.

The Information Market Observatory (IMO), being part of the European Commission DGXIII, strives to improve the knowledge and understanding of the European electronic information services markets. It has co-financed a joint undertaking of associations and research institutions in the EU Member States to analyse the European supply of electronic information services. This survey was coordinated by EIIA (European Information Industry Association) and the results have been published in an EIIA report in 1993.

#### Recent trends

The electronic information services sector is very dynamic and has posted continuous growth over the recent past: from 1989 to 1992 turnover in current prices increased by 19.2 % annually, faster than the economy as a whole and also faster than other dynamic markets of the information technology sector. In spite of this, electronic publishing still represents a small percentage of the total turnover of traditional publishers.

EIIA survey figures show that the EU-based electronic information supply industry as a whole has not been seriously affected by the recession of 1991 and 1992, with the exception

**Table 1: Electronic information services  
Main indicators for the EU (1)**

	1989	1990	1991	1992

**Table 2: Electronic information services  
Online and offline service revenues in EU, USA and Japan**

(billion ECU)	1989	1989	1990	1991	1992
EU	2.5	2.8	3.1	3.3	3.6
USA	5.0	6.0	6.9	8.2	9.3
Japan	0.7	1.0	1.2	1.3	1.3

Source: Information Market Observatory

of the information services linked to the financial sector (especially real time services which are the most mature sector of the industry). Optical media continue to post strong growth, but still generate low revenues compared to on-line services.

According to the EIIA survey, in 1992 total revenues of professional electronic information averaged 4 212 million ECU, up 21.4 % from 1991. 86.5 % of these revenues (3.6 billion ECU) came from on-line information, while 11.2 % (471 million ECU) came from off-line information (such as magnetic and optical media, document delivery, consultancy) and 2.3 % (97 million ECU) from audiotex professional services.

On-line services turnover increased by 16.7 %, from 3 121 million ECU in 1991 to 3 643 million ECU in 1992. In 1992, 53.6 % of the revenues originated from real-time services (mostly financial services), the remaining coming from non real-time services. By far the most consulted services are financial and business data bases: altogether they accounted for 87 % of the total turnover of the on-line information market in 1992. From 1991 to 1992 financial data bases turnover fell by about 12 % while business data bases turnover was flat. Other kinds of electronic information, like scientific, technological and governmental, play a minor, but increasing, role: the latter has in fact the highest growth rate.

Off-line information services grew more quickly than on-line services: from 1991 to 1992 with a growth rate of 55.3 %. CD-ROM revenues generated by EU-based publishers amounted to 153 million ECU, almost twice the value reported

the previous year. A remarkable leap in the CD-ROM market is expected in the next few years because of the planned introduction of many new multimedia titles by the major publishing and computer companies, and because of the rapid penetration of CD-ROM drives both in the professional and in the consumer market. Out of the overall EU production of commercial CD-ROM titles, 39 % came from the United

Kingdom, 16 % from Germany, 12 % each from Italy, France and the Netherlands.

Employment is increasing as well. In 1992, the EU total number of employees in the electronic information services sector was close to 37 000 (10.7 % more than in 1991). The workforce employed in off-line services, accounting for 17 % of the total, posted strong growth in 1992 (+68 % to 6 300), while the number of workers employed in on-line services slightly dropped to 23 000 (down 3 % from 1991).

#### International comparison

According to IMO, in 1992 the EU market of on-line and off-line information services was less than half the USA market (9.3 billion ECU), but was also almost three times the size of the Japanese market (1.3 billion ECU). Moreover, the electronic information market showed stronger growth in the USA than in the EU (while, hit by the economic downturn, the Japanese market was flat in 1991-1992), thus increasing the gap between the EU and the USA.

North America is the greatest worldwide producer of on-line ASCII databases. In 1992 there were 1 269 database producers in the USA, 792 in the EU and 182 in the rest of the world. In both the EU and Japan, USA suppliers account for about one-third of the market.

In 1992 Japan was the world's largest single audiotex market, followed by the EU, then the USA, while the EU videotex market is by far the largest single market in the world.

In 1992 there were 4 millions of CD-ROM drives installed worldwide (nearly twice the number reported the previous year). The USA had the highest installed base of players (67 %

of the total, or 2.7 million). In the same year, there were 400 000 CD-ROM players installed in Europe (almost 10 % of the total number), and 1 million units in Asia (because of the large Japanese market).

According to the UK-based publisher TFPL, in 1994 there is a total of 1 781 CD-ROM publishers and multimedia enterprises in Europe (compared with 640 at the end of 1992). At the same time, the number of CD-ROM titles produced by EU publishers only reaches a total of 1 583, giving an average of less than one title per publisher. This compares with 1 508 multimedia CD-ROM enterprises in the USA, with an output of 3 299 titles.

The USA electronic information suppliers have some very significant points of strength: economies of scale in large English-speaking domestic and international markets, economies of scope through major supermarket host services. Moreover they enjoy a big producer and user experience and, in general, a strong information technology industry and a very high level of public and private investments on R&D.

#### Foreign trade

Most of the on-line revenues of EU suppliers came from Member States' consumption, this was 70.9 % of total revenues in 1992. 39.5 % of suppliers' revenues came from national markets and 31.4 % from intra-EU trade. Videotex and audiotex services are almost exclusively consumed in the country of origin. Exports outside of the EU account for 29.1 % of total revenue. Figures about imports are not available, though a trade deficit with USA seems very likely.

Over 90 % of CD-ROM revenues of EU suppliers originate in the EU, with titles suppliers mostly addressing their national market. On the other hand, although precise figures are not available, the volume of CD-ROM titles imported into the EU (especially from the USA) is undoubtedly high.

### MARKET FORCES

#### Demand

End users of information services are a very broad category which can be divided into business and residential customers. So far the business users have been the most important customer segment due to their bargaining power and their use of the most sophisticated data bases. The business end users of on-line electronic services can be identified mainly among the following categories: banks and finance, services and research companies, media, manufacturing and commercial companies, institutions, universities, unions and other associations.

The most requested subjects are related to financial and business information. Banks, financial and insurance companies

are the most important users of on-line financial and business data bases, together with the main industrial and commercial companies. Information services are used by industrial and commercial companies to assist them to verify clients' and suppliers' reliability (consulting business data bases), while the enquiry of scientific, technological and patents databases supports R&D activities.

According to EIIA, there are approximately 1.25 million business users of on-line professional services in the EU (600 000 professional users of non-videotex services, and 800 000 of videotex services, with a possible overlap between the two categories of users).

The residential customers mainly utilise cheap and user-friendly technologies, like audiotex and videotex. CD-ROM are used by both segments of users, but most of the demand still comes from the professional users (lawyers, accountants, tax advisors, etc.) who need timely and extensive information

to assist them in their planning, marketing and production functions. According to EIIA, in 1992 EU CD-ROM publishers sold close to 78 000 subscriptions to professional users and over 250 000 discs of non-subscription products. However, the mass market is developing more quickly than the professional one, thanks to the marketing push of personal computer suppliers that seek to diversify into new markets to reduce dependence on the saturated business segment. The computer industry targets the residential customers for multimedia systems (personal computers with integrated CD-ROM drives). Publishers also try to penetrate this new market, as evidenced by optical media which - if they are not likely to substitute the traditional paper-based publishing products - already post significant penetration in the mass markets of the United Kingdom, Germany and France.

Audiotex is a fast growing medium, as it is easily accessible (only a telephone is needed to access this service). In 1993, audiotex services were already available in almost all of the EU countries thanks to the deregulation process which is currently underway. The growth of this service is favoured by the diffusion of dial tone multifrequency telephone sets. In 1992 the total revenue generated by the EU audiotex market reached 836 million ECU, with a potential growth of 150 % to 2 billion ECU by 1995. Revenue is generated exclusively on a national basis and mainly originates from consumer-oriented services. 87 % of the EU revenue is concentrated in three Member States: the United Kingdom, France and the Netherlands.

By contrast, the diffusion in the EU of videotex services is very slow. Videotex technology was mainly developed in France by France Telecom. In the 1980s, France Telecom supplied free terminals to a large number of users, creating demand for information services supplied by private providers. Currently, there are about 7 million Minitel service users and more than 10 000 information providers. In 1993 the Minitel market accounted for more than 80 % of the European market for videotex services. The most popular Minitel services are telephone directories, tourism and transport information and reservation services, home banking, home shopping, weather news and other information and entertainment services. Videotex is also developing in Germany (where almost 500 000 terminals were installed at the end of 1993) and Spain (over 400 000 terminals), while its diffusion is still limited in the United Kingdom and Italy. In Germany and Spain professional information services are the most popular ones. Because of

the different technical standards of the videotex systems, there is not an EU integrated market in this area.

### Supply and competition

The business data bases market is divided into many segments according to the content of the data bases. Generally, a few operators control the market in each segment. For instance Reuters (UK), Telerate (USA), Telekurs (CH) and a few other companies control the market for real time financial information services, while operators like Dun & Bradstreet (USA) and the Japanese Teikoku Databank are among the main firms in the company profile area of data bases. Esa-Irs, Questel (F), Dialog (USA) are the main competitors in the scientific and technological services markets.

Scientific and financial information services are typically an international market where global suppliers are the most important players. Global competitors are generally USA and EU companies. In some other important market segments (such as laws and company profiles) national suppliers are the most important because of the deep knowledge of their domestic market, with the exception of Dun & Bradstreet (USA) in the company profiles segment.

While the on-line information market is rather concentrated and international, barriers to entry are low for the potential suppliers of content for the consumer CD-ROM market. As a result, together with the EU biggest publishers, there are hundreds of CD-ROM titles producers. United Kingdom database publishers are the most important producers of commercial CD-ROM titles in Europe, followed by suppliers from Germany, Italy and the Netherlands.

Most of the companies that provide audiotex and videotex entertainment and information services are domestic-based. In each country there are hundreds of companies supplying these kinds of services. For instance, in the videotex business there are more than 18 000 service codes in France and more than 3 000 information providers in Germany. Cultural, linguistic and, to a certain extent, technical differences, prevent services from going international.

## INDUSTRY STRUCTURE

### Companies

Although the USA competitors dominate the information services industry, many EU information and media corporations can compete worldwide, like Reuters, Reed International (UK) and Elsevier (NL) which merged in 1993, Pearson-Financial Times (UK), Bertelsmann (D) and Hachette (F). EU publishers have a number of points of strength, like the ownership of a rich and diverse information content base, large and established markets for professional electronic information in key industrial sectors, the growing availability of high speed digital networks like ISDN (Integrated Services Digital Network) resulting from the liberalisation of the telecom sector, and the language diversity. But they also suffer from market fragmentation, oversupply of national host services, perceived overpricing of services, cross border transaction costs, and technical barriers due to the incompatibility of the different national standards. EU information providers are strong in such sectors as chemical, pharmaceutical and financial services.

Most of the companies in the CD-ROM market are small; the entry fee in this area is low, so there is a constant renewal of operators. In spite of the fragmentation of the supply side in this phase of rapid development, it's very likely that the concentration process will be rapid. In fact the market, still domestically-oriented, will become global very fast (as happened in the movie and software industries). Some global companies, like Microsoft (USA), are already emerging in the new content industry.

### Strategies

The EU electronic information service sector is characterised by a small number of large firms and a large amount of small firms. In general, European companies are smaller, less vertically integrated and more nationally oriented than their USA counterparts. The process towards concentration is very strong: databases and information services attract conglomerates in a way that telecoms, television, computer hardware and software do not. Much of the large volume (though relatively of small value) of merger and acquisition concerns the conglomerates buying market share in order either to absorb or eliminate competition (as in the case of the acquisition of Data-Star (CH) by Knight-Ridder (USA), buying entry into new segments of the markets or market expertise. Reuters, for instance, absorbed Vamp Health (UK) in 1993 to penetrate the healthcare market. According to Broadview Associates, in 1993 there were 895 M&A deals in Europe in the information technology area (which includes telecommunications, computer and software services), half of which being accounted for by the information services sector. However, the average size of the transactions related to information services (14.3 million ECU) was below that of hardware and telecom services. The largest single identified transaction was the 541 million ECU that Reed-Elsevier paid to Macmillan in 1993 for the Official Airline Guide.

The formation of Europe Online in mid 1994 is significant not only because of the importance of its founders (Hachette, Burda, Pearson, etc.), but also because it replicates almost exactly the financially successful Astra project (financed by the Luxembourg government) and because it provides a European-owned transmission medium for direct broadcast TV. Europe Online intends to perform the same function for information services of the CompuServe, America Online type.

### Impact of the Single Market

Although the EU is the second largest market for electronic information services in the world after the United States and the market is growing rapidly, its growth is restricted by the fact that the market is not truly integrated. A high proportion of turnover (+/- 70 per cent) is on line across national frontiers.

There are two main problems: the high cost of international communications compared with equivalent distance national calls (and with the cost within the US), and the high cost of making, often small, international payments which discourages particularly small users. The cost of international telephone calls is falling thanks to technological developments and liberalization, but the high cost of making small payments in foreign currencies seems rather intractable. A third problem, which inhibits suppliers of information from putting their data into circulation especially on line, is the lack of a common EU legal framework. In addition to copyright, issues of concern are privacy of data, integrity of information, responsibility for false or misleading information, and how to deal with "compilation" works. A directive which attempts to tackle these problems is being discussed at present.

## REGULATIONS

**Table 10: Electronic information services  
Annual change of value added and employment**

(%)	1994	1994-1997
Employment	9.7	8.0
Value added	14.7	12.8

Source: Databank

The disquiet concerning content piracy is severely affecting the development of the electronic information market. In 1992 the European Commission published a draft directive aimed at avoiding database piracy and at protecting electronic media copyright. By the end of 1994, however, there was no agreement on the draft text at Council level.

Another major concern for electronic information companies and for users is the protection of privacy, especially in the case of trans-border data flows. These problems call for a harmonised solution at EU (and possibly at world) level. A number of EU-supported projects, such as CITED (Copyright in Transmitted Electronic Documents), are already under way for the development of copyright and security mechanisms for network publishing.

Also audiotex and videotex services need an appropriate legal framework in order to avoid abuses such as false or no price indications, or "empty" services, and unwanted cultural and social consequences, especially with regard to adult services. To reach this objective, a number of regulatory models have already been implemented in the EU: the regulating political authorities like in France; the independent (self-regulating) commission, like in the United Kingdom; the contracts for service providers containing restriction, like in Italy and Germany; no restriction at all, like in the Netherlands and Belgium.

## OUTLOOK

The spread of the services will be helped by the liberalisation and the opening to competition of the telecom market and by the expansion of new high performance networks, like EURO-ISDN.

The growth in the CD-ROM and audiotex market will also be very significant. Perspectives of the industry are very good: in 1997 there will be over 78 million of CD-ROM drive installed worldwide. The on-line information will also enjoy a very good rate of growth: between 1993 and 1997 this market will grow annually more than 8 % on average worldwide.

Demand for information services will continue to benefit from the stimulus created by the Single European Market. The EU

electronic information market will potentially rank as the biggest in the world. Internet will represent a big opportunity for the EU information providers. But EU producers are facing the challenge of the USA competition (especially in the CD-ROM segment) on international markets, in particular in the emerging ones of Eastern Europe, Asia and the Pacific Rim.

# Telecommunications services

## NACE 79

*Of the three large trade regions, the EU has the largest number of telephone lines in the world, with 170 million lines (roughly the same as the NAFTA countries).*

*In 1992 the telecommunications services sector employed slightly more than 860 000 persons, down by 5.8 % from 1991. This downward trend is bound to accelerate with the privatisation of the telephone operators to come, but will be counterbalanced with the development of new telecommunications services (mobile, value added network services, telematic applications, etc).*

*The mobile communications market continues to post fast growth: at the end of 1993, the number of subscribers to cellular telephone services had reached 8.7 million in the EU, an increase by 47 % compared to 1992.*

*In general public carriers still have the monopoly of the basic telecom services, but competition is increasing in the international and domestic arena because of the liberalisation of data services and mobile communications markets. New competitors, particularly American carriers and computer companies, are emerging. Users are getting very sophisticated and differentiated: paradoxically, the more the EU telecom market moves towards integration, the more demand moves towards segmentation.*

*The information highways are put at the heart of Europe's future competitiveness. With regard to the launch of multimedia services, telecom carriers are testing the commercial potential of services such as video on demand. However, the development of new video-services will be gradual, due to the large volume of investment that will be necessary to build the multimedia network.*

### INDUSTRY PROFILE

#### Description of the sector

Telecommunication services permit interactive connection between persons, computers and terminals through many kinds of networks such as telephone, coaxial cables, optic fibres, microwaves and satellite networks. They also permit the diffusion of information from a single point to multiple points such as direct satellite broadcasting for television or data transmission.

Telecommunications services provide basic services like telephone or telex, where the messages are simply transmitted by the networks, or Value Added Services (VAS) like electronic mail, EFT (Electronic Fund Transfer), EDI (Electronic Data Interchange), where the messages are stored, processed and repackaged by a computer system (or service provider) along the route before being received from the addressee.

The transmitted information can be voice, data or images. Until recently, each type of information required the use of a specific network (like telephone, telex, or packet switching networks). However, new networks, like ISDN (Integrated Services Digital Network), allow for integrated distribution of voice, data and fixed or full motion image.

The telecommunications services sector has a long tradition of national monopoly in Europe and elsewhere in the world. Several countries have made a serious attempt at liberalisation, notably in the USA and the UK. The advent over the last decade of cellular mobile telecommunications networks and independent data networking services (e.g. Internet) have introduced new players into this market. Furthermore, the broadcasters, increasingly using cable distribution and tending to increase private networks, promise to become important players too. These events could drastically change the nature of telecommunications services and their economics over the next decade. This article describes the status quo, focusing mainly on the bulk of existing telecommunications services which are offered by traditional national operators. The advent of new players and services is in the air, but is only beginning to show in market share and results.

#### Recent trends

New technologies derived from microelectronics, optics and information technology, such as digitalisation of exchanges and transmission (that give the possibility to transmit either voice, data and image as a flow of bits that can be read and elaborated by computers), fibre optics (that permit broadband transmission) and advanced software, allow the transmission of an increasing variety of intelligent services for the benefit of many different segments of customers. Increasing differentiation of technologies and services permit to satisfy an increasing range of users needs. In particular, thanks to the availability of new networks (such as ISDN, satellite, and optic fibre network) and of data compression technology, the need of bandwidth for new services that require a vast amount of data (like video transmission) promises to no longer be a bottleneck for the customers.

These new technologies are also prompting the prices of the long distance services and those offered to business users, to fall dramatically. For example, the cost of a submarine

cable circuit per hour has fallen from almost 0.6 ECU in 1970 to less than 0.02 ECU in 1992 (in 1958 it costed 8.3 ECU); the cost of a satellite circuit followed a similar trend. Prices, especially for the business customers, are also strongly pushed down by the emerging competition. Competition between telephone carriers, mobile services and cable operators is also increasingly affecting the residential market. For instance, radio access to the local households is often cheaper than laying telephone lines; also coaxial cable, used for transmitting television, could also carry telephone signals at a marginal cost.

The EU hosts some 152 million telephone lines, which compares to about 144 million in the USA and almost 58 million in Japan. However, the number of lines per 100 inhabitants was 44 in the EU in 1992, compared to 53 in the USA and 46 in Japan.

EU telecom carriers are generally state-owned carriers, although some are privatised, wholly or in part. Only in the UK, Sweden and Finland has generalised competition been

allowed, including both data and basic telephone services. The geographical distribution of the production of telecom services in the EU depends mostly on the size of the domestic market of the national telephone carrier. Germany, the United Kingdom, France, Italy and Spain are the major markets of the European Union. In spite of the telephone monopolies, many new comers are entering the newly opened EU mobile and data commercial telecom markets. USA carriers and, to a lesser extent, computing companies, are taking advantage of these new opportunities.

In the period 1980 to 1991 gross investments made by telecom carriers in the EU showed a notable increase. In 1992, the economic recession and the weight of previous investments resulted in a 6 % decline in gross investments to about 34.2 billion ECU. In spite of this drop, the revenues generated by EU telephone carriers amounted to about 100 billion ECU in 1992, up 10 % from 1991. Telecom revenue represents about 2 % of the EU gross domestic product.

In 1992 total employment averaged slightly more than 860 000, a decrease by 5.8 % from 1991. Considering that the average growth rate of total turnover is about 10 % per year, this drop in employment means that the sector is rapidly gaining productivity.

