## 1 INTRODUCTION: AIMS, BACKGROUND AND ANALYTICAL PERSPECTIVES

### *Overall Objectives*

The main objective of the study is to map the structure and pattern of innovation outputs, in the form of the newly gathered data from the Community Innovation Surveys (CIS) on the introduction of new products, across European countries and industries. At a descriptive level the analysis focuses on examining differences and similarities in the sectoral distribution of innovative output across countries. At a more analytical level it examines how variations in innovative output relate to variations in firm size and export performance.

### *Analytical Approach*

There are two basic elements in the approach that we take in considering the measurement and analysis of innovative activities.<sup>1</sup> The first is that such activities are best characterised by complexity and variety. The inputs to innovation can comprise a wide variety of functional activities - from basic research to incremental improvements in production. The knowledge requirements for innovation also vary widely amongst sectors - from the relatively focused and science-based product development in pharmaceutical firms, to the broad development of a range of product, process and component technologies in automobile firms. And the output of innovative activities can also vary greatly along a number of dimensions - for example, product-process-service, size, complexity, performance.

This means that no single measure is able to capture all the dimensions of the innovation process. Each of the traditional measures, such as R&D expenditures and patenting data, have their own advantages and disadvantages that must be spelt out when using them in any analysis. Table 1 summarises the nature and the main advantages and disadvantages of the various measures, other than those from CIS, developed and used over the last 20 years.

The second element of our approach is that descriptive facts and comparisons are important:

- in throwing fresh light on theoretical problems (eg, the role of business R&D in both innovation and imitation; the role of time lags between innovation and imitation in determining patterns of international trade);
- in clarifying important practical and policy problems (eg, through international and inter-firm comparisons of innovative activities and innovative outputs).

---

<sup>1</sup> A fuller discussion of our approach to measurement of innovative activities is contained in Patel, P and Pavitt, K (1995): "Patterns of Technological Activity: their Measurement and Interpretation", in Stoneman, P (ed) *Handbook of Economics of Innovation and Technical Change*, Oxford, Blackwell.

**Table 1 Strengths And Weaknesses Of Measures Of Innovative Activities**

MEASURE	STRENGTHS	WEAKNESSES	POSSIBLE LEVELS OF COMPARISON		
			Country	Industry	Tech Field
RESEARCH AND DEVELOPMENT	•regular and recognised data on main source of technology	•lacks detail (technical fields and specific firms) •strongly underestimates small firms, design, production engineering, and software	✓	✓	X
PATENTS	•regular detailed and long-term data •compensates weaknesses of R & D statistics	•uneven propensity to patent •misses software	✓	✓	✓
SIGNIFICANT INNOVATIONS	•direct measure of output	•measure of significance •cost of collection •misses incremental improvements	X	✓	X

✓ = Yes      X = No      ?=Maybe

**Table 1 Strengths And Weaknesses Of Measures Of Innovative Activities**

MEASURE	STRENGTHS	WEAKNESSES	POSSIBLE LEVELS OF COMPARISON		
			Country	Industry	Tech Field
EXPERT JUDGEMENTS	•direct use of expertise	•finding independent experts •judgements beyond expertise	?	✓	✓
PRODUCT ANNOUNCEMENTS	•close to commercialisation	•misses in-house process innovations, and incremental product improvements •possible manipulation by marketing and public relations	?	✓	X
TECHNICAL EMPLOYEES	•measures tacit knowledge	•lack of homogeneity of qualifications	X	✓	✓
ACTUAL VS PREDICTED MARKET VALUE	•tries to measure firms' efficiency in asset exploitation	•cannot distinguish innovation from other intangible assets, or from monopoly •difficult to make international comparisons	?	✓	X
			✓ = Yes	X = No	?=Maybe

Thus in this report it is important to present the new data from the CIS in the context of what is known about the innovation process from past analyses using different measures and methods. For example, in terms of country analysis, Archibugi and Pianta (1992) and Patel and Pavitt (1995), as well as the European S&T Indicators Report (1994) contain analyses of the strengths and weaknesses in technology for European countries. In terms of analysis by size we know that large firms are important sources of innovation in R&D intensive sectors and small firms in machinery (see Pavitt *et al* (1987) and Patel and Pavitt (1991)). It is in the context of these types of analyses that we interpret the results from CIS.

## 2 CIS DATA AND METHODOLOGY

This section is concerned with outlining the main elements of the measures of innovation output used in the report along a number of dimensions: main variables used, their main advantages and disadvantages, and sectoral and country coverage. It is not concerned with evaluating the way in which CIS was implemented as this has already been the subject of the study reported in the 'Evaluation of the Community Innovation Surveys (CIS) - Phase 1' (1994).

### ***Data and Measures***

This report is based mainly on data from section 8 of the CIS Questionnaire: Impact of Innovation Activities. In particular it uses the answers to question 15 on sales and exports due to unchanged products, those due to products incorporating incremental changes, and those due to products incorporating radical changes. It also uses information from the answers to question 16 which disaggregates sales due to new products into those that are new to the enterprise and those new to the industry.

Thus we are able to construct the following eight measures:

- Proportion of sales from new products (sometimes referred to as SNP below). In terms of the results of the questionnaire this is defined as *Total Sales\*(1-V15A\_1)*
- Proportion of sales from products incorporating incremental change (SNPInc): *Total Sales\*V15A\_2*.
- Proportion of sales from products incorporating radical change (SNPRad): *Total Sales\*V15A\_3*.
- Proportion of export sales from new products (ENP): *Total Exports\*(1-V15B\_1)*.
- Proportion of export sales from products incorporating incremental change (ENPInc): *Total Exports\*V15B\_2*.
- Proportion of export sales from products incorporating radical change (ENPRad): *Total Exports\*V15B\_3*.
- Proportion of sales from innovative products new to the firm (SNPFir): *Total Sales\*(1-V15A\_1)\* V16\_1*.
- Proportion of sales from innovative products new to industry (SNPInd): *Total Sales\*(1-V15A\_1)\* V16\_2*.

Each of these is an indicator of product innovation at different levels of significance and in particular measures the rate at which firms renew their product range with innovations and the degree to which these innovations contribute to sales.

### ***Advantages and Disadvantages***

As Table 1 shows all measures of innovation have their advantages and disadvantages. When compared with these other measures, the main advantages for the sales and exports in new products are:

- They are a direct measure of output of the whole innovation process, ie., they measure directly the economic impact of innovation within firms.
- They include information on firms which generate innovation as well as those that use innovation, which is very important for the service sector.
- They are comparable across countries, industries and firms of different size classes.
- They can be directly related to other industrial and firm level data, such as production, value-added and employment.

The main drawbacks are:

- They miss out process innovations which may be just as important as product innovations in some industries (such as industrial chemicals).
- There are real difficulties in measuring incremental and radical changes in complex products such as automobiles and aircraft.
- They rely on subjective assessments by firms, which presents problem of interpretation as shown by the French and Spanish results below.
- At present they lack any time series comparisons.
- Also at present they lack comparison with other regions at the world technological frontier: US and Japan.

### ***Sectors, Countries and Size Classes***

In principle data are available for 13 European countries, who conducted surveys based on CIS methodology, and 65 sectors (at 2 digit NACE classes). Annex Table A1 shows the number of firms by country and by NACE class that contained any information on the 8 measures outlined above.

In terms of countries, we made the following decisions, affecting the analysis in this report, based on the information in this table:

- Greece is ignored altogether as it does not report any sales in new products
- UK has been included in some of the aggregate comparisons below but has too few observations to make reliable comparisons
- Luxembourg has been included in some of the aggregate comparisons, but is combined with Belgium for some of the more detailed analysis

It is also worth noting that only 6 out of the 13 countries have information on all 8 measures: France only has information for 2; Netherlands and Portugal on 5, and Spain and Ireland on 6.

In terms of sectors we have made the following aggregations of the NACE classes:

- Other category which includes all the NACE classes from 37 onwards as well as classes 10-14 and 23.
- Food, Drink and Tobacco which combines classes 15 and 16
- Textiles, Clothing and Leather which combines classes 17, 18 and 19
- Paper, Pulp and Wood Products which combines classes 20 and 21
- Electrical which combines classes 30 (Office Machinery and Computers) and 31 (Electrical machinery), although they appear separately for the aggregate analysis.

Thus the analysis below is concerned with a total of 17 sectors (as listed in Annex Table A3).

In the analysis of size distributions below we distinguish between the following categories:

Small Firms: those with less than 100 employees

Medium-sized firms with more than 100 but less than 500 employees

Large-sized firms with more than 500 employees

### ***Construction of Sectoral Means***

In constructing the above measures at the sectoral level, the denominator used is the total sales (or exports) for only those firms reporting sales (or exports) in new products for a particular country or sector. The implications of this for the interpretation of the results are that: greater weight is given to large firms and that comparisons are only being made for those firms that report some 'innovation output' and not for the whole industry.

## **3 MAIN RESULTS**

In this section we analyse the data from CIS to address the following questions:

- What are the differences and similarities in the distribution of innovation outputs across industries and countries?
- How much of the variation in innovation outputs can be explained by industry and by country specific factors?
- How do variations in innovation outputs relate to variations in R&D intensity, firm size, and export performance?

We present the results in the context of what is known about the innovation process from past analyses using different measures and methods.

### 3.1 *Consistency of the eight measures across industry*

We begin this section by examining the similarities (or otherwise) of the patterns shown by the eight measures of innovation for each country across industry. Table 2 (based on the correlation matrices reported in Annex Table A2) shows the number of correlations that are statistically significant at the 5% level for each country in terms of the proportion of innovation output by industry and in terms of industry rankings. Thus for all countries combined, all 8 measures show a remarkably similar pattern across industries: 27 of the possible 28 unique correlations are significant in terms of levels and all 28 in terms of rankings. Similarly, for Italy, Norway, Germany and Benelux the pattern shown by each measure is highly consistent. On the other hand for Portugal, Spain and Denmark the degree of consistency is much lower.

**Table 2 Similarities in Innovation Output by Country: Correlations for 8 indicators across 17 sectors**

*Correlation coefficients that are significantly different from zero*

	Shares	Rank	Out of
Germany	19	21	28
Spain	7	7	15
Netherlands	6	6	10
Denmark	15	15	28
Belgium & Luxembourg	19	19	28
Portugal	3	3	10
Ireland	13	14	15
Italy	24	27	28
France	1	1	1
Norway	24	25	28
UK	na	na	na
All countries combined	27	28	28

### 3.2 *Inter-Country and Inter-Industry Distributions of Innovation Output*

In innovation studies there has been a debate concerning the relative role of industry-specific and country-specific factors in shaping the rate and direction of innovative activities of firms. Some argue that country specific factors in the form of the degree of rivalry, financial and educational institutions and the various inducement mechanisms are the dominant influence (Porter (1990) and Patel and Pavitt (1994)). Others suggest that sector-specific factors such as technological and market opportunities are more important (Malerba and Orsenigo, 1995). In the light of these debates we address the following questions in this section:

- What are the differences and similarities in the distribution of innovation outputs across countries and sectors?
- Are ranking of industries similar across countries in the proportion output from new products?
- How are these distributions related to R&D intensity and to other measures of innovation intensity?