The mobile communication subsector continues to post strong growth: worldwide the subscriber base reached 32 million users in 1993, averaging an annual growth of 45-50 % between 1986 and 1993. In the EU at the end of 1993, there were 8.7 million subscribers to the cellular telephone services, up 47 % from 1992. The number of the new mobile telephone

(1) Estimates

Source: ITU: Telecommunication Indicators for Western & Southern Europe

connections outstrips new fixed line connections in some countries, such as Scandinavia and the United Kingdom. If current growth levels are maintained, at the end of 1994 there will be 13 million subscribers in the EU, 22 million in the USA and nearly 50 million worldwide.

The level of telephone lines penetration is much higher in the EU than in Eastern Europe and the former Soviet Union. In 1992, there were 11 main lines for 100 inhabitants in Hungary, 9 in Poland and 14 in the former Soviet Union. In addition, the quality of the services offered in Eastern Europe is very low compared to western standards. As a matter of fact, the average waiting time to have a telephone installed often reaches 10 years in Eastern Europe; in addition, long distance and data communication services are very poor. According to the OECD, the weakness of telecommunications services in this region is the most serious infrastructure obstacle to exports. However, even if east European countries show a high potential for growth of their telecom markets, telecommunications investment scenarios are very uncertain because of the economic problems and financial shortages of these countries. A report by the OECD calculates that 167 billion ECU are needed to bring the average line density from 17 % in 1993 to 35 % by 2000. Although most of the funds must inevitably be local - tariffs have increased sharply in every East European country and the rise is likely to continue - Eastern governments want to close the gap basically through privatisation of their domestic telecom carrier.

In the last few years, there has already been a flurry of activity by western companies in Eastern Europe. EU and USA com-

panies have signed many partnership agreements with telecom carriers of East European countries (that still maintain the majority stake in the joint ventures) such as the partnerships made in Poland, Hungary, Romania. The first privatisation in Eastern Europe is set to be that of Matav, the Hungarian state-owned operator.

#### Foreign trade

International telecom services are regulated by a very complex and stable mechanism: the system of international accounting rates and settlements, which is the main cost-and-revenue-sharing mechanism underlying international trade in telecommunications services. The revenue of the carriers depends on the traffic and also on the different tariffs fixed by each country. Large price differences between countries for international calls explain much of the trade surplus or deficit of the countries in this sector. Because of its high tariffs for international telecommunications, the EU has traditionally run a trade surplus with the USA, the main partner for extra-EU communications. It is very likely, however, that this trade surplus will quickly shrink, as a result of the general drop of EU long distance tariffs.

The system of international settlements has come under increasing pressure, particularly as the imbalances between what countries pay out and what receive have grown. There are other factors explaining the breaking of this international agreement, such as the expansion of the international multi-lateral closed-user-group networks, as SITA and Swift, international capacity reselling, the diffusion of new ways of trading

in international telecommunications systems, such as international freephone numbers and calling cards.

## MARKET FORCES

### Demand

The telecommunications market is increasingly segmented by services and specific categories of users. Both residential and business user needs are rapidly evolving and becoming increasingly sophisticated. As a result, the more the EU telecom market becomes global, the more the market segments itself along the lines of technologies and types of services.

The evolution of telecommunications services is very rapid: for instance from 1988 to 1992 the number of telex lines declined by an average 13 % per annum, while the number of fax lines grew by 40 %. In the next few years, electronic mail through computer networks like Internet, will likely substitute (at least partially) fax services.

Intelligent networks provide services for both the residential users, the price sensitive segment of the telecom market, and

for the business and corporate users, the performance sensitive segment. New intelligent services such as caller identification, follow me, credit card calling, audio conference, free phone, intelligent fax, audiotex and Virtual Private Network (VPN) are bound to spread fast. On average an EU telephone subscriber calls three times less than the average US subscriber; it is therefore not surprising that EU carriers use intelligent services as the most important means to increase traffic and revenue per line. So far, banks, insurance companies, building societies, hotels, airlines and services companies are the major business users of the services offered through intelligent networks.

Although the growth in telephone subscribers is modest in the EU, the demand for telephone services is still growing, as evidenced by the high annual growth rate of both local and long distance traffic (about 10 %). The EU carriers use intelligent services as the most important means to increase traffic and revenue per line.

Mobile communication has been very successful, being accepted by both business users and an elite group of residential

**Table 9: Telecommunications services

customers. Due to new technologies such as PCN (Personal Communication Network), that have been designed from the outset for the domestic customer and small business markets, prices will decrease over the next few years and a major share of residential users will be able to afford mobile telephone services. Tariffs have also been adjusted by competitors to take into account customers segmentation.

Datacom services are also at the brink of a major leap ahead in technologies. The increasing need to exchange data among the computers of departments within companies, and also among companies linked through business relations, pulls the demand for data networks, like X.25 public and private networks. There is also an increasing demand expected for transmitting large data flows and video signals through ISDN and high speed broadband networks of both private and public origin. Fast transmission of data and video could change the way people work and live and could also favour the growth of less developed regions and countries

The VAS (Value Added Services) market, on the contrary, is still suffering from bottleneck problems. Demand exists, but the lack of diffused and accepted standard still hampers further expansion. Demand is also rising from multinational companies, as management of worldwide networks requires negotiation with many national telecom authorities. Large companies tend to prefer to deal with a single telecom company for worldwide telecommunications provision, and to get a "one stop shopping" service from a single global carrier, or super carrier, with sole responsibility for genuine end-to-end provision. Demand from corporate organisations is also rising for services such as facility management and outsourcing: large companies increasingly focus on their core activities and prefer to delegate the management of their networks to specialised telecom or computing companies.

With regard to the launch of multimedia services, all the carriers are testing the commercial potential of services such as video on demand: however the new services and options presented to consumers raise the question whether there will be enough money to support new media technologies and products without removing the financial support currently provided to traditional media. The investments needed to build the multimedia network will be huge, especially if the fibre or the cable is to replace all the existing telephone lines in individual applications. For example, it is estimated that the investment necessary to install the cable in the United Kingdom will reach 15 billion ECU. For this reason, some analysts doubt that the broadband network for multimedia services will be built within the next decade.

The customer will increasingly determine the trends of the new markets, and telecommunications companies are compelled to make a larger use of sophisticated marketing research techniques to explore the needs of the users, to forecast the customers' reactions before offering and promoting their services.

### Supply and competition

New competition pushes the public carriers to fix the prices of each service according to the cost specifically sustained. Public carriers are bound by strong competition to re-balance tariffs by heavily decreasing their prices for long distance calls and for services directed to business users, while generally a an increase occurs for local calls and for services addressed to residential users. Therefore, the norm of cross-subsidisation between long distance and local calls, and between business and residential users will diminish in importance.

The increasing threat derived from the liberalisation of data and VAS markets, and from the entrance in the market of powerful players like IBM (USA), DEC (USA) and other computer companies and foreign carriers, is tackled by the domestic carriers, through the increasing supply of new intelligent services and high performance digital networks like ISDN.

ISDN, VPN and outsourcing are major challenges for public carriers: their goal is, in fact, to provide private networks for large business users whilst encouraging small and medium business users to make the best use of public networks.

Pushed by changing technology and rising competition. EU carriers are searching for international partnerships. The new alliances target products for large multinational corporations; they generate the largest volume of long distance traffic and have the strongest bargaining power. As a result, new global "supercarriers" are emerging and new partnerships are taking place.

The first partnership has been set up between BT (UK) and MCI, the biggest USA long-distance carrier after AT&T. A second alliance was set up between France Telecom, Deutsche Bundespost Telekom and Sprint (USA). A third was formed between Unisource (the four-way alliance among the Dutch, Spanish Swedish and Swiss telephone companies), AT&T and KDD, the Japanese international carrier.

As the big corporate customers, long distance calls, data and mobile services (where the market is already open to competition) normally account for a big share of the revenues and, overall, of the incomes of the telephone carriers, in the

long term this trend will undoubtedly represent a threat for the biggest carriers that will not adapt themselves to the new competitive environment.

The building up of multimedia information highways will give rise to stiff competition. Unlike the USA, where over 60 % of households subscribe to cable TV, cable is not much diffused in the EU. The only countries having a developed cable network are Germany, Belgium, Luxembourg, the Netherlands, Ireland, Sweden and Finland. By contrast, there are less than one million subscribers to cable pay-TV in France and in the United Kingdom, and none in Italy. However, many operators are striving to enter the cable market. In the United Kingdom cable operators already offer cable TV and local telephone services. In addition, national carriers like BT, France Telecom, Telecom Italia, Telefonica and Portugal Telecom started to build new optical fibre and coaxial cable networks within the next three to four years, in order to be able to offer video on demand, broadcasting and telematic services like home shopping, video games, teleducation or teleworking.

Private and public carriers are engaged in building new digital mobile communications networks on the GSM (Global System for Mobile) standard, the European unified standard established by ETSI (European Telecommunications Standards Institute). Thanks to this unified standard, EU operators are ahead of the USA carriers that are still implementing two different standards for digital mobile communications. GSM permits the use of multiple channels, is secure and provides a large amount of digital services for the customer. However, prices for GSM services and terminals are currently higher than the prices for analogue services and terminals. In such a competitive environment for mobile services, the players have to strive for enlarging their customer base, often through traditional marketing methods, such as advertising and the offering of a range of new services at lower prices.

#### Production process

Thanks to the digitalisation of the network and the introduction of OSS (Operating Support Systems), telecom carriers can heavily cut the expenses for monitoring and maintaining the networks and for supplying new services. Between 1985 and 1990 the annual average growth of productivity of EU telecom operators varies from 1.5 % in the Netherlands to 11.4 % in Portugal, while the United Kingdom, Germany, France, Spain and Italy post annual rates between 3 and 6 %. The diffusion of digital networks like ISDN, GSM and satellite telecommunications, will certainly accelerate this trend. Therefore carriers will be able to cut the prices for the benefit of the customer.

## INDUSTRY STRUCTURE

### Companies

Generally speaking, national telecom operators are very large and profitable companies with a large number of employees. They also sustain big efforts in investments for improving the networks and offering a broad range of services.

The top EU network operators are Deutsche Telecom Bundespost (D), BT (UK), France Telecom (F), Telecom Italia (I), and Telefonica (E). These companies rank among the 15 world leading telecom carriers. Out of these 15 world leaders, 9 are located in the USA, 5 in the EU and one in Japan.

### Strategies

EU public carriers operating in a quasi-monopoly regime are preparing themselves to tackle new competitors in an opening market. EU carriers are engaged in a deep restructuring process and in increasing their productivity. Many carriers are changing their organisation in order to focus on emerging services and markets and be more flexible and nearer to the customer. Some telecom carriers, like BT, STET Telefonica and Portugal Telecom have set up new companies for operating in specialised markets, like mobile communications, multimedia or data network markets.

Telecom carriers' goals are to introduce flexible pricing and sophisticated services (like network management and outsourcing), especially for the benefit of the largest business users, and to increase the traffic generated by the residential customers with products like "intelligent services".

The need to introduce intelligent systems, data bases and software for monitoring the network and offering more services to the customers has a big impact on the telecom carriers' strategies of partnerships with computer and software and computing services companies. For instance, France Telecom has recently signed a partnership with the computer services company Sema (F), while STET (I) has bought Finsiel, an Italian computer services company.

Telecom carriers are also preparing offensive or defensive strategies concerning internationalisation. European Telecom carriers are very interested in the process of privatisation of many national carriers that is underway all over the world. For instance, France Telecom and STET, on one side, and Telefonica on the other side, bought minority shares of the privatised Argentinean telecom carrier. The northern zone was granted to France Telecom and STET and the southern zone to Telefonica. Both new companies are leading the modernisation of the Argentinean telephone network. Telefonica is also managing networks in other countries, such as Chile and

Peru, while France Telecom is in Mexico. Recently France Telecom set up a joint-venture with Deutsche Telekom and Sprint and bought private data carriers in the United Kingdom, Germany and Italy. BT, allied with MCI, joined with Banco de Santander (E) for offering new data services to the Spanish market.

A new field of alliances and competition is emerging: the one of multimedia services. Most of the EU carriers, as their USA counterparts, strive to set up new partnerships with media companies. Such alliances are necessary for succeeding in the multimedia market as customers are not attracted by new technologies but by new contents and solutions (TV programmes, movies, telematic services). The content is a very scarce and costly resource: for this reason France Telecom, BT, Deutsche Telekom and STET (through Stream) strive to

get the control of this critical factor by setting up national and international partnerships with media companies, such as Canal Plus (F), Bertelsmann (D) or BBC (UK).

### Impact of the Single Market

The Single Market program calls for, on the one hand, the establishment of Europe-wide integrated networks and, on the other hand, the liberalization of the provision of services and infrastructures. Although not a Single Market objective, the liberalization of the market will lead in most cases to the privatization of existing state owned operators. Procedures for public procurement mean that state owned monopolies can no longer maintain privileged relationships with preferred suppliers. Even without the single market program, telecoms monopolies would have been under threat. For example, satellite communications enable private operators to offer inter-

national services and foreign regulatory bodies such as the FCC in the United States demand equal access for their own operators in return for access to the US market. At present, under EU legislation, value added services, private networks, data transmission and mobile communications have been opened up to competition in most EU countries. The basic fixed voice network is to be liberalized on January 1, 1998, at the latest in all countries except Spain, Portugal, Greece, Ireland and Luxembourg, but is already liberalized in the UK and Sweden and is likely to be so in some other countries before that date.

Pan European GSM mobile phone networks have been established and work is going ahead to set up pan-European ISDN and broadband networks. Infrastructures often based on cable TV networks for the local loop and on the networks of electricity companies, railways and motorway operators for long distance are being set up at both national and European level as an alternative to the networks of traditional operators who, despite their obligation to lease lines to their competitors, could retain undue influence.

## ENVIRONMENT

Telecommunication services have a positive impact on the environment, as they reduce the need for physical transport, and consequently pollution. Many services such as satellite remote sensing and telemonitoring, are used for monitoring air, water and soil pollution. Remote sensing services are also used for managing and preventing disastrous events. One minor environmental problem posed by telecommunications is the negative visual impact on the countryside from large transmission stations.

## REGULATIONS

The EU telecom regulation provides a liberalised framework for all categories of services excepted voice telephony and telecom infrastructure. However, the pace and the method of introduction of liberalisation vary according to the laws and regulations in the EU Member States. The United Kingdom liberalisation example of the 1980s (the United Kingdom was the first EU country to privatise its national carrier and to open its telecom market to competition) is likely to be followed by other countries. Already Sweden and Finland have created a liberalised telecom environment.

In the majority of countries, the VAS and the terminals markets are very open to competition. Following an EU directive, at the beginning of 1993, liberalisation came into force for some other telecom services, such as data networks, audiotex, videotex and intelligent fax (free in Sweden). Resale of leased lines and satellite transmission of data through VSAT are usually subject to national regulation but are increasingly allowed. In the field of cellular communications, there is at least a duopoly situation in each Member State. Cable TV is highly regulated at national level in France and Germany, but is very open to competition in the United Kingdom and Sweden. However, a certain degree of deregulation is likely to take place in France and in Germany in particular, as private capital is needed to promote and fund multimedia services.

According to the EU deliberation of June 1993, the liberalisation process will be completed in 1998, when the majority of the EU Member States will also be obliged to open the market for telephone services. The liberalisation of the telecom network infrastructure market should be completed by 1998, following agreement by the Council in November 1994. These factors will have a major impact on the structure and the rate of growth of the sector, which is expected to grow very fast. However, the liberalisation process is not easy: five out of the twelve EU Member States gained exemption from liberalisation of their telephone services: Greece, Spain, Portugal

**Table 12: Telecommunications services**

Value added	5.5	5.3

Source: Databank

and Ireland until 2003, and Luxembourg until 2005. However, it might be that earlier implementation of competition occurs in some of these countries.

In most countries with a privatised carrier or PTT, the company is the largest on the local stock exchange. This fact explains why all privatisation plans have been phased, although political factors also weighted heavily. In fact all the EU telecom privatisation plans (in the United Kingdom, Denmark, and the Netherlands) have been, or are being, carried through in stages. In the United Kingdom the process lasted 9 years before completion. A similar course is planned with the largest of the forthcoming flotation, the one of Deutsche Telekom, scheduled for 1996. STET, the Italian state holding for telecommunications, is scheduled to be privatised during 1995, and France Telecom in 1996. In Portugal, the government will sell 25 % to 30 % of Portugal Telecom in the first half of 1995. Greece, Iceland and Belgium are considering strategic partnerships.

The processes of privatisation and of liberalisation of the telecom markets continue to have a major consequence: the creation of public authorities, or regulatory bodies of the telecom sector. In many EU countries regulatory bodies, as OfTel in the United Kingdom, are already being set up. They regulate competition between the domestic carrier and other national and foreign private operators, preventing monopolistic positions and taking into account the needs and interests of end users. In many countries the regulatory body still decides on the basic services tariffs. But, following the United Kingdom example, the price cap mechanism for fixing tariffs has been increasingly adopted by other EU Member States (the price cap mechanism is the automatic increase of a ceiling for the telephone tariffs according to the level of inflation minus a certain level of previously fixed productivity growth).

## OUTLOOK

The telecommunications market will change rapidly because of the introduction of new broadband digital networks, new services and increasing competition. Totally original services are expected in the market, like, for example, video on demand. All the major EU carriers are testing the new multimedia technology and are trying to foresee the major applications and the degree of acceptance by potential users. Video on demand could have a big impact on the diffusion of other technologies and on markets like satellite TV, video recorders and cable TV.

Among other services currently underway, there are the development of high speed networks based on the frame relay protocol (for connecting local area networks), virtual private circuits, broadband services (for transmitting high volumes of data and full motion picture) especially targeted to the business users, intelligent mobile services based on GSM networks; satellite services for data transmission; network management and outsourcing. Also the potential of growth in East European markets is very promising, notwithstanding their current financial troubles.

New players, together with the traditional national operators, will emerge. Worldwide, three or four global companies are likely to stand out: AT&T, BT and Japan's NTT.

In the "Global information society " report carried out by a group of prominent personalities chaired by the Commissioner Bangemann and endorsed by the European Council of June 1990, the building up of information highways is put at the heart of Europe's future competitiveness. To reach this objective, the report calls for a market-driven revolution and recommends that EU governments accelerate the ongoing process of telecom liberalisation. But there is a risk: the creation of the information super-highways could widen the gap between rich and poor, affluent and remote areas. There are no simple solutions to this very complex problem. However, in order to close this gap, governments and EU organisations should support new regulations to give the maximum number of users access to basic multimedia services. And additionally, for poorer regions of the EU, provide financial support to enhance their telecommunications infrastructure.

In order to realise their common vision of the global information society, the governments of the G-7 group recently agreed to collaborate on the basis of the following principles: promote dynamic competition; encourage private investment; define an adaptable regulatory framework; provide open access to networks; ensure universal provision of and access to services; promote equality of opportunity to citizens; promote diversity of content (including cultural and linguistic diversity); recognise the necessity of worldwide cooperation with particular attention to less developed countries.

# Education

## NACE 94

*In a constantly changing world, education is called upon to play an increasingly important role in preparing young people to enter the business world.*

*Public expenditure on education represents approximately 10 % of total public expenditure in most EU countries, compared with figures of 12 % in Japan, 14 % in the USA, and 15 % in Switzerland. Europe's future will be built essentially on the quality of its human resources and therefore on the past and future ability of EU Member States and economic actors to develop and disseminate training at school level. Through its content, organisation and the quality of its training and formation, education is the most important factor in meeting the demand and the changing conditions on the labour market. In this sense, education is the most important investment in every country.*

### INDUSTRY PROFILE

#### Description of the sector

The sector comprised under NACE 94 includes all structured teaching activities in schools or universities that issue diplomas at any level.

The structure and the evolution of the teaching sector reflect the way in which each country has responded to its demographic and economic characteristics (mainly in terms of activity and jobs), and has anticipated foreseeable developments.

The organisation of education varies across Member States, with different priorities given to technical and professional teaching, varying importance of part-time education, and country-specific systems of degree levels, diploma types and graduation ages, particularly in higher education. Also, the importance of private education varies considerably across Member States.

#### Recent trends

The share of students in the total population has stayed constant in most countries, though population growth is declining. The proportion of the population younger than 15 year old is decreasing in most countries. This means that individuals receive education during a longer period of their life.

Demographic evolution in EU Member States is generally weak. Between 1980 and 1990 population growth has varied from almost zero percent in Belgium, Denmark and Portugal till 0.5 % in France, Luxembourg and the Netherlands.

This lack of demographic vitality has resulted in a relative ageing of the population of the Member States and a decrease of the number of potential school entrants (Table 1 and Figure 1). For example, between 1980 and 1992 the proportion of the population under 15 year old to the population between 15 and 65 year old fell from 27 % to 24 % in West Germany, from 34 % to 23 % in Italy, and from 42 % to 27 % in Spain. In the USA this ratio stood at 33 % in 1992, and in Japan at 28 %. These countries also have a smaller proportion of people in the age group older than 65 year.

This unfavourable trend affects all Europe, the less developed countries (particularly in Southern Europe) reducing their differences with the more developed countries. It is leading to a decrease of the size of the educated population and of their proportion in the total population.

Nevertheless, school attendance has remained almost constant (see Tables 2 and 3). One reason for this are changes in the period of compulsory education. Figure 2 shows the duration of compulsory education, varying from 8 years in Italy till 12 years full-time in Northern Ireland. In the Netherlands, Belgium and Germany education also is compulsory for 12 years, but in the last 1 or 2 years only part-time.

Recent proposals for changes in the education system generally aim at extending the period of compulsory education, either by lowering the starting age (Belgium, Luxembourg) or raising the school-leaving age (Italy). Luxembourg has recently lowered the starting age from 6 years of age to 4 to help immigrant children to integrate better into the education system. Portugal has decided to extend the duration from 6 years to 9 years in order to raise the overall level of education of the population.

reduce the very high illiteracy rate, and enable a greater number of young people to enter higher education. Spain wishes to extend the period of compulsory education both to align with the other countries and to guarantee all its citizens a comprehensive basic education.

The increase in the number of people being educated is to a large degree caused by the extension of programmes (secondary technical and professional education, tertiary education) to meet needs in the job market and technical developments. However, this increase is also owing to the longer time periods that students have to spend (compulsory education) or need

to spend in the education system. The trend of longer education periods reflects both an increasing need for higher education, as a protection against unemployment, and the political desire of many countries to offer as many students as possible the opportunity to complete secondary studies.

In Table 4 is shown very clearly the very large increase in the number of students enrolled in tertiary education. Between 1975 and enrolment in tertiary education expanded by 60 %, whereas the number of students receiving primary education decreased by more than 23. The drop in the total school population almost equals the difference between the fall in the

number of primary students and the increase in the number of higher education students. In most countries the second of these opposite trends only partly compensates the negative effect of the first trend.

The participation of girls clearly catches up with that of boys, as is illustrated in Figure 3. Important differences between girls and boys remain, however, in the nature of education. In most countries girls are overrepresented in general education and underrepresented in technical/vocational studies.

#### Education as employment

About four million people were employed in the education sector in the EU in 1987-88 according to the OECD (taking into account only primary, secondary and special education and excluding administrative staff). About 1.5 million people worked in primary education schools, about 2.4 million in secondary schools and 0.1 million in special schools.

In 1992 almost 9 million people were employed in the education sector in the EC according to Eurostat (taking into account all types and levels of education). About 37 % of

the people worked in primary education schools, about 60 % in secondary schools and 3 % in special schools.

#### Private education

In Europe, private education, in other words education that is not directly under the authority of the State, exists in varying degrees across countries. Its importance is a function of the level of education provided and on the nature of the relationship with the State, particularly the involvement of the State in financing private education. Thus, the proportion of private education in Belgium and the Netherlands is very high owing to the fact that it is entirely financed by public funds. There are also hybrid formulas in which State participation methods vary. The higher the amount paid to private school financing by the State, the larger the proportion occupied by private schools in the education system. There are many reasons explaining why the private sector exists and the varying support given to it. These include religious and historical factors, along with a possible difference in quality, and the offering of special programmes.

Recently in France an agreement was reached with the Catholic education sector (17 % of all pupils) on the recruitment and

training of teachers, contributing to a greater equality of educational opportunities, irrespective of the type of school. In Denmark during the last ten years, the number of municipal primary and lower secondary schools has undergone a drastic decline of 12%. On the other hand the number of private schools has increased by 22.5%. The greater number of private schools means cost savings to the public authorities.

#### The pedagogic environment

Table 5 shows the trend towards a reduction in the number of students per teacher. This reduction is motivated by the pedagogic reason that teaching efficiency improves when there are fewer students, but also follows from the slow adjustment to demographic changes.

These numbers relate to national averages and hide important regional differences. The number of students per teacher falls

in some regions due to population drops, but at the same time increases substantially in other regions, notably in suburban areas. Urbanisation is almost complete in countries in Northern Europe (97 % urbanisation ratio in Belgium), but is continuing in other countries, particularly in the South (for example the urbanisation ratio is 32 % in Portugal). This will result in further adjustments in the number of students per teacher.

#### primary schools

Apart from Spain, there are no countries where the structure of primary education is being changed. In the curricula most important changes relate to increasing attention to foreign languages, as is the case in Greece, France, Spain, Italy and Scotland.

In some countries health- and environmental education are receiving greater attention.

#### Secondary schools

Secondary education is the sector where the largest differences between teaching in the various countries are found. These differences are related to subject matter (general or polyvalent compared with technical or professional), and also to its or-

ganisation (full-time and part-time or apprenticeships). This is also the sector where most attempts are made to improve effectiveness by changing the organisation of education.

Two types of policy measures are observed. The first relates to the specification of the various education paths that provide access either to university or to advanced vocational training, depending on the path chosen. Such policies are focused on in France, the Netherlands and Spain. In other countries growing attention is paid to low-achieving pupils and the prevention of early school-leaving.

As is shown in Table 6 in the school year 1991/1992, general or polyvalent full-time education represented 39 % of all education at the higher level of secondary education in the EU. This ratio varied from 20 % in Germany to 77 % in Ireland, compared with 72 % in Japan and 100 % in Canada and the USA. This variation reflects differences in national policies, which emphasise in varying degrees technical and professional formation and therefore preparation for entry into the labour market.

As a whole, higher level secondary education in the EU is geared towards professional needs, but approaches vary greatly across countries.

### Higher education

The challenges faced by the EU (relating to trade competition, research and development, demography) have already resulted in a drop in the proportion of unqualified labour. This trend will undoubtedly continue.

Higher education remains an important area of current concern. Issues include conditions of access, the provision of scholarships and bursaries, the autonomy of education and the need for reforms.

In general we see a clear growth in the number of students in higher education and the number of diplomas conferred (see Tables 7 and 8). Participation in higher education varies across Member States. These differences largely follow from the initial situation, characterised in the case of Greece, Portugal and Ireland by a relatively low proportion of students in higher education. These countries are catching up. Higher education is for them an important factor in the political objective of creating the ability to meet the main economic and social challenges.

The proportion of women having received higher education has increased from 40.4 % in 1975 to 46.4 % in 1985 (more than 50 % in France and Portugal) therefore approaching the proportion of girls in the 5-24 year old population.

#### Scientific characteristics of the higher education

Given the changes in high level abilities related to new technologies the share of natural sciences and engineering students at universities is of particular interest. Table 9 shows the varying importance of science education in EC countries (the data do not include non-university science education, which exists in some countries - for example Engineering Schools in France). The large differences are determined by two sets of factors:

- historical and cultural factors, which partly explain the share that each country assigns to engineering sciences and natural sciences in university education compared with the total number of subjects, and the share of each of these sciences;
- socio-economic factors, relating to the importance given to engineers in economic activities. If this importance increases, the profession of engineering receives both higher esteem and reward. The case of Japan is an example in this respect.

#### Overseas students

Table 10 shows there are very large differences in the presence of foreign students in higher education, both in absolute and relative terms. There is a very strong correlation between the origin of foreign students and the history of the host country (former colonies, common language, which is obvious in the case of France, Belgium and the Netherlands) The geographical mobility of students is still low, both globally and between countries in the EU. This is explained by:

- the fairly limited knowledge of the characteristics and possibilities of higher education in other countries;
- the non-existence of a genuine common labour market;
- the fear of additional financial costs;
- lack of understanding of the language.

#### Economic factors

Education is generally considered as a public consumption item, with a price close to zero and which, in any case, does not reflect the costs to produce it. However, it also exists as a private consumption item with a price determined freely by the providing schools. In addition, education is an investment item since it affects the future income of the individual and the nation.

The two main indicators of expenditures on education are public expenditures on education as a percentage of the Gross Domestic Product (GDP), and public expenditure on education as a percentage of total public expenditure (Table 11).

The indicator of the ratio of public teaching expenditures to GDP shows a wide dispersion across countries (6.3 % for the Netherlands, 4.9 % for the United Kingdom, 3.1 % for

Source: OECD Indicators

Italy). This is not surprising considering the difference in the development level of the observed countries. However these major differences are being reduced by the catching-up movement in less developed countries. Another influence to reckon with are the changes in compulsory education. It is interesting to note that in exactly the countries with the highest levels in the early 1970s (the United Kingdom, the United States and Canada) education expenditures dropped most during the period under consideration. The reverse phenomenon is true for countries with the lowest ratios, particularly Greece and Portugal. It is therefore right to conclude that a catching-up movement in the countries lagging behind contributed to convergence of expenditures on education. These countries in-

crease efforts in education as a function of their economic development level.

It is also interesting to consider the differences in expenditures for primary and secondary versus tertiary education in Table 12. The ratio of public expenditures on tertiary education to expenditures on primary and secondary education is lowest in Luxembourg (about 4 %) and highest in the Netherlands (almost 60 %).

#### Comparison by PPP

The complex nature of education creates serious problems for the evaluation of education expenditures and quality, and makes comparisons between countries very difficult. In order

Source: OECD: Education expenditures, cost and financing trench analysis, 1970-1988

to compare education expenditures between countries, a common measure is needed. The concept of Purchasing Power Parity (PPP) specific to education, recently developed by the OECD, allows to convert different foreign currencies into a same unit by taking into account the relative purchasing power of different currencies. Using this method, the relative effects of education expenditures and their changes may be analysed more precisely.

The first indicator (Table 13) shows the expenditure per student expressed as proportion of GDP per head, evaluated at PPP. The indicator reveals a difference between less developed countries in the EU and the more economically advanced countries, although the difference between these two groups tended to reduce between 1970 and 1988. The two fundamental reasons have already been mentioned: demographic changes and efforts made to reduce the differential by countries such as Portugal, which achieved an increase in expenditure by 100 % between 1973 and 1988. Greece only maintained its level of 50 % relative to the Netherlands. The indicator has been fairly stable in other countries, except the United Kingdom which experienced a major drop, representing the relative disengagement of this country's government from financing education, in particular since the middle of the 1980s. It therefore appears that, measured by the PPP method, a fairly constant relation between public expenditures per student and GDP per capita has been maintained in recent years.

The second indicator (Table 14) shows the share of public education expenditures in total public expenditures, in PPP terms. This constitutes another approach to compare public education expenditures. The trend of the European countries studied is downward in nearly all cases, which would be a concern if part of this trend were the result of a relative reduction in the educated population.

EU countries classified as less developed generally have lower values than the other Member States or than the USA and Canada. This also confirms the fact that education expenditures are a function not only of the development level, but also of priorities and choices defined by governments. The case of West Germany is undoubtedly partly a result of demographic changes and of efforts made in education in the 1960s.

Convergence of the indicator over the observation period (1970-1988) has resulted in lower values recorded for all countries. This decrease is also owing to the less important relative increase in education expenditures relative to other items in national budgets.

Considering demographic changes in European Community countries and the ratio of the 18- to 25-year olds within the total population, it is interesting to note the attitude of the

various governments towards higher education. This comment is particularly important because of the fact that European institutions are strongly encouraging the development of higher education and the mobility of European students by the implementation of EU programmes. Three trends can be observed over the period 1970 - 1988: the trend characterised by Portugal which made a major effort in its higher education and with an average growth over this period of 11.4 %; the trend in Ireland, Greece and Italy where growth has been between 5.5 % and 7.3 %; and finally the one typical of other countries with growth rates between 1.5 % and 2.1 % which appears to characterise an apparent maturity of financial efforts made for this level of education.

While real expenditure on higher education has been increasing in all countries studied, measured in PPP terms, they can not be said to grow continuously. The conclusion is rather one of individual efforts (major infrastructure or education projects) succeeded by periods of stability. Considering the important economic challenges facing Member States, it would be interesting to evaluate the long run economic effects of public expenditures on higher education. Unfortunately, measurements of this effectiveness can often only be made based on economic and social results observed several years after the expenditures were made.

#### *EU policies and Financing*

During the 1980s, the EU has launched a number of actions and programmes in the field of vocational training. Several training programmes were adopted, each having a precise aim: PETRA (initial training); FORCE (continuous training); COMETT (cooperation between firms and universities); EUROTECNET (promotion of qualifications linked to technological innovation).

On December 6, 1994 the European Council has adopted the LEONARDO programme which aims at setting up a global policy for vocational training in the EU. The programme has been endowed with a budget of 620 million ECU for the period 1995-99.

LEONARDO is based on the idea of life-long training. In this respect, initial and continuous training must be seen in the framework of a general conception of vocational training as a permanent process, aiming at ensuring the insertion and the evolution of the individual in the professional life.

In order to promote professional training at EU level, LEONARDO will put into practice three measures:

- the creation of transnational pilot projects for the setting up of common training models, the training of trainers, the anticipation of future needs, etc.;

- the creation of exchange and placing programmes, which will allow young people, students, trainers and human resources managers to follow part of their vocational training in another Member State;
- the development of knowledge in the field of vocational training, through a number of enquiries and analysis to be made at Community level, e.g. on the anticipation of future needs, the transparency of qualifications, new learning processes, etc.

In parallel to the LEONARDO programme, the EU has also developed the SOCRATES programme in the field of education. The programme aims at building on the achievements of previous programmes in the field of education, such as ERASMUS, EURYDICE and LINGUA.

SOCRATES seeks to pursue several objectives:

- to develop the European dimension in education at all levels, so as to strengthen the spirit of European citizenship;
- to promote a quantitative and qualitative improvement of the knowledge of the languages of the EU, in particular those which are less widely used and taught;
- to promote intensive cooperation between institutions in the Member States at all levels of education;
- to encourage mobility of teachers and students;
- to encourage the academic recognition of diplomas, periods of study and other qualifications;
- to encourage open and distance education in the context of the programme;
- and to foster exchanges of information and experience.

Impact of the Single Market

The free movement of persons can be seen as the single most important beneficial effect of the Single Market Programme on the education sector. This is especially applicable to students and teachers in the field of higher education. The exchange is stimulated by programs like ERASMUS and LINGUA, which in turn have resulted in further development and new initiatives.

As beneficial effects can be seen:

- students who visit universities abroad for a certain part of the curriculum;
- more opportunities to do the term of probation in another country;
- contacts between teachers while preparing these exchanges;
- combined efforts to start new studies, which take place in a number of countries;
- teacher training abroad, as refresher courses;
- new curricula like 'European studies', as a separate study or as a specialisation within another programme;
- revival of interest for foreign languages.
- The mutual recognition of diplomas is an important formal barrier which has recently been addressed, thereby increasing the mobility of students. However, students who want to gain experience in one of the other EU countries still encounter a lot of practical obstacles. A considerable number of institutions are not yet prepared to welcome everybody since a number of measures are not yet fully realised.
- Education is an important contributor to better qualified human capital, thereby strengthening the competencies to compete. In future, co-operation between institutions should further increase to realise a better economic position in certain regions and to enhance the clustering of special expertise in spearhead projects.

## OUTLOOK

Education in the EU faces a number of developments, which simultaneously constitute tasks to be addressed.

The first development concerns higher education. In this respect European education systems must:

- increase the proportion assigned to scientific and technical programs in order to satisfy the needs of senior technicians and engineers in the various economic sectors;
- increase relations between economic sectors and education by making more use of engineers and research workers from industry in education, and by engaging in common projects;
- increase harmonisation of curricula and teaching programmes between universities and countries, in order to improve collective vitality while maintaining individuality.

Some progress has already been made in these fields. These efforts must be increased and consolidated, and also made better known. The various EU projects contribute towards this.

The second development concerns improving the overall efficiency of education systems. This efficiency may be measured by the number of diplomas currently conferred, but in reality its effect as investment will be felt throughout the subsequent careers of the students graduated.

To advance in both tasks outlined above new education techniques (remote education, interactive computer assisted education...) should be integrated, to allow teachers to concentrate on their main objective: to learn future workers how to learn, i.e. to instruct them in self-training, which will prepare them for any needed adaptation throughout their professional careers.

The problems faced by the education system in adjusting to the labour market, which have contributed to the 15 million unemployed in 1990 (annual average), require urgent solutions. The young need methods of reinserting them into school activities (giving them the same opportunities as those that have been able to follow standard curricula), or to include them in training programs to acquire operational skills meeting the needs of economic sectors. For job seekers who have already had a professional activity, experience has shown that reconversion problems are better solved when they are anticipated. The example of companies that have implemented reconversion operations (possibly leading to diplomas), sometimes months or years before a reduction in the workforce materialises, demonstrates the benefits such programmes.

Finally, we should emphasise the effects, which will increase in future years, of the arrival into the secondary education systems of the smaller numbers of students currently in primary education. The question of a reorganisation or redeployment of infrastructures and teaching facilities, and in numbers and abilities of teachers, has already arisen in some countries and will arise in the other. The ability of education systems to provide solutions will affect the qualitative and quantitative development of higher education.

In short, the basic tasks of education policies in the EU and in the Member States is to mobilise the needed financial resources and teachers to provide education that can promote competitiveness and social harmony within the EU.

# Health care services

## NACE 95B1, 95C1

Health services account for approximately 7.5 % of GDP in the EU, and 5.5 % of EU employment. Although national health systems vary significantly across countries, on average about half of total expenditures on health is accounted for by hospitals. Another 15-20 % is spent on pharmaceutical products, the remainder relating to "other" medical expenditures (including primary care).

Over the past decades, real health spending grew at a rapid rate, increasing its share of overall public expenditure and raising concern about the future financing of health services. About 78 % of total spending on health is, indeed, covered by public insurance systems, the share ranging from close to 70 % in the Netherlands to 85 % or so in the UK. The decade of the 1990s will likely see major changes in health systems aimed at further increasing the overall efficiency of these services (i.e. reducing the cost while maintaining and if possible increasing the quality of the services and the accessibility to all). Important changes in the regulatory environment have either recently been implemented or are in the pipeline. All actors in this sector will have to adapt to these changes. Restructuring is already under way in two key segments of the market (hospitals and pharmacies).

### INDUSTRY PROFILE

#### Description of the sector

Health services encompass all services supplied by:

- medical doctors (generalists and specialists), dentists and veterinarians;
- pharmacists;
- drug stores;
- chemists;
- paramedical centres;
- hospitals, clinics and polyclinics;

- registered nursing homes, psychiatric institutions and other special treatment centres;
- first-aid centres and health centres;
- home medical services supplies;
- nursing services (including leased nursing care services);
- mobile medical equipment services;
- rehabilitation services.

Total spending on health, on the other hand, includes all personal medical services (by hospitals, paramedical service suppliers, doctors etc., including purchases of medical products), as well as all "collective" expenditures such as public health programmes, investment in medical equipment, the administration of the health sector, the financing of regulatory bodies, etc.

In other words, measured on a "turnover" or "expenditure" basis, the activity of this sector includes the purchases of pharmaceutical products and of medical equipment. Although medical equipment only accounts for a small share of total spending on health (about 1-1.5 %), this is, however, not the case of pharmaceutical products. Nevertheless, because the production and sales of pharmaceutical products is covered in a separate monograph (in the Chapter 6), here we focus on the trends in activity by all the actors listed above, leaving the detailed discussion of the trend in demand and prices of pharmaceutical products aside (except where it is specifically relevant to the activities of the above-mentioned agents).