### 3.2.1 *Aggregate level by Industry*

Figure 1 shows the results for innovation outputs by industry for all 12 countries combined. The main points to note are:

- 1 There is a high proportion of sales and of exports in new products for the sample as a whole: 42% and 48%. This ranges from more than 60% (Exports and Sales) in Motor vehicles to 20% or under in Paper and Wood. In general the figure shows that there is a higher share of new products in exports than in sales.
- 2 The industries with the highest proportions of output in new products are generally the ones we would expect:

- Office Machinery
- Motor Vehicles
- Other Transport
- Electrical Equipment
- Radio, TV and Communications Equipment
- Instruments

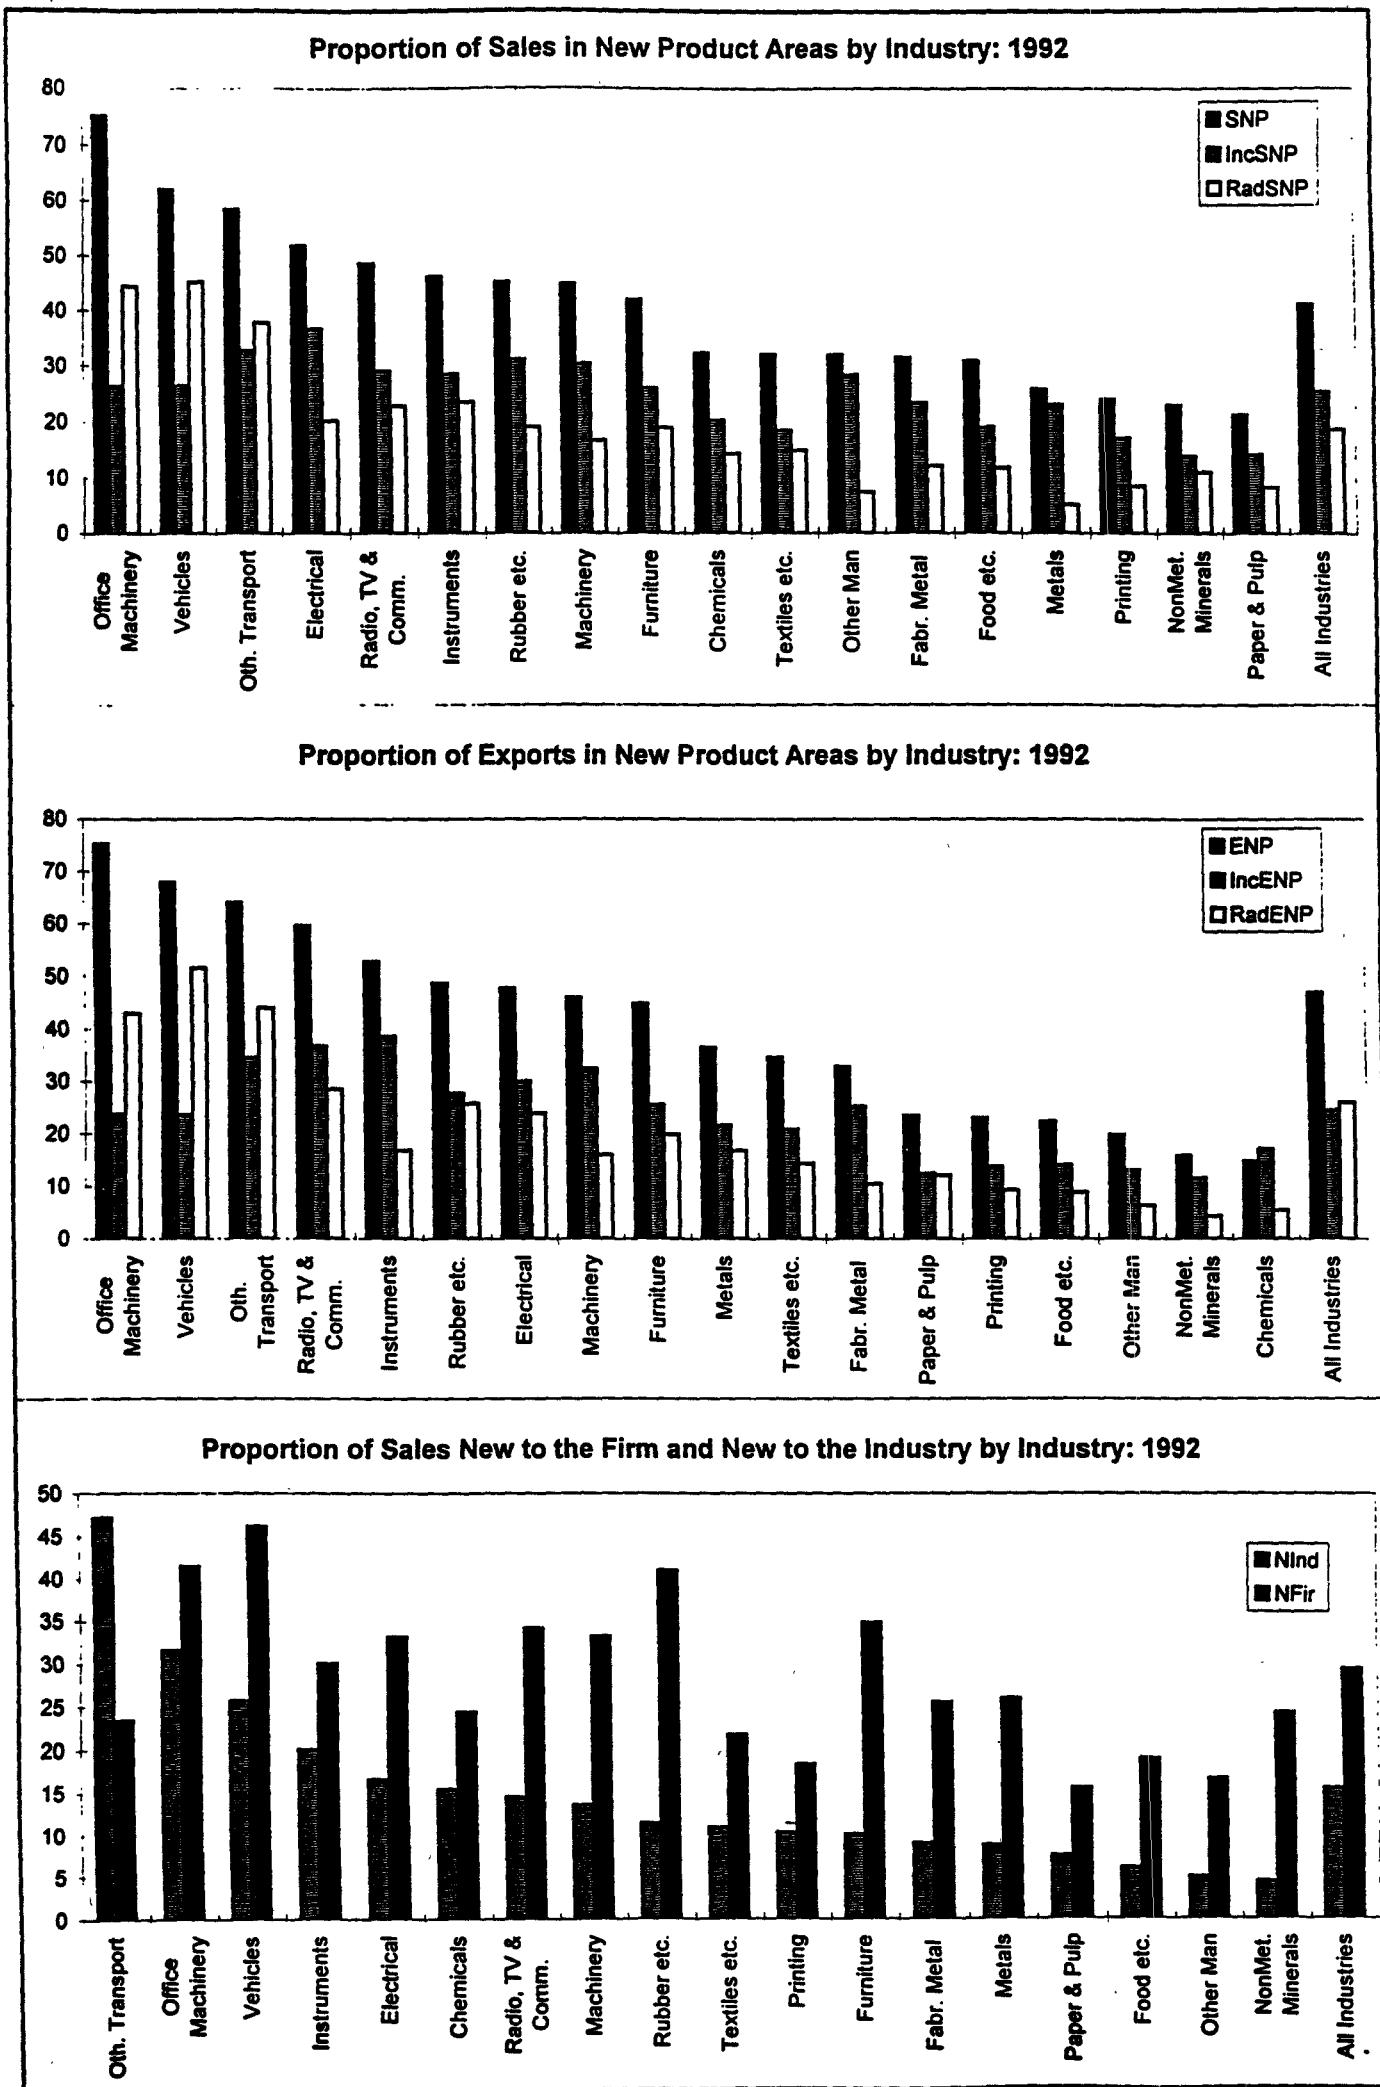

Indeed these are precisely the industries that have higher than average R&D intensities and are generally regarded as being at the forefront of innovation. The only anomaly is that chemicals appears as below average in terms of innovation output but is above average in terms of R&D intensity. One explanation for this could be the fact that in this industry (especially in industrial chemicals) process innovation is much more important than product innovation.

The lowest proportions of output in new products are in :

- Fabricated Metal Products
- Food, Drink and Tobacco
- Basic Metals
- Printing and Publishing
- Non-metallic Mineral Product
- Paper, Pulp and Wood Products

However even in these industries more than 20% of sales and exports are in new products.

**Figure 1. Innovation Output by Industry for all Countries Combined**

### *3.2.2 Aggregate level by Country*

Figure 2 compares the output in new products for each of the 12 countries. It shows wide variation in innovation performance amongst countries, ranging from around 60% of sales in new product for Germany to less than 30% for Norway. In general there is a great deal of consistency in what the different measures show, especially SNP and ENP. The main points to note are:

- Germany has consistently more output in new products than all the other countries
- France and Norway have less output in new products than all the other countries

The main anomalies that emerge when these results are compared to those from other analysis of country differences (such as those based on R&D and Patenting, see Archibugi and Pianta (1992) and Patel and Pavitt (1995)) are that:

- the French position is too low and
- the Spanish and possibly the Portuguese position is too high.

Indeed there is a very low correlation between industry financed R&D as a proportion of GDP as reported in the OECD data and the proportion of sales in new products. This implies that there are some country specific biases in the way in which some firms responded to the CIS questionnaire, and care will need be needed in interpreting the results of country comparisons.

### *3.2.3 Comparisons across sectors and across countries*

This analysis is based on comparing the 17 industry means for each of the 8 output measures, for each of the 10 countries. The basic data appear in the Annex Table A3. We address 3 related sets of questions:

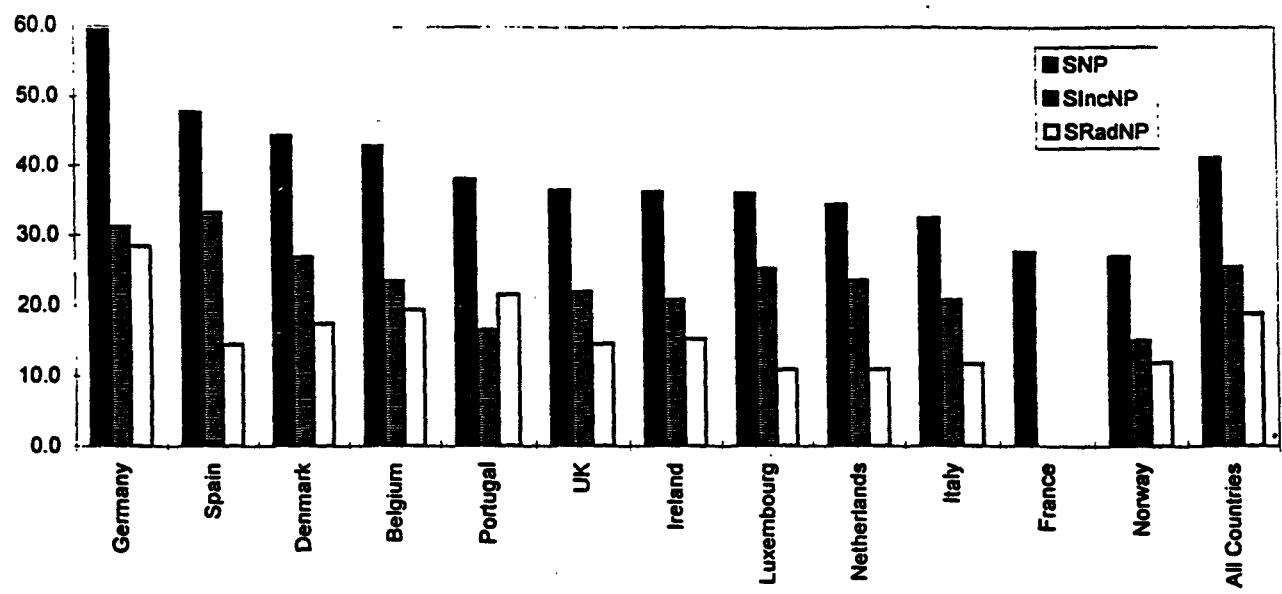

- At a descriptive level, which are the sectors in which country A is more innovative than all other countries?
- What are the similarities between countries: how similar is country A to country B in terms of innovation output across industry?
- How much of the variation in the innovation outputs can be ascribed to industry and how much to country?

### *3.2.4 Sectoral strengths in Innovation Outputs*

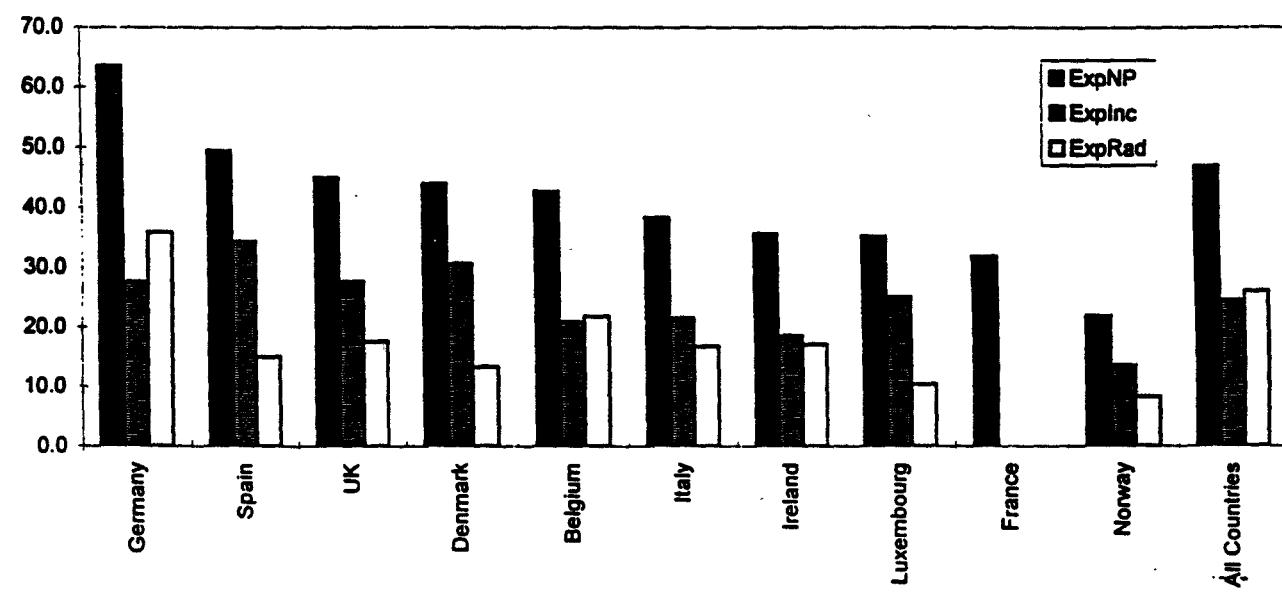

Given that sectors differ greatly in the sources, rates and directions of their innovative activities the aim here is to examine, for each measure of innovation output, a particular country's performance within an industry in relation to all other European countries active in that industry. This we do by comparing, for example, the mean for sales in new products for country A in industry B with the mean of all countries combined for industry B. The main drawbacks of using this as a measure of strength and weakness are: (a) country-specific biases, for example, France, Norway and Italy have consistently lower output in new products

**Figure 2. Innovation Output by Country**

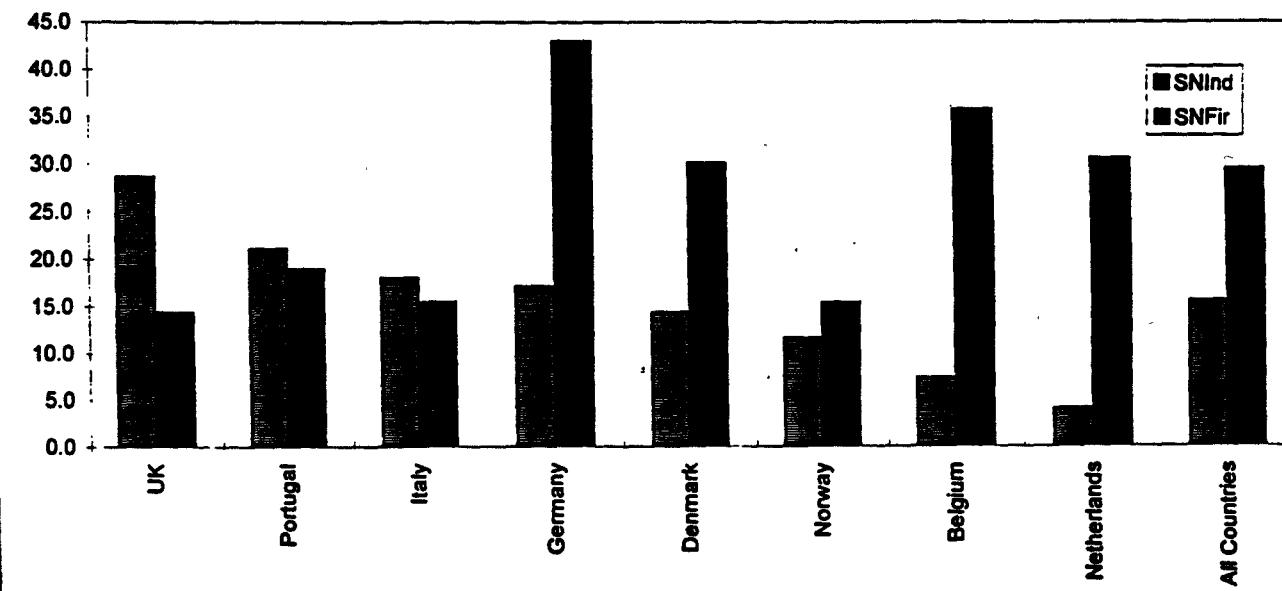

**Proportion of Sales in New Product Areas by Country: 1992**

**Proportion of Exports in New Product Areas by Country: 1992**

**Proportion of Sales New to the Firm and New to the Industry by Country: 1992**

for most industries; and (b) lack of comparison between Europe and the US and Japan, especially in industries where these two regions are ahead in terms of innovation.

The results of this analysis, for sales and exports in new products are presented in Figures 3 and 4.<sup>2</sup> For the other 6 measures, see Annex Table A4. The following product groups emerge as areas of strength for each country from these comparisons:

Germany	Rubber and Plastics; Instruments, Motor Vehicles, and Other Transport
Netherlands	Printing , Electrical and Radio, TV and Communications
Belgium & Luxembourg (combined)	Printing, Chemicals, Non-metallic minerals, Fabricated Metal products, Non-electrical Machinery and Radio, TV and Communications
Denmark	Textiles, Paper and Wood, Chemicals, Basic Metals, Non-electrical Machinery and Other Transport
Ireland	Chemicals, Metals and Non-electrical Machinery
Norway	Food, Drink and Tobacco, Fabricated Metal products and Furniture
Portugal	Food, Drink and Tobacco, Fabricated Metal products
Spain	Food, Drink and Tobacco, Paper and Wood, Non-metallic minerals, Fabricated Metal products, Radio, TV and Communications, and Furniture
Italy	Non-metallic minerals and Electrical (especially for exports),
France (possibly)	Electrical
UK (possibly)	Non-electrical and Electrical equipment

Some of these confirm previous results: for example, Germany's strength in Rubber and Plastics and Motor Vehicles, Netherlands' in Electrical and Radio, TV and Communications and Denmark's in Chemicals. However there are certain areas of strength for countries that do not appear in these data: Germany in chemicals, Italy in Machinery, Textiles and Furniture, and France in Communications.