A second introductory remark is that, although statistics on health exist in all EU Member States, caution has to be exerted in making international comparisons. This is the case firstly because of the limited comparability of data, and secondly because of methodological problems arising from comparisons of data from different economic, institutional and demographic structures. Among the many problems that arise are the fact that:

- National accounting systems for health service expenditures mainly reflect domestic accounting needs, as opposed to a desire to appropriately reflect the activity of the sector. In some countries, thus, the administration of the health system is considered to be part of the health sector, but this is not the case everywhere. In France, for instance, the social security employs some 80 000 people, or one twentieth of total health services employment, but this is not reported in the total employment figure for the health sector, as it is part of the social security accounts.
- The distinction between "health" and "social" services is not clear. Different Member States interpret these in different ways. There is, in particular, no universally accepted definition of "hospital", "nursing home" or "special treatment centre". In Sweden, for example, psychiatric aid and aid to mentally retarded is classified as "social" spending, whereas elsewhere it is included in total expenditures on health.
- In certain countries, some health services are provided as charities and are thus not reported in the statistics, or are valued differently from market services. This raises the problem of comparing the "value" of a given service across countries.
- In some Member States, entire segments of the health market are controlled or operated by the government sector, which, again, is not the case in others. This creates distortions in the classification of information and in the valuation of the services.
- Within the health sector itself, definition problems can arise due to differing regulatory environments. It is, for instance, extremely difficult to correctly assess the value added of hospital services, as most accounting systems do not dis-

tinguish the external services that are provided by hospitals from regular hospital services. This tends to inflate the expenditure figure attributed to hospitals in those countries where hospitals do have an important part of their revenue which comes from "external" services. Even so, hospital in-patient care is generally much better documented than ambulatory and preventive care.

The statistical information available from national sources is thus neither consistent nor comparable across countries. The data source which is used for international comparisons here is the OECD. For many years indeed, the OECD has undertaken to harmonise health statistics and present them in a more comparable format than what is available from national sources. Another source of data is the pilot survey of European countries carried out by the Working Party for Comparative International Health Statistics.

### Recent trends

Within the EU, total spending on health accounts for approximately 7.5 % of GDP, or more than 8 % of total private and public current expenditures. Since the mid 1980s, there has been a distinct slowdown in the growth of nominal expenditures on health. This trend was reinforced after 1990 as regulatory changes aimed at limiting the public sector deficits curbed both the demand and the supply of health services.

On the demand front, changes in reimbursement systems involving an increase in the share of the cost which is to be paid by the patient, a closer monitoring of medical practices and restrictions on minor ailments being supplied with prescription treatment have negatively impacted both the number of visits to the doctor and the "average value" of the prescriptions. On the supply side, some of the direct implications of the regulatory changes have been reductions in the number of hospitals (often the smaller ones) and in the number of pharmacies (through changes in ownership leading to an increased concentration of this sector also). Finally, controls on the fees charged by the providers of medical services have also been reinforced in order to limit the growth in nominal spending.

All these measure, combined with the general effects of the economic slowdown on consumer spending, have spilled over to nominal and real income growth in the sector, and are now also having an impact on employment levels.

### International comparison

In 1991, total spending on health within the EU amounted to 405 billion ECU, which compares with a figure of 180.1 billion ECU for Japan and 606.7 billion ECU for the US.

Per capita, average spending in the EU amounted to 1 171 ECU, slightly lower than the Japanese figure of 1 449 ECU figure and much lower than the US figure of 2 379 ECU. In fact, although per capita spending in the EU is generally considered to be excessive, the share of total expenditure on health in total private and public expenditure spending is, at about 8 %, well below the US figure of 13.4 %.

Important differences between the EU and the US also exist both in terms of the organisation of the health market and in terms of the source of financing. In the EU, approximately 78 % of total expenditures on health are financed by the public sector, whereas in the US this share is only about 35 %.

### Foreign trade

Trade in health services covers medical services provided in one country to residents of another country. This can be the case for patients located near the borders or for migrants, and also includes emergency care during international transits and patients being treated in other countries because the required service cannot be provided domestically. There are also some centres of excellence which rely upon patients travelling internationally to maintain continuous specialty services or further develop pioneering work.

Intra-EU trade in health services is comparatively limited when compared to the total value of health services provided within the EU. Such trade is, however, not restricted to neighbouring countries, so that there is both intra-EU and extra-EU trade in this sector. Extra-EU exports of health services consist of all services provided by an EU health service organisations to residents of a non-EU Member State, for instance from an African country or from Latin America. These patients generally seek the services of highly specialised hospitals or clinics that offer superior treatments to those found in their home countries. Similarly, imports of health services are those expenditures on health services made by EU residents in a non-EU country.

It is generally recognised that the EU has a net surplus on its medical trade balance, although the exact magnitude of this surplus is difficult to ascertain. Data on trade in services are indeed somewhat unreliable, given that only a relatively small proportion of these "international" health services are subject to reimbursement by national health organisations. The "true" value of the services often goes undeclared.

## MARKET FORCES

### Structural trends

On average in the EU, 1 171 ECU are spent per year on health, on a per capita basis. This compares to annual per capita spending of 1 253 ECU on food, drink and tobacco, and of 191 ECU on clothing, for example.

Until the mid 1980s, total expenditures on health were rising much faster than GDP or domestic demand, both in nominal and in real terms. In western Europe, the share of health spending in total private and public expenditure spending grew from 3.7 % in 1960 to 5.1 % in 1970, 7 % in 1980 and 8.1 % in 1991. Given that in most Member States it is public insurance systems which cover the lion's share of total expenditures on health, this rapid growth in demand has become a major source of concern for national governments.

The main cause of the increase in health spending has been an increase in expenditure in real terms, as opposed to price developments. Within Europe, price increases in the health service sector have, indeed, remained limited, largely as a result of regulatory controls.

The growth in real spending, which amounted to 5.4 % per year on average in western Europe in the 1970s, and to 2.5 % per year on average in the 1980s, can be attributed to:

- the increased share of the population which is covered by the national health system (this factor now ceases to influence spending, as nearly 100 % of the population is covered within the EU);
- demographic developments, in particular increased demand for services from an ageing population, combined with an increased life expectancy of individuals;
- the expansion of the health delivery system;
- changing demands from consumers;
- the increasing sophistication of modern medicine, which increases the unit value of given services and influences the types of services that are provided.

In 1990, the percentage of the total population aged over 65 ranged between 11.4 % (in Ireland) and 15.7 % (in the UK). In total, there were close to 49 million people aged over 65 in 1990 in the EU. With the increase in life expectancy and taking into account the present age structure of the EU popu-

lation, the total number of individuals aged over 65 is currently rising at an average annual rate of about 1.5 %. This clearly boosts total demand for health, particularly for nursing services (both domestic and external).

Another factor of increase in "real demand" for health services is that nowadays health makes routine use of technologies unimaginable only two decades ago. New diseases have also been discovered, new treatments have been developed and new services have been introduced (such as screening programmes) adding to the problem of spiralling costs. Most of these developments have created and will continue to create a need for more specialised service providers. Finally, the cost of equipment increases continuously, which impacts that of medical supplies and treatments in general.

Compared to the growth in volumes, that in prices has been moderate. This is largely due to regulatory controls. On average over the decade of the 1980s, the estimated rate of inflation on health services in western Europe was 0.5 % higher than the overall rate of inflation in the economy, the difference for pharmaceutical products being -0.5 % per year and for hospital and related services +1.1 % per year. This latter figure, however, does not appropriately reflect gains in productivity posted by hospitals, such that the true underlying price increase for health services is probably lower than the overall rate of inflation in the economy. In the US, in contrast, the price index of health services (including pharmaceutical products) grew 2.7 % per year faster than overall inflation, largely due to the rapid increase in pharmaceutical product prices (+3.8 % per year faster than overall inflation in the economy) which have largely remained uncontrolled.

Figure 1 shows the decomposition of total spending on health in the main European countries into hospital consumption, pharmaceutical product sales and other and Figure 2 compares spending on health per capita to the share of total expenditure on health that is financed by the public authorities.

Figure 2 presents average figures for western Europe, based on OECD data. There are, however, important differences in the structure of health spending by country which reflect differences in the regulatory environment and in the incentives systems within each Member State. For instance, the proportion of expenditure in hospitals in total health spending is higher than the west European average in Denmark, Greece and the Netherlands, and is lower than average in Germany, Belgium, Ireland and Luxembourg. In 1990, on average 46 %

Source: OECD "Health Systems"

of total expenditure on health in western Europe was spent in hospitals. This compares with a share of 14.4 % for pharmaceutical products, and the rest for primary care and other.

The fast growth in real health expenditure within the EU during the 1970s was mainly attributable to a rapid expansion of services provided by the hospital sector (incl. specialised medical institutions). Over the same period, the share of pharmaceutical expenditures (which includes the margins on pharmacists) decreased, and so did "other" medical expenses. During the decade of the 1980s, hospital expenditures were brought back under control and the share of expenditure on pharmaceutical products remained broadly stable, while that of primary services grew rapidly. Two exceptions to this general pattern within the EU are Italy and the Netherlands, where expenditures on pharmaceutical products grew faster during the 1980s than other health related expenditures, including primary care.

### Employment

The definition problems in assessing the number of people that are employed in the health services sector are at least as complex as the statistical problems in valuing the services that are provided. The definition of the categories of health service employees has tended to change over time, creating gaps or discontinuities in the time series and making international comparisons extremely hazardous. Even where the number of individuals working in a given market segment is reported (for instance, the number of nurses in hospitals or the number of physicians in activity) some of these (23.5 % on average in the EU) only work on an occasional or part time basis (see Table 5). The share of part-time workers is as high as 52.6 % in the Netherlands and 41.7 % in the UK. Finally, especially amongst the liberal professions, such as doctors, the individuals often continue to be registered after reaching retirement age, even when they are no longer or only occasionally practising.

It is nevertheless estimated that within the EU as a whole the health sector provides employment to 7.9 million people, more than 5.5 % of total employment. Table 6 shows the distribution of employment by function.

On average within the EU, physicians account for 13.5 % of the total workforce in the sector, and dentists for 2.4 %, whereas pharmacists represent 2.9 % of total employment and nurses and midwives 27.8 % of total employment.

The trend in employment by category is discussed in more detail below in the section on Industry Structure. The total trends shown in Table 4 are difficult to interpret, given that no figure was available for Italy until 1992, and the unification

of Germany caused a discontinuity in the total employment trend in that country also. Nevertheless, it is safe to say that the number of people employed in the health sector has increased continually over time, in line with the growth in demand for these services.

### Institutional factors

One of the main features of the health services sector which distinguishes it from other service sectors is the source of revenue. There are four main sources of revenue for the service providers: the public health insurance system, private health insurance, personal incomes and government subsidies. Within the EU, it is public spending on health which accounts for the lion's share of total expenditure on health (Table 2 and 7). Table 2 shows the total share of expenditures on health which is financed by the public sector, whereas Table 7 breaks the source of financing further showing the exact contribution of the government sector versus the social security system, private insurance, personal incomes and other.

Public health funds are collected through sickness fund agencies (such as ziekenfondsen in the Netherlands or the mutuelles in Belgium), through national insurance contributions or from taxation. In contrast, private insurance is paid by people who opt for additional or alternative coverage to national health provision, or who are excluded from coverage by the national health system because of a too high income level (as in Germany) or other reasons.

Other sources of revenue for the health sector are non-reimbursable contributions made by patients directly to the health provider. These payments can be relatively important but are not necessarily correctly assessed in overall health spending statistics. Another problem in terms of statistical reporting arises from the fact that in some countries it may not be necessary to make payments for most health services, whereas in others payments must first be made by the patients or their relatives and then be reclaimed through sickness funds.

On average, however, the share of total health spending which is financed by the public sector within the EU has stabilised around 78 %, the rate of reimbursement being close to 90 % for hospital services and much lower for pharmaceutical products.

Not surprisingly, the organisation of the "supply-side" of the sector partly reflects the organisation of revenue by origin, in that in the countries in which national health systems are most developed, the share of "public-owned" or "public-operated" health services is higher. This is typically the case of the UK and Denmark.

**Table 4: Health care services  
Number of persons employed**

### Government policies

The objective of government policies in the health sector is not to limit costs but to maximise efficiency gains (i.e. improve the price/quality ratio). The big policy issue for the sector is thus how to increase efficiency while ensuring social equity. Two sub-questions are:

- the public/private debate: is there an optimal allocation of health services between public/private operators, and if so what is it?
- how can one ensure an appropriate level of competition in the sector while ensuring that quality services remain accessible to all at a socially acceptable cost.

There have been more answers to these questions than there are Member States in the EU. In general, however, governments have pursued these objectives by:

- controlling prices;
- controlling demand (in particular by putting limits on prescriptions for small ailments or through the introduction of RMOs in France);
- increasing the permeability between the different segments of the health market, by encouraging shifts in some types of expenditures from one segment of the market to another (reducing the length of stay in hospitals to substitute it by primary care, or increasing the number of drugs that can be purchased without a prescription, or encouraging self-medication)

The long run effect of such measures on health spending is, however, largely unknown. There are, indeed, obvious trade-offs between short and long term health spending. Would a reduction in the length of a hospital stay not increase the re-admission rate? To what extent would an increase of primary care (regular doctor's visits, preventive care) reduce the demand for specialised medical services, in particular hospital care? There are not enough studies available to date to answer these questions unambiguously, the more so since the problem has to be analysed on a case by case basis (i.e. including by type of medical problem, the answer for a caesarean section differing from an open heart operation).

In view of the increased need for controlling spending while at the same time guaranteeing access to all to quality services, new concepts have recently emerged, such as QALYs (or Quality-Adjusted Life Years). Cost-effectiveness studies are also gaining popularity.

Monitoring compliance is also an increasingly important element of these analyses, as it has been demonstrated in a number of cases that the monitoring of compliance plus the expenditure on the drugs were cheaper "over the life-time" than the risks of non-compliance (which can lead to hospitalisation).

Below, we review some of the key segments of the market in more detail, and discuss the implications of recent regulatory measures on the level of activity and on employment by segment.

### INDUSTRY STRUCTURE

#### Personal medical services (doctors, dentists, veterinary)

In all EU Member States, the number of doctors in activity has increased continuously since the early 1970s. In 1991, there were 935 000 physicians in activity within the EU, compared to 635 000 in the US. The average number of doctors per 1 000 inhabitants in the EU hovers around three, although there are wide variations by country. The density of physicians is for instance comparatively high in Greece, Spain and Belgium, and comparatively low in Ireland, Italy and Luxembourg.

In comparison, there were 166 300 dentists in activity in 1991, the average number of dentists per 1 000 inhabitants varying between 0.2 in Italy and Spain and 0.9 in Greece and Denmark, with an EU average of 0.48.

The market for primary care is heavily regulated. The market is segmented by country, but the segmentation differs across countries as some services can be provided by one category of health providers in one country and by another in another country. In Spain, the Netherlands and the UK, for instance, only a generalist can refer patients to a specialist. In Belgium, people can go directly to the specialist without a prior consultation, which implies that there are certain medical acts which can be done by both.

There are no reliable statistics on total incomes earned by physicians and dentists within the EU. In France, total private & public expenditure on medical services outside hospitals accounted for about 13 % of total expenditure on health in 1991. In the Netherlands, the figure was a little lower, at about 11 %. This compares with a figure of 19 % in the US. The rate of reimbursement of these medical expenditures by the public sector was 62 % in France, 53 % in the Netherlands and 35 % in the US.

As indicated above, one of the ways governments are trying to reduce overall spending on health is by increasing com-

petition between sub-segments of the market. This has a mixed effect on the activity of physicians in terms of levels, but definitely changes the nature of the work they perform. On the one hand, new technological developments now make it possible to treat certain problems within the doctor's surgeries instead of in hospitals. On the other hand, policies to encourage self-medication would tend to reduce the number of visits to the doctor, thereby negatively influencing this sector's activity. The net effect on costs, especially on long term costs, is, however, largely unknown.

Another implication of the tightening of the regulatory environment for health is on training. At present, 95 % of on-going training of doctors is financed by the pharmaceutical companies, who organise seminars, conferences and congresses to keep them informed about the latest developments in medical science. The sector fears that measures to reduce "advertising" expenditures by pharmaceutical companies will have a negative impact on overall expenditures by these firms on training in this sector, which could also have long term effects or shift the responsibility for on-going training onto public authorities.

### Hospitals, homes

During the 1980s and early 1990s, the share of hospitals in total expenditure on health decreased slowly. The supply of hospital services, measured by the number of beds available, also decreased progressively. According to the OECD, the share of hospital expenditures in total spending on health in France decreased by 5 points between 1983 and 1989. A similar reduction was observed in Denmark (though over a longer period) while in the UK, where hospital spending accounts for less than 25 % of total expenditures on health compared to more than 30 % elsewhere, it has remained approximately stable. This is sharp contrast with the situation in the 1960s and 1970s when, despite strong macroeconomic pressures aimed at limiting the growth in expenditures, the growth in services provided by hospitals continues to increase faster than private consumption. Recent changes in the regulatory environment, such as the 1987 measures to contain hospital costs in Germany and the measures by the Belgian Ministry of Health and Social Affairs in the same year, have thus succeeded in offsetting the natural trend towards increased hospital spending which results from progress in medical science and technology.

Hospitals, taken in the broad sense, account for the lion's share of total expenditures on health within the EU. There are very different types of hospitals within the EU, some being more or less specialised, some being for longer stays

while others for acute care, some private and some public, some big and some small. In four EU countries (Belgium, France, Italy and Ireland), there were 5 777 hospitals in 1991, with an average number of beds ranging from 132 (in Ireland) to 286 (in Italy) in the public sector, and from 58 (in Greece) to 203 (in Belgium) in the private sector.

The organisation of the hospital sector within the EU largely reflects national regulatory environments and national heritage. In general, private commercial hospitals are newer to the system and reflect developments in health insurance paid to private sickness funds or commercial insurance companies. These complement the public infrastructure by providing additional hospital, clinic, day centre and nursing home facilities. In the UK, for instance, nursing home facilities are almost entirely private. In Italy, private hospitals are part of the general hospital system working under convention (law 833/78) within the national health services.

The home care and primary care sector is also relatively new in its present form. Home-care probably existed before hospitals. In most EU countries, family doctor practices, which provided almost all primary care in the 1960s, were progressively replaced by health centres, until this trend stabilised in the late 1980s. There is now also an important trend of specialised physicians leaving the institutional environment to open practices in the community.

Day hospital care, enabling the patient to be sent home after a minor operation, is slowly spreading in the EU and is encouraged as a cost reduction measure, even though the long term effects on health costs are not fully assessed. Some hospitals have expressed interest in working with hotel groups (this is the case for instance in France). These would provide facilities next to hospital complexes to cater for aftercare of patients who have undergone minimally invasive surgery such as laparoscopic surgery.

Institutions which provide care for chronically ill patients and the elderly have also seen a sharp increase in numbers, as they respond to the needs to an ageing population.

Major changes are thus currently underway within the hospital sector. In addition to the above trends, some Member States (in particular Germany and Belgium) have taken cost containment measures which imply a reduction in the number of hospitals and an increased concentration of existing hospitals into larger units. These measures were based on the observation that the average length of stay (and the total number of days spent in hospitals) increases the more beds were available in the country. The sector is likely to see further

changes in the 1990s as the rate of occupancy of beds is still low in many areas.

Employment by the hospital sector is difficult to measure, as it includes different categories of personnel, many of whom also exert a professional activity outside the structure of hospitals. The past trend in the number of physicians has already been described above. Available surveys on the trend in and level of employment by nurses and other specialised personnel reveal huge differences across countries, which reflect more the great diversity of structures and categories of personnel than fundamental structural differences. The total number of nurses and specialised personnel in activity by country is nevertheless reported in Table 9.

### Nursing

The rising demand for health and the ageing of the EU population have caused the number of active nurses to increase considerably, and have also led to significant changes in the scope of nurses' practice. This is evolving in two opposite directions. On the one hand, there is a shift towards more basic forms of care (care provided to elderly in residential services and the community). On the other hand, the development in medical technologies and the changes in the case mix of patients creates a demand for highly specialised, more technical forms of care in acute hospitals.

The fact that training and education systems still vary significantly across countries, as does the regulatory environment, means that there is little cross-country mobility of health personnel (although there is a large body of Community directives which aim at facilitating workers' mobility). In the nursing sector, this implies that there are shortages of staff in certain countries, namely in France and Portugal. Elsewhere, shortages did appear at some point in time due to the rapid growth in demand for nurse care, but this has now either been re-absorbed, or demand itself has been curbed through regulatory measures. In Belgium, for example, the shortage of nurses is regulatory induced, in that the legal staffing norms (number of nurses per 30 hospital beds) are very tight (for cost control reasons).

Notwithstanding the fact, contrary to general belief, there is no structural shortage in labour supply in this market segment, there is still in many countries an inadequacy of demand and supply. This problem could be solved without increasing total health costs by using less-qualified caring personnel for a

range of supportive tasks and for logistics aid, organising in effect a redistribution of the workload.

### Pharmacists

In 1994, there were 188 662 pharmacists in activity within the EU. This represents roughly 2.5 % of total health employment. Contrary to the trend in the number of physicians, the number of pharmacists has tended to remain stable in past years.