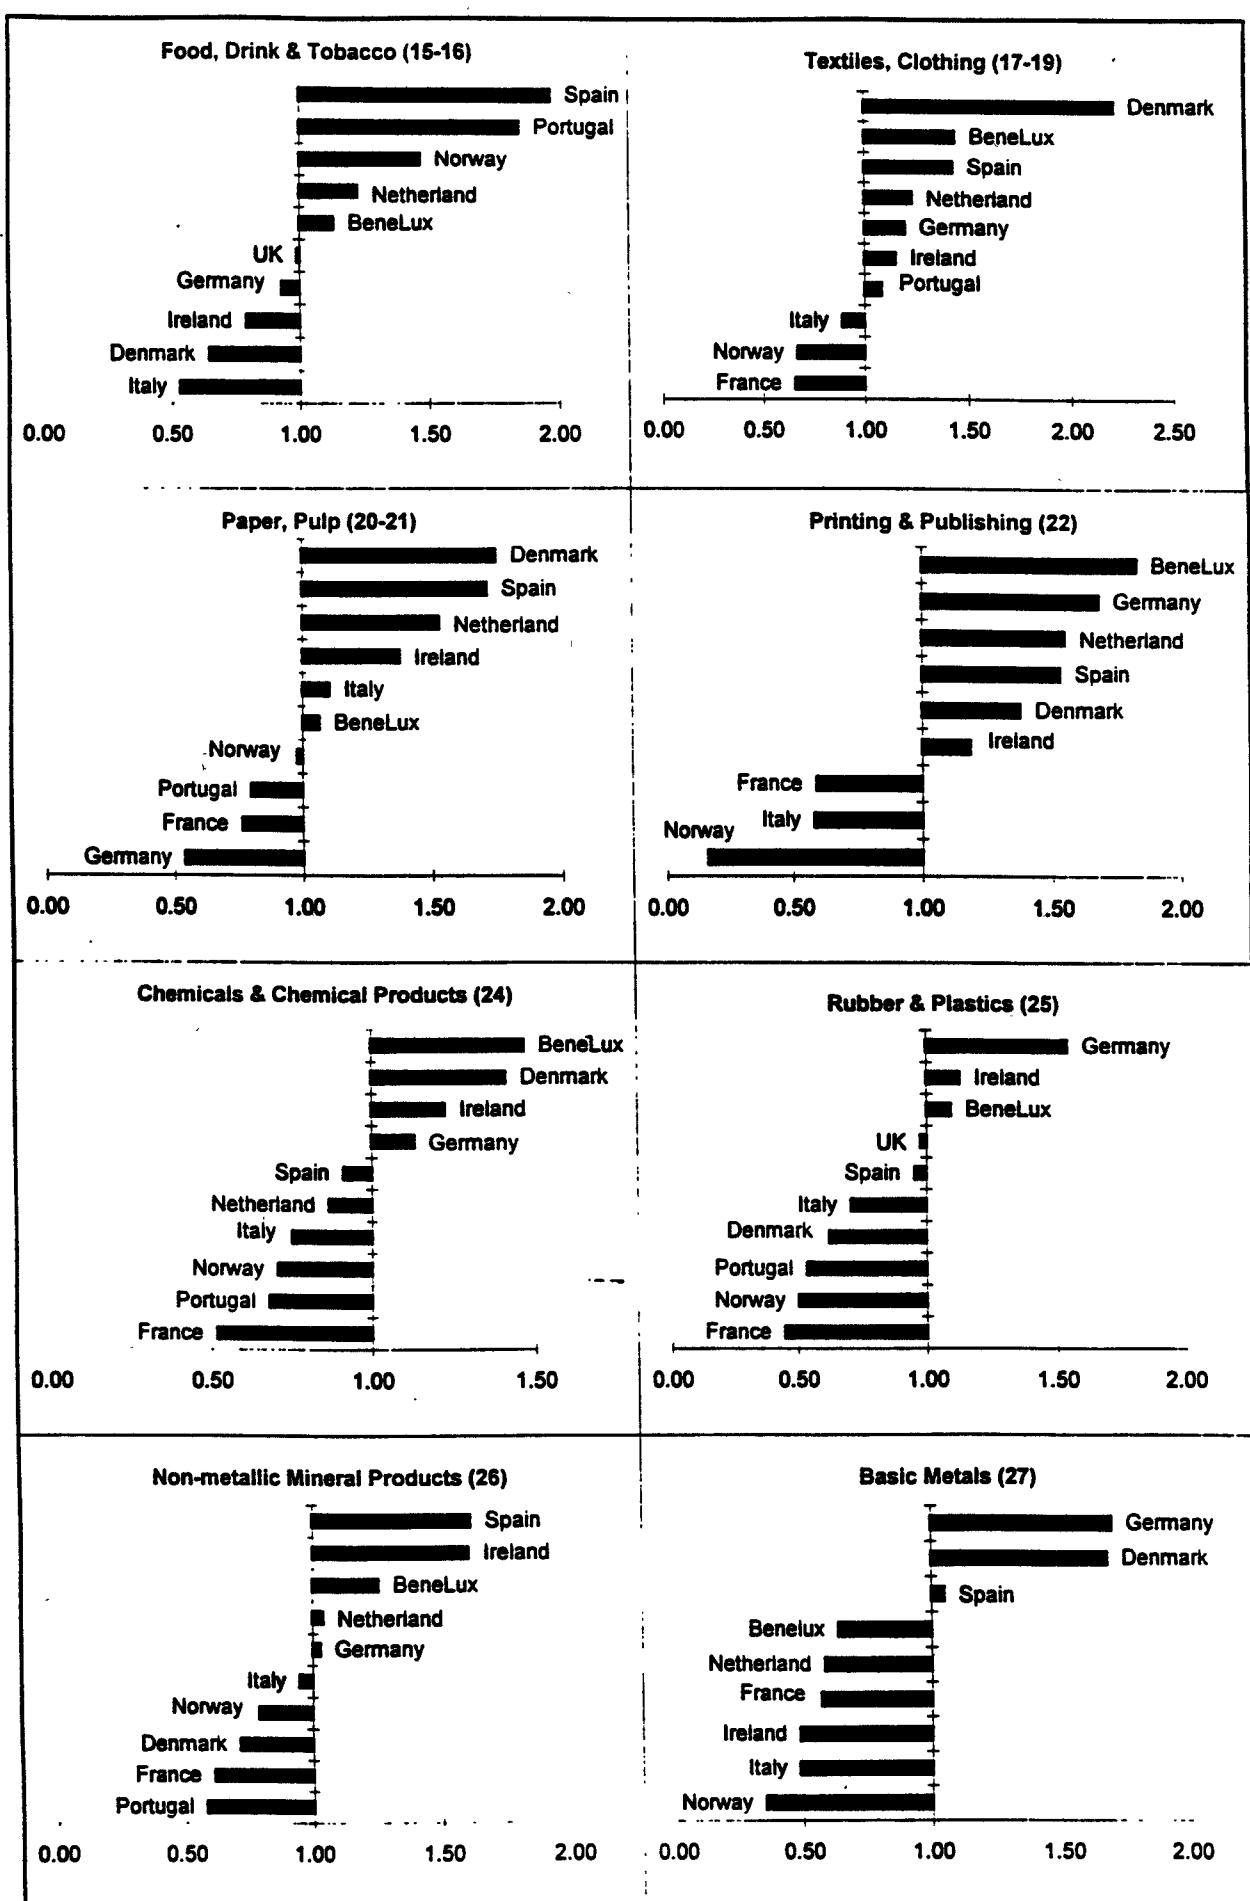

### 3.2.5 *Similarities between countries*

The above analysis suggests that there are major differences between countries in the patterns of innovation output across sectors. In Annex Table A5 we examine systematic similarities and differences amongst the 10 countries by means of correlation matrices for each of the 8 measures. Table 3 uses this information to see the extent to which countries are related to each other. In particular, it shows that France and Italy have the most similarities with the

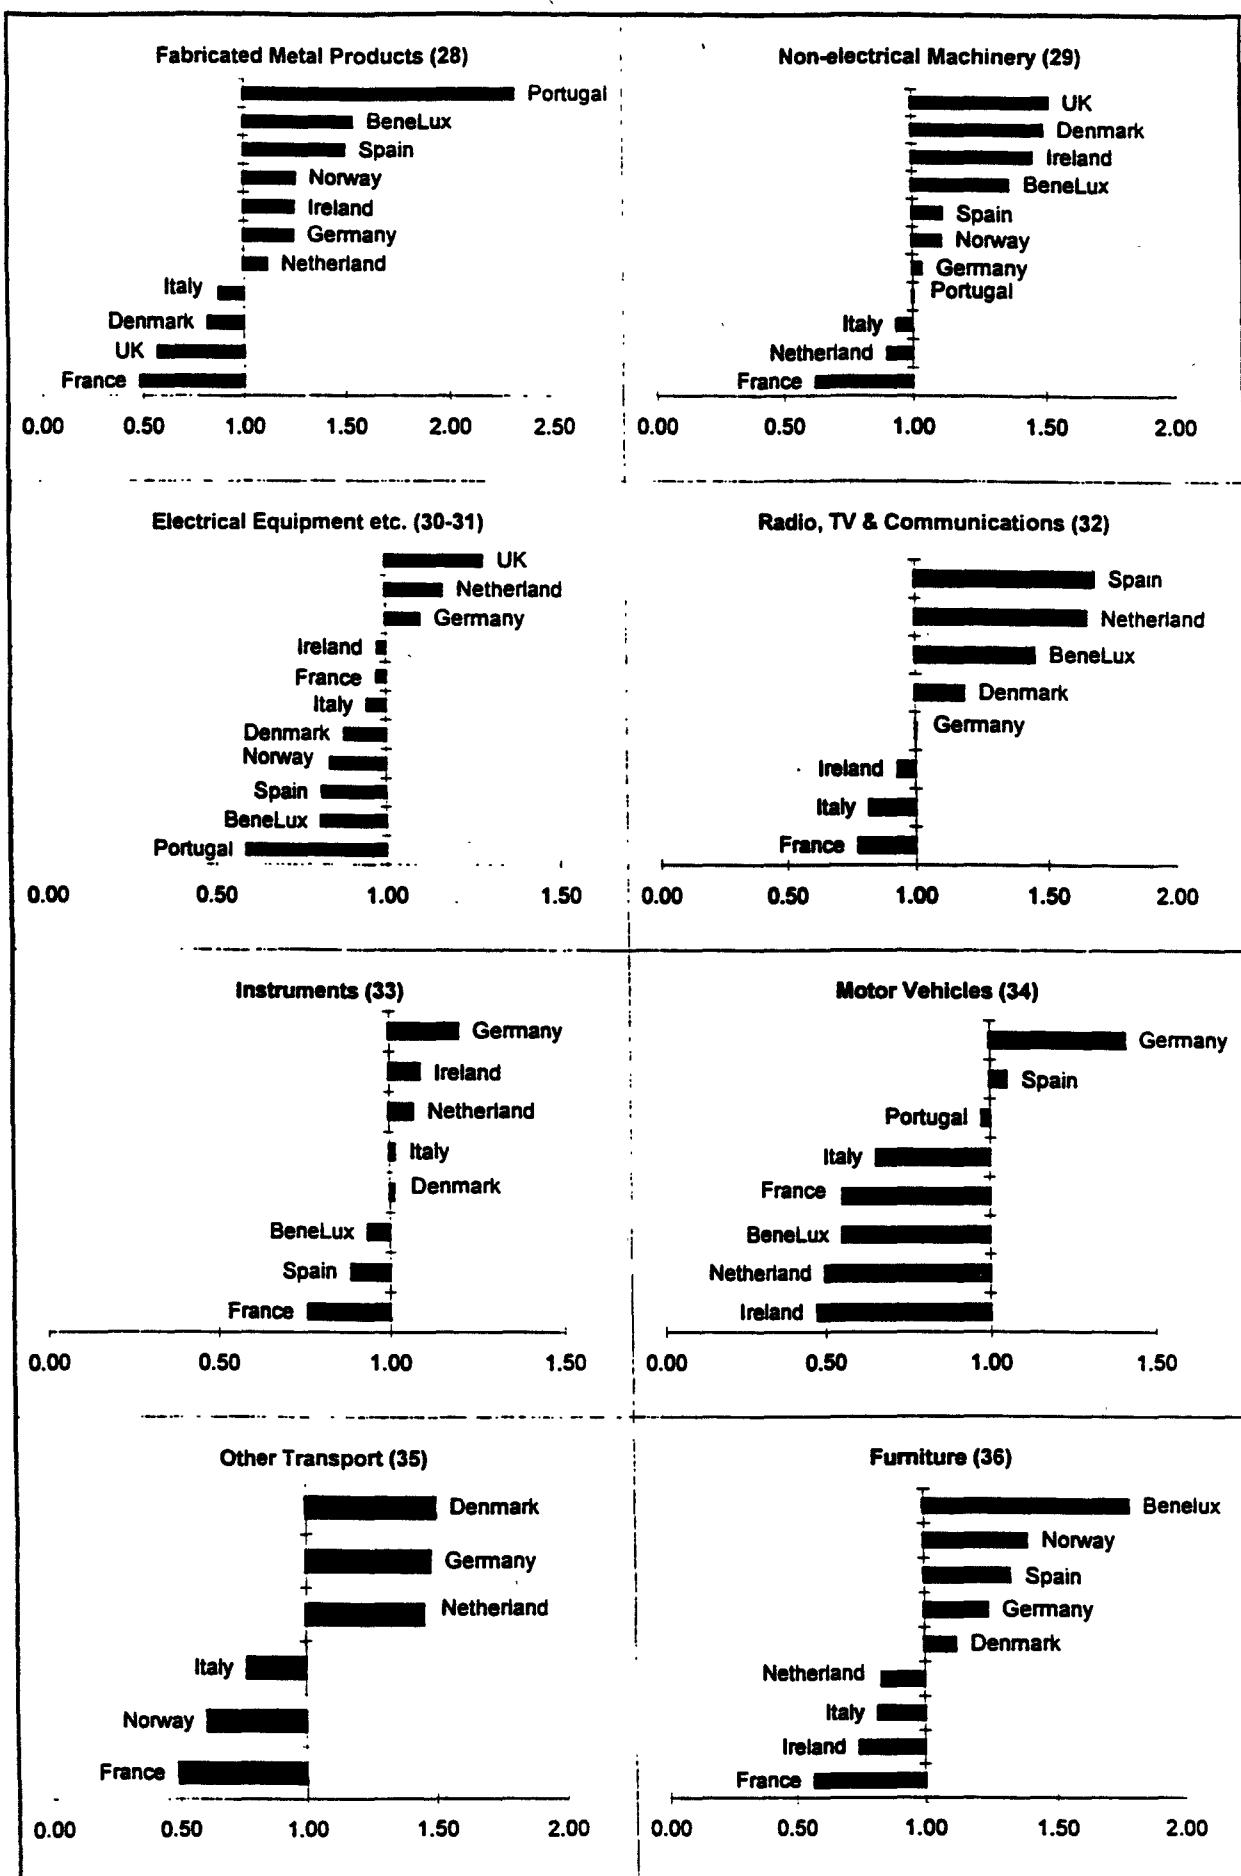

---

<sup>2</sup>In these figures we have eliminated all industries with less than 10 observations.

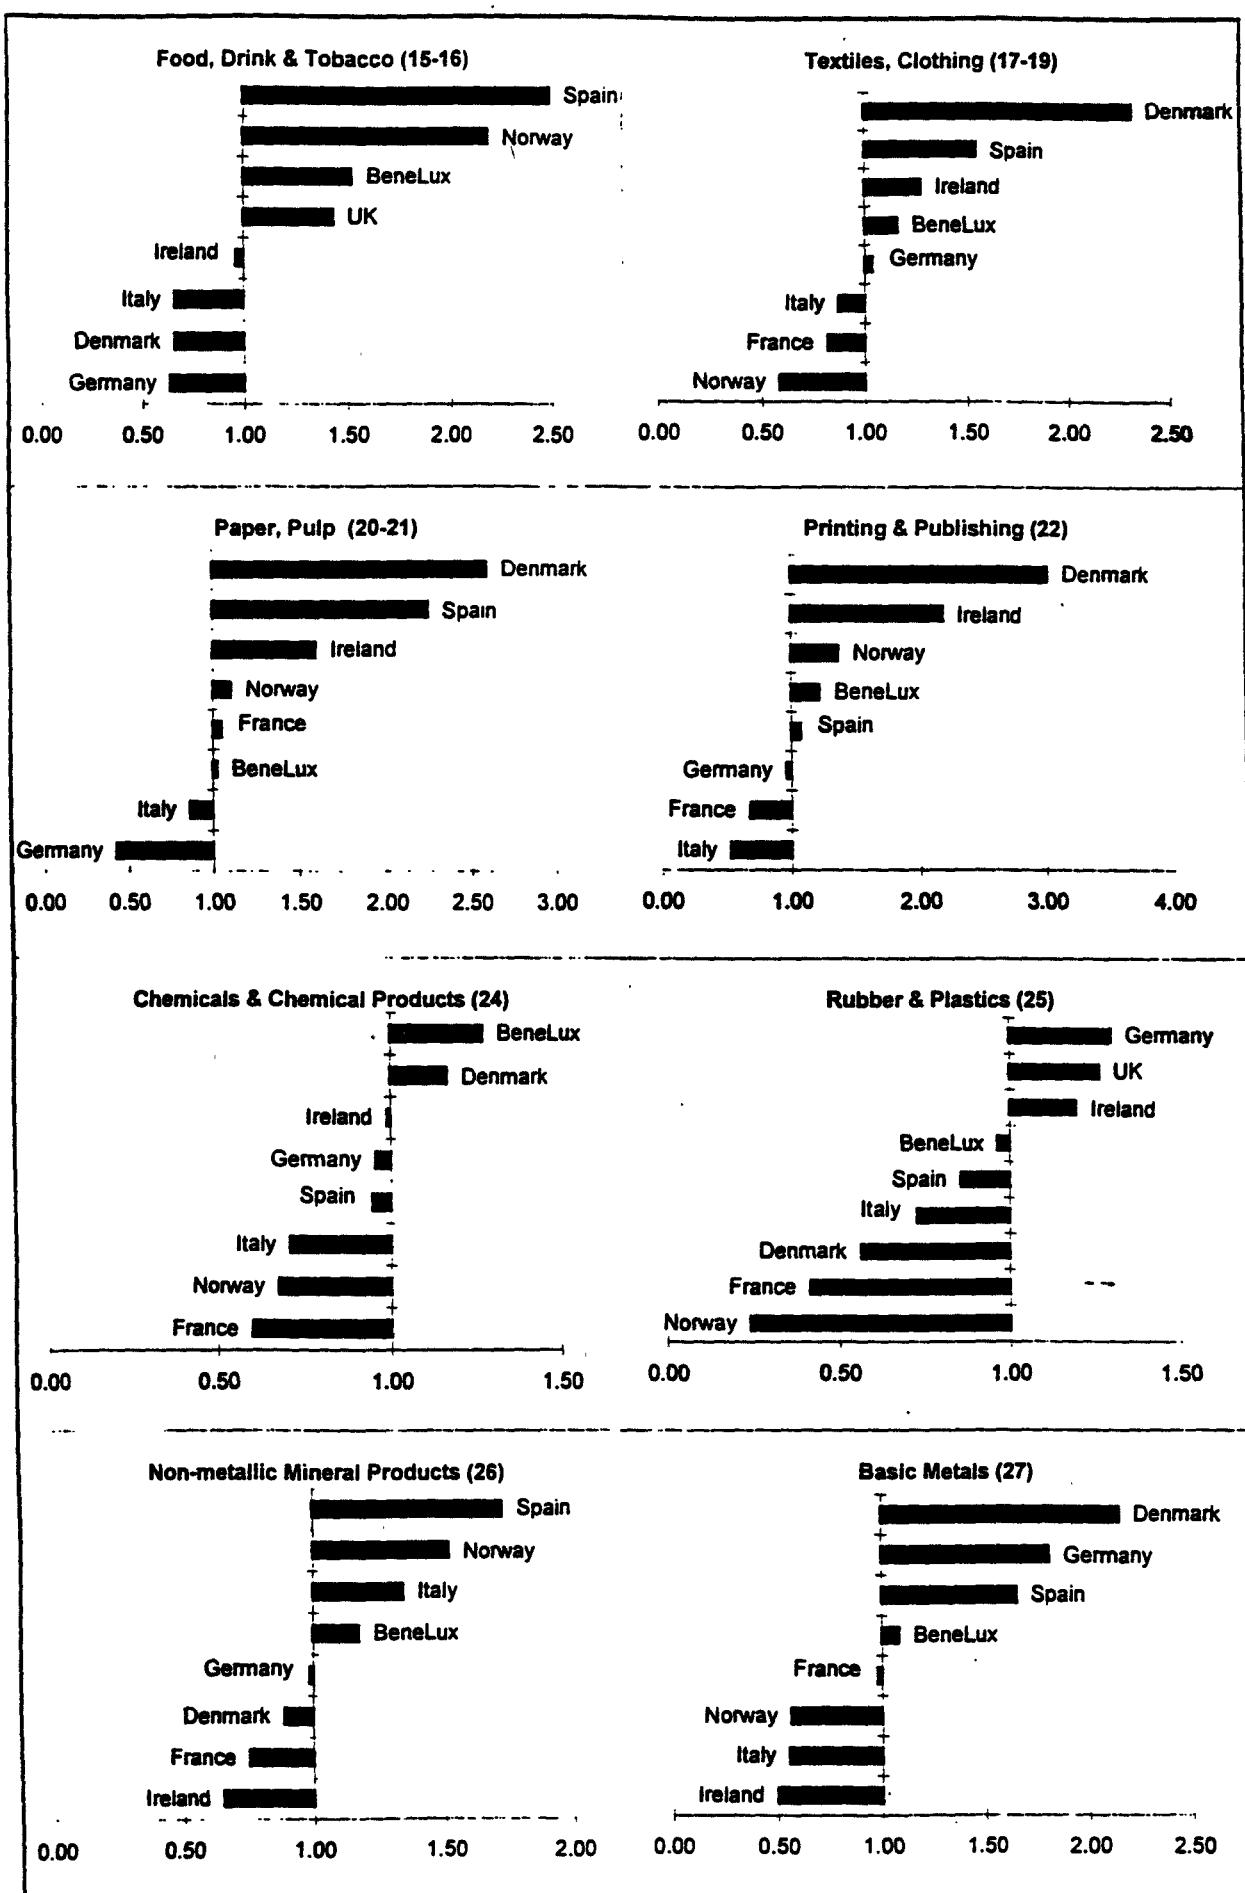

**Figure 3. Sectoral Strengths in Innovation Output: Share of Sales in New Products Compared to the Industry Average**

Across all countries	21	23	5	5	12	12	11	13	3	3	4	8	7	3
Out of Total	45	45	36	36	36	36	28	28	21	21	21	21	21	21

other European countries, ie, their pattern of innovation outputs across the 17 sectors is similar to most other countries. Also the pattern for Portugal is different from that of all other countries. In general, there are more similarities among countries for sales and exports in new products than the other measures.

### 3.2.6 *Analysis of Country and Industry Effects*

In this section we analyse the relative importance of country and sector effects in explaining the variance in innovation outputs at two levels: at the level of industry and at the level of company.

#### 1 At the Industry level

The following table summarises the results of the analysis of variance of industry/country means for sales in new products. It shows that around 60% of the total variance in the proportion of sales in new products is explained by industry and country factors. It indicates that industry effects are more important than country effects as although both are statistically significant, industry accounts for more of the variance than country.

**Table 4 Sales in New Products Analysis of Variance of at the Industry Level**

Source	DF	Sq SS	Adj MS	F
Industry	16	22607.4	1413.1	8.53*
Country	10	9422.2	942.2	5.69*
Error	134	22194.2	165.6	
Total	160	54223.8		

\* Denotes Significance at the 5% level

#### 2 At the Company level

However, as shown in Table 5, at the company level the results of the analysis of variance are somewhat different. Firstly only around 11% of the total variance in sales in new products is due to industry and country effects. Secondly the relative importance of the industry and company effects changes: country now accounts for more of the variance in sales in new products than industry. This shows that there is considerable intra-industry variation which needs to be taken into account when comparing industry means as in the analysis above.

**Table 5 Sales in New Products Analysis of Variance at the Company level**

Source	DF	SS	MS	F
Industry	16	19.78	1.24	15.78*
Country	10	83.21	8.32	106.22*
Interaction (Ind+Cou)	160	37.52	0.23	2.99*
Error	16748	1311.98	0.08	
Total	16934	1560.13		

\* Denotes Significance at the 5% level

### 3.2.7 Comparisons of Innovation Outputs and Innovation Inputs

In this section we analyse the relationship between innovation output on the one hand and R&D intensity and innovation intensity (total innovation costs as a proportion of sales) on the other. As the following table, based on industry means, shows there is a significant relationship between the two sets of variables. In other words, industries with higher proportions of output in new products are also those with higher R&D and innovation intensity.

**Table 6 Correlations between Innovation Output, R&D Intensity and Innovation Intensity at the Industry level**

N = 145

	SNP	SNPInc	SNPRad	RDInt
SNPInc	0.85*			
SNPRad	0.78*	0.40*		
RDInt	0.40*	0.24*	0.43*	
InnInt	0.24*	0.12	0.28*	0.52*

\* Denotes that the coefficient is different from zero at the 5% level

### 3.3 Firm Size and Innovation Outputs

The past fifteen years has shown that empirical results on the relationship between firm size and innovation intensity are sensitive to the sample of firms, and to the measure used for innovative activities. In the 1960s, an r-shaped relationship was established between innovation intensity and size in large US firms, when using patenting as the indicator of technological activities (Scherer, 1965). In the 1970s, systematic data on large US firms' R&D expenditures showed a linear relationship between innovation intensity and size (Soete, 1979). In the 1980's, a U-shaped relationship was found, in UK firms covering all size

categories, between size and innovation intensity measured as numbers of significant innovations divided by employment (Pavitt *et al*, 1987), thereby revealing the inadequacy of R&D as a measure of innovative activities in firms with fewer than 1,000 employees (Kleinknecht, 1987). Our more recent work using R&D and patent statistics for large firms showed a linear relation between firm size and the volume of innovative activity (Patel and Pavitt 1992).

Thus in this section, we examine the distribution of innovation intensity (proportion of total output that is in innovative products), according to firm size broken down by sector and country. In particular we address the following questions:

- Are small firms more innovative than large firms?
- Are there any variations by country and by industry?

The size categories we consider are based on employment and the assumption we have made is that firms have been consistently defined in the survey.<sup>3</sup> Thus small firms are defined as those with less than 100 employees, medium size firms with between 100 and 500 employees and large firms with more than 500 employees.

Two caveats needs to be borne in mind when interpreting the results below:

- (a) small firms are often new firms which come into being to sell new products and hence by definition a greater share of their output would innovative.
- (b) Results by size will only be reliable if the surveys were conducted by means of a stratified random sample.