In 1994, there were 108 135 pharmacies scattered over the EU. On average, each pharmacy covers a population of about 3 200, the number varies significantly across Member States (Table 10).

Similarly to other segments of the health market, the market for pharmacies is still heavily regulated at the national level. There are two EU directives which set minimum standards applicable throughout the EU. Directive 85/432 aims at an increased harmonisation of the legislative, regulatory and administrative framework for the activities of pharmacies, and Directive 84/433 relates to the mutual recognition of diplomas, certificates and other titles and includes measures aimed at facilitating the establishment of pharmacists in the EU. There remain, however, important differences in the national regulatory environment which prevent pharmacists from circulating freely across the EU. These relate to the right of ownership and to the number of businesses that are authorised. In certain Member States, for example, pharmacies have to be owned by a pharmacist. This is the case in the Netherlands, Spain, Italy and Portugal. In France and Denmark, a license is required. In Luxembourg, there is a mixed system with some pharmacies owned by pharmacists coexisting alongside state (or personal) concessions giving the pharmacists a license to practice. In Belgium, more than 40 % of the pharmacies belong to a commercial organisation, and there are others owned by non-pharmacists. Belgium, however, requires a dedicated pharmacist to run the business. In Ireland also, ownership and operation are dissociated. A non-pharmacist can own a pharmacy provided that he/she gives its management to a pharmacist. The same applies to the UK, where only one third of the pharmacies are owned by individual pharmacists.

A second barrier to establishment is the fact that, in most Member States, the number of pharmacies operating is regulated, generally on the basis of population density or geographic criteria. Belgium for instance has the highest number of pharmacies per capita, and the possibilities for creating

**Table 6: Health care services

Source: OECD estimates

new ones are very limited. A unit must serve at least 2 000 inhabitants in areas with population of less than 7 500 inhabitants; 2 500 inhabitants in cities with population of between 7 500 and 30 000, and 3 000 in cities with population of more than 30 000 inhabitants. Of course, there can be derogations based on population density in the area. Similar criteria apply in Spain and in most southern Member States (including France). In the northern countries, in contrast, in particular in Germany, Ireland, the Netherlands and the UK, the opening of a pharmacy is not subject to such limitations. The pharmacies nevertheless have to be registered, with the registration body often acting as an advisor, although it is not entitled to reject applications on competition grounds.

Other regulations apply, for instance with respect to the preparation of medical products for human or animal consumption, to the delivery of products or to the provision of certain services (advice to customers) or even to the list of products which can be sold in pharmacies.

Finally, mainly in the southern Member States, the profit margins by pharmacists are under regulatory control. This is part of the government control policy on pharmaceutical product prices. The margins to be applied in each country typically depend on the price of products and their nature (prescription pharmaceutical or OTC). Differences in pharmacists' profit margins, in VAT rates and in pharmaceutical product prices across the EU thus explain a large part of the observed dispersion in pharmaceutical product prices to consumers.

The fact that margins are set by category of product, however, creates an incentive for the pharmacist to sell the most expensive drugs. In France, there have even been cases of pharmacists boycotting new products on the basis of the fact that they were cheaper than their substitute (this was the case with a soluble aspirin introduced in competition to Aspégic, at a 20 % lower price a few years ago). Increasingly, thus the system is being revised in order to avoid this type of distortion.

In the UK, the Department of Health does not exert direct price control on medicines, but there are non-statutory agreements negotiated between the government representatives and the pharmaceutical industry. Recently, a "blacklist" of products has been introduced as a threat on those companies which do not respect the terms of the agreements or refuse to cut prices. (In 1993, a 2.5 % price cut was part of an agreement between the department of health and the negotiating committee of the association of the British Pharmaceutical Industry (ABPI)).

In France, measures to curb spending on health have included a surtax on advertising of pharmaceutical products aimed at curbing volume growth: the tax has been increased from 5 % to 9 % over a two year period. Another measure introduced in France at the beginning of 1994 relates to the publication of "Références Médicales Opposables" (RMO), which give guidelines to doctors on the way they should prescribe medicines to their patients under various sets of circumstances. Should these "norms" or recommendations not be followed systematically, the doctors can be fined, or incur other penalties (déconventionnement). The publication of the RMOs in early 1994 did, in fact, lead nearly overnight to a significant reduction in the prescription of certain drugs, in particular antibiotics and anti-ulcer drugs. Other measures under discussion in France at the beginning of 1994 but not implemented in the end included the definition of a given (reimbursed) price per therapeutic family of products. This system is currently applied in Germany. Difficulties arising with this system were the definition of consistent therapeutic families and the fact that the German experience has shown that it can induce a slippage of expenditures on pharmaceutical products that are excluded from the reimbursement system. The net effect could thus be a growth in overall spending on health, as opposed to a decrease. In view of the above difficulties, no single reimbursable price per category of product was implemented but instead the margins on pharmaceutical products have been modified so that they are now inversely proportional to the price of the drug.

In 1993, France had already reduced the rate of reimbursement by 5 points in 1993, which already led to a significant fall in health spending. As a result, in the first four months of 1994, the turnover by pharmacies in France was down by 3 % in nominal terms.

More generally, past measures to control spending on medicines in Europe have typically taken the form of:

- price controls on prescription drugs;
- increased patient co-payment;
- the removal of products from reimbursement;
- restrictions on minor ailments being supplied with prescription treatment.

Given that the income earned by pharmacists depends on the authorised margin and on demand for pharmaceutical products, all the above measures have caused a fall in sales and incomes on prescription dispensing, the traditional activity of pharmacists. Prescription sales indeed still account for about 80 % of the total turnover of pharmacists. These measures have

Source: OECD "Health Systems"

also created strong incentives for pharmacists to diversify away from prescription pharmaceuticals into OTC drugs, cosmetics and other general health products.

Another development under consideration is to increase the responsibilities of pharmacists in providing medical advice, hopefully reducing in that way the number of primary visits. Surveys conducted within the EU have shown that over 75 % of the patients indeed wish the pharmacist to hand over their prescriptions and engage in some advisory activity.

Such development could, however, have important consequences on the organisation of the sector and on the pricing of services. It is important to note that this trend is partly in conflict with another trend within the pharmacists business, which is to increase the emphasis on sales of OTC products on which margins are not controlled. For pharmacists to undertake an advisory role in an effective way one would expect that the service would have to be remunerated appropriately. This will be difficult to achieve given the ongoing trend towards increased distribution of non-prescription drugs by retail stores, which puts downward pressure on the margins of these products.

### Impact of the Single Market

The health sector is regulated at national level. To date, very few measures have been adopted to further integrate the hospitals markets. Among the measures which did have some (albeit limited) impact on the sector are those related to the freedom of establishment and the free movement of persons. Other relevant measures include the problem of patients protection, which has led to the adoption of the notion of fault presumption, while the problem of environment protection has led to the resolution on hospital wastes. On the other hand, training and education programmes have contributed to improve the qualifications of employees. However, while some other integration measures have been realised, there has been so far been little evidence of positive effects coming from them. Increased cross-border movements have not led to price harmonisation, and the liberalisation of public procurement seems to have had little impact on the sector.

Remaining barriers to trade are important, and mainly reflect the fact that social security systems differ significantly across countries. Further harmonisation of the health market is conditional on some approximation of national health systems.

### REGULATIONS

The health system is organised on a national basis, with still wide variations in the organisation of the supply and the

sources of financing across countries. The broad lines of the various national systems are briefly described below.

### Belgium

In theory, all Belgians have health coverage through social security. Social insurance has two general schemes: for paid workers and for self-employed. Self-employed have the choice of whether they wish to have full or partial coverage. Companies in Belgium are increasingly offering group insurance to their employees, included in employment benefit packages. These cover extra hospital costs, such as private rooms, other comforts and non-reimbursed medical products.

The social security (public insurance) system is itself financed by contributions from employers and employees and by State subsidies.

Primary health is provided by private general practitioners, pharmacists, dentists and nurses. There are health services (private or public) which are delivered at home. The patients have free access to health services, and free choice of the practitioner whatever the financial circumstances.

Primary health is paid for (and reimbursed by the insurance) on a fee-for-service basis. In case of poverty or insolvency, health is provided by social assistance centres.

Most Belgian hospitals are either private (non-profit) organisations, or belong to the public sector (this applies mostly to the social assistance centres run by the communes). Private "for profit" hospitals have been largely forced out of the system by hospital funding regulations which prevent them from benefiting from state subsidies for equipment and construction. In addition, there are various preventive medicine services, such as industrial medicine and school medicine.

### Luxembourg

The public health system in Luxembourg is organised through a national compulsory social security scheme. There are nine different insurance companies.

The insurance system is financed by assessments from employers and employees, and by contributions from the State. Primary health is provided by private general practitioners, pharmacists, dentists and nurses, and, as in Belgium, there are health services (private or public) delivered at home. The patient normally has free access to health services, and free choice regardless of his/her financial situation. For different examinations, however, the patient needs the approval of the medical control.

Primary health is paid directly by the patients, who are then reimbursed by the insurance company. For hospital expendi-

tures, in 1993 a budget system replaced the previous "fee for service" system, though the physicians fees are not included in the hospital bills.

Hospitals belong either to the private sector (mostly congregations) or to the public sector (run by communes). Others are institutions of public utility.

### Denmark

In Denmark, public health schemes cover the entire population and only allow for limited private insurance schemes, in connection with user payment (in the area of medicine and dentistry). General services provided by doctors and hospitals are free of charge. About 85 % of the financing of the Danish national health service comes from general taxation. In addition, the counties and municipalities are entitled to levy their own taxes. The health system itself is organised at two levels: at county level and at district level. The 16 counties are responsible for running and planning the major health services, such as hospital services and primary health services. The 275 districts, on the other hand, are responsible for the running and planning of most of the social care systems and for certain local health services (such as home nurses, school health and dental services).

In 1989, there were 111 hospitals in total, 300 pharmacies and 13 600 physicians, as indicated in Tables 7 and 9. There were only two private fee-charging hospitals representing less than 0.5 % of total hospital beds.

### France

Almost every person in France is covered by health insurance. The financing of the health system is based on the principles of national solidarity and mutualisation. There are, however, different schemes reflecting a persisting degree of corporatism, which makes itself felt in the varying degree of coverage available to different categories of employees. As in Belgium, thus, some workers pay additional health insurance schemes to have full reimbursement for all services.

The major portion of health costs is paid by the Social Security system, the remaining part being covered by the individual or by optional mutual insurance schemes. The system itself is funded by compulsory contribution from the employees and their employers.

Provision of treatment outside the hospitals can be provided either by physicians practising privately, chosen freely and paid by the patient, or by public dispensaries which are staffed by salaried physicians. The general principle concerning medical consultations is that the patient pays on a fee-for-fee basis,

after which the Social Security system reimburses a percentage of the expenses incurred.

The French state's commitment to the national hospital programme is revealed by the fact that there are public hospitals (centres hospitaliers) in every major town in France. About 40 of these are very large complexes with university affiliation. Private hospitals are numerous but small in size. Roughly 54 % of the 200 000 beds in the private hospital sector are owned by commercial enterprises, 2 % of these being psychiatric institutions. Private hospitals concentrate on the more profitable therapies, as illustrated by the low percentage of long stay beds in the private sector. The share of the private sector is nevertheless progressively increasing in this market segment.

### Germany

Approximately 90 % of the population is insured under GKV, the statutory health insurance system which covers all the low and medium income earners. High income earners may join voluntarily. In practice, the rest of the population (approximately 10 % or seven million) are either privately insured or receive supplementary benefits with automatic health insurance coverage. Patients are free to select the doctor and hospital of their choice, and access to health is available to all citizens, regardless of their financial insurance status.

The statutory health insurance schemes are financed by matching contributions from insured employers and employees. Hospitals are financed by a combination of government subsidy and statutory and private health insurance sources.

The provision of health in Germany is thus primarily a public function, but can be carried out by local authorities or independent non-profit and private facilities. Following the October 1990 unification, East Germany took over the guidelines of the West. This has, however, required a difficult adaptation process. Full harmonisation will not be completed for another few years.

The state and local governments account for less than half of the hospitals. Private hospitals compete on an equal footing with the public hospitals, as they obtain funds through a dual financing system. Funds for capital items are provided by the state and local governments, while other income comes from earnings against treatments. The fees are agreed between hospitals and local sickness fund organisations, and are calculated on a fee per day basis. In 1989, Germany (west) had 3 046 hospitals. The number of hospitals is now declining.

## Greece

Greece's National Health Service came into being in 1983, replacing the previous social security system. The new system puts greater emphasis on prevention and attempts to remove social inequalities in health services provision, as well as curbing the growth of the private sector.

Approximately 95 % of the population is covered by an insurance fund. In total, there are 80 funds providing health coverage, four of them being particularly important. The largest is the IKA (which provides coverage to 2.56 million employees and to 2.62 million of their families, or 26 % of the total population). Second is OGA (which covers 1.91 million agricultural workers and 0.59 million members of their families). TEBE follows with 0.48 million artisans and 0.82 million members of their families, and the government has the fourth largest fund, covering 0.19 million employees directly plus 0.27 million members of their families, as well as retired civil servants). Voluntary hospitals and private clinics are licensed to provide additional health services.

Most of the expenses on health are reimbursed by the State. For hospitals, the share of government financing is 80 %, with another 10 % by insurance companies and the rest from other sources.

All employees in Greece have to be insured with a governmental insurance organisation. Nevertheless, since the quality of services offered by the public sector is not always up to expectations, patients frequently contribute out of pocket expenses for private care or rely on supplementary private insurance.

## Ireland

Ireland's national health system is financed from taxation and from the government's Health Insurance Scheme. One fifth of the population is covered by additional private health insurance. The Department of Health allocates funds to the eight boards which provide health services on a regional basis.

Access to health services is divided into 2 categories of clients: some have access to the full range of services, whereas the remaining are entitled to free in-patient hospital services in public wards, to most specialist out-patient services, a maternity and infant health services and a drugs refund scheme.

In recent years, the Irish national health system has made efforts to contain health costs, which amounted to 9.3 % of GNP in 1991. In particular, a programme of rationalisation of the acute hospital system has been carried out, involving the merger of small hospitals with larger units. The basis of

this rationalisation has been the concentration of expensive equipment, facilities and scarce skilled staff at large units in order to maximise the benefits for patient care.

Because Ireland's population is much younger than the EU average, the structure of demand for health services is very different from that of other Member States. Part of the reorganisation of the sector has thus also taken the form of a decrease in the number of in-patient facilities, and an increase in day care and out-patient facilities reflecting the latest trends in the delivery of hospital services.

## Italy

The Italian National Health Service (NHS) came into being in 1979, replacing a sickness fund service. The health services are financed by government funds other than taxation, and by general taxation. In effect, there are four financing mechanisms: each independent work or employee must pay in a set quote. Each employer, whether public or private, must pay an additional sum for each of his employees. A surtax is paid by independent workers which is called the health tax. Any additional sum needed is covered by the national government.

Many Italians are increasing their health coverage through private insurance. There are approximately 1.5 million private policies providing coverage to approximately 3.7 million people. Generali is the main insurance group involved in the private insurance system in Italy, accounting for roughly 14 % of private insurance contracts. RAS, SAI and Fondiaria have market shares of 9 %, 7 % and 5 % respectively. Access to health services is available regardless of financial of insurance status of the client.

Health is organised on a regional level. Of the private hospitals, 90 % are permitted by the national health system to provide services to national health service patients. They work within a convention made by local health units (USL).

A law of December 1991 requires that for 1 000 inhabitants there must be 6 beds, one of which must be for rehabilitation or long-stay. This standard applies to public and private hospitals alike. Private hospitals are paid on a daily rate basis. Those which are accepted in the plan are reimbursed by local health units for services that they provide to patients insured under the national health service plan.

## The Netherlands

Health in the Netherlands is decentralised and organised to a large extent by sickness funds and local authorities. This reflects the fact that, historically, the system has developed through the efforts of voluntary private organisations. At present, there are more than 70 sickness funds. Not every person has the same rights concerning coverage. Persons with above average incomes for example are not entitled to full reimbursement by the national system. Private insurance is available for those not covered by the general federal programme. Regarding payments, fees and costs of products must be paid by the patients, but most are recoverable from the ziekenfonds retrospectively. Reimbursement rules also vary from one locality to another.

The system itself is financed from personal contributions by employees, by contributions from employers and government subsidies.

Local and regional authorities are responsible for ensuring that the health services they provide comply with national standards.

Public and privately owned hospitals operate under the same conditions. A part of their budget is provided by the Ministry of Health, and the rest comes from reimbursement given by the ziekenfondsen (sickness funds).

The Netherlands has 752 hospitals, most of them private, although most are owned by religious groups or non-profit organisations. Most new major private hospital investments have been made by Dutch universities. Community care is provided mainly by the Cross Associations (private and religious in character), which run many nursing homes. The Netherlands has the most developed nursing home system in the EU. General practitioners provide most primary care. They are nearly all self-employed. Some have grouped to form health centres and obtain subsidies from the central and local governments.

### Portugal

The Portuguese health system is largely run by the public authorities. In 1990, a new health law was voted, which changed access and quality of the services in a major way. The administration of the services is organised at central, regional and local level: central authorities are responsible for planning and evaluating services, for developing norms for the functioning of institutions and services, and for carrying out technical inspections. Regional authorities are to implement health policy, to carry out certain investigations and for training and research in the health sector, among other. It is, however, the local bodies which are responsible for running the health centres.

The National Health System is funded from the State's general budget. The cost of assistance within the public health organisations is to a large extent met by the National Health Service. There is, however, still a private sector which operates alongside the national system and which operates according to different rules.

During the 1980s, significant investments were made by the Portuguese authorities in order to upgrade the hospital sector. Several major new hospitals were thus built, in order to ensure that the population had a health service comparable to the rest of Europe.

At present, private hospitals contribute about 20 % of the total number of beds, or about 54 090 in 1990. Many of these are run by institutions of religious and social character.

Some specialised services such as dialysis centres have been set up by private companies, such as WR Grace.

### Spain

In Spain, there is a mixture of public and private health systems, the public one predominating. The core of the system is the national health insurance scheme which covers approximately 97 % of the population. Participation is compulsory for wage earners. The social security system can contract services of other public and private hospitals as supply is not sufficient to meet demand, such that there is a strong private system which provides secondary coverage to millions of people.

Some 85 % of the financing of the system comes from the Central Administration, and 15 % from the Territorial Administration. Of the 85 % from the central administration, 80 % comes from general taxation and only 20 % from social security (through social contributions).

The major Spanish public-owned hospitals have either regional or municipal status. These are supplemented by private hospitals owned by the Red Cross, universities, religious concerns and private companies. The number of private hospitals is much greater than the number of public ones. However, in terms of number of beds, private hospitals account for only about one third of the total hospital capacity.

Private enterprise hospitals of foreign and local ownership account for about 15 % of all beds. Many have closed since the late 1980s, owing to the Ministry of Public Health and Social Security's policy to make the public hospitals more efficient by increasing bed occupancy rates. However, this has allowed many new investors to establish themselves by buying up financially troubled private hospitals.

Towards the end of 1980s the British private health group, BUPA (a provident society) decided to invest in Spain. It owns Sanitas, one of Spain's major private health groups. Another major group is Agbar-Salud.

### United Kingdom

The United Kingdom's National Health Service (NHS), which replaced a partial mutual insurance system in 1948, provides

core coverage for the British population. The NHS is funded almost entirely by taxation: most treatment is free, and only 20 % of prescriptions attract the small flat rate charge. There is a strong primary care system based on General Practitioner (GP) partnerships contracted to the local Health Authority, funded on a per capita basis. There are moves underway to expand primary care further, with GP partnerships building health centres with a mixed professional staff.

Secondary care in the NHS is purchased by local Health Authorities, although some budgets can be delegated to GPs, allowing them to exercise choice for their patients. An increasing proportion of secondary care is purchased privately: 19 % of the population has private medical insurance. Roughly 20 % of secondary care is privately provided, but in some specialties where NHS services are poor, the share is much higher. Long term residential and nursing care is purchased through a mixture of private and public expenditure, although by far the majority of provision is private.

Recently the government has attempted to introduce competition into the public health sector. This seems to have produced some innovations in service provision but has been controversial. It is unclear whether perceptions of the quality of service provided by the NHS have improved overall.