### *3.3.1 Aggregate comparisons by industry*

Figure 5 shows the results for innovation outputs (Sales and Exports in new products<sup>4</sup>) by industry for all 12 countries combined. The main points to note are:

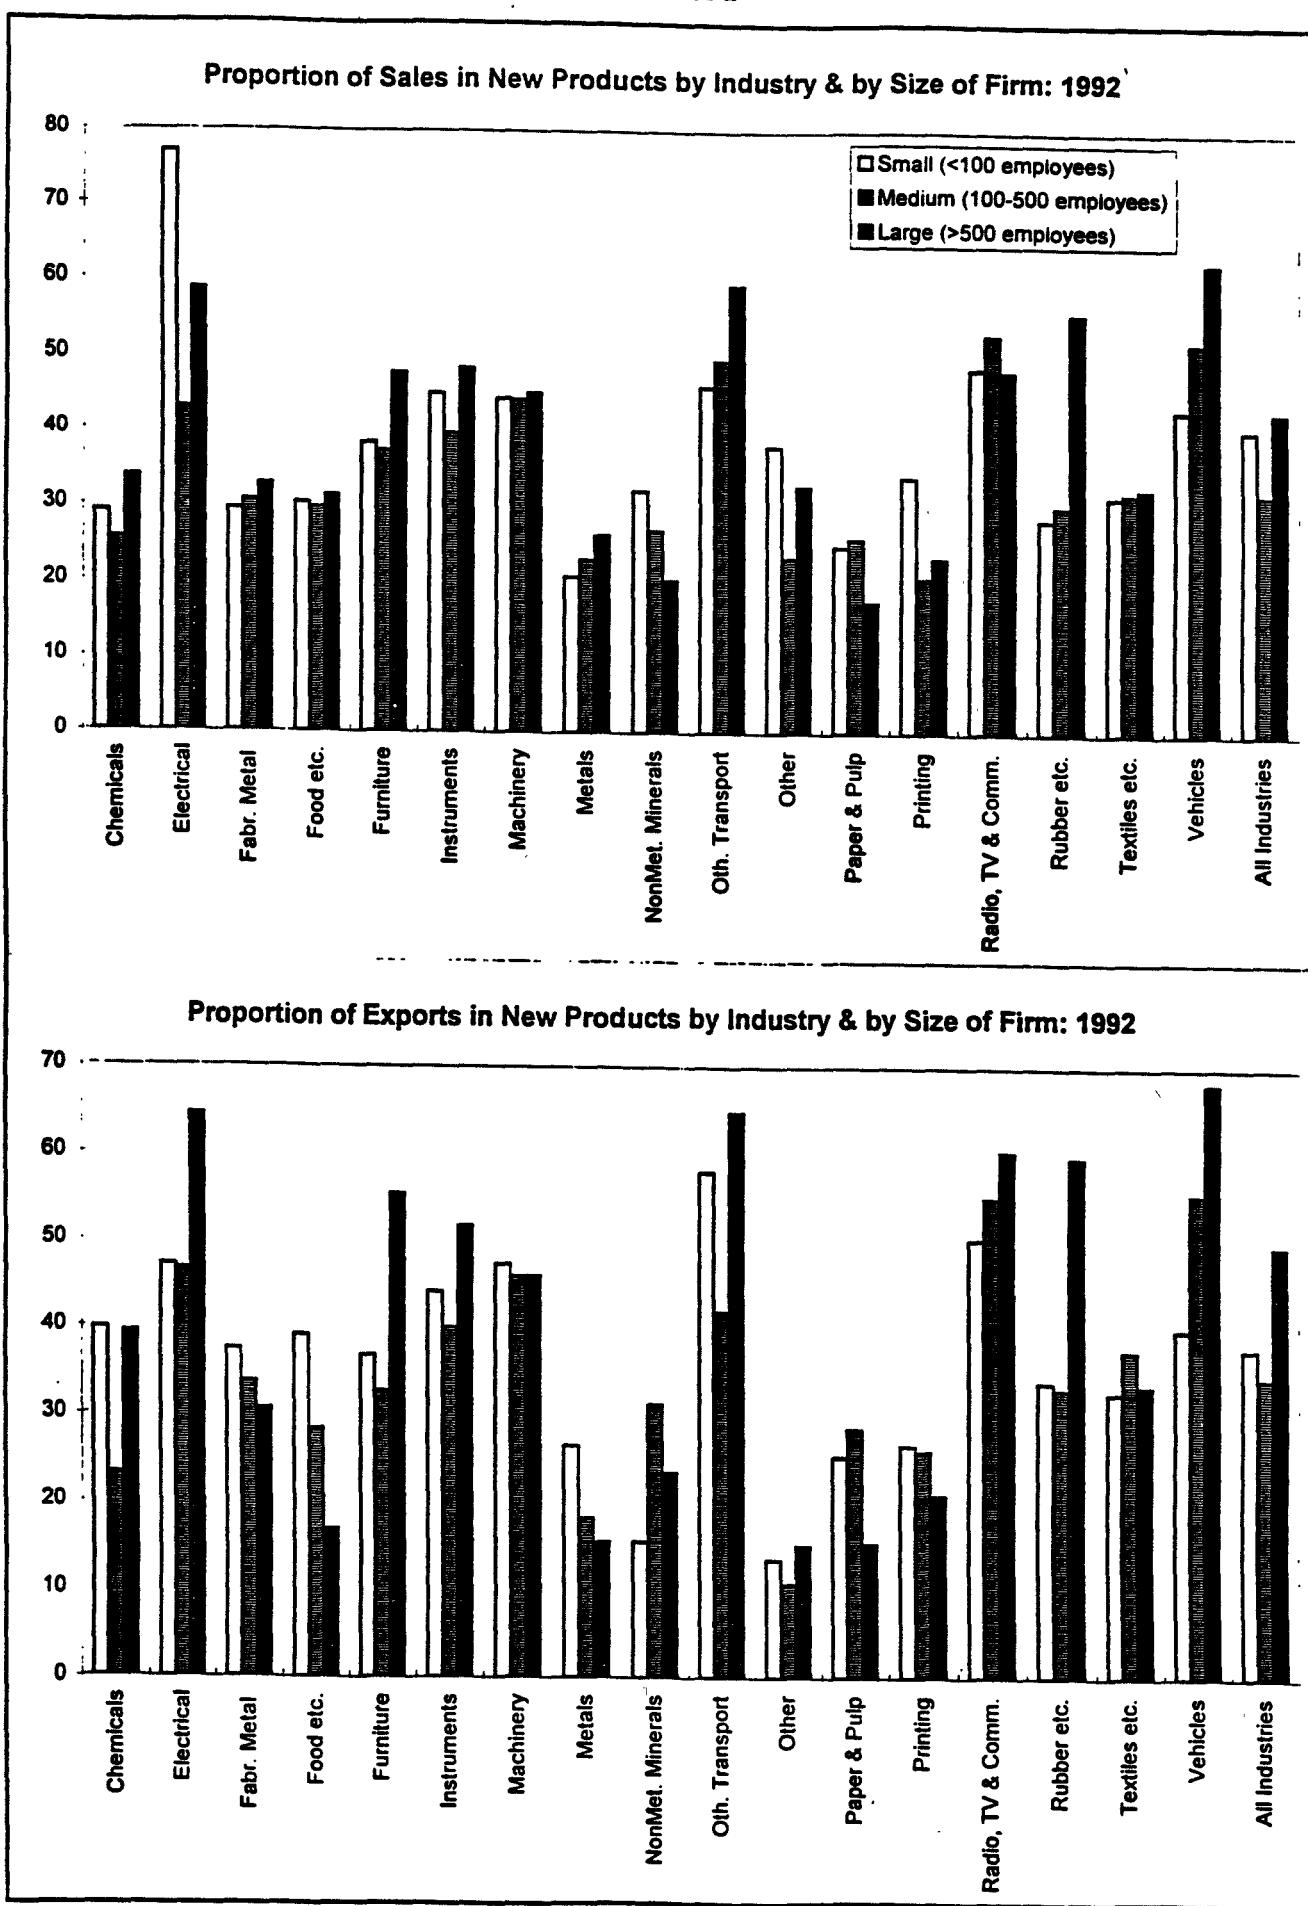

- For the sample as a whole large and small firms have a higher share of innovation outputs than medium-sized firms. There is one major difference between exports and sales in new products: large firms have a much higher intensity than small firms in exports.
- The same U-shaped relationship is also found in Chemicals and Instruments
- Large Firms have a much higher intensity in Rubber & Plastics; Motor Vehicles; Other Transport; Furniture and Metals (but not in terms of exports).
- Small Firms have a much higher intensity in Paper & Wood; Printing; Non-Metallic Minerals; Electrical (not in terms of export in the last two sectors).

---

<sup>3</sup>The CIS 'Evaluation' report seems to indicate that in the case for Belgium, Germany and the Netherlands establishments as well as enterprises might be included. Thus the results by firm size may be biased in the case of these countries.

<sup>4</sup>See Annex Table A6 for details of the other measures.

**Figure 5. Innovation Output by Industry and by Size of Firm for all Countries Combined**

### 3.3.2 Aggregate comparisons by Country

Figure 6 shows the results for innovation outputs (Sales and Exports in new products) for each of the 12 countries. Given the different industrial mix in the different countries the picture at the country level is mixed:

- Both small and large firms are much more innovative than medium-sized firms in Germany and Belgium and Luxembourg combined.
- Small firms are much more innovative than large or medium-sized firms in Portugal and Norway.
- For France, Italy and Netherlands large firms are more innovative;
- Lastly in Spain, Denmark and Ireland there is very little difference between the size classes.

### 3.3.3 Comparisons by industry and country

Figures 7 and 8 show the proportion of sales and exports in new products by size classes within each industry by country.<sup>5</sup> They are based on data reported in Annex Table A6. The main point to emerge from these comparisons is that there is no clear pattern in terms of the greater or lesser innovation intensity of different size classes: in the same industry some countries have large firms with significantly higher intensity than average and others have small firms with significantly higher intensity. This is confirmed statistically in Annex Table A7 where we regress the means of the size classes for each country and each industry on 3 dummy variables: one for each size class. In these regressions there are only 5 cases (out of a possible 153) where the data can distinguish between the size classes. Thus large firms have a higher intensity in Rubber and Plastics (SNPInc) and small firms in Textiles and in Instruments (both SNPRad).

In Annex Table A8, we use the same technique to examine differences amongst countries in innovation intensity of different size classes, ie., we regress all the industry/size means for a country on the 3 size class dummies. In the main there very few cases in which the data are able to distinguish between the innovation intensities of the different size classes. These results show that large firms are more innovative in France (SNP), Denmark, Italy and the Netherlands (SNPInc), and small firms in Belgium and Luxembourg combined.

### 3.3.4 Firm Size and Innovation Outputs at the Company level

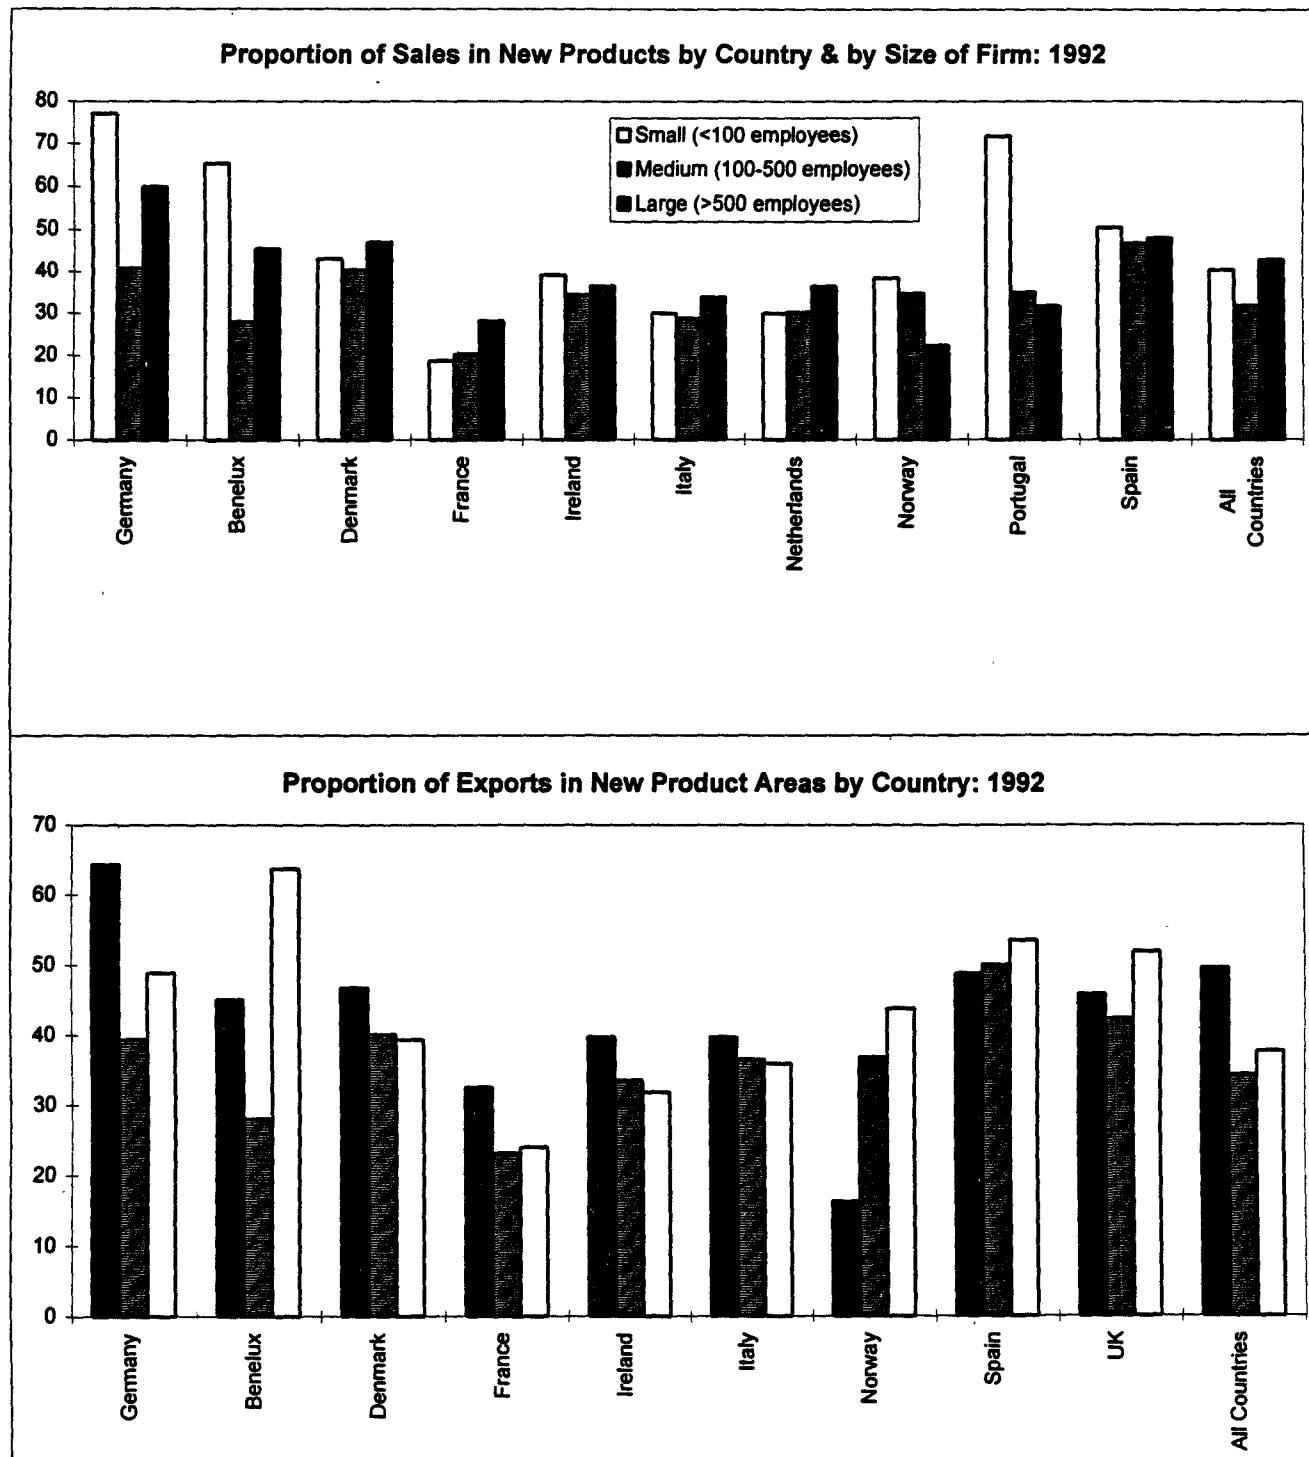

In this section we test the relationship between firm size and innovative performance at the company level in the form:

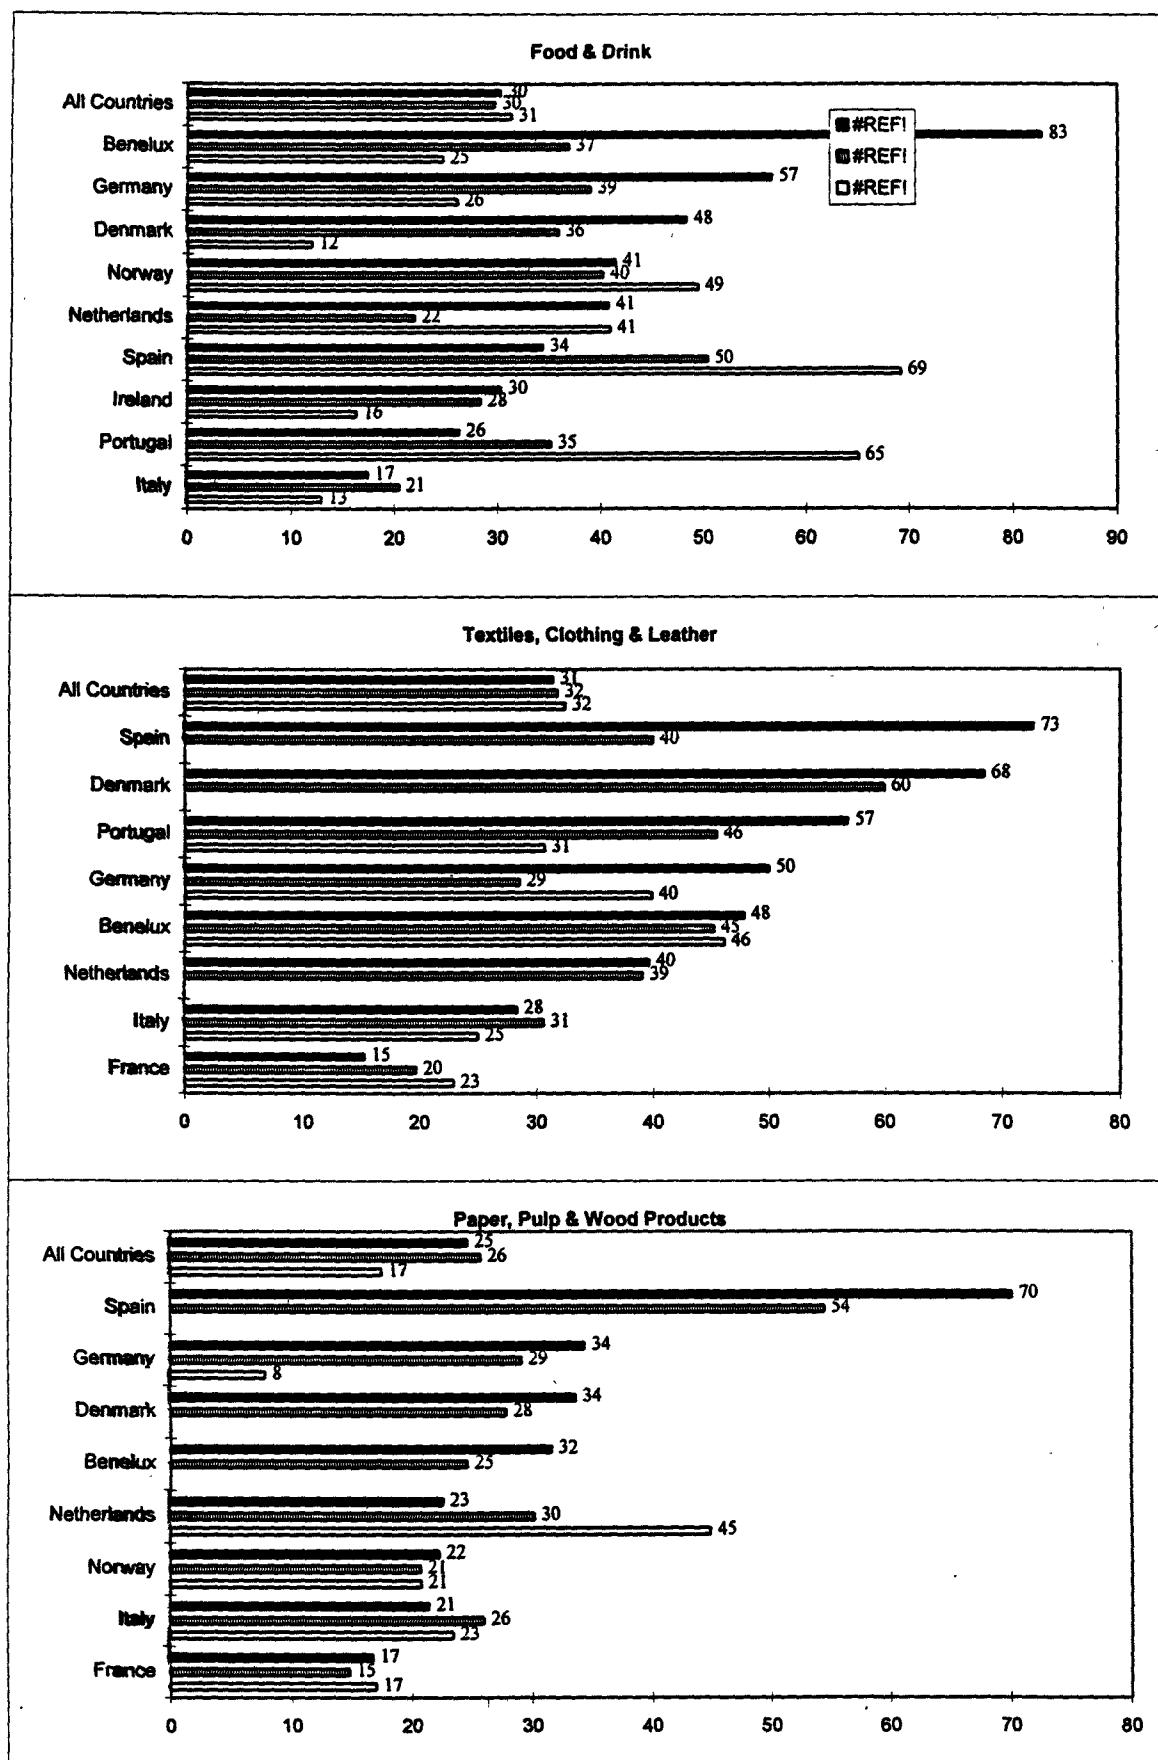

$$\begin{aligned} \log(\text{innovative activity}) &= a + b \log(\text{size}), \text{ where} \\ \text{innovative activity} &= \text{company's Sales in New Products} \\ \text{size} &= \text{company's Total Sales}; \end{aligned}$$