---

## OUTLOOK

---

Future demographic developments in the EU will pose and additional challenge to public authorities as they will likely translate into continued rapid growth in demand for health. Demographic trends are indeed dominated by a low birth rate in nearly all EU Member States, increased rates of participation of women to the labour force and the ageing of the population. To this upward influence of demographic changes on demand for health one should add on-going progress in medical science, which also puts upward pressure on expenditures.

The regulatory environment of the sector, although it is in many countries in the mist of change, is still mainly national. It is not clear yet to what extent the changes currently under way at national level will lead to a greater harmonisation of health systems across the EU. In general, in seeking to maximise efficiency gains in their national systems, governments have until now followed very different approaches, not necessarily mutually consistent nor transposable from one Member State to another.

Without pre-judging the future organisation of the sector in the EU, what is nevertheless clear is that future growth in demand for these services will continue at a rate which is close to or slightly higher than the real GDP rate (about 3.5-4 % per year), while the trend in prices will likely remain severely curtailed. This will stabilise the share of total expenditures on health in total private and public expenditure spending at around 7.5 % in the long run, though with a decreased share of public financing. The latter will happen both because of the slowdown in nominal expenditure growth, and because of the efforts to curtail nominal expenditure growth, and because of the progressive reduction in the share of expenditure which is reimbursed to the patients from the public health schemes, thereby continuing the trend observed since the mid to late 1980s.

## Overview

### NACE 971, 972, 973, 974, 345.2

*Over the last decade, demand in the audio-visual sector has enjoyed double digit growth, in spite of adverse effects of economic recession. The Union's music recording business is still dominant world-wide but has suffered from recent economic sluggishness. Extra-EU trade balance with the US is heavily negative in film production. Growth in feature film production is stagnant while the fall in number of cinemas and attendance is further weakening the revival perspectives of this sector. However, overall growth prospects remain very healthy with the technological revolution currently taking place in digital transmission and reception.*

### INDUSTRY PROFILE

#### Description of the sector

The audio-visual sector groups four main sub-sectors: film production (NACE 971); film distribution (NACE 972); cinemas (NACE 973); radio and television broadcasting (NACE 974). The music recording sector, although being part of NACE 345, is also considered within this chapter.

There is a growing interconnection between these activities:

- The development of TV films and videos is at the heart of the difficulties the cinema industry has encountered over the past few years. This phenomenon is accelerated by growing VCR penetration across the Union (56.7 % of TV homes in 1993) and by the explosion of private TV channels, notably satellite and cable, in many countries. 1993 penetration of TV households was 6.6 % and 19.5 % respectively for satellite and cable.
- A more recent "bridge" has appeared through video-discs, a medium that allows the music recording sector (and its key European players) to offer complete audio-visual entertainment to its existing customers. However, development has been slow, with player sales a mere 110 000 units throughout Europe in 1993.

#### Recent trends

Although information abounds about audio-visual sectors, consistent data are rare. The specialised IDATE Institute estimates

that the leading 100 audio-visual companies world-wide have achieved global sales of 122 billion ECU in 1993.

Broadcasting represents the bulk of the market, followed by cinema distribution and integrated companies (in both broadcasting and cinema). Music recording holds only a tiny portion of the global audio-visual market.

An illustration of this global approach is the ongoing concentration of the sector: the Top 50 Companies grew at a 10 % rate between 1992 and 1993, while the Top 100 grew at a 16 % rate, in search of critical mass business or country-wise.

There has been an increasing move towards television film viewing, in the context of diminishing cinema attendance and reducing numbers of cinemas - from 23 300 screens in 1983 to 17 400 in 1993 - as well as increasing TV and VCR penetration. The decline in cinema viewing appears more recently to have stopped in 1993, with the main markets (France, Germany, the UK and Italy) stabilising each at around 115 million spectators. However, a 22 % drop in attendance is reported from 1983 to 1993 in the EU.

Film production has been slow to develop in the Union. 520 feature films were produced in 1993 against 450 in the US, but film production investments were respectively 960 million ECU and 3 600 million ECU. European production continues to be affected by the importance of US films, which have been stable over the past years at 73 % of EU's cinema revenues. Lately, the number of EU co-productions has increased from 32 % to 36 % of films in 1993 and this can be seen as an encouraging move towards a business rejuvenation.

By contrast, a real explosion of TV broadcasting has occurred in Europe, following deregulation in the 1980's. The number of TV channels grew from 40 in 1981 to 165 in 1993 (129 in the EU alone), more than 50 % of which were private.

Although 1993 was a difficult year for the music industry, with a 2.5 % decrease in retail sales, growth is still to be found in markets where CD penetration remains low (Italy, Spain, Portugal, Greece) and significant hopes are placed in the development of new markets, notably in Eastern Europe.

#### International comparison

In 1993, the EU had a 32 % share of the world audio-visual market, behind the USA (37 %) but in front of Japan (25 %).

In the period 1992-93 the USA performed very well, with a 23 % increase in sales. In contrast, growth in the Japanese

Source: IDATE

market slowed to 10 % and came to an halt in Europe (1 %), partly as the result of the crisis of public TV broadcasters.

### Foreign trade

Overall, the European audio-visual industry has a negative trade balance with the United States, which grew from 2 986 million ECU in 1990 to reach 3 102 million ECU in 1994.

In the case of film production, this has partly been the result of a number of structural handicaps affecting the European film industry, notably the reduced intra-EU circulation of audio-visual products. The persistence of such disadvantages continues to make US products more attractive.

For some sectors of the industry, customs figures are less relevant: music record companies, for example, organise manufacturing independently of market location. In addition, individual country situations vary (e.g. in France, Greece and Italy, national recording artists comprise 40-60 % of the market).

Intra-EU trade remains relatively limited, though some countries are more favourably inclined toward European products than others: for example, France and Italy are significant importers of other European films (typically between 30 % and 40 % of their respective markets, based on distributors' share of box office revenue).

## MARKET FORCES

### Demand

The world audio-visual industry has grown by more than 11 % yearly since 1990. In Europe, this growth has been fuelled by a number of factors:

- increasing penetration of equipment (still below US or Japanese levels);

- technology changes bringing in new equipment (e.g., CD's) or new transmission methods (e.g. cable, satellite, HDTV);
- more hours per day dedicated to audio-visual entertainment (though films, TV and music demand has been undermined by the rise of electronic games);
- diversification of income sources, notably the development of the Pay-TV and of subscription-linked revenue;
- the commercial dynamism of producers (particularly the Americans) and the aggressive marketing of distributors such as HMV or Virgin Megastores which have helped push music/video demand.

In addition, consumer demand is characterised by an increasing sophistication in terms of quality of service and levels of choice. This development is, in turn, being encouraged by the revolution in equipment types, transmission and reception methods.

While audio-visual sales have grown overall, there has been a shift in balance of sales which reflects evolving consumer tastes, technology changes and price/quality trade-off:

- Between 1983 and 1993, average cinema admission per head dropped from 2.54 to 1.94 (1.71 in 1992) while VCR penetration jumped from 10 % to 57 %.
- Similarly, music recording sales in value grew by 8 % per annum between 1989 and 1993, driven by a 24 % per annum increase in CD's against a 43 % decrease in LP's.

An attempt to size the audio-visual market - independently of company sales - has been made by IDATE and confirms the overall clout of the US versus the EU in all areas except TV license fees, due to important public broadcasting.

**Table 3: Audio-visual services**  
**Market strength by region, 1993 (1)**

### Supply and competition

Major changes in the industry environment are leading to a restructuring of supply within the European audio-visual market.

These developments include deregulation (for example, that of television in the 1980s or even more broadly telecommunications), technological innovation (cable TV, Laser disc, DCC as well as HDTV) and the increasing capital intensity of the audio-visual industry (More and more essential to anticipate successfully the development of multi-media).

On the one hand, high growth sectors attract new entrants, often from within other media sectors. A striking example of this has been the explosion of broadcasting channels - in particular private, cable and specialist stations - since deregulation.

In addition, investment requirements and economies of scale are increasingly driving industry consolidation across Europe, despite the continued existence of specialised independent companies (e.g. the private music labels). There is an increasing development of multi-media audio-visual groups emulating the US "majors" (e.g. Bertelsmann-D, PolyGram-NL) and large industrial groups (e.g. Bouygues-F) investing in the sector.

### Production process

The production process and technological development play a key role in the audio-visual industry as major drivers of future demand.

An innovation which is already having a major impact on the different media - and will have a significant influence on developments in the next decade - is the introduction of digitalised pictures and sounds.

In the music industry, Philips's Digital Compact Cassette (DCC), Sony's MiniDisc and digital cable radio transmitted directly are important new technologies being developed to rival the CD.

The development of High Definition Television (HDTV) is expected to lead to a transformation of the whole chain from film production to reception and will have an impact on industries and sectors outside the realm of the audio-visual.

HDTV is closely linked, financially and commercially, with three sectors: telecommunications consumer electronics, professional equipment and the components industry, where the USA, Japan and Europe have different strengths.

Beside HDTV, another fast developing market is 16:9 wide-screen TV. In 1994, 150 000 such TV sets were sold, and 430 000 are forecast to be sold in 1995. Already 22 TV services operate in 16:9 in eight Member States, with 30 000 hours of 16:9 programming to be transmitted up to 1 July 1995.

The introduction of HDTV services is no longer the immediate objective. Instead, there is a consensus among market players that the introduction of the HDTV screen format - 16:9 wide-screen - is more strategically important and achievable. The advantage of 16:9 as a policy focus is that it bypasses the debate on technologies. 16:9 can be delivered using analogue or digital technologies

Innovations in the audio-visual industry also have an impact on large computer groups which, for some time, have been operating digital systems. These groups are investing currently in research and development for a new tool, the multi-media, capable of treating sound, image and text. Apple, for example, has already joined forces with Sony and IBM for research into a product combining video and microcomputer.

The term multi-media should include any means of delivery, whether via a network (e.g. cable, satellite, telephone, over-the-air) or via some form of packaged media (e.g. floppy disk, ROM cartridge, compact disc, smart card/memory card). However, the most likely commercially attractive candidate for immediate consumer market development is the compact disc (CD).

In spite of standardisation issues, strongest sales have been taking place in the market for multi-media computers, i.e. personal computers with CD-ROM drives attached or built-in. Typical applications are the Photo CD, launched in 1990 by

Kodak and Philips and the Video CD standard, announced by Philips, Matsushita, JVC and Sony in 1993 as a common format for the storage of 74 minutes of linear full motion digital video.

## INDUSTRY STRUCTURE

### Companies

The EU accounted for 32 % of the top 50 companies in the world in turnover terms. Within the EU, Germany is in the lead position with an 11 % share, followed by the UK, which accounts for 8 % of turnover of the top 50 audio-visual companies.

Within the different European countries, levels of industry consolidation vary. Italy derives a 4 % share from two large groups, Fininvest and RAI, whereas 4 companies in France make up just under 4 %. Germany has 6 companies in the top 50, as against 5 in the UK. Indeed, two German groups, ARD and Bertelsmann, rank amongst the top 15 world audio-visual enterprises.

The increasing importance of European groups - which, as a block, had overtaken the US in 1992 - is in part due to the growing importance of private broadcasting. Nevertheless, no one group in European film/video/TV as yet rivals the global approach of the US "majors", which in part explains the EU trade deficit in this sector.

In the music recording sector, however, European companies have not only been successful in taking a significant share of the world market (40 %) but also account for 3 of the top 5 global companies, with Sony and Time Warner.

### Strategies

Strategies of the major European audio-visual groups have focused around the need to achieve critical mass, the desire to diversify into new growth areas and the aim to secure access to larger international markets. A series of important mergers and acquisitions have taken place, though many have been limited to a national scale (e.g. those of Bertelsmann and Fininvest).

Within each media segment, the specific drivers behind this consolidation have varied. In music recording (e.g. PolyGram or Thorn EMI) and in cinema film distribution (e.g. UFA or Rank Odeon), expansion strategies have derived from the need to secure a strong local and international European network. In TV and film production, a recognition of the need to counter American professionalism and domination has prompted much of the restructuring.

### Impact of the Single Market

The measures related to the audio-visual services sector within the Internal Market programme have not yet been fully implemented. Major problems remain when trying to overcome language barriers, piracy and standardisation. The internal market has also not yet provided the Union with the necessary

instruments to spawn a real common information area. The complete integration of the EU market for audio-visual services relies on the further development of infrastructures, the liberalisation of services (i.e. Member States should have less restricting licensing regimes) and the enforcement of competition, as well as increased competitiveness on the part of the film and TV programmes production industry.

## REGULATIONS

The draft directive on the use of television transmission standards has reached a common position in the Council. Unlike its predecessors (the so-called MAC directives), there is no longer a single objective (HDTV) with a particular technical approach mandated. The intention is to provide a regulatory framework in which the market players can introduce new services of different kinds: for instance, 16:9 widescreen television using either digital or analogue technologies, etc.

## OUTLOOK

While economic recession has undoubtedly had some impact on growth in demand, the audio-visual industry overall has enjoyed double digit growth over the last decade. Rapid technological change and the increasing convergence of the audio-visual market with other sectors such as electronics and information technology make precise forecasts difficult, though prospects continue to look very positive.

The European audio-visual industry is facing a number of key challenges in the countdown to the twenty-first century. These include the need:

- to build a European production industry which can seriously compete with the commercial and technical professionalism of its American counterparts
- in broadcasting and in music recording, to capitalise on a strong position in the home market (broadcasting) and on a world scale (music recording)
- to remain at the forefront of the technological revolution in transmission and reception (including digital systems, HDTV and multi-media tools).

# Film and video

## NACE 971, 972

The European film industry is dominated by two long-term trends which deeply influence its current and prospective financial situation: firstly, the supply of feature-length motion pictures as well as fictional TV works is facing ever increasing competition from American producers in terms of both cost and quality of releases and public acceptance; secondly, demand for films is moving steadily away from public consumption in cinemas towards more individual access via TV or VCR.

Over the past few decades, the European film and video industry has faced rapidly evolving developments in the marketplace: decline in global film output, lower short-term returns as a result of diminishing attendance in cinema houses, deferred revenues from TV and video sales, and reduction of production costs to levels offered by competing countries.

In response to these changes, most European players in the industry are currently restructuring their activities: merging to set-up European groups; integrating the process of financing, manufacturing and distributing movies; combining international trade (importing and exporting films or technical skills) into local operations; as well as monitoring the commercial and financial impact of distributing through different channels.

### INDUSTRY PROFILE

#### Description of the sector

The film and video industries involve three types of activity:

- Production: the financial and artistic conception of motion pictures and TV fictions is project-managed by "producers" from inception to release. European producers are concentrating both horizontally (through alliances) and downstream (through integration of operational/commercial activities).
- Manufacturing: the physical making of films is supported by a host of specialised technical contractors: studios, laboratories, equipment manufacturers, and sound specialists.

Figure 1: Film and video  
Total volume broadcasted of TV fictions and films in the EU

(1) Estimate  
Source: CNC, estimated by LEK

- Distribution: the commercial release of films is performed by cinema operators (either networked or independent), by video publishing companies and through portfolio management of stocked works.

These activities are today frequently consolidated through the development of large groups combining production and technical capabilities (Granada, Bavaria, SFP) or production and distribution (Gaumont, MGM). Multi-media conglomerates are also seeking to add value to their distribution assets by entering into production (Bertelsmann, Canal+, Bouygues, Polygram, Fininvest).

Overall, in 1993, the European film industry has estimated total sales of 2.7 billion ECU, second only to the American movie industry (estimated total sales of 4.4 billion ECU).

### Recent trends

The European film and video industries continue to be affected in a number of different ways by two long-term trends: the increase in international competition and the move towards more individual viewing on TV screens:

#### Production

The overall production of feature-length motion pictures in the EU is stagnating around 500 films per year. Diminishing attendance (-36 % between 1982 and 1992) and the related reduction in the number of cinemas (-31 %) undermine prospects for a much larger European offering.

The market share of imported works is huge (83 %) and still increasing (Table 2). Over the last ten years, American films have doubled their market share in France and Italy, while increasing it by more than half in Germany, Belgium and Spain. At the current time, American productions represent 73 % of EU cinema revenues, with more than 80 % of the proceeds in Germany and the UK.

This decline runs parallel to an increase in the production of fictional works for television (e.g. a doubling over the last ten years in France), which in turn has served as a spearhead

for a growing involvement of multi-media groups in movie production.

#### Manufacturing

The manufacture of films is a sector which has remained relatively resistant to the changing market-place. The turnover for contractors to feature films is stagnant at an estimated 350m ECU, of which 70 % derives from French and Italian producers.

An increasing share of revenue emanates from fictional TV. For example, the latter accounts for 55 % of UK producers' expenditure in 1992, an increase of 11 % over 1991. Non TV-oriented contractors have frequently run into financial trouble (e.g. Cinecittà).

Despite the continuing existence of small/medium specialised companies, increasing capital expenditure needs have led to a growing trend towards acquisition of these manufacturing contractors by large financial holdings (Arnold & Richter, Rank, Virgin, Brent Walker, Tectis, VDM) or by production or distribution groups.

### Distribution

The distribution of films reflects the shift towards TV screen viewing as television is overtaking the traditional cinema houses as a channel of access to movies

Europeans are offered ten times more films by TV networks than by cinemas. Italians and Germans are offered an average of 15 to 20 films a day, the French and British an average of 4 or 5. Over ten years (1985-95) the average global EU offering on all networks is believed to have increased from 30 to 85 films per day. A similar growth rate is observed for TV fictions.

Video sales are increasing in line with VCR sales. With a 57 % rate of VCR equipment penetration, European households spend an average ECU 50 per year on video cassettes (86.5 ECU per European video household), i.e. five times the amount devoted to cinema tickets (10 ECU).

Cinema houses have stabilised their decline after a drastic reduction of both average attendance and number of cinemas. In 1992, seat sales per cinema had dropped 30 % relative to the early eighties in France, Germany and the Netherlands. Per capita film consumption at cinemas in this period dropped between 20 and 50 % in all countries but the UK where the decline had taken place earlier. These figures, however, when put in perspective over the last three decades, show a marked slowdown of the decline, in addition to a resumption in attendance in the UK. Each of the major markets (France, Germany, Italy, UK) seems to be converging toward the 100 million spectators per year mark. The recent development of multiplex theatres in certain countries is playing a significant role in the recent recovery.

### International comparison

The European situation is not unlike that observed in Japan and the US with regard to TV screen viewing, despite a dif-

ferent industrial outlook in the US. In both countries, progressive TV and VCR penetration of households has been accompanied by a decline in cinema attendance. However, in the US and Japan, cinema attendance began to stabilise in the early Seventies, a process which did not occur until recently in all European markets except for the UK.

The US film industry has aggressively expanded its export sales during the eighties. Its market share in the EU progressed from 45 % to 73 % in ten years. In 1992, as domestic sales in the US (4.4 billion USD) accounted for less than half of industry revenues, American majors continued to increase their penetration in the EU and elsewhere.

### Foreign trade

Intra-EU trade (estimated at 150m ECU) is limited in comparison with the bulk of film imports from the USA: US films sales to the EU amount to 2.13 billion ECU or ten times EU sales to the US.

Intra-EU trade is unevenly shared between countries: France and Spain are strong importers of other European films (10 % of each market); other countries (e.g. Germany, Italy, UK) devote less than 5 % of their markets to their neighbours' productions. French and British movies are favourites among Europeans, whereas Italian and German movie-makers have lost ground during the last decade. In all countries (except France), demand for European films has collapsed over the past few years.

## MARKET FORCES

### Demand

While the global demand for movies has never been as strong as today, European consumer preferences, in terms of product

**Table 7: Film and video  
EU trade balance with USA, 1992**

(million ECU)	Films

Source: IDATE estimates from MPAA, AFMA, CSO (UK)

content and viewing mode, do not favour a strengthening of national film and video industries in the EU in their current state of operation. Faced with a need for wider geographical diffusion and higher-budget films to compensate for restricted national audiences, European producers are failing to develop an appropriate product-policy.

The European audio-visual consumer, provided with an unprecedented offering of movies on TV screens, has considerably increased his consumption. It is estimated that the individual spectator watches 50 movies per year on his TV as opposed to 2 in a cinema.

This dominance of the television offering (most of it free of variable charge) is reinforced by the increase in cinema seat prices. Ticket prices have tripled in real terms in most European countries since 1955. While this has softened the impact of attendance decline on cinema revenues, notably in France, it has rendered cinema an expensive access to films, thus perpetuating the vicious circle of declining attendance.

Faced with a limited customer base in households, distributors tend to favour film releases which fit best with customer demand: The high marketing/finance budgets available to US producers (8 million ECU per film or more than 4.5 times the EU average) has helped them to focus on such aspects. Such has been the making of American box office successes and their popularity in Europe. Only in France and Italy, where the public is more attached to films peculiar to their culture, has this success been slightly muted. In both countries, the share of domestic releases is consistent with their share of box office ratings.

### Supply and competition

As the economics of film-making change with the diversification of distribution channels, players in the industry adjust their approach to multimodal viewing and the necessity to reduce financial risk through international distribution. During the seventies, American producers went through a restructuring process and are now reaping the rewards. The Europeans began the same process in the late eighties and are accelerating it in the nineties.

The key challenge to European film-makers is to develop a capacity to engineer films likely to attract a large international audience. Many obstacles have delayed the acquisition of such a skill: language barriers for German, Spanish, Italian or French films which have to be dubbed before international release, limited financing which prevents producers from in-

**Table 8: Film and video**

tegrating some ingredients of a commercial approach (expensive casting, special effects, market testing), dependence on government support (especially in France, Germany and Spain) favouring films with a more artistic and cultural content.

However, industry outlook is rapidly evolving in the nineties and the formation of large, integrated and often multi-media groups as key players is likely to increase European producers' ability to offer works with wider potential. Such groups, which integrate the various production to distribution stages, can plan their return on investment over the period of modern film development: While ticket sales are the major constituent of cash flow during the first year of a box office release, there is a gradual diversification as the film is increasingly shown via different channels (Video, Pay-TV, Pay per view, international sales).

In summary, it would seem likely that European film supply will be focused in the future on two types of production:

- low-budget, low-revenues movies reflecting the personal talent of a director (such movies also co-exist with blockbusters in American production) or a particular element of national culture; or,
- commercially conceived works which are adequately financed to sustain both the cost of commercial ingredients and a long life-cycle with a wide and international audience. The financing, casting, directing, technical making and marketing of such products are likely to lose much of their national roots and become European or European/American ventures.

### Production process

New technologies (video, digitalisation, HDTV) are being progressively integrated into the production process (e.g. synthetic imaging). This development is leading to a reduction in the technical difference between cinema and TV work. Their final impact is therefore likely to strengthen the move towards private viewing on TV screens.

The reduction in production costs is a matter of concern for producers and is a prime cause for the delocalisation of some contracted activities. The latter, when labour intensive (e.g. studio work) is sensitive to the differential in wage levels in Southern and Eastern Europe. Productivity gains in the classical sense are not expected outside limited technical operations (computer-assisted special effects, final cut and video sequences).

Rationalisation is also being forced upon distribution. Operating costs are better spread in multiplex theatres, while advertising and marketing expenses are syndicated by the large

networks. A possible future transfer to digitalized copies will also reduce the celluloid duplication cost inherent to a large and simultaneous distribution.

## INDUSTRY STRUCTURE

### Companies

In reaction to their loss of market share, European producers are increasingly organising into larger groups with some degree of control on distribution or production facilities: Although it is premature to speak of European entities, significant national groups are being created through mergers and acquisitions integrating production and technical contracting. Examples are Granada in the UK, Bavaria in Germany, SFP in France. A far cry from the American "majors" such as Time Warner, MGM or Viacom Paramount, they are nevertheless close to the stage where they can offer the financial and technical backing to truly international products.

Other large production groups have developed from the growing interest of industrial, financial or audio-visual companies in cinema investment: Canal+, Bouygues and Chargeurs in France, Kirch, Bertelsmann, Scriba & Deyhle, Neue Constantin in Germany, Polygram in the UK, Penta and RCS in Italy.

Distribution is also an area of important concentration: MGM-Pathé-Nordisk-Canon (536 screens), UFA cinema (445 screens), UGC (374 screens), Pathé Cinema (331 screens), UCI/Cinesa (319 screens), Rank Odeon (309 screens). Many of these chains are offspring of American producers who seek to secure access to the European spectator. This concentration is having the beneficial effect of modernising and upgrading the theatres, the dereliction of which had been an effect, as well as a cause, of the attendance decline.

### Strategies

The strategies of the key players and the resulting consolidation process are still very much limited to a national scale:

- In Italy, Fininvest (the largest communication group in Europe) has fostered Penta which can be considered as the first European "major" with a strategy of expanding into production and distribution throughout Europe and North America.
- In the UK, TV companies diversified early into film production. BBC Films, Channel 4, Zenith, Granada, Euston and LWT concentrate, with the music giant Polygram, much of the capacity to produce international movies, in some cases in close association with American interests (e.g. Island's World).

- In France, Canal+ (with Studio Canal+) and Bouygues (with Ciby 2000) follow the same strategy of vertical integration with a view to producing a larger share of the films and TV fictions needed to fill their programmes and thus increasing production and distribution margins. Their ultimate target is also the North American market where Canal+ is already producing movies.
- In Germany, large groups such as Kirch and Bertelsmann are following a more prudent strategy than Penta and Canal+, keeping a lower profile on the international scene. Independent producers (e.g. Neue Constantin, Scriba und Deyhle) participate financially in international (American) works without yet producing directly at that level. The latter are also reinforcing their integration of a distribution network in Germany.

Overall, the strategies aimed at expanding the network of modern, multiplex cinemas are likely to boost growth in cinema attendance, as was the case in the UK. In this respect, Pathé Cinema and Gaumont (Seydoux family), UFA Theatre, Warner Bros., MGM/Pathé and many independents are voicing the most ambitious strategies: their planned investment implies a growth of 37 % in European multiplex theatres in the next two years.

### Impact of the Single Market

The "Television without frontiers" directive has put in place a framework that seeks to allow for the development of transborder broadcasting. Likewise, the Commission work in the field of copyright protection ensures that works can be effectively protected when distributed across the Union. Both measures enhance the opportunities for the European film and video industry to benefit from the scale of the Internal Market.

In the field of cinema, the Commission is applying competition law to try and ensure that the distribution industry becomes more open.

### REGULATIONS

Public financing was introduced as early as the Sixties (the Golden Age of European film industry) in several countries to help cinema resist the new competition from TV and later its competitive disadvantage against the US "majors".

Goals assigned to public funding vary between countries: Germany, Luxembourg, Greece seek primarily to support the technical industries associated with film-making; Italy, Belgium, The Netherlands and Portugal try to foster artistic creation; Spain and France aim at both the industrial and creative goals.

Three European bodies enact the EU's policies vis-à-vis the film industry: the Commission's Media Plan (200 million ECU over three years to help national producers and technicians adopt a European scope); Eurimage, which depends from the Council of Europe (co-funding of European productions); and Eureka, an inter-governmental institution in which the European Commission is represented (incentives to use new technologies, education and cooperation with eastern Europe).

The Media program, adopted in December 1990 by the European Commission, has dedicated ECU 200 million over 5 years to the European audio-visual industry:

- Support for distribution up to 85 million ECU;
- Support for production up to 65 million ECU;
- Support for developers of new technologies in audio-visual production of 20 million ECU;
- 10 million ECU for professional development;
- 15 million ECU for development in countries with limited production capacity.

In 1994, the European Commission has carried out a vast consultation process within the European audio-visual sector. The exercise was based on the conclusions of the Green Book "Strategic options for the strengthening of the film industry in the framework of the EU audio-visual policy" (COM(94) 96 final of 06/04/1994).

### OUTLOOK

The issues that the European film and video industries will be facing in 1995 and beyond are already clearly perceptible:

- There is a need for pan-European alliances between the key players to enable production risks for films with international potential to be better supported.
- Producers, authors and technicians must create a new team approach and jointly strive to achieve a balance between the commercial approach sought by producers, while retaining the quality and personality of European films.
- The motivation behind state incentives needs to move from a defensive to a more offensive stance on the international scene, albeit continuing to support the expression of national cultures.
- Cinema distribution must continue to upgrade its service, offering a competitive alternative to TV viewing.
- Distributors need to adjust to a longer product life-cycle by better monitoring the long-term marketing of a film through its various channels.

# Television

## NACE 974

The television market encompasses three main activities: production, methods of transmission and reception and finally, broadcasting. Program production, undermined by the competitiveness of American imports, is a poorly developed sector in Europe despite support at both the EU and national level. Transmission and reception systems are constantly evolving through technological development in areas such as cable or satellite and High Definition Television (HDTV). The broadcasting industry is extremely competitive following deregulation in the 1980s and the rapid growth in the number of private channels. In 1993, total television revenues in EU reached 23 billion ECU.

### INDUSTRY PROFILE

#### Description of the sector

##### Production

Films, game shows, documentaries, series, cartoons - the television programmes which count for more than three and a half hours of European viewing time daily - are produced by independent companies and multimedia groups. The smaller independents rely extensively on service providers and specialists in audio-visual equipment to which they subcontract the technical aspects of production.

##### Transmission and reception

Televisions nowadays operate on analog transmission systems, using three different norms (NTSC e.g. in North America, PAL in most of Europe, SECAM e.g. in France and French speaking countries). Hertz transmission is the most widely used in Europe but poor reception and problems of frequency capacity have led to the development of cable and satellite.

Digital transmission services - possibly starting in Europe in 1995 - will permit many more services to be transmitted thanks to digital compression which enables radio spectrum to be exploited more efficiently for TV broadcasting. Of course, the complete transition from digital to analogue will take place over a long period, probably 20 years. It is easier in terms of technology and of spectrum availability to introduce satellite and cable digital services than terrestrial digital services. The European Digital Video Broadcasting Group has defined speci-

Figure 1: Television  
Number of hours broadcasted in EU

Source: Screen Digest

fications for digital satellite and cable which have become ETSI norms and ITU recommendations.

##### Broadcasting

Broadcasting is the responsibility of broadcasters which may operate one or more television channels. In the 1980s, technological developments and deregulation led to the increasing emergence of private channels in Europe. The number of national broadcasting stations grew from 40 in 1981 to more than 165 in 1993, of which over 50 % were private. These include pay channels, specialised channels, as well as private generalist channels competing directly with their public counterparts.

##### Recent trends

##### Production

The production industry in Europe has suffered from structural weaknesses (few mostly undercapitalised large companies) which have prevented it from keeping up with the rapid growth in broadcasting demand. Between 1985 and 1993, the volume

of programs broadcast passed from 205 000 hours to 720 000 hours.

In contrast, available European supply increased by a mere 60 %. The limited resources of small national players has reduced the possibility that catalogues will get built-up. This explains the important share of repeat showings (estimated at 27 % in 1993) and the significant development of purchases of TV programs outside the European Union (about 40 % in 1993).

Despite funding on a European and national scale, broadcasting and production obligations and Community programmes such as MEDIA, the level of European production is still insufficient, especially in some programme areas such as cartoons, drama and fictional programming (series), or creative documentary.

#### Transmission and reception

There are 127 million households in Europe of which 122 million have a television set. 20 % of TV households receive television by cable and 7 % by satellite. Major differences exist between Southern Europe where cable penetration is low (only 23 % of Greek households in cabled areas are connected, while in Spain, Italy and Portugal, cabling is practically non-existent) and more northerly member states (Belgium: 99 % penetration in cabled areas; Holland: 95 %). Satellite penetration follows a similar geographical pattern.

Finally, High Definition Television (HDTV), the new standard of television reception, promises to be the major development of the twenty-first century. Widescreen (16:9 format) and improved definition television receivers have recently entered the market: in 1994, total European sales of 16:9 widescreen TV sets reached 150 000 units (100 000 in France only, as 16:9 broadcasting started there first).

### Broadcasting

Since the end of the 1980s, increased competition has led to growing financial problems for the broadcasting channels, which have been faced with a reduction in their shares of advertising revenue. This in turn has led to the development of new services such as pay channels as well as specialised channels.

### International comparison

The Americans have the highest rate of penetration of televisual equipment in the world: 2.4 television sets per household and a penetration rate of 80 % for videorecorders. Close behind are the Japanese, with 1.5 television sets per household and

a penetration rate of 81 % for videorecorders. By contrast, the European Community averages just over 1 television per household. Videorecorder penetration is only 57 %, though there are significant country variations (Italy with 40 % and the UK with 75 %).

### Foreign trade

The EU trade deficit for program production was 1.25 billion ECU in 1992. On average, European countries import around two-thirds of fictional broadcasts. In the case of some channels, this figure is even higher (90 % for the French station M6 and 100 % for A3, the Spanish broadcaster).

American producers control some segments of television programming in Europe (notably fictional programming), though the presence of the Japanese is increasingly felt, particularly in cartoons. According to IDATE estimates, in 1992 the Americans exported 1.33 billion ECU of programs of which about 60 % was destined for the European Union. By contrast, American imports from the EU represented a mere 770 million ECU.

The trade deficit in production revolves around European producers' dependence on program demand from the national broadcasting channels, a function of their insufficient size and inability to risk investing in more speculative projects. Broadcasters, in turn, are hostage to the needs of audience maximisation, limiting the possibilities for development of programs with international appeal. European producers have therefore been unable to build up a sufficient stock of programmes to promote the export market as well as to meet growing internal demand.

## MARKET FORCES

### Demand

Despite the fact that penetration of television sets already exceeds 100 % in European households, there remains potential for growth in the installed base owing to the advent of video games and the decrease in equipment prices. This phenomenon is already manifesting itself in countries such as the UK and Spain where 50 % and 39 % of households, respectively, possess a second television.

In more recent times, the videorecorder has shown rapid growth (between 1989 and 1992, penetration moved from 43 to 57 % in Germany, from 20 to 40 % in Italy and from 35 to 56 % in France).

The effect of this development in the installed base of audiovisual equipment on demand for television may in part be counterbalanced by other factors. For example, the Institute Médiamat noted a 20 % reduction in viewing time between 1990 and 1993 by young Europeans in the 14 to 20 age range. This may be the result of the development of the electronic games market and, to a lesser extent, that of multi-media.

Television viewers are increasingly sensitive to the choice and diversity of programs (hence, the success of pay TV and specialist channels such as MTV and Eurosport) and the possibility of customising their viewing (e.g. through development of interactive systems).

### Supply and competition

The deregulation of the 1980s has led to a wide diversity of channels (four times more channels in 1993 than in 1981) and to a number of pan-European broadcasters, resulting from the development of cable and satellite TV. Channels can be grouped into the following categories:

- "Generalist" channels (e.g. ARD (DK); BBC (UK); RA1, Canale 5 (I); TF1, FR2 (F); TVE2 (E)): Principally public channels in competition with the private stations, aiming for a balance between public service (information, education, culture) and commercial appeal for the sake of audience maximisation.
- "Thematic" channels (e.g. BSKyB (UK), La 7 (F), RTL (L), Nederland 3 (NL), Eurosport, etc.): these channels tend to specialise in one specific subject such as sport, films, information.

The new areas of research and development in the supply of televisual products centre around three main axes:

- the search for increased viewing comfort and perfection, with high definition television, 16:9 broadcasting and the introduction of digital sound;
- the increase in supply of programs through the multiplication of channels as a result of digital methods;
- development of interactive methods, a veritable combination of micro-computer and CD technology.

### Production process

Despite financial and technical obstacles, the race for high definition television has started. This revolution owes much to the development of digital technology, a process of compression and transmission of binary elements.

The digital system has numerous advantages:

**Table 7: Television**  
**EU trade balance with USA, 1993**

(million ECU)

Exports USA to EU	1 330
Exports EU to USA	77
Balance EU/USA	-1 253

Source: IDATE estimates from MPAA, AFMA, GSO (UK)

- It is possible to compress up to one hundred times more information on a channel, i.e. between three to eight programs. The immediate result is a reduction in the cost of transmission of these programs.
- The information is evenly recorded (unlike with analog systems) and interference between channels presents less of a problem. This creates the possibility of broadcasting the same program on the same frequency from different points.
- Digital production, transmission and reception offer a better and more constant quality of image.
- With digital TV, it is possible to transmit programs on mobile and portable TV sets via cable and satellite, with terrestrial transmission to follow.

## INDUSTRY STRUCTURE

### Companies

#### Production

Television in UK is among the most involved in domestic productions: about 70 % of programs broadcasted for BBC and ITV are British productions. English broadcasters finance 100 % of their orders and pay a production fee of 10/12 % to producers.

In France, TV production financing is supported by producer investments, channels and CNC (Centre National de la Cinématographie). The eldest production company, SFP, is currently undergoing a restructuring process, whereas independents such as Hamster and AB Production have recently produced profitable TV fictions for French TV.

TV production in Germany is very integrated because, on the one hand, producers are often subsidiaries of broadcasting channels and, on the other hand, public channels have acquired huge studios to ensure themselves their productions.

In Italy, virtually the entire production volume is represented by Fininvest or by RAI. Independent producers difficulty in imposing their know how, with the exception of those who have previous cinema experience.

In other European countries, there are only few small operators in this field.

#### Transmission and reception

Two main types of company are involved in the development of new technologies of transmission and reception:

- Electronic groups such as Philips (12 billion ECU of turnover in consumer electronics), Thomson (4.4 billion ECU), Nokia (1.1 billion ECU) in the area of HDTV equipment.
- Cable operators developing future techniques of transmission (France Telecom, TeleWest, NYNEX).

#### Broadcasting

In Europe a hundred or so broadcasting stations figure amongst the 6 diversified communications groups:

- Bertelsmann (3.2 billion ECU of turnover in 1993) with three channels (RTL Plus, Premier and Vox), focused on the German market.
- The group Kirch (1.16 billion ECU in 1993, which holds stakes in Sat 1, Premiere, DSF, Pro 7 and Kanal Kanal also focused on the German market.
- Fininvest (2.4 billion ECU of audio-visual turnover in 1993) controls three channels in Italy (100 % of Canale 5 and Rete 4, 55 % of Italia 1). It also has involvement in the German market (21 % of Tele 5) and the Spanish market (25 % of Tele Cinco).
- The CLT (L) (1.99 billion ECU of audio-visual turnover in 1993) remains the group with the most extensive presence in Europe: 66 % of the Belgian channel RTL TV1, 25 % of RTL 4 (NL), 25 % of M6 (F), 46 % of RTL Plus (D) and 29 % of RTL Luxembourg.

Two groups are present in the pay television market: Canal Plus (F) with 1.53 billion ECU of turnover in 1993, which owns 25 % of Canal Plus Espagne, 42.7 % of Canal Plus Belgique and 37.5 % of Premiere in Germany; the Murdoch group (News Corp.) (2.8 billion ECU of audio-visual turnover in 1993) which with BSkyB has a quasi-monopoly in the UK.

Major public and private channels have generally shown substantial growth during the 1980s even if the multiplication of channels generated by new transmission modes (cable and satellite) led the sharing of advertising revenues.

### Strategies

#### Production

European producers have increasingly aligned themselves with groups in the United States. Since 1989, the number of joint ventures has developed steadily. TV channels are more and more involved in TV productions both for an operational and financial viewpoint.

### *Transmission and reception*

France Telecom, having launched the satellite Telecom 2 for broadcasting programs in D2 MAC, is currently developing transmission systems adapted to the future norms of digital broadcasting.

In the equipment market, smaller European players such as the Finnish group Nokia are hard pressed to compete with the Japanese electronics giants ( Matsushita, Hitachi, Sony). Philips has made a major commitment to the interactive compact disk. Thomson was the sole supplier of digital decoders for US DirecTV 150 channel service which started in 1994: its audiences are growing fast and other manufacturers are participating now.

### *Broadcasting*

Already present in newspapers and publishing, the Bertelsmann group has taken advantage of the opportunities presented by the appearance of the private television channels in Europe.

Kirch, which supplies most of the public German channels with films and series has also followed a strategy of moving into broadcasting via the private channels.

The lead position of the group Fininvest in private Italian television allowed Silvio Berlusconi to invest rapidly in related activities - private channels elsewhere in Europe, international film production, advertising - and to diversify into other media forms such as newspapers and publishing.

The CLT, with its eight channels in five European countries, has a clearly stated strategy: to develop its presence abroad through the generalist channel segment.

Canal Plus is the only operator to have concentrated principally on its original core business: pay television. Today, its strategy is one of vertical integration into cinema production and a search for partners in the development of new technologies.