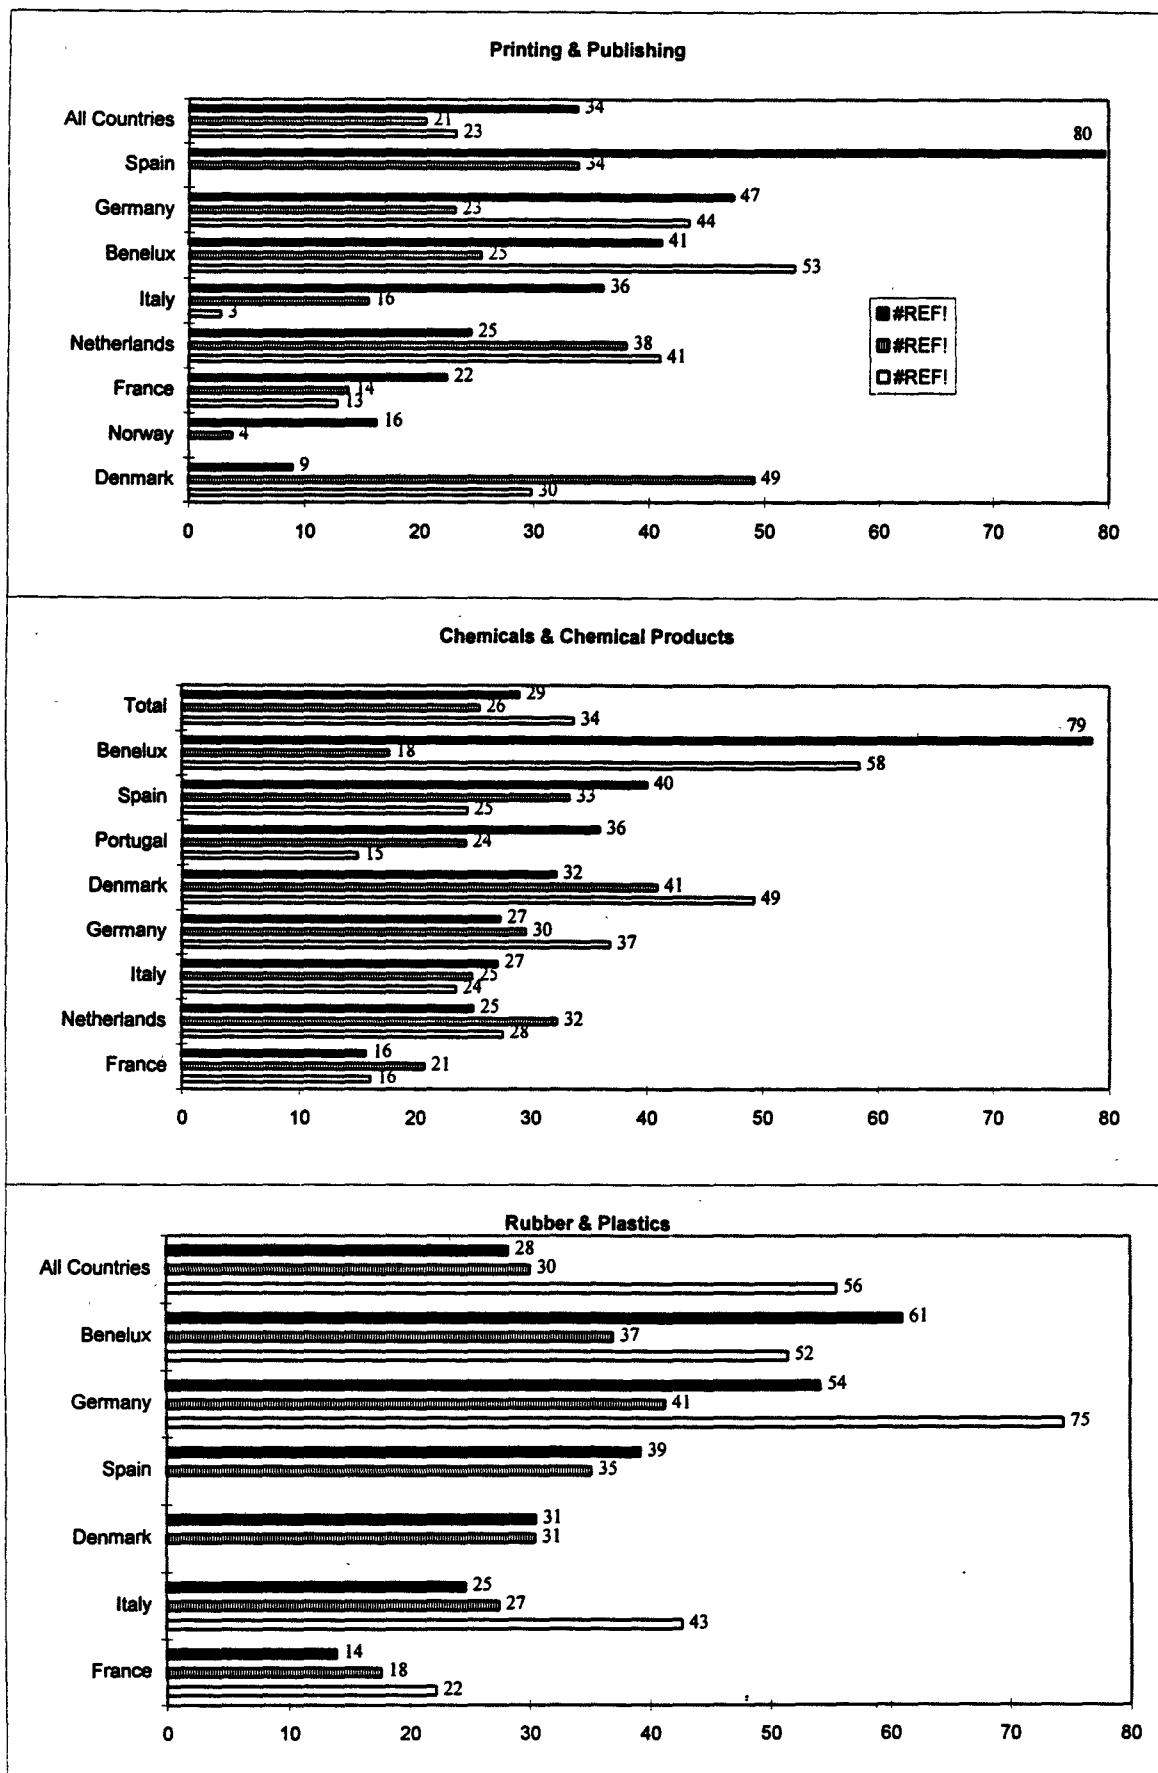

---

<sup>5</sup>In these figures we have eliminated all industries with less than 20 observations, and size classes where there are less than four observations.

and a value of "b" significantly greater/lesser than unity shows increasing/decreasing innovative performance with firm size.

Table 7 shows the results of the above regression for all the companies in the sample answering the question on Sales in New products. Increases in innovation outputs with total sales are not significantly different from proportionate in 7 out of the 17 sectors: Rubber and Plastic, Fabricated Metal Products, Machinery, Instruments, Vehicles, Other Transport and Furniture. In only one sector innovation intensity increases with size: Radio, TV and Communications. In 9 other sectors and in aggregate, innovation intensity decreases with firm size, ie., small firms are more innovative than large firms. This is especially the case in Paper, Pulp and Wood products and in Non-Metallic Minerals.

**Table 7 Relationship between Firm Size and Innovation Output.**

*Dependent Variable: Log (Sales in New Products)*

Sector	Coefficient Log Sales	Std Error	R-Sq (Adj)
Food Drink and Tobacco	0.923*	0.020	0.69
Textiles, etc	0.958*	0.020	0.65
Paper & Pulp	0.888*	0.028	0.63
Printing & Publishing	0.933*	0.032	0.65
Chemicals	0.953*	0.015	0.79
Rubber and Plastic	0.964	0.025	0.66

#### 4 Exports and Innovation Outputs

The importance of innovation for export performance in the OECD countries has already been confirmed statistically (Soete, 1981; Fagerberg, 1988) using industry and country level data over time. The CIS data allow us to explore the relationship at the firm level. Thus we examine the extent to which firms' export shares vary, not only as a function of their

innovativeness, but also as a function of their country (eg, we know that size of country is inversely related to export shares) and their sector (eg, transport costs influence the propensity to export). In Table 8 we therefore regress variations in export shares as a function of country and sector, as well as of indicators of innovative activities.

**Table 8 Relationship between Export Shares and Innovation Output at the Firm Level**

*Dependent Variable: Export Share*

Sector	Coefficient % Sales in New Products	Std Error	R-Sq (Adj)
All Sectors Combined	0.051*	0.008	0.16
Food Drink and Tobacco	-0.020	0.027	0.23
Textiles, etc	0.057*	0.024	0.11
Paper & Pulp	-0.034	0.032	0.21
Printing & Publishing	0.020	0.025	0.08
Chemicals	0.121*	0.043	0.21
Rubber and Plastic	0.126*	0.033	0.23
Non-Metallic Minerals	0.065*	0.033	0.08
Metals	-0.003	0.070	0.37
Fabricated Metal Products	0.019	0.021	0.08
Machinery	0.091*	0.019	0.07
Electrical	0.043	0.031	0.19
Radio, TV & Communications	0.068	0.052	0.29
Instruments	0.039	0.036	0.29
Vehicles	-0.002	0.042	0.16
Other Transport	0.131*	0.053	0.09
Furniture	0.019	0.037	0.06
Other	0.016	0.024	0.02

Regression for each sector includes country dummies;  
The regression for All Sectors includes industry and country dummies  
\* Denotes significance at the 5% level

The results show that for the sample as a whole there is a positive relationship between export shares and innovation intensity (after controlling for country and industry effects), ie., higher proportion of innovation outputs leads to higher export share at the company level.<sup>6</sup> This is particularly the case for firms in the following sectors: Textiles, Rubber & Plastics,

<sup>6</sup>This is also confirmed at the industry level. The correlations between the industry means for export shares and innovation output are: 0.24 for share of sales in new products, 0.20 for those incorporating incremental change, and 0.22 for those incorporating radical change. Each is significantly different from 0 at the 5% level.

Chemicals, Non-Metallic Minerals, Machinery and Other Transport. However, there appears to be no relationship between innovation and export shares in the so called high-tech product groups: Electrical (which includes Computers) Telecommunications and Instruments.

## 5 MAIN FINDINGS AND CONCLUSIONS

The main results of analysing innovation outputs in European industry from the Community Innovation Surveys (CIS) are:

- There is a great deal of consistency amongst the 8 innovation output indicators. The most robust, in measuring consistent inter-industry differences, is the proportion of sales that are due to new product introduction.
- Aggregate inter-industry differences in innovativeness as revealed by the output indicators are in general similar to those shown by R&D intensities. The main exception is chemicals where process innovations, which are not measured in the CIS, are important.
- The analysis of inter-country differences, both at the aggregate level and in sectors of relative strength and weakness, gives results that are not consistent with those from other analyses based on different measures of innovativeness. The main reason is probably inter-country differences in subjective assessments of product innovation.
- Both industry-specific and country-specific factors significantly influence firms' rate of product innovation, but nearly 90% of inter-firm variance remains unexplained. This indicates that firm-specific variables have a considerable influence.
- The analysis by firm size shows that there are very few signs of increasing returns to size in product innovation, and more of decreasing returns. The inclusion of process innovations might affect these results.
- There is a positive and significant relationship between innovation outputs and the share of exports.

The last two findings show that the data from CIS are capable of generating unique results. For example this is the first time that we are able to analyse the relationship between firm size and innovation across a whole range of size classes and also for Europe as whole. These data will also enable us to analyse a range of policy-related relationships between innovation outputs and other innovative activities in the future: for example, that between the relative importance of internal sources of innovation (compared to sources external to the firm) and the various measures of innovative output.

However there remain a number of (as yet) unresolved problems in undertaking inter-country comparisons. Some of these have also been highlighted in '*Evaluation of the Community Innovation Surveys (CIS) - Phase 1*' (1994). In our view the value of the data from CIS will

be greatly enhanced when: (a) results are available for surveys undertaken in the US and Japan; and (b) time series comparisons are possible.