The other pay TV group, Murdoch's BSkyB, bases its strategy on the emulation of the great American success stories (MTV, CNN, ESPN), and is very active in the field of new technologies (in cooperations with Canal+)

### **Impact of the Single Market**

The impact of the Single Market has not caused major changes in the Television industry. Even though there has been a boost in demand for TV Programs, supply of truly European products has been puny due to national markets' fragmentation: the main focus has been placed on satisfying national audiences rather than increasing circulation of European films. The EU internal market program has certainly helped to harmonise rules concerning the broadcasting of TV Programs produced by independent sources, whose recommended quota is 10% of European channels hourly volume (TV without frontier Directive). Nevertheless, diffusion of cable and satellite television enabled European viewers to have direct access to stations from other EU countries, thus hampering agreements between European broadcasters. In addition, the various transmission systems have not yet been harmonised. So far, due to national rivalries, the internal market has not altered this situation because producers are not yet willing to push for standardisation; in this area, the role of governments is essential

---

## **REGULATIONS**

### **Production obligations**

Broadcasting is regulated by the Television directive, which allows for Member States to impose restrictions on the broadcasters established in their territories.

Obligations vary according to Member States. For example, British channels are obliged to obtain 25 % of their hourly volume from independent producers.

At the same time, the European Commission Directive "Television beyond borders" recommends a minimum of 10 % of channel hourly volume to be sourced from independent producers.

### **Broadcasting obligations**

The Directive 89/552, the so-called "Television without frontiers" directive, sets up rules for TV programming in the EU. Various national obligations fix European broadcasting volume at between 25 % and 60 % of total volume depending on the Member State. The European Council has recommended that European productions represent "the majority of volume of hours broadcast."

Concerning independent production, broadcasters have the choice between devoting 10 % of the budget for programming to European audio-visual programs or 10 % of broadcasting time.

The Media program, adopted in December 1990 by the European Commission, has dedicated ECU 200 million over 5 years to the European audio-visual industry:

- Support for distribution up to 85 million ECU;
- Support for writing and development of programs up to 65 million ECU;
- Support for developers of new technologies in audio-visual production of 20 million ECU;
- 10 million ECU for professional development;
- 15 million ECU for development in countries with limited production capacity.

---

## **OUTLOOK**

Continued European efforts to make headway in the program production industry may begin to reap rewards in the coming decade, though the battle is by no means won. It is likely that increasing cooperation with American groups will assist in this process, as would the development of a system of centralised production, favouring the emergence of a major European production group.

Digital technology seems to have found its place as the transmission system for the future, owing to its numerous advantages. Cable operators, electronics groups and computer giants are set for the race for multi-media. In addition, computer groups are developing multi-media tools integrating voice, text and image.

As for the broadcasters, the market will continue to be competitive, with public channels increasingly unable to survive on licence fees and TV stations generally suffering from a drop in advertising revenues. In parallel, the trend towards pay stations and particularly, specialist stations (with narrower targets and smaller market shares), is expected to continue.

# Music recording

## NACE 345.2

*Difficult economic conditions adversely affected sales in the EU for the recorded music sector again in 1993. Retail sales decreased by 2.5 % (in nominal terms) compared with 1992, owing to difficult conditions in several countries, e.g. France, UK and, to a lesser extent, the Netherlands, Spain and Italy. In contrast, Japanese and American sales showed strong growth with 17.4 % and 10.9 % increases respectively. However, the few corporations that lead the European industry can build significantly on the development of new markets in Eastern Europe in the future.*

### INDUSTRY PROFILE

#### Description of the sector

The recording industry ranges from the selection, management and production of artists to the manufacturing, marketing and distribution of "Long Play" or "Singles" recorded on media such as Compact Discs, Vinyl Discs and Compact Cassettes. This sector represented 7.6 billion ECU in 1993 for the European Union as a whole. Three European groups (PolyGram, Thorn EMI and BMG) capture close to 40 % of the world market while Germany, the UK and France represent 73 % of EU consumption and 21 % of the world market.

#### Recent trends

This sector follows a long-term cycle, which is closely correlated to the introduction of new technologies. Vinyl LPs peaked (with 1.2 billion units sold worldwide) in 1981; cassettes reached a plateau in 1989 (1.5 billion units), and further growth is still expected from CDs (1.4 billion units in 1993). Philips's DCC and Sony's MiniDisc so far have failed to compensate for the momentum gradually lost in the cassette market.

Another underlying trend is industry consolidation in a market where production economies of scale are critical. The acquisition of Virgin Records (production and distribution) by Thorn EMI in 1992 was a clear illustration of this trend. Indeed, a large number of independent EU record companies have been

acquired by the "majors" over the past years (Erato, Vogue, Avrep, etc.).

#### International comparison

In 1993, the EU represented 29 % of world sales, ahead of Japan (17 %) but behind the US (32 %). Consumption patterns remain quite different in these markets: the importance of record rental in Japan (where there are as many rental shops as record retail outlets) is combined with the highest CD hardware penetration in the world (133 %). In the US, CD penetration is much lower (75 %) but portability has proved a key growth factor (the success of the "Walkman" pushed cassette player penetration in American homes to a peak of 3.2 units vs. 2.3 in the EU).

EU countries offer a very contrasted picture: in 1993, Dutch consumers spent an average 35 ECU per capita on music recording, benefiting from a very high CD penetration at a record 113 %; in contrast, Greek consumers only parted with some 8 ECU per head with a mere 12 % CD penetration. The three leading EU markets, Germany (2.3 billion ECU), the UK (1.7 billion ECU) and France (1.6 billion ECU) today rank among the top five in the world.

#### Foreign trade

Because of their transnational market positions and the low cost of transport, record companies tend to organise manufacturing independently of market locations: customs statistics are therefore not meaningful. However, two patterns are worth noting.

First, most European markets are heavily penetrated by the "international pop" repertoire. This category typically represents 60 % of national sales, with domestic artists contributing around 30 % and classical recordings filling the remaining 10 %. Notable exceptions are Greece, Italy and France, where national artists make up 40-60 % of the markets.

Additionally, beyond the visible trade of records and tapes, the impact of invisible exports is extremely significant for exporting countries. The Policy Studies Institute in the UK estimated that in 1988 the ratio of invisible to visible exports for the UK was seven, thereby generating over one billion Pounds, i.e. twice as much as films, video and broadcasting put together.

## MARKET FORCES

### Demand

In value terms, music recording is one of the few economic sectors that has enjoyed high compound growth across Europe since 1989. A number of factors have an impact on this level of demand.

General economic conditions obviously prevail. Hoare and Govett Investment Research recently illustrated the close correlation between GDP growth and "music value growth" in Europe over the past ten years. Also, it is often believed that younger age groups represent key buyers for this sector. It appears that this was indeed true when older generations had not had the opportunity to buy records in their youth. Recent US data suggests that music buying habits are carried up by the age profile (the share of US music sales made to persons aged 15-19 years has already fallen from 24 % to 17 % in the four years to 1991, while the amount accounted for by 30-39 year olds increased from 19 % to 23 % over the same period). Europe's ageing population is expected to follow a similar pattern and, therefore, should not have too negative an impact on the sector's future growth.

Changes in technology are obviously critical. The "technological cycle" described earlier would appear to link demand to new hardware development. This is certainly true in the case of CDs, but probably less so for DCCs and MiniDiscs.

The move towards CDs has radically altered the balance of volume sales by media: CDs have grown in the EU by 24 % (compounded annually) since 1989 while LPs decreased by 43 % each year. The value impact of the switch has led to an annual value growth of 8 % over the same period. Indeed, the CD segment is still growing very fast in countries where CD hardware penetration is low (Greece, Portugal, Spain, Italy), but strong growth has been recorded over the past four years in the more "penetrated" countries such as Belgium, Denmark and Germany as well.

Another positive effect of new media is that they allow enhanced profits for record manufacturers. Increased value-added has led to much higher price points thus helping to increase market values in spite of sluggish volume growth.

Finally, commercial dynamism cannot be underestimated. Record marketing has become more professional in the EU, owing in part to television advertising, which provided a welcome boost to the French market in 1988. More recently, distribution has played a significant role in pushing market growth, adding competition on prices. Virgin Megastores or HMV outlets have opened in most EU countries, and mass retailers such as supermarkets (which represent 50 % of retail market in France) have helped push demand.

### Supply and competition

Over 60 CD production plants exist within the EU today. Most of them are owned by major record companies, although some independent companies remain, e.g. MPO (F) and Nimbus (UK). The music recording industry obviously has become a very capital-intensive business, where competitiveness is a direct function of economies of scale, thus driving industry consolidation across Europe.

With retailers gaining influence over buying decisions, price positioning becomes more critical to the marketing mix. Beyond exchange rate fluctuations (particularly with the USD), the 1993 retail price of a Pop Music CD, indexed 100 in the US, was 45 % higher in France, 35 % in the UK and 17 % in Germany. Yet, by early 1993, member countries had largely succeeded in realigning VAT rates so that their range has become much narrower. Italy has the lowest rate (12 %) and Denmark the highest (25 %). France experienced a very favourable boost when the rate was brought down from 33.3 % to 18.6 %, in 1987.

### Production process

Technological development is a key driver for this industry. The impact of CDs has considerably rejuvenated the market, quickly offsetting the LPs rapid decline. It is generally believed

**Table 3: Music recording

 Source: IFPI

that there is no danger of CD growth ceasing in Europe anytime soon. This is true even for highly penetrated markets such as the Netherlands. For example, estimates expect CD hardware penetration in Japan to grow from a current 133 % (the highest in the world) to over 140 %.

In 1988, the cassette became an astonishing worldwide success, attaining world volumes 50 % greater than those of LPs and CDs combined. In Western Europe alone, cassette recorders reached 230 % penetration. Industrialists are hoping to emulate this with the take-off of two new technologies described below.

DCC (Digital Compact Cassette) has been developed to offer digital quality using a medium very close to the traditional analogue cassette. Its real portability (superior to CD) is key, as is its "back-compatibility" (traditional cassettes can be played on DCC hardware).

Multiple copies are prevented by an internal "deteriorating" device. The Dutch group Philips, allied to Matsushita, is the contender for this system. It is estimated that some 26 000 DCC were sold worldwide in 1992, but no official data has been released as of late. However, DCC has failed to breakthrough in the US and Japan and is performing poorly in most European countries except the Netherlands. In the UK, for example, Our Price, the largest music retailer, ceased stocking DCCs in April 1994, followed by US-owned Tower Records.

The MiniDisc (developed by Sony) also offers recording facility (and multiple copying prevention) but is not back-compatible. Sales of MiniDisc players reached 400 000 units in 1993, of which European markets accounted for one-third. While it has been successful in Japan, sales have been dis-

appointing in the rest of the world. Currently, it seems that neither the software industry nor the retail trade have a clear need for a new digital recording medium.

Another technology worth mentioning is direct transmission of recorded music along cables, telephone lines or via satellites. Such systems (e.g. DMX/BSkyB or Digital Cable Radio Associates/Warner/Sony) are already operative in the US.

## INDUSTRY STRUCTURE

### Companies

The recorded music industry is highly concentrated, with six multinational groups sharing about 75 % of the world market. However, beyond the few independent companies that have managed to survive, e.g. Harmonia Mundi (F) or Nimbus (UK), the majors expand cautiously when establishing a local presence. As an example, Thorn EMI owns 64 record companies and 22 music publishing companies in 38 countries. Local labels generally enjoy a large degree of freedom in their management. Overall, the IFPI comprises some 600 members in the EU, 250 of which are in Germany alone.

The six leading groups in the industry are usually vertically integrated in hardware and/or retail. They are PolyGram (75 % controlled by Philips, NL), Sony Music Entertainment (JPN, with CBS label), Time Warner (WEA, US), Thorn EMI (UK), Bertelsmann Music Group (BMG, D) and MCA (JPN). European dominance is striking: three of the five world leaders are EU companies, representing close to 40 % of the world market.

**Table 5: Music recording**

## Strategies

The combination of capital intensity with market internationalisation (the majority of European markets are dominated by international pop and classical), means that economies of scale are critical and, fortunately, achievable. Most players, therefore, have sought to secure a wider international position, as well as to enrich their repertoire. Vertical integration upstream brings substantial marketing power and flexibility (e.g. Virgin/EMI). Technologically, synergies between CBS and Sony's MiniDisc or PolyGram and Philips' DCC are no less significant.

### PolyGram

Probably the "purest" of all competitors, it has 81 % of its 1993 7.4 billion Dutch Guilders of sales in music and is the European leader (22 % market share, up to 32 % in France). PolyGram has been building up its international network, through the recent acquisition of several US companies (A&M, Island Records, and Motown) and the opening of new subsidiaries in Eastern Europe. PolyGram is leader in the classical department (40 % market share) with international labels such as Decca, Philips Classic, Verve Jazz or Deutsche Grammophon.

It is also one of the largest operators in the European music mail order business through Britannia Music (UK), Dial (F), Sound Plus (D) and PolyMond (I). The group has started building a position in music publishing and, more importantly, in the movie production and distribution business (9 % of sales in 1993, planned to grow to 25 % by 2000). The com-

pany's current strategy is to transform itself into a global entertainment company to take advantage of the opportunities in multi-media that most informed sources and forecasters agree will snowball through the 1990s.

### Thorn EMI

The much publicised Virgin acquisition in June 1992 boosted EMI Music's global market share to almost 14 %, thus giving it the fourth position in front of BMG. Thorn EMI is more diversified than PolyGram and only derived 41 % of its 4.3 billion Pounds of revenues from music and music publishing in 1994 (up from 15 % in 1986). EMI Music employs over 8 000 people.

The group benefits from a strong presence in the very profitable activity of music publishing (EMI Music is a world leader with over 25 % market share). It is also diversified in: music retailing, through the HMV Group (179 stores, half of which are in five markets outside the UK), TV, VCR and other electronic hardware rental. Recent divestments include lighting fittings and majority interests in Thames Television and GB Glass. Discussions about further divestments in the security and electronics businesses are continuing.

One of Thorn EMI's objectives is to balance its international portfolio, which led to its acquisition of the US jazz & rock specialist Chrysalis in 1990. In 1993, a majority stake was taken in Monitor. In 1994, Thorn EMI acquired Intercord, a strong German independent label.

Strategic collaborative investments also were made in Europe and the US in both music television channels (VIVA, in Germany) and digital cable radio (Music Choice US), two areas of potential growth. The company is exploring additional investments and partnerships in new digital, interactive and multimedia technologies in order to remain at the forefront of the music business.

### Bertelsmann Music Group (BMG)

With 14 % of the world market, BMG ranks fourth in the world and is the third European music record company. 47 % of its 5.2 billion DM sales (25 % of consolidated sales) were achieved in Europe in 1993 against 33 % in North America. International expansion over recent years has remained a key objective, owing to acquisitions of small and medium-sized labels such as Vogue, Avrep (F), Deutsche Harmonia Mundi (D) or joint ventures with Pressing (I), Stageway and Norsk (Norway); and Jive Records and LaFace Records (US). In 1994, BMG acquired the Italian record company Ricordi, the second biggest acquisition since RCA.

**Table 7: Music recording  
Share of the world market**

(%)	1991	1992	1993
PolyGram	18.7	15.9	15.6
Sony (CBS)	18.0	17.9	15.0
Warner	16.4	16.3	14.4
Thorn-EMI	13.9	13.5	13.9
BMG	13.1	14.4	10.0
MCA	11.1	10.2	6.1
Others	8.9	11.8	25.0
Total	100.0	100.0	100.0

Italia	28
Nederland	5
Portugal	4
United Kingdom	3

Source: IFPI

BMG is now active in 45 countries and is the third player in the biggest world market - the US - with a 13 % market share. However, Europe remains its most profitable market.

BMG as a global music company is trying to strengthen its position in new markets and is now present in most East European countries. The strategy pursued is twofold: growth through careful development of local artists and further acquisition of creative labels.

Finally, BMG has taken the strategic decision to enter the interactive entertainment market by selling CD-ROM products mainly in the videogames and "educational entertainment" markets.

### Impact of the Single Market

The music recording sector association, IFPI, views the impact of the Single Market as relatively ineffective. In the view of the association, piracy and Intellectual Property Rights (IPR) are issues that have not been properly dealt with by the internal market programme. In fact, although a well established network of legislative instruments has been created to foster industry's competitiveness, its effective implementation constitutes the sector's major concern. In this sense, the association wishes that the role of the European institutions be that of catalyser of regulations and of Member States' capacity to enforce legislation. The industry is all the more worried when it comes to consider the implications of IPRs theft in the contest of the new Information Society: here, protection of product content and implementation of its juridical aspects should move along parallel lines. Also, clear-cut legislation deems necessary for gradual elimination of margins of subjective interpretation. Now that internal barriers are progressively disappearing, focus is on difficulties that EU companies encounter when entering third country markets (i.e. quotas, market access, censorship and IPRs protection).

### ENVIRONMENT

It is worth noting that the main environmentally-related issue in the music recording industry only surfaced in the US where the conventional "longbox" CD packaging, unknown in Europe, was dropped in April 1993, following an initiative from the Recording Industry Association of America (RIAA). This will reduce consumption of packaging material considerably.

### REGULATIONS

Piracy is the major problem for the industry. It is estimated that, over the last decade, some 10.2 billion ECU were lost in the world as a direct result of piracy, mostly through cassettes but increasingly with CDs.

Although this issue is more relevant in countries such as Poland, Kenya, Norway or Switzerland, the problem has affected the EU also. A major battle was fought and won in Greece where a 1983 Supreme Court decision enabled its reduction of piracy from 75 % to 23 % in 1993. Piracy rates are generally much lower in other EU countries (except for Italy, with a surge from 15 % in 1992 to 28 % in 1993), but its annual cost to the German industry was still estimated at close to 68.4 million ECU in 1990. Indeed, in recent years some retailers in Germany and France have been guilty of importing records at reduced costs from countries where the duration of copyright protection is comparatively short (e.g. 25 instead of 50 years). With this in mind, a new law on neighbouring rights was passed in the Netherlands in March 1993.

Recently, the GATT Agreement on Trade-Related Intellectual Property Rights (TRIPS) has been a landmark in the development of international intellectual property protection. Now, substantive norms for protection and enforcement provisions represent a significant body of laws with which to shape the exercise of intellectual property rights and their defence throughout the world. However, further negotiations will be needed to address private copying, public communication rights and protection of copyright management technologies, which are some of the elements of the record industry's future.

In addition, the question of protection of privacy as regards the processing of personal data will have to be addressed in the context of new distribution systems which rely on the processing of personal data for ordering or billing purposes.

### OUTLOOK

Economic recovery, technological development and the take-off of the sector in new countries should offer very positive prospects for the music recording industry in the coming years. European firms anticipate competitive technological developments and are likely to benefit as well from the opening of new markets in Eastern Europe or Asia.

# Panorama of EC industry

## *Short-term supplement*

To complement the annual publication *Panorama of EC Industry*, Eurostat, in collaboration with DG III, produces a supplement six times a year. This bimonthly offers comments, tables and graphs on the latest available information on Community industry.

Each issue starts with a macroeconomic overview and a review of general industry trends. Then the short-term trends and structural aspects of two specific sectors are analysed. The sectors vary from issue to issue within the year, with a view to covering the main industry sectors once a year.

### Contents of the publication

#### Statistical indicators

##### *Short-term indicators*

- index of production
- producer price index
- capacity utilisation
- external trade indexes

##### *Structural indicators*

- value added, turnover, investment
- employment, productivity, labour costs
- trade balance
- trade indicators

There are methodological notes at the end of the publication.

#### The sectors by issue

# PUBLICATION ON SERVICES

**What are services  
in Europe?**

## Services in Europe are:

- 1 ♦ Distributive trade
- 2 ♦ Transport
- 3 ♦ Hotels, restaurants, catering, travel agencies
- 4 ♦ Credit institutions
- 5 ♦ Insurance
- 6 ♦ Information, communication, business services
- 7 ♦ Audio-visual services

**What does the publication  
contain?**

## The publication contains:

### *AN OVERVIEW ON SERVICES IN EUROPE*

This chapter gives a global description of services through national accounts figures.

With **more than 30 diagrams**, this chapter outlines the composition of services, compares market services at international level in terms of **value added at market prices and employment**.

Methodological comments are also included.

### *BUSINESS STATISTICS ON SERVICES*

This chapter is divided into seven sectoral parts. It provides data on key figures on EU and EFTA countries for the period of 1985 - 1991.

Six economic variables have been selected from the MERCURE database: **number of enterprises, number of local units, turnover, value added at market prices, number of persons employed and number of employees**.

**Where is the publication  
available?**

## This publication is available at:

OFFICE FOR OFFICIAL PUBLICATIONS OF THE  
EUROPEAN COMMUNITIES, L - 2985 Luxembourg

*The projects related to the MERCURE Information System on Services are conducted by the  
D4 Unit : "Distributive trades, services and transport" headed by Mr. Lancetti  
Eurostat, Bâtiment Jean Monnet, Unit D4, L-2920 Luxembourg*
